PC-DMIS Overview

PC-DMIS Overview: Introduction

PC-DMIS is a full-featured, geometric measurement package. It translates the high-level commands required to measure parts into the detailed steps necessary to drive a Coordinate Measuring Machine (CMM). PC-DMIS incorporates the Microsoft Windows interface to create, as well as execute, measurement routines. You can begin the measurement process by taking advantage of the drop-down menus, dialog boxes, and icons. The versatility of PC-DMIS's user interface also provides a way to customize the software to meet individual specifications.

The primary goals driving the design of PC-DMIS for Windows are flexibility and user friendliness. To meet these goals, PC-DMIS provides a flexible environment allowing for real-time error correction as opposed to a long debugging process, characteristic of some other geometric software packages. It is dimension-oriented to reduce the need to analyze and interpret the results of CMM measurements. The techniques used for measurement routine programming on a CMM are straightforward and, with practice, systematic. This documentation does not attempt to completely describe the dimensional inspection process. If additional information is needed on the fundamentals of dimensional inspections, please contact your software representative.

To see what's new in this version, from the PC-DMIS Home page, choose **What's New**.

The main topics in this chapter include:

- Organization of Manual
- Automating PC-DMIS
- Software Configurations

This documentation contains the core documentation needed to operate PC-DMIS. However, due to PC-DMIS's modular nature, additional documentation may be installed on your computer system. Click the **Contents** tab on your help file to view the other files installed.

Organization of the PC-DMIS Core Documentation

This documentation is divided into numerous main chapters and some supplemental appendices. To give you an idea of the documentation layout, the following list provides a brief description of each chapter.

To get help with how to search the Help documentation, see the "Using the Offline Help" topic in the PC-DMIS Help Center.

- "PC-DMIS: An Overview" - This is the current chapter you are reading. It gives a brief overview of PC-DMIS and the contents of the PC-DMIS documentation.
- "Navigating the User Interface" - This chapter describes the PC-DMIS user interface and how to customize it to suit your needs.
- "Using Basic File Options" - This chapter discusses the basic file operations that you can use to start a new measurement routine, save it, and exit PC-DMIS, and so on.
- "Using Advanced File Options" - This chapter discusses the more advanced file operations such as how to import and export CAD files and execute your measurement routine.
- "Setting Your Preferences" - This chapter describes the setup options and measurement routine parameters.
- "Editing the CAD Display" - This chapter describes how to use the Graphic Display window to edit the display of your CAD file.
- "Editing a Measurement Routine" - This chapter describes the Edit window and how to edit your measurement routine.
- "Using the Edit Window" - This chapter describes how to use the PC-DMIS built-in editor to create, debug, edit, and execute your measurement routine.
- "Using Other Windows, Editors, and Tools" - This chapter discusses additional windows, editors, and tools.
- "Using Toolbars" - This chapter discusses the main toolbars and toolbar icons.
- "Defining Hardware" - This chapter describes how to define probes, machines, quick fixtures, and tip calibration.
- "Creating Auto Features" - This chapter describes how to create single-click automatic features.
- "Creating Measured Features" - This chapter describes how to create measured features.

- "Constructing New Features from Existing Features" - This chapter describes how to construct features from other features already in your measurement routine.
- "Creating Generic Features" - This chapter describes how to create generic features and the ReadPoint command.
- "Creating and Using Alignments" - This chapter describes how to create, save, and recall alignments.
- "Using Gages" - This chapter describes how to use quick-check tools to measure various system and feature characteristics.
- "Using Legacy Dimensions" - This chapter describes the legacy dimensions.
- "Using Geometric Tolerances" - This chapter describes how to dimension your features with geometric tolerances using Feature Control Frames and symbols from the GD&T standard.
- "Scanning Your Part" - This chapter describes basic and advanced scan options.
- "Inserting Move Commands" - This chapter discusses various commands that can control machine or probe motion.
- "Branching by Using Flow Control" - This chapter covers commands that control the flow of your measurement routine.
- "Tracking Statistical Data" - This chapter explains how to track and use statistics in your measurement routine.
- "Reporting Measurement Results" - This chapter walks you through reports, the Report window, report and label templates, custom reports, and forms.
- "Inserting Report Commands" - This chapter discusses the report commands that you can insert into your measurement routine.
- "Using File Input / Output" - This chapter explains how to work with file input and output in your measurement routines to open files to read from them, write to them, and other file operations.
- "Using Expressions and Variables" - This chapter describes how to create expressions and how to assign expression results to variables.
- "Adding External Elements" - This chapter covers how to use external applications, scripts, measurement routines, and other objects in your measurement routine to further enhance its capability.
- "Using Multiple Arm Mode" - This chapter describes how to use PC-DMIS with dual-arm CMMs.
- "Navigating and Displaying Multiple Windows" - This chapter describes how to navigate between and view open windows.

In addition to the above sections, the PC-DMIS documentation provides appendices that document the following:

- "Working in Offline Mode"
- "Using Inspection Plans in PC-DMIS"
- "Using a Wrist Device"
- "Working in Operator Mode"
- "Using Shortcut Keys and Shortcut Menus"
- "Modifying Setting Entries"

Documentation Conventions

The following conventions are used throughout the documentation:

Boldface Text

The boldface font is used when referring to:

- Dialog box elements
- Dialog box titles
- Command buttons
- Menus and menu items
- Toolbars
- Toolbar icons
- Text that you must type

Some examples:

- Select the **File | New** menu item.
- Access the **Open** dialog box.
- Click the **Save** button.

Boldface is also used on **Notes**, **Warnings**, **Hints**, and **Examples**.

When referring to menus and menu items inside procedures and other topics, the documentation directs you to a menu in this fashion:

Menu | Submenu or **Menu Item | Menu Item**

However, since you can customize your menu locations and names, this documentation only displays the default locations for menu items.

Italicized Text

Italicized text is primarily used for *emphasis*. For example, "If…the probe hits an obstruction, it will *not* automatically stop".

Italicized text may also be used for book or manual titles and arguments in programming.

Uppercase Text

Uppercase text is generally used when referring to:

- Acronyms (such as VDAFS, DMIS)
- Time (such as 9 A.M. and 4 P.M.)
- Device names (such as LPT1, or COMM PORT 2)

In those instances where elements of computer programming are displayed, the following items also use uppercase:

- Control classes
- Data formats
- Environment variables
- Handles
- Hooks
- Indexes
- Macros
- Statements
- Structures
- System Commands
- Values

Underlined Text

Underline is used for emphasis when appropriate, but usually emphasis uses *italicized text*.

Hyperlinks are also underlined.

Numbered Lists

Ordered lists show a series of steps in instructions and procedures and other sequential lists. They are also used to identify elements in diagrams and images.

For example,

1. Choose **File**.
2. Select **New**.
3. Fill in the **New Measurement Routine** dialog box.

Note Boxes

Throughout the documentation, you'll find special boxes that offset the documentation. Here is what they mean:

This indicates a note.

This indicates an important note.

This indicates a hint.

This indicates an example.

This indicates a caution. Failure to follow a caution may result in data loss or hardware damage.

This indicates a warning. Failure to follow a warning may result in bodily harm.

Automating PC-DMIS

PC-DMIS supports full automation from any third-party software. For example, you can create your own customized application and use automation commands to launch and use PC-DMIS via that application.

For complete information on the automation commands that control PC-DMIS, and on supported BASIC language commands, see your "PC-DMIS Basic Language" documentation and "Automation Objects" documentation for additional information.

Software Configurations

If you have purchased the necessary modules, and your license is properly configured, you can launch PC-DMIS in different configurations. To do this, you can add these switches to the shortcut command line, batch file, or command prompt window that launches the application.

Available Software Configuration Switches

/f - You can use this switch for Offline mode.

/u - You can use this switch for user privilege level when you log onto the system as an administrator.

/o - You can use this switch for Operator mode.

/r - You can use this switch for Reverse Axes mode on Arm2 of a multiple arm system.

/p - You can use this switch for Pro mode. You cannot use this switch with the **/c** switch.

/c - You can use this switch for CAD mode. You cannot use this switch with the **/p** switch.

/d - You can use this switch for Debug mode for the current session.

/envFile - You can use this switch to run PC-DMIS with the selected environment or with the default environment.

/envFile: <name of the environment> - You can use this switch to run PC-DMIS with the specified environment.

/nc0 - You can use this switch to run PC-DMIS without the CNC functionality.

/5unique - You can use this switch to run PC-DMIS without this functionality.

/cmt - You can use this switch to run PC-DMIS without this functionality.

/dccscanning - You can use this switch to run PC-DMIS without this functionality.

/displaycad - You can use this switch to run PC-DMIS without this functionality.

/f - You can use this switch to run PC-DMIS in Offline mode.

/fullcrashdump - You can use this switch to have PC-DMIS generate more detailed crash report files than normal. These more-detailed crash report files can help Hexagon programmers track down what caused the product to hang or stop responding. A full crash dump also includes screen captures. If you don't use this switch, the software uses the standard crash reporting. Standard crash reporting does not include screen captures.

/laserinterface - This switch allows you to choose the laser stripe controller and its associated functionality. You can add the specific controller after the colon:

- /laserinterface:cms
- /laserinterface:mercury
- /laserinterface:romerintegrated

/laserprobe - You can use this switch to run PC-DMIS without this functionality.

/masterslave - You can use this switch to run PC-DMIS without this functionality.

/nc0 - You can use this switch to run PC-DMIS without the CNC functionality.

/nocontactprobe - You can use this switch to run PC-DMIS without this functionality.

/nocrashdump - You can use this switch to disable crash report files in PC-DMIS.

/nomigrate - You can use this switch to prevent the migration of entries and data files from a previous version. This switch can provide you with a clean "out of the box" experience. Only use this switch if you are sure you don't want to transfer key settings and calibration data from a previous version. To use this switch, add it to whatever shortcut or command you use that runs PC-DMIS for the first time as an administrator. When you do this, PC-DMIS does not copy your settings or data files from the most recent version.

/o - You can use this switch to run PC-DMIS in Operator mode.

/p - You can use this switch to run PC-DMIS in Pro mode. You cannot use this switch with the **/c** switch.

/r - You can use this switch to enable Reverse Axes mode on Arm2 of a multiple arm system.

/remotepanel - You can use this switch to run PC-DMIS without this functionality.

/rotarytable - You can use this switch to run PC-DMIS without this functionality.

/sheetmetal - You can use this switch to run PC-DMIS without this functionality.

/statsoutput - You can use this switch to run PC-DMIS without this functionality.

/systemv - You can use this switch to run PC-DMIS without this functionality.

/toolchanger - You can use this switch to run PC-DMIS without this functionality.

/u - You can use this switch to force PC-DMIS to run with normal user privileges even if you log onto the computer as the administrator.

/vision - You can use this switch to run PC-DMIS without this functionality.

/wrist - You can use this switch to run PC-DMIS without this functionality.

/DCILOAD:<file> - You can use this switch to load a file using Direct CAD Interfaces (DCI) where <file> indicates the complete path and file name of the model.

/DCTLOAD:<file> - You can use this switch to load a supplied part model using the direct CAD translators where <file> indicates the complete path and file name of the model.

/ISPROE - You can use this switch to specify that the software uses the .prt file in Creo (both NX and Creo use the same .prt file name extension). This follows the **/DCILOAD** switch.

/NC0 - You can use this switch to run PC-DMIS in normal Offline mode when you run PC-DMIS NC. The CNC licenses option is defined as greater than 0 in your portlock.

DCI/DCT Examples

- This command line launches PC-DMIS and loads an .igs CAD model using PC-DMIS Direct CAD Translators (DCT):

  C:\Program Files\Hexagon\<version>\Pcdlrn.exe New.prg /DCILOAD:d:\partmodels\hexblock_wireframe_surface.igs

- This command line launches PC-DMIS and loads a .prt CAD model from the NX Direct CAD Interface (DCI):

  C:\Program Files\Hexagon\<version>\Pcdlrn.exe New.prg /DCILOAD:d:\partmodels\hexblock.prt

- This command line launches PC-DMIS and loads a .prt CAD model as a Creo DCI:

  C:\Program Files\Hexagon\<version>\Pcdlrn.exe New.prg /DCILOAD:d:\partmodels\proe.prt /ISPROE

Routine of Shortcut Modification with Switches

1. Access the directory where the PC-DMIS executable shortcut is located. This directory is used:

   C:\ProgramData\Microsoft\Windows\Start Menu\Programs\2026.2\

2. Right-click in the directory and select **New | Shortcut**.

3. Follow the on-screen instructions to have the shortcut point to where the PC-DMIS executable (pcdlrn.exe) is located (wherever you installed it).

4. Add any of the command line switches (or arguments), following the shortcut's full path to the executable:

    So, if you want to run PC-DMIS *pro* in *Offline* mode, the target location would look something like this:

    "*C:\Program Files\Hexagon\<version>\PCDLRN.exe" /p /f*

    Where <version> is your version of PC-DMIS.

You can also tell PC-DMIS to automatically open a specific measurement routine (or measurement routines) by appending a pathway string pointing to a measurement routine as a command line argument.

- When you specify a measurement routine to load, however, you do not need the ***/*** character required for the other arguments discussed above.
- To open more than one measurement routine, type a space between each additional path.
- If your file name contains spaces, put the path within quotation marks.

    For example, if you wanted to launch two measurement routines named *test.prg* and *test2.prg* in Offline mode from a directory called "My Measurement Routines", the target locations might look something like this:

    "*C:\Program Files\Hexagon\<version>\PCDLRN.exe" /f "d:\my measurement routines\test.prg" "d:\my measurement routines\test2.prg*"

The most common modes are Offline and Online. These two distinct products are designed to meet particular needs. They can be used together to create a complete measurement routine, measurement analysis, and reverse engineering system.

These configurations and other configurations are explained below in greater detail.

Comparison of Offline and Online Modes

Since both the Online and Offline modes of PC-DMIS share the same features and functions, this documentation describes the use of both products. However, in some instances, a particular feature of the software in Online mode does not apply to the software in Offline mode. These cases have been noted where appropriate.

Offline Measurement Routine Programming

You can use PC-DMIS in Offline mode to develop and debug measurement routines away from the CMM by editing a part created in Online mode, by importing a CAD input file, or through a DMIS measurement routine. You can then directly execute the measurement routine in Online mode, or export (post processed) into DMIS or one of several vendor-specific formats. You cannot directly drive a CMM in Offline mode.

To start PC-DMIS in Offline mode, do the following:

1. Turn on your computer and all its peripherals, and log on to your computer.
2. Double-click with the left mouse button on the **Offline** icon in the PC-DMIS Program Group.

3. Use PC-DMIS to program your part's measurement routines. If you are new to PC-DMIS, see "A Simple Tutorial" in the PC-DMIS CMM documentation for help.

The "Working in Offline Mode" appendix describes the particulars of working with PC-DMIS in Offline mode.

Online Measurement Routine Programming

You can use PC-DMIS in Online mode to execute measurement routines, quickly inspect parts (or sections of parts), and develop measurement routines directly on the CMM. PC-DMIS in Online mode does not function unless it is connected to a CMM or other measuring device. Offline programming techniques work in Online mode.

To start PC-DMIS in Online mode, see the "Getting Started" chapter in the PC-DMIS CMM documentation. It covers the CMM startup and homing processes.

PC-DMIS CMM

PC-DMIS CMM works with your Coordinate Measuring Machine (CMM) to inspect your parts. PC-DMIS was the first CMM software to:

- Use CAD models in the inspection process.
- Directly link CAD systems and measurement software through its Direct CAD interface (DCI) technology.
- Implement a full set of sheet metal measurement routines tailored for the automotive industry.
- Digitally simulate measurements in an offline virtual CMM environment.
- Easily align complex, contoured parts using our breakthrough iterative alignment technology.
- And many, many more.

PC-DMIS CMM comes in various standard configurations. Each is carefully tailored to meet the needs of a specific group of customers. Also, PC-DMIS offers a wide range of optional modules for doing specific tasks. This means that users can fine-tune the software to meet specific needs.

PC-DMIS Pro – The baseline PC-DMIS CMM package offers customers who don’t need to integrate CAD into their inspection process a powerful, easy-to-use metrology software package. PC-DMIS Pro, with its built-in **Quick Start** routines, lets users get up and running on their CMMs with a minimum of fuss.

PC-DMIS CAD – Brings CAD to the inspection process. PC-DMIS CAD lets customers create inspection programs and evaluate measurement results taking full advantage of their CAD models. The software provides the tools you need to work with CAD files ranging from simple 2D drawings through complex 3D solid models.

PC-DMIS CAD++ – Enhances the capabilities of PC-DMIS CAD with sophisticated tools for high speed scanning, sheet metal measurement, part alignment and the like. PC-DMIS CAD++ makes measuring complex shapes easy.

Items that are specific to contact probes and CMMs are discussed in the PC-DMIS CMM documentation. Other information can be found in this PC-DMIS Core documentation.

PC-DMIS Vision

This special version of PC-DMIS allows you to use certain optical probing devices to measure features. If you've purchased this module, see your "PC-DMIS Vision" documentation for additional information.

PC-DMIS NC

This special version of PC-DMIS allows you to perform part measurements using Numeric Control (NC) machine tools. These machine tools are also referred to as CNC (Computer Numerical Control) machines. If you've purchased this module, see your "PC-DMIS NC" documentation for additional information.

PC-DMIS Laser

This module of PC-DMIS lets you use a laser probe to easily measure your parts by passing a laser stripe over the part to collect large amounts of points which are then interpreted and defined into features. If you've purchased this module, see your "PC-DMIS Laser" documentation for additional information.

PC-DMIS Portable

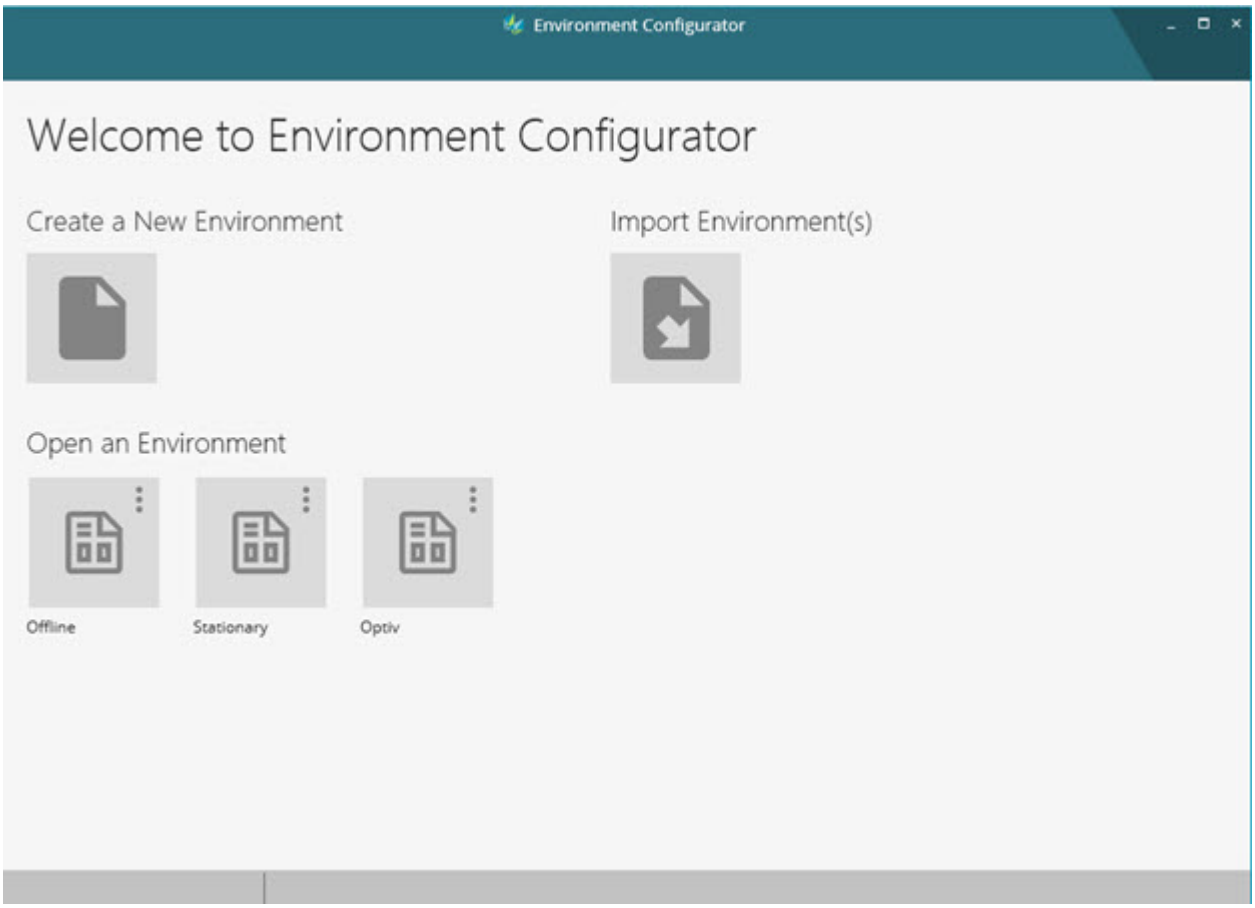
The PC-DMIS Portable configuration works with portable measuring devices to inspect your parts. Portable devices are manually operated measuring machines that are relatively easy to move to new locations due to their size and design. See the "PC-DMIS Portable" documentation for more information.

PC-DMIS Gear

PC-DMIS Gear is a software product that works in conjunction with PC-DMIS to allow you to quickly and easily measure any gear parts you have. If you've purchased this module, see the "PC-DMIS Gear" help file that gets installed with the PC-DMIS Gear application for more information.

We hope you will enjoy using PC-DMIS and find it a useful and powerful tool. If you have any suggestions or comments, please let us know. We are always looking for ways to improve our product.

Environment Configurator



You can use the Environment Configurator utility to define, open, and import PC-DMIS environments.

You can define an environment and select that environment before you open any measurement routine.

- To define an environment, select **Edit | Create/Edit Environment** from the Home page.
- To select an environment, select **Edit | Select Environment File** from the Home page.

About the Environment Configurator: Introduction

PC-DMIS generates an environment file automatically based on your current license configuration. The file contains this information:

- Interface type
- Non-Contact Sensor type

When you launch PC-DMIS, PC-DMIS uses this information to connect to the online device.

Hexagon now ships with offline license to support these interfaces:

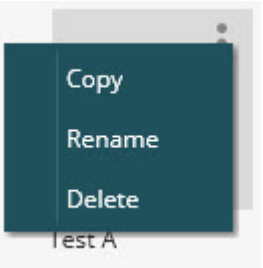
- All machine interface
- All Laser interface
- All Vision interface
- All Portable interface

The environment file allows you to configure offline PC-DMIS with a UI that closely matches your online environment.

The Menu

In the **Open an Environment** area, Environment tiles have their own menu that is accessible from the **More Actions** button located in the upper-right of each tile.

To show the menu, click the **More Actions** button. The menu shows a list of actions that you can do with the environment:



Copy - This menu item opens the **Copy Environment** dialog box to provide a name for the copied settings.

Rename - This menu item opens the **Rename Environment** dialog box to provide a new name.

Delete - This menu item deletes the environment from the view.

Opening a Measurement Routine in a Selected Environment

To open a measurement routine in a selected environment, follow these steps:

1. From the Home page, select **Edit | Select Environment File**. This menu shows all the items that you created on your computer.
2. Select the environment.
3. PC-DMIS shows a message to inform you to re-start the application to use the new environment. Click **OK** to re-start PC-DMIS.

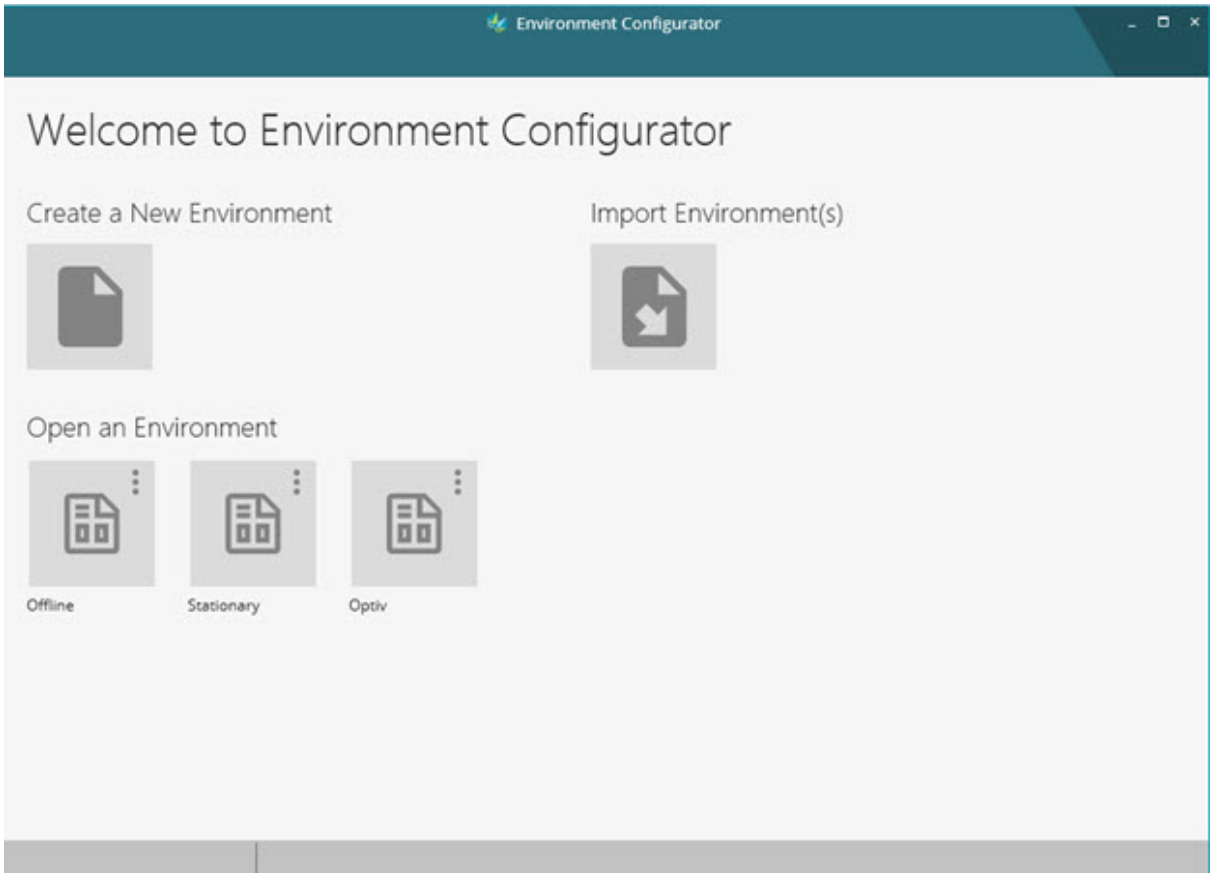
- For online stationary devices (CMM and Optiv), PC-DMIS only shows the environment that corresponds to the device. PC-DMIS selects it by default.
- For Portable devices, PC-DMIS shows all portable environments. You must select your environment.
- For offline, PC-DMIS shows Stationary, Optiv, and all Portable environment options. To select an environment, follow steps 1 through 3.

Creating and Editing an Environment

To create an environment, follow these steps:

You must run PC-DMIS as an administrator.

1. From the PC-DMIS Home page, select **Edit | Create/Edit Environment**. This opens the **Environment Configurator** dialog box.



Environment Configurator Dialog Box

   The dialog box has three areas that you can use to create a new environment, import an environment, or open an environment.

2. To create a new environment, click the **Create a New Environment** tile to open the **New Environment Name** dialog box.

3. From the **New Environment Name** dialog box, in the **Environment File** box, type a name.

4. Click **OK**. This opens the screen to define the hardware and PC-DMIS settings.

5. After you complete the definition of your new environment, click **Save**.

To edit or open an existing environment, follow these steps:

1. From the **Open Environment** area of the **Environment Configurator** dialog box, click a tile that you want to edit.

2. Make the changes in the **Hardware Settings** and **PC-DMIS Settings** tabs.

3. Click **OK**.

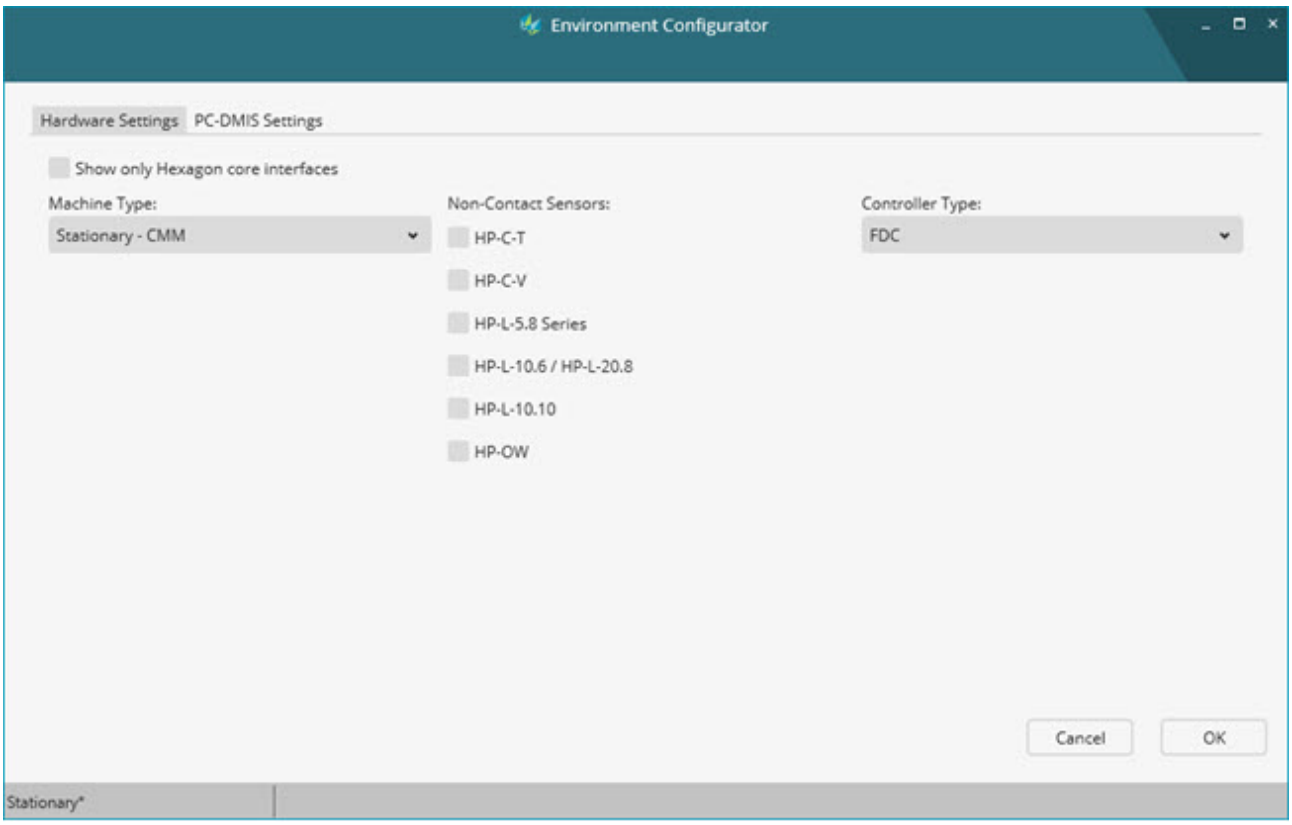
To import an existing environment that you generated from another online device, follow these steps:

You can use this option if you have a separate offline license that allows you to select an environment that corresponds to your machine.

1. From the **Environment Configurator** screen, click a tile that you want to edit under the **Import Environment(s)** area. This opens the **Select file(s)** dialog box.
2. From the **Select file(s)** dialog box, navigate to the desired folder and select an Environment Files (.json) file.
3. After you select a file, click **Open**. This adds the item under the **Open an Environment** area.
4. From the **Open an Environment** area, click a tile that you want to open. This opens the screen with the **Hardware Settings** and **PC-DMIS Settings** tabs.
5. From the **Machine Type** list on the **Hardware Settings** tab, select **Stationary - CMM** or **Stationary - Optiv**.
6. From the **Controller Type** list, select **Offline**.
7. Click **OK**. This adds the environment under the **Open an Environment** area.

Hardware Settings

From the **Hardware Settings** tab, define the **Controller** and **Sensor** settings.



Environment Configurator Dialog Box - Hardware Settings Tab

Show only Hexagon core interfaces - This check box filters the **Controller Type** list to display only those controllers that are manufactured by Hexagon.

Machine Type - This list lets you select the device type:

- Stationary - CMM
- Stationary - Optiv
- Portable

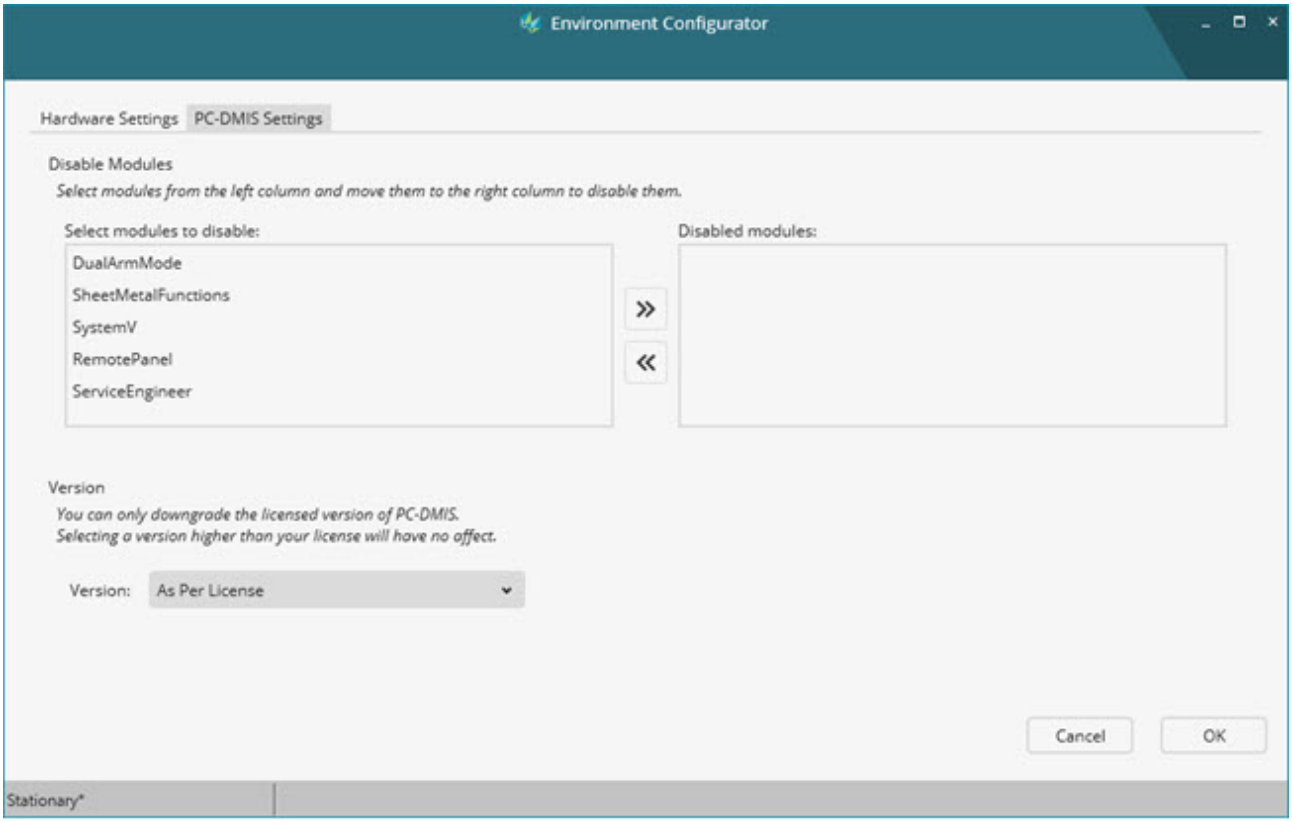
Based on what you select from the **Machine Type** list, PC-DMIS updates the list of **Non-Contact Sensors** and **Controller Type**.

When you select a combination of sensors that PC-DMIS doesn't support, PC-DMIS displays a message in the Environment Configurator's Status bar to indicate this.

PC-DMIS Settings

The **PC-DMIS Settings** tab lets you configure the options that you want to use to start PC-DMIS in a desired way. If you don't make any configuration changes, PC-DMIS starts with the default options.

With these settings, you can define **Startup Options** and **Version**.



Environment Configurator Dialog Box - PC-DMIS Settings Tab

Disable Modules

This area allows you to disable (and enable) application modules associated with your license.

You can disable license options that you don't need. To do this, follow these steps:

1. From the **Select modules to disable** list, select the modules that you want to disable.

   To select multiple modules, press Ctrl and then click more modules.

2. Click **Disable selected module(s)** to move the selected modules from the **Select modules to disable** list to the **Disabled modules** list.

To enable one or more modules, follow these steps:

1. From the **Disabled modules** list, select the modules that you want to enable.

   To select multiple modules, press Ctrl and then click more modules.

2. Click **Enable selected module(s)** to move the selected modules from the **Disabled modules** list to the **Select modules to disable** list.

Version

This area lets you select a specific level of PC-DMIS.

You cannot select a PC-DMIS level higher than your current license.

From the **Version** list, select a PC-DMIS license that you want to use to open your measurement routine.

The options available are **As Per License**, **Pro**, **Cad**, **Basic**, and **Premium**.

Navigating the User Interface

Navigating the User Interface: Introduction

This section introduces the main areas of the PC-DMIS user interface. This section also highlights ways to customize some of PC-DMIS's graphical options to best meet individual needs. (Additional information on these available options can be found in the "Editing the CAD Display: Introduction" section.)

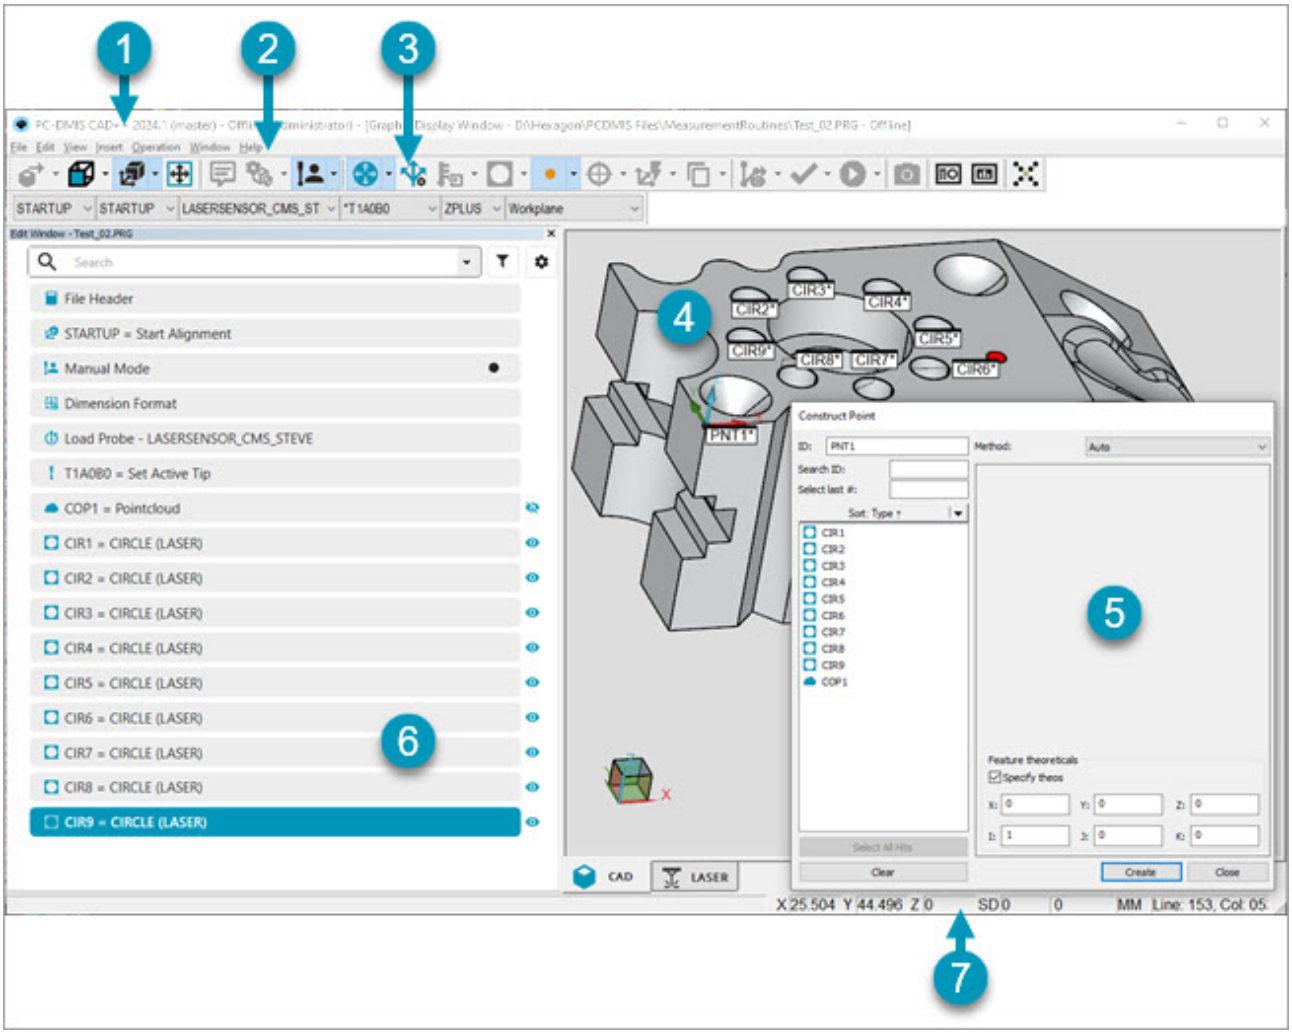
Each topic listed below illustrates a specific feature of the interface. The following are covered in this section:

- The User interface
- The Home Page
- The Menu Bar
- The Toolbar Area
- The Graphic Display Window
- The Status Bar
- Dialog Box Description
- Customizing the User Interface

PC-DMIS provides the flexibility for you to use the mouse or keyboard to enter commands or select options. PC-DMIS also provides shortcut menus and shortcut keys to frequently-used commands. See the "Using Shortcut Keys and Shortcut Menus: Introduction" section.

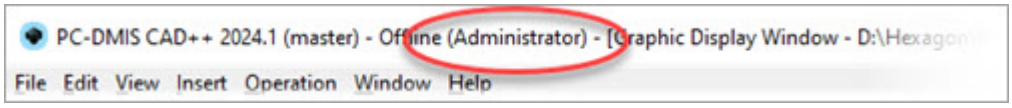
The User Interface

The PC-DMIS user interface is divided into several distinct areas, each of which fulfills a specific function or supplies needed information. A brief description of each screen area is listed below. (Additional information is located throughout the documentation as indicated.)



Example showing PC-DMIS user interface.

1. The title bar displays the PC-DMIS version information, its Offline or Online state, and if it's in administrator mode. If PC-DMIS is Online, it also displays the name of the machine.



2. The menu bar contains the menus and menu items available from the PC-DMIS application. For information, see "The Menu Bar".

3. The toolbar area contains toolbars with frequently used commands. You can right-click in the toolbar area to access these toolbars. See "The Toolbar Area".

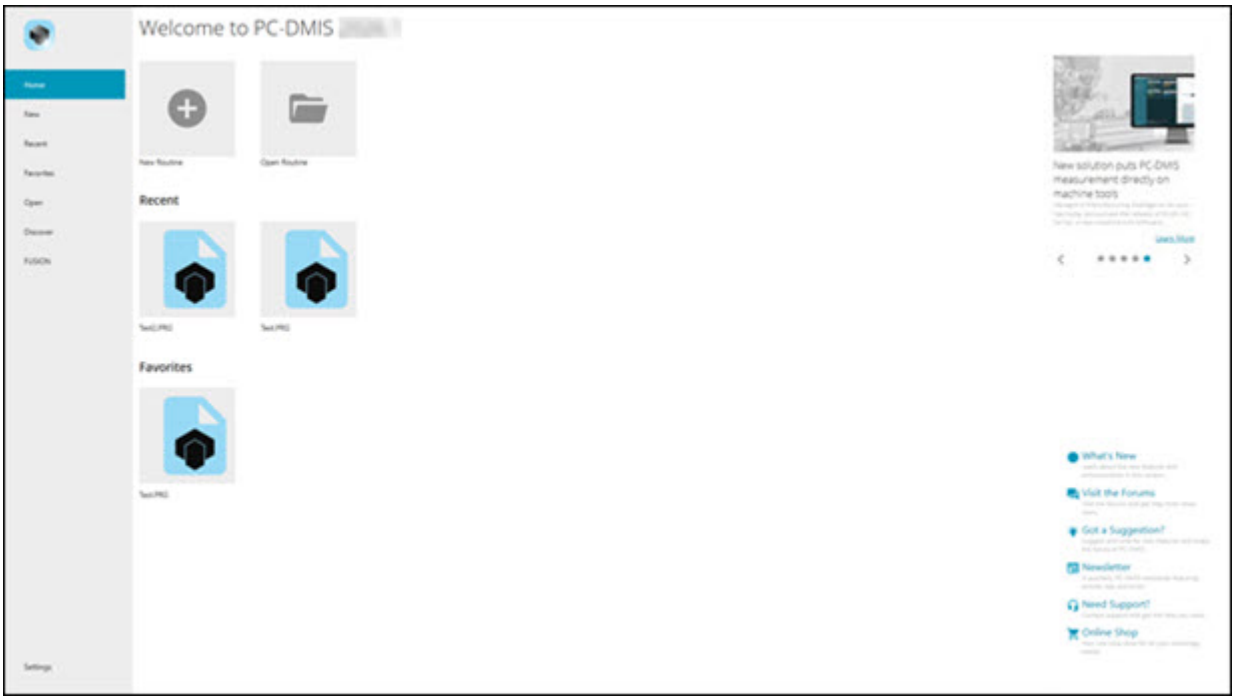
4. The Graphic Display window presents graphic representations of the part (the top view is shown in the illustration). The size of this area remains constant. However, you can divide the display area into as many as four different views of the part. For information, see "The Graphic Display Window".

5. Dialog boxes are the main communication channels between PC-DMIS and the user. Available features appear in the dialog box, and you can enter most input data through it. For information, see "Dialog Box Description".

6. The Edit window displays the measurement routine. This window allows you to access specific commands within the measurement routine and make changes to meet individual specifications. See the "Editing a Measurement Routine: Introduction" and "Using the Edit Window: Introduction" chapters for fully documented operations of the Edit window.

7. The Status bar displays information important to the current operation. This includes information such as the probe's current position, the probe calibration data, standard deviation of the last feature measured, the number of hits, and other information. It also contains a message area to display prompts and pertinent information about the operation in progress. For more information, see "The Status Bar".

The Home Page



The Home page is the first screen you see in PC-DMIS before you open a measurement routine. It's also the screen you see if you close all measurement routines but not the application. The Home page contains different views (such as **Home**, **Recent**, **Favorites**, **Open**, and **Discover**) that let you access measurement routines on your computer and perform other actions. The Home page also provides useful links to community sites, news, and product videos.

You can still use **File | Open** and **File | New** to open and create measurement routines.

By default, the Home page is visible when you start PC-DMIS and you don't load a measurement routine. If you don't see it, you may need to enable it. To do that, mark the **Show Home Page** check box in the **General** tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**). For information, see "Show Home Page" in the "Setting Your Preferences" chapter.

The Left Pane

From the Home page, the left pane lets you access these views:

- **Home** - This view provides tiles to create or open measurement routines. It also has its own **Recent** and **Favorites** embedded views. **Recent** here shows a row of tiles for the most recent measurement routines. **Favorites** here shows a row of tiles for the most recent items that you marked as favorites.
- **New** - This view shows templates from which you can create new measurement routines. When you first use PC-DMIS, this view contains these out-of-the-box templates:
  - **Blank Template** - This option creates a simple measurement routine, similar to the measurement routine creation from the **File | New** menu.
  - **Portable Execution Template** - This option creates a measurement routine intended for execution by portable devices.
  - **Q-DAS Export Template** - This option creates a measurement routine with pre-existing statistics and tracefield commands to export measurement info to the Q-DAS software.

  You can also modify any existing measurement routine and use it as a template. For more information, see the "Using Measurement Routine Templates" topic in the PC-DMIS Core documentation.
- **Recent** - This view shows tiles for all the recent measurement routines. It can show more than the single row of recent measurement routines available in the **Home** view.
- **Favorites** - This view shows tiles for all the items that you marked as favorites. It can show more than the single row of recent favorites available in the **Home** view.
- **Open** - This view shows tiles for any measurement routines or sub-folders within defined folders.

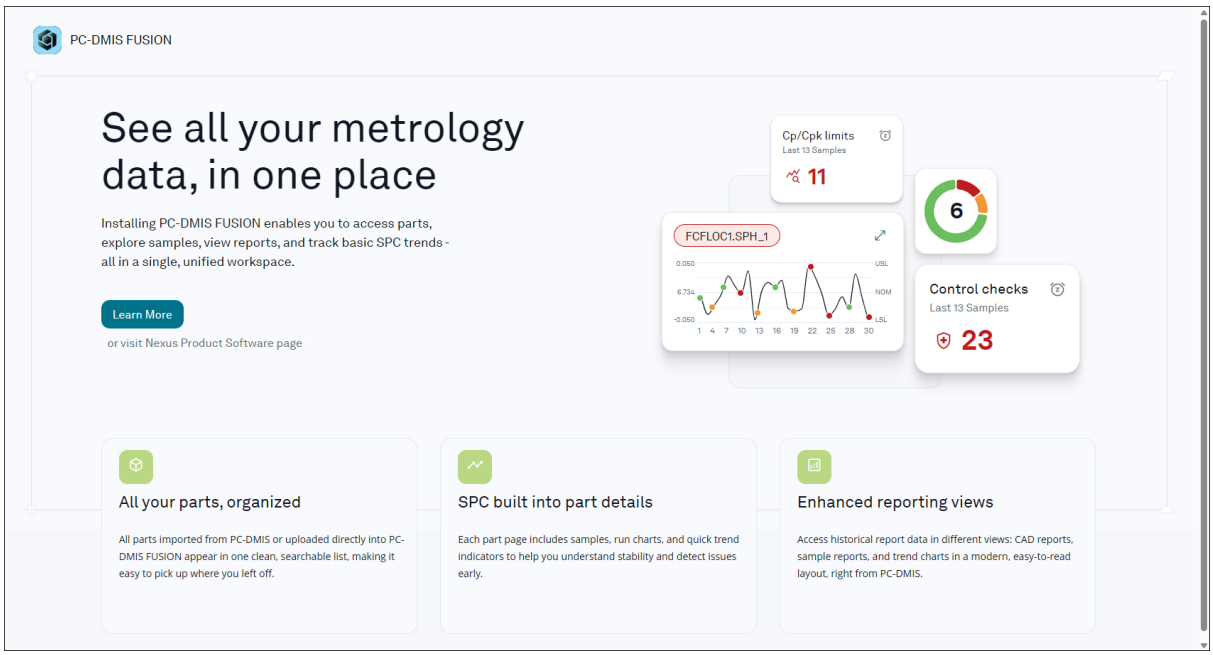
  By default, PC-DMIS shows the contents of this folder for the current version:

  C:\Users\Public\Public Documents\Hexagon\PC-DMIS\2026.2

You can define additional folders or hide folders from **Settings** if you run PC-DMIS as an administrator.

- **Discover** - With an Internet connection, this view shows these two tabs:
  - **Videos** - This tab provides a list of videos that showcase items, such as:
    - PC-DMIS product highlights
    - PC-DMIS how-to videos
    - Related products
  - **Example Routines** - This tab provides a list of example measurement routines with commands already in them to perform specific tasks or measurements. A descriptive picture on each tile shows the relative concept.
    - The measurement routines are grouped according to level. The level number represents the relative difficulty in the concepts involved.
    - Some items use automation scripting to accomplish their tasks. The descriptive pictures on the tiles use this small scroll icon in the bottom-right corner to indicate that scripting was used:

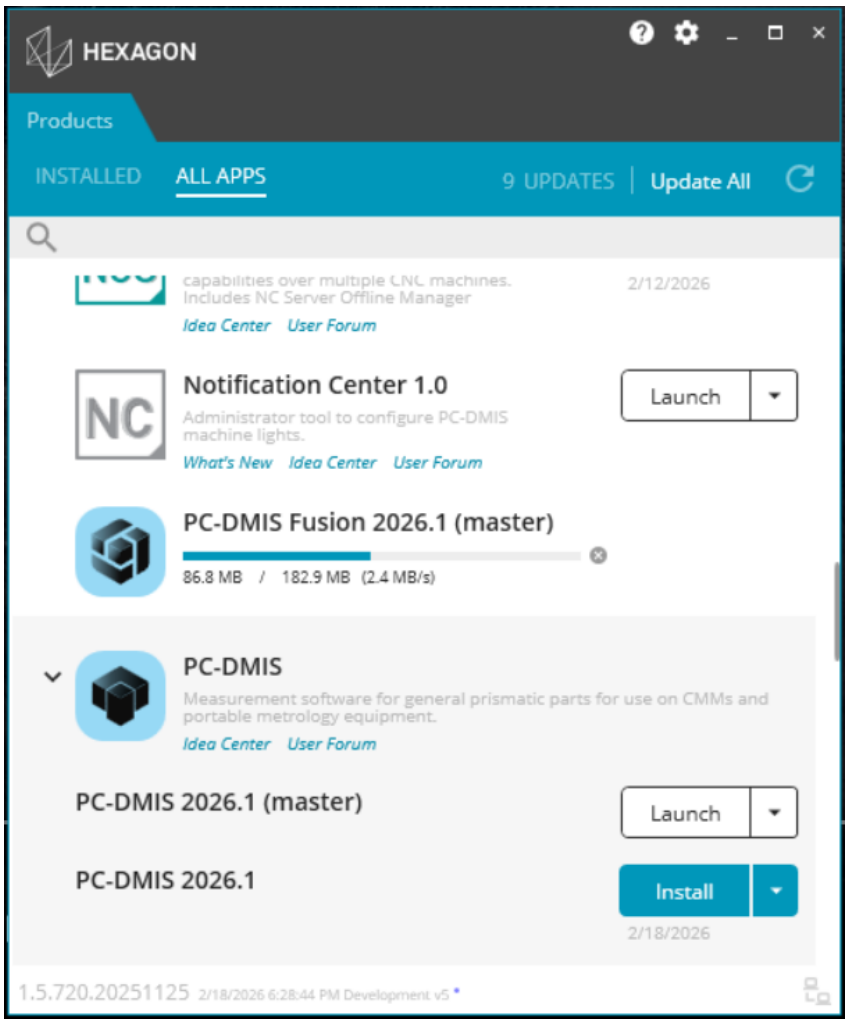
    - You can use the **...** menu on the tile to download measurement routines to the default measurement routine directory and add them to **Favorites**. You can also hover your pointer over measurement routines and use the download button ( ) to download them. Once downloaded, you can use the **Show in Folder Explorer** button ( ) to open the file in File Explorer.
- **FUSION** - This view initially shows a **Welcome** tab with information about the PC-DMIS FUSION application.



PC-DMIS FUSION brings all your metrology data together so you can:

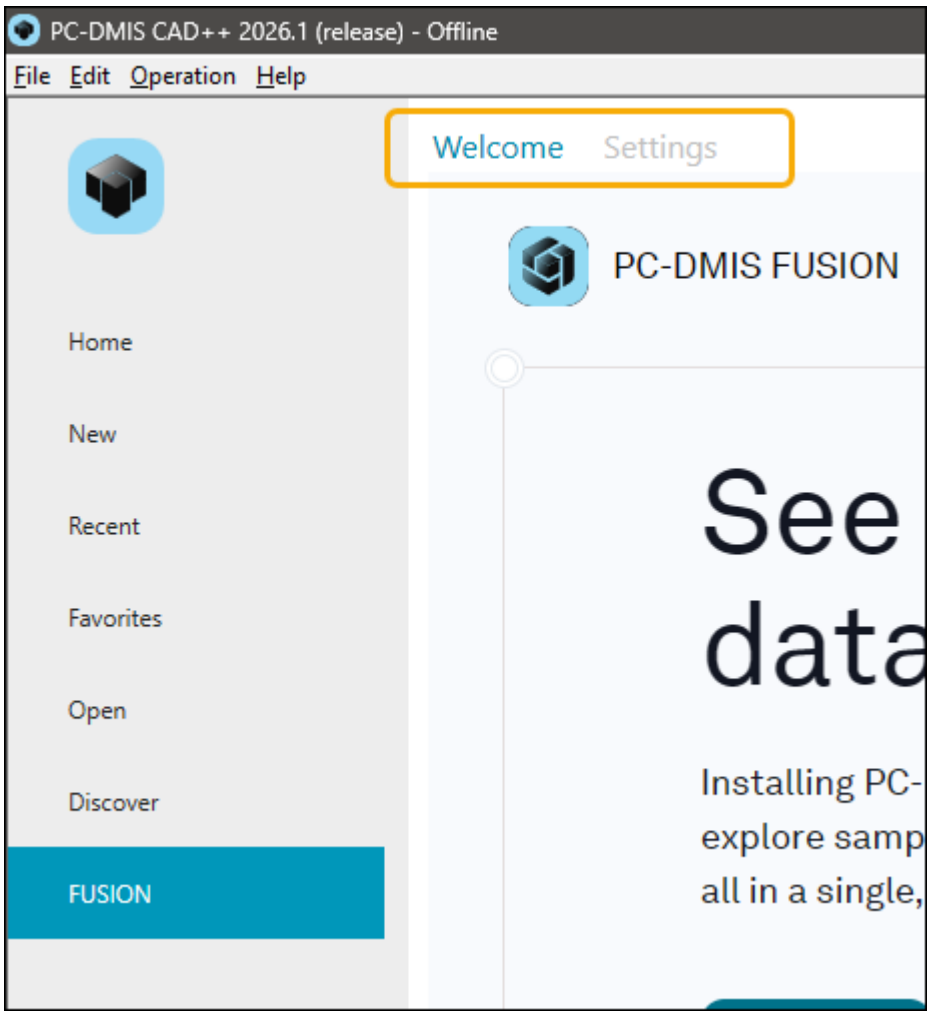
- Review PC-DMIS results and reports
- See sample-level details over time
- Explore SPC trends
- View part information in a central dashboard

To install PC-DMIS FUSION, from the **Welcome** tab, click **Learn More**. Once you have a license to use this application, you can download and install it from the Universal Updater application.



(For information on system requirements and installation instructions, see the PC-DMIS Fusion Release Notes.)

This installs the application on the same computer as PC-DMIS. Once you install PC-DMIS FUSION, on PC-DMIS, a **Settings** tab appears next to the **Welcome** tab within the **FUSION** view.



You can use the **Settings** tab to control how PC-DMIS sends your part data to the PC-DMIS FUSION application. PC-DMIS sends only what you choose to send, and all sent data remains on your computer. For more information, see "PC-DMIS FUSION Settings".

If PC-DMIS FUSION is not installed, only the **Welcome** tab is available.

Settings - This view shows the settings for the Home page.

The Right Pane

The right pane shows information and other options that change based on the current selected item.

Initial View

Initially, from the Home page's right pane, you can see links for these items. Most of these require an Internet connection to access:

- What's New

- Visit the Forums
- Got a Suggestion?
- Newsletter (available only if you have a current Software Maintenance Agreement)
- Need Support?
- Online Shop

Items for Measurement Routine

Once you select a measurement routine, the right pane changes to show a **Details** pane of the measurement routine's details:

At the top of the **Details** pane, you can see the routine's name and its thumbnail image. To the right of thumbnail image, the **Creation Date** shows the exact date and time that the measurement routine was created.

Change Thumbnail - This button appears over the measurement routine's thumbnail image. It allows you to change the thumbnail if you run PC-DMIS as an administrator. Note that the image is also linked with Inspect. This means if you change a thumbnail image in PC-DMIS, it also occurs in Inspect and vice versa.

Preview Pane - This area displays the CAD preview image if the measurement routine uses a CAD file. You can click **Set image as thumbnail** to create a thumbnail from the CAD preview image. You must run PC-DMIS as an administrator to change this thumbnail.

Favorite - In this area, you can click the star icon to add the measurement routine to favorites or to remove it from favorites.

Nickname - This box lets you type a nickname for the measurement routine. The actual file name in your folder structure is unaffected. The nickname only affects the name that you see in the **Favorite** view.

Open - This button opens the selected measurement routine.

Open Online - This option determines whether to open the measurement routine in Offline or Online mode. This option appears only if you have Online and Offline on your license.

Include CAD - This option determines whether you want to open the CAD file associated with the measurement routine.

Path - This text shows the folder path to the selected measurement routine. It is also a link that you can click on to open that routine's folder in the File Explorer and select the .prg file.

Open Folder Explorer - This button appears when you access the **Discover** tab from the left pane and then click on an example measurement routine. This button

opens File Explorer to the folder for the downloaded example measurement routine. The button becomes unavailable once you download the example measurement routine.

Items for Templates (New tab)

Once you select a template from the **New** tab, the right pane changes to shows details for the measurement routine you want to create. The **New Measurement Routine** dialog box from **File | New** contains this same information:

Nickname - This box defines the nickname for the measurement routine. By default, this matches the name of the template you selected. For more information, see "Nickname" above.

Part Name - This box defines the name of your part. The .prg file that PC-DMIS creates also uses this same name.

Location - This box defines the folder where you want to create the measurement routine.

Serial Number - This box defines the unique serial number for the part. This item is optional.

Revision Number - This box defines the revision number for the part or the measurement routine. This item is optional.

Units - This list defines whether the measurement routine uses millimeters or inches for the units of measure. The units you choose needs to match the units of the template file you selected.

Create - This button uses the above information and creates the measurement routine in the location folder.

Create Online - This option defines whether the measurement routine is an offline measurement routine (not connected to the machine) or an online measurement routine (connected to the machine).

- In an offline measurement routine, you can create the measurement routine and commands without a CMM, even if PC-DMIS is connected to a CMM. You define the features to measure with the CAD model.
- In an online measurement routine, you use the CMM's probe and jog box to teach PC-DMIS the features that you want to measure.

Items for Discover

Once you select a video from the **Videos** tab, the right pane changes to shows details for the selected video.

Launch - This button will launch the video in your default internet browser.

Settings

From the Home page, these are the available settings. To access the settings, you need to meet these conditions:

- Run PC-DMIS as an administrator
- PC-DMIS must not be in Operator Mode
- PC-DMIS must not be in Protected Mode

General Settings

Current Theme - This changes the look of the application between **Dark** and **Light**. You must re-start the application to see the new theme.

Internet Access - These two options let you customize Internet access for the Home page:

> **Allow Automatic Internet Access (News)** - This option enables the top-right news panel.
>
> **Allow Manual Internet Access (Links)** - This option enables all links to the Internet; these include the links on **Home** and the measurement routines and movies on **Discover**.

When disabled, the Home page has no access to items on the Internet.

Folder Explorer

PC-DMIS Routine Locations - In this section, you can click **Create New User Folder** to create new user-defined folder settings with pathways to folders with pre-defined or custom extensions. You can only make changes in this section if you run PC-DMIS as an administrator.

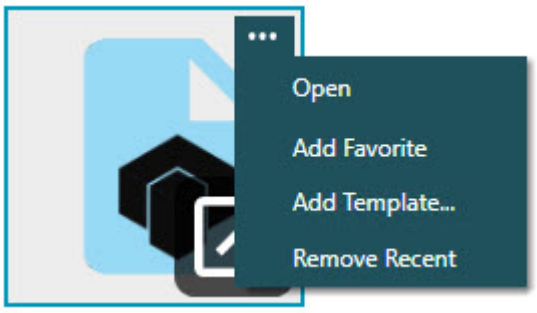
> **Label** - This option provides a simple label for the folder that appears under the folder in the other views. If you don't type anything here, the software uses the default file or folder name.
>
> **Path** - This option shows the pathway for the user-defined folder. You can define the pathway when you create it. If you want to change the path, you need to delete the specific user-defined folder setting and recreate it.
>
> **Extensions** - This box filters the files that PC-DMIS shows in the Home page. You can define this filter when you click **Create New User Folder**. You can add multiple filters as long as you separate them with commas. For example, you can type or select ***.prg** to show PC-DMIS measurement routines. You can type ***.*** to show all the files. If you want to change the extension, and you've already defined a user-defined folder setting, you need to delete the specific user-defined folder setting and recreate it.

- **Toggle Folder Visibility** - This option changes the visibility state of the user-defined folder. With this option, you can hide folders so they don't appear in **This PC.**

- **Delete This Setting** - This button appears next to user-defined folders. When you click it, PC-DMIS removes that user-defined folder from the **Settings** screen. The actual folder in Windows Explorer remains untouched.

Create New User Folder - This linked text adds a new user-defined folder setting that you can define.

The ... Menu



The **...** menu resides on top of measurement routine tiles on the Home page. To show the **...** menu, click on a measurement routine tile. This menu shows a list of common actions you can do with the measurement routine. Some of these options are identical to those contained on the **Details** pane. You may find these options useful if you don't want to use the **Details** pane to perform them:

- **Open** - This menu item opens the routine for edit or execution.
- **Add Favorite** - This menu item adds the routine to the **Favorite** view.
- **Add Template** - *This menu item only appears if you run PC-DMIS as an administrator.* It creates a template from the measurement routine. An **Add Template** dialog box opens so that you can type a name and description for the template. A template is helpful if you have commands you want to use over and over in new measurement routines. You can set up those commands in a measurement routine and create a template from it. For more information on this process, see "Using Measurement Routine Templates".
- **Remove Favorite** - This menu item removes the measurement routine from the **Favorite** view.
- **Remove Recent** - This menu item removes the measurement routine from the **Recent** view.
- **Edit Template** - *This menu item only appears if you run PC-DMIS as an administrator.* It shows an **Edit Template** dialog box so that you can modify a template description.

- **Remove Template** - This menu item removes the template from the **New** view.

Creating a Routine

1. From the Home page, click **Home**.
2. Click the **New Routine** tile to show the **New Measurement Routine** dialog box.
3. Fill out the dialog box and click **OK** to close the dialog box.

PC-DMIS also adds the routine to the **Recent** view.

Using Measurement Routine Templates

You can make a measurement routine, or part of a measurement routine, act as a measurement routine template. On the PC-DMIS Home page, you can then create other measurement routines from this measurement routine. This is useful when you frequently create the same commands over and over for new measurement routines.

Adding a Template from a Routine

1. Run PC-DMIS as an administrator.
2. From the Home page, from that measurement routine's tile, access the ... menu option.
3. Choose **Add Template** to show the **Add Template** dialog box.
4. In **Template Name**, give the template a descriptive name.
5. In **Description**, type a description of the template.
6. In **Units**, choose the measurement units of the template.
7. Click **OK** to create the template and add it into the **New** view on the left pane.

By default, the template includes all the commands from the first `LOADPROBE` and `TIP` commands to the end of the measurement routine.

PC-DMIS stores the template in a folder that matches your template name at this location:

C:\ProgramData\Hexagon\PC-DMIS\2026.2\Templates\

Controlling What Ends Up in a Template

If you want to include only parts of your measurement routine as template commands, you can control that with some special start and end Document comments.

1. Open a measurement routine that you want to use as your template.

2. Locate the commands that you want PC-DMIS to insert into new measurement routines.
3. Surround the commands you DO want to include with these Document comments:
    - #TEMPLATE_COMMAND_START_POINT#
    - #TEMPLATE COMMAND_END_POINT#

    > The commands between the template start and template end Document comments are what PC-DMIS adds into the new measurement routine when you create it from the template. PC-DMIS excludes commands that are *outside* of those comments.

4. Save and close the measurement routine.

Creating a Routine from a Template

1. From the Home page, from the left pane click **New** to show the available templates.
2. From the **New** view, choose the template from which you want to create a new measurement routine.
3. From the right pane, fill out the following:
    - In **Part Name**, type the name for the part. PC-DMIS uses this in the measurement routine's filename.
    - In **Location**, define where to store the measurement routine.
    - Fill out **Serial Number** and **Revision Number** as needed.
    - Select the **GD&T Standard** as needed.
    - In **Units**, select the same units as used by the template.
    - If PC-DMIS is in Online mode and you have the PC-DMIS functionality for offline measurement routines, decide if you want to connect the measurement routine to the machine or if it's an offline measurement routine. If you want it to connect to the machine, turn on the **Create Online** option. If you want an offline measurement routine, turn off the **Create Online** option.
4. Click **Create** to create the measurement routine.

The GD&T standard affects Size or Geometric Tolerance commands in your measurement routine. The standard you select does not affect legacy dimensions. You can change the selected GD&T standard at any time from the **Geometric Tolerances** tab of the **Setup Options** dialog box. However, because the setting applies to the entire measurement

routine, depending on the measurement routine's content at the time of change, it may behave differently.

For information on the **Geometric Tolerance** tab, see "Setup Options: Geometric Tolerances tab" in the "Setting Your Preferences" chapter.

Editing a Template's Description

1. Run PC-DMIS as an administrator.
2. From the Home page, from the left pane click **New** to show the available templates.
3. From the **New** view, choose the template whose description you want to modify.
4. From the **...** menu option, click **Edit Template**.
5. From the **Edit Template** dialog box, modify the **Description** and then click **OK**.

Editing a Template's Commands

1. In the File Explorer, navigate to this folder where PC-DMIS stores the templates:

   C:\ProgramData\Hexagon\PC-DMIS\2026.2\Templates
2. Locate the folder for your template. The folder name is the same as the template name.
3. Inside that folder, open either the **MM** or **Inch** folder.
4. Double-click the .prg to open it inside of PC-DMIS.
5. Modify and save that .prg.

Another way to modify the template is to modify the original measurement routine, and then re-create the template with the same name.

Removing a Template

From the **New** view, you can modify the template's description:

1. Run PC-DMIS as an administrator.
2. From the Home page, from the left pane click **New** to show the available templates.
3. From the **New** view, choose the template you want to delete.
4. From the **...** menu, click **Remove Template**.

Opening a Routine

1. From the Home page, click on one of these views: **Home**, **Recent**, **Favorites**, or **Open**.

2. Double-click on the tile that you want to open. You can also click once on a tile, and from the **...** menu, click **Open**.

PC-DMIS also adds the routine to the **Recent** view.

Removing a Routine from Recent

1. From the Home page, click the **Recent** view.
2. Select one or more routine tiles.
3. Click the **...** menu that appears in the upper right of the tile.
4. Click **Remove Recent** to remove the routine from the **Recent** view.

Adding Items to Favorites

1. From the Home page, select one or more measurement routines.
2. Click the **...** menu that appears in the upper right of one of the measurement routines.
3. Choose **Add Favorite**.
4. Click the **Favorites** view to see the newly-added item.

You can also use the **...** menu to add an item to **Favorites**. For information, see "The ... Menu".

Removing Items from Favorites

1. From the **Favorites** view on the Home page, select one or more routines.
2. Click the **...** menu that appears in the upper right of one of the routines.
3. Choose **Remove Favorite**.

You can also use the **...** menu to remove an item from **Favorites**. For information, see "The ... Menu".

Changing the Theme

1. From the left side bar on the Home page, click **Settings** to show the **Settings** screen.
2. From the **Settings** screen, change **Current Theme**, to either **Light** or **Dark**.
3. Restart PC-DMIS.

Adding Routine Locations

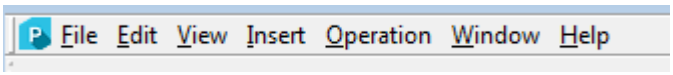
1. Run PC-DMIS as an administrator.
2. From the left side bar on the Home page, click **Settings** to show the **Settings** screen.
3. From the **Settings** screen, click **Create New User Folder** to define the new folder location.
4. For the new folder, define the **Label**, **Path**, and **Extension** values.
5. Click the **Confirm** button ( ) to accept your new location.
6. Click on the **Open** view to see the newly-added folder.

Disabling Home Page

1. Open or create a measurement routine.
2. Choose **Edit | Preferences | Setup** to show the **Setup Options** dialog box.
3. From the **Setup Options** dialog box, click the **General** tab.
4. From the list of check boxes on the **General** tab, clear **Show Home Page**.
5. Click **OK** to close the dialog box and accept your change.

The next time you close all your routines, you won't see the Home page.

The Menu Bar



The topics below give a brief description of each menu. For additional information, see the appropriate chapter as needed. PC-DMIS also provides a variety of shortcut menus. These menus are discussed in the "Using Shortcut Keys and Shortcut Menus: Introduction" chapter.

To get help on specific menu items, position your mouse pointer over the menu item, and press F1.

File

The **File** menu lets you open, save, and print files, access the Edit window, run measurement routines with the Execute Mode, and exit out of current measurement

routines. For more information, see the "Using Basic File Options: Introduction" and "Using Advanced File Options: Introduction" chapters.

You can control the number of files that PC-DMIS displays in the bottom half of the **File** menu. For details, see the "`MostRecentFileList`" topic in the PC-DMIS Settings Editor documentation.

Edit

The Edit menu allows you to edit your measurement routine preferences, your measurement routine, or the CAD display.

- To edit your preferences, see the "Setting Your Preferences: Introduction" chapter for complete information.
- To edit your measurement routine via the Edit window, see the "Editing a Measurement Routine: Introduction" and "Using the Edit Window: Introduction" chapters for complete information.
- To edit the display of the CAD drawing, see the "Editing the CAD Display: Introduction" chapter for complete information.

View

The view menu allows you to access all the windows, editors, and toolbars available to PC-DMIS. See the "Using Other Windows, Editors, and Tools: Overview" chapter for complete information.

Insert

You can access the bulk of a measurement routine's commands from the **Insert** menu.

Most of the chapters that comprise this documentation come from the options and submenus displayed on this menu.

- You can find the information for the options on the **Hardware Definition** submenu in the "Defining Hardware" chapter.
- You can find the information for the options on the **Feature** submenu in these chapters: "Creating Auto Features", "Creating Measured Features", "Constructing New Features from Existing Features", "Creating Generic Features".
- You can find the information for the options on the **Alignment** submenu in the "Creating and Using Alignments" chapter.
- You can find the information for the options on the **Dimension** submenu in the "Using Legacy Dimensions" chapter.

- You can find the information for the options on the **Scan** submenu in the "Scanning your Part" chapter.
- You can find the information for the options on the **Move** submenu in the "Inserting Move Commands" chapter.
- You can find the information for the options on the **Flow Control Command** submenu in the "Branching by Using Flow Control" chapter.
- You can find the information for the options on the **Statistics Command** submenu in the "Tracking Statistical Data" chapter.
- You can find the information for the options on the **Report Command** submenu, including the ability to add Diminfo and Pointinfo boxes onto your CAD display and into your measurement routine, in the "Inserting Report Commands" chapter.
- You can find the information for the options on the **File I/O Command** submenu in the "Using File Input / Output" chapter.
- The options on the **Modules** submenu represent the toolkit modules installed with PC-DMIS.
- You can find the information for the remaining options on the **Insert** menu in the "Using Expressions and Variables " chapter and the "Adding External Elements" chapter.

Operation

The items on the **Operation** menu are discussed in various topics of the documentation.

Window

The **Window** menu allows you to manage the display of all open measurement routines. See the "Navigating and Displaying Multiple Windows" chapter.

Help

The **Help** menu provides these menu items:

Search - This item opens the introduction page for the PC-DMIS Getting Started help. From there, you can search across the entire PC-DMIS Help content. To access the PC-DMIS Help, select this item from the **Help** menu, or press F1 at any time. The first time you run the Help after installation, it may take several seconds. Thereafter it opens more quickly.

Using Help - This item opens the PC-DMIS help file to the "Using the Help: Introduction" chapter. The topics there provide hints and tips about searching for and locating information in the help.

Offline Help - This item determines whether PC-DMIS shows the offline help whenever you access the Help content. A check mark next to this menu item means PC-DMIS uses the offline help even if you have Internet access. No check mark means PC-DMIS uses the online help. If you don't have Internet access and you don't have the offline help installed, PC-DMIS shows a message to inform you that you need to either connect to the Internet or install the offline help.

Release Notes - This item shows the readme.pdf that ships with this version of the software. The readme.pdf contains information about this version of PC-DMIS.

About - This item opens the **About** dialog box. This dialog box gives you specific version and license information. It also provides a unique **Machine ID** for your computer, which may be used in some status and notification messages.

Selecting Options from the Menu Bar with the Keyboard

To open a menu and browse through the options using the keyboard, press the Alt key followed by the underlined letter in the name of the menu to be opened.

For example, you can see that the "V" in the V**iew** menu option is underlined. This means you can press the Alt + V keys to open the **View** menu. You can use a similar approach to select options within the **View** menu. Simply press the underlined letter that corresponds with the menu option. (i.e., Cut: press the "T" key).

Menus also can be opened using the arrow keys.

To do this:

1. Press the Alt key to switch to the menu bar.
2. Use the Left or Right Arrow keys to move to the desired menu.
3. Use the Up or Down Arrow keys to select an option.
4. When the desired option is highlighted, press the Enter key.

Shortcut keys also have been assigned to many of the options. The shortcut key is shown to the right of the command or option.

See the "Using Shortcut Keys and Menus" chapter for more information.

The Toolbar Area

PC-DMIS provides you with a variety of toolbars composed of frequently used commands. These toolbars can be accessed in one of these two ways.

1. Select the **View | Toolbars** submenu and select a toolbar from the menu provided.
2. Right-click on PC-DMIS's **Toolbar** area and select a toolbar from the shortcut menu provided.

Once you have a toolbar in the toolbar area, you can move the toolbar by first clicking on the space between the left or right edge and a button and then dragging the toolbar to a different location.

For in-depth information on all of PC-DMIS's toolbars, see the "Using Toolbars" chapter.

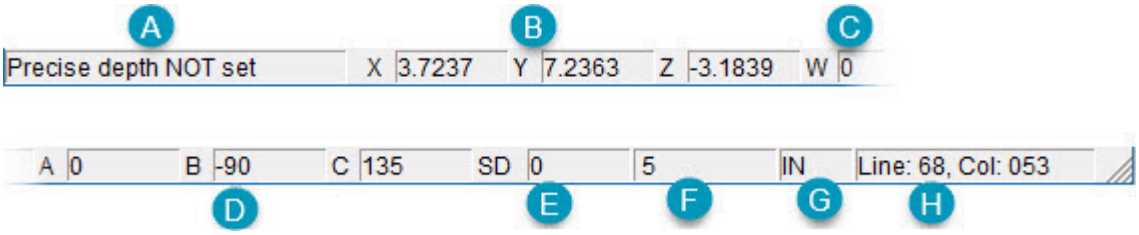
The Graphic Display Window

The Graphic Display window, quite simply, displays graphics. This window is opened by default when you create or access a measurement routine. To hide or view this window, select the **View | Graphic Display Window** menu option. This window displays the following:

- A multi-paned graphical representation of an imported CAD part, the probe, and any simulated machines or fixtures.
- The measured, auto, and constructed features and their ID labels.
- The scans, dimensions, GD&T callouts, and text box displays.

The Graphic Display window is an integral part of PC-DMIS. For information on editing the Graphic Display window and altering the screen display, see "Editing the CAD Display" chapter. For information on how to set up the Graphic Display window, see "Setting Up CAD and Graphics". For information on how to use the Graphic Display window, see the topics below.

The Status Bar



The Status bar displays the following:

A. **Message Box:** The left-most box displays instructions and other information regarding the current procedure or command.

B. **X, Y, and Z boxes:** These boxes show the X, Y, and Z position of the probe. Clicking on any of the three coordinate displays within the Status bar will cause the **Auto Move Point** dialog box to appear. (See "Inserting a Move Point Command" in the "Inserting Move Commands" chapter for additional information regarding DCC Move Point.)

C. **W:** Angle of Rotary Table.

D. **A, B, and C boxes**: These boxes show the A, B, and C wrist angles for a three-axis wrist probe such as a CMS probe. Your wrist probe may only support two axes. In that case, this portion of the Status bar only shows A and B.

E. **SD:** This shows the standard deviation of the last feature measured.

F. **# of Hits:** This shows the number of hits currently taken.

G. **IN/MM:** This shows the current unit of measurement used for the measurement routine.

H. **Line:** This box displays a number that indicates the current line where the cursor is located in the Edit report. **Col:** This text displays a number that indicates the current column where the cursor is located in the Edit report.

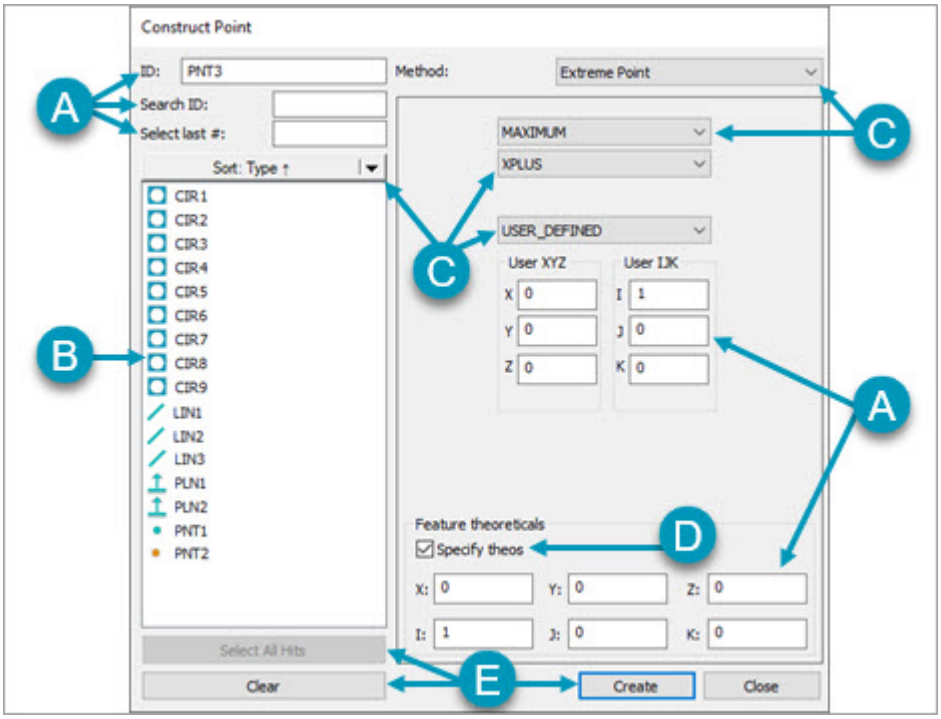
Status Bar Manipulations

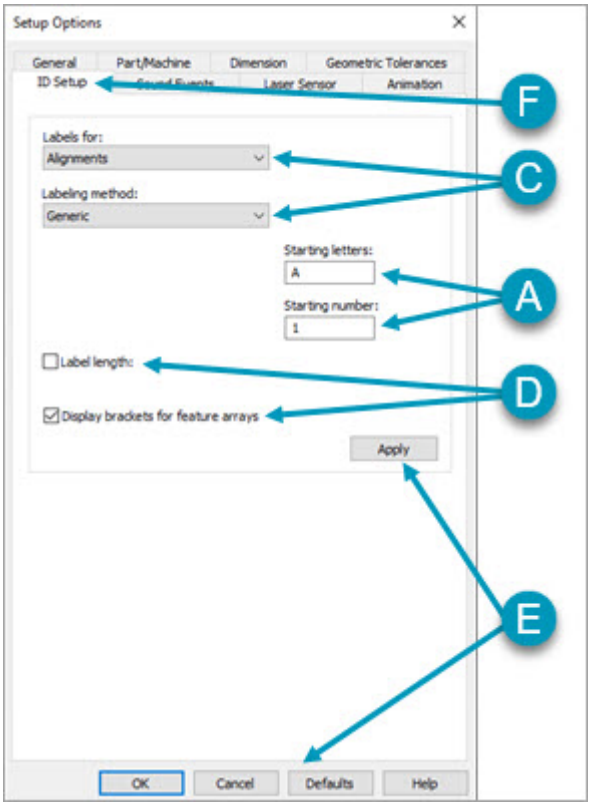
- To increase the size of the Status bar, select **View | Status Bar | Large**. Due to its increased size, this large Status bar only displays the **Message**, the **XYZ**, the **SD**, the **# of Hits:**, the **Line:**, and the **Col:** boxes.
- To put the Status bar back to its normal size, select **View | Status Bar | Normal**.
- To hide or show the Status bar, select **View | Status Bar | Hide Status Bar(s)**.

Dialog Box Description

A dialog box provides various boxes and buttons (called controls) that you can select to tell PC-DMIS how to carry out a command. Sometimes a dialog box shows the default settings already selected, which if satisfactory, can be left as they are. After you modify a dialog box, click **OK** to carry out the command. To cancel the command and close the dialog box, click the **Cancel** button.

The graphics illustrate some features common to most dialog boxes in PC-DMIS.





A - Edit Boxes or Fields

B - List Box

C - Drop Down List Box

D - Check Boxes

E - Command Buttons

F - Tabs

Edit Box

An edit box allows you to type in a desired value or name. In this documentation, edit boxes are simply referred to as "boxes". Edit boxes common to many of PC-DMIS's dialog boxes are listed here:

ID= [Feature]

This box shows the Feature or Dimension identification or name for the features or dimensions to be created.

To change the ID:

1. Select the previous ID.
2. Type a new ID.
3. Press the Tab key.

For the rules that apply when you type an ID, see "Setup Options: ID Setup tab" in the "Setting Your Preferences" chapter.

For a Dimension ID:

- You can change only the number portion of the ID and reset the dimension counter to a desired count.
- You can change the text portion of the ID and set it as the default text for subsequent dimensions. (See the **ID Setup** tab of the **Setup Options** dialog box in the "Setting Your Preferences" chapter.)

Search ID

In the **Search ID** box, you can type the feature (or dimension) IDs to use in the current operation. You can use this box to search using meta-character search options. The feature or dimension IDs will be highlighted in the appropriate **Feature List** box (or **Dimension List** box).

If you type a feature's ID in the **Search ID** box and press the Enter key, PC-DMIS selects that feature from the **Feature List** or **Dimension List** box.

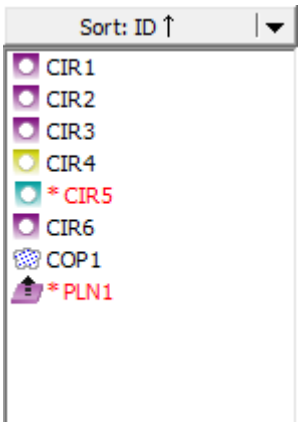
Select Last

In the **Select Last #** box, you can select the last of a certain number of features (or dimensions). For example, if you wanted to select the last four features that were created, simply type **4** and press the TAB key. PC-DMIS will highlight the features selected in the **Feature List** box.

List Box

A list box is similar to an edit box; however, changes cannot be made to the listed values. This documentation refers to either "list" or "box" for the list box. Lists common to many of PC-DMIS's dialog boxes are listed here:

Feature List box



Feature List Box

A feature list box contains a list of the available features within a measurement routine. PC-DMIS uses the selected features to define alignments, construct new features, create dimensions, and perform other tasks. You can select features by following the instructions in the "Selecting Features Using the Graphic Display Window" topic in the "Editing the CAD display" chapter.

You can also use the Graphical Hit Selection method to select inputs to your alignment, construction, or dimension. For details, see "Graphical Hit Selection Method".

You can add new features while the dialog box is open if you use the QuickFeature functionality. PC-DMIS selects the features in the list as you create them. For more information on creating QuickFeatures, see "Creating QuickFeatures" in the "Creating Auto Features" chapter.

A feature displayed in red text with an asterisk (*) to the left of it represents a feature that has been skipped during measurement routine execution.

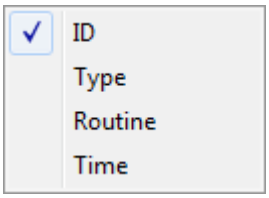
For details on how PC-DMIS reports dimensions that use skipped features during execution, see the "Reporting a Dimension Using a Feature Skipped During Execution" topic in this documentation.

You can deselect selected (highlighted) features with the **Clear** or **Clear List** buttons.

If you are attaching an external measurement routine (see "Attaching an External Measurement Routine" in the "Adding External Elements" chapter), PC-DMIS also lists the variable (or pointer) used to reference the attached measurement routine. A plus sign (+) appears to the left of the pointer. Clicking this plus sign expands or collapses a view of all the features in the attached measurement routine.

Sorting the Features

Clicking the drop-down arrow button located at the top of the **Feature List** box displays the various sorting methods available as shown below.



Feature List Sort Menu

Once a selection is made, the list is automatically sorted based on the selected option. As new items are added to the list, clicking on the **Sort** button will re-sort the list based on the currently sorted options shown on the button. Re-clicking the button will sort the list in reverse as shown be the up or down arrow to the right of the displayed sorting method.

Sorting Options Defined

- **ID** - Sorts the list alphabetically based on feature ID.
- **Type** - Sorts by feature type. In this case, the feature's ID is used as a secondary sort criteria.
- **Routine** - Sorts the list based on the order the feature appears in the measurement routine.
- **Time** - Sorts the list based on the times the features were last measured.

Dimension List box

The **Dimension List** box contains a list of all the dimensions that were created within a measurement routine. You can edit or analyze a dimension by selecting the desired dimension in the list box and selecting the desired changes or options in the associated dialog box. You select multiple dimensions at a time by holding down Ctrl or Shift and clicking on another dimension.

Inside the **Edit Dimension Info** dialog box, if the dimension already has a Dimension Info box associated with it, PC-DMIS shows an asterisk (*) symbol next to the dimension ID in the list. If the dimension info is hidden in all current views, it adds a number sign (#) symbol next to the ID.

For example, suppose you have a roundness dimension named RND1 for a circle named CIR4. If the roundness dimension already had a DIMINFO box associated with it, yet that DIMINFO box was hidden from all views in the Graphic Display window, the ID in the list would look like this:

Example showing asterisk and number sign symbols.

Check Boxes

Click on check boxes to turn options on or off. The option is considered "on" when a check mark appears inside the box. You can select multiple check boxes.

Command Buttons

A command button carries out an action. The command buttons that are common to most dialog boxes in PC-DMIS are listed here:

Apply - This button applies your selections to the dialog box but keeps the dialog box open for further changes.

OK - This button saves, applies the changes, and closes the dialog box. On some dialog boxes, this button inserts commands into the Edit window.

Cancel - This button ignores any changes and closes the dialog box.

Delete - This button removes items (such as created features, dimensions, probe files, alignment information, and so on) from certain list boxes. In the **Delete CAD** dialog box, the **Delete** command button deletes selected nominal features. For more information, see "Deleting CAD".

Last - This button selects the last item in the associated list box.

Last Two - This button selects the last two items in the associated list box.

Select All - This button selects all the items in the associated list box.

Defaults - This button updates the default settings of several parameters. When you create a new measurement routine, it reflects any changes that are stored as the default values.

The default values are stored in the JSON file. You can update these parameters through the appropriate dialog box or use the *PC-DMIS Settings Editor* to edit the setting entry itself. This application is included with your PC-DMIS install set. For more information, see "Modifying Setting Entries".

- If you click the **OK** button without clicking the **Defaults** button, the defined parameters apply only to the active measurement routine and will not affect the entries.
- If you change a parameter and then click the **Defaults** button, PC-DMIS updates the entries to redefine the default to the current entry.

The **Defaults** button allows you to store and apply new default values to new measurement routines created later on.

Recall - This button calls back the original factory settings as long as the original values haven't changed through clicking the **Defaults** button. In that case, PC-DMIS returns the stored values in the JSON file.

For information on how to use the **Machine Options** dialog box to restore original factory settings by reading them from the controller, see "Setting Up the Machine Interface" in the "Setting Your Preferences" chapter.

Create - This button applies changes made in certain dialog boxes and creates features, dimensions, scans, and so on. It then places the created item into the Edit window and the Graphic Display window.

The **Create** button won't close the dialog box. To close the dialog box, click the **Close** button.

Close - This button closes the dialog box. The **OK, Apply**, or the **Create** button doesn't automatically close the dialog box with some dialog boxes (where you may want to select further options).

Clear - This command button clears the highlight of any selected item from the list boxes. In some cases, this button completely removes items from certain list boxes (such as the AB positions from the **New Angles List** box).

In some dialog boxes and tabs, the **Clear** button clears any values that were entered or changed before either the **Apply** or the **OK** button was clicked and restores the "built in" values in PC-DMIS. If you have used the **Default** button to store default values, then PC-DMIS restores those values.

Undo - This button reverses changes that you made using the **Apply** button (or the **Generate** button in DCC scans). Once you click the **OK** button, you cannot reverse the changes.

Help - This button opens the online Help topic associated with the current dialog box.

Dialog Box Tabs

Some dialog boxes contain tabs. These tabs act as identifying markers much like a folder's name in a filing cabinet would. Click on a tab to bring a desired window or options in front of the other tabs. Any options or commands associated with that tab are then displayed.

Drop-Down List Box

A drop-down list box works like menus. Click on the drop-down arrow icon to the right of the current choice, or press the Alt key and then the Up or Down arrow key on the keyboard consecutively. Press F4 to display the available options. Press the key(s) again to close the list. The software shows the current choice in the highlighted box.

Accessing Dialog Box Options

You can use the mouse or keyboard to access the options within a dialog box. To use the mouse to access an option, simply point to the desired option and click.

The keyboard offers a variety of ways to move between available options:

- Press the **Tab** key to move to the next available option.
- Press **Shift + Tab** to move to the previous available option.
- Press the **Arrow** key to display a current drop-down list.
- Press the **Enter** key to select the current command.
- Press the **Space Bar** to select the current check box or button.

Scrolling the Edit Window

The Edit window can be moved in the same manner as a dialog box. See "Moving Dialog Boxes".

The Edit window has scroll bars for viewing additional data in the window.

To scroll:

1. Place the mouse pointer on one of the scroll arrows.
2. Click or hold the left mouse button.

PC-DMIS scrolls the text in the scroll arrow's pointed direction. For example, to scroll down, select the down scroll arrow with the pointer and click the left mouse button.

See the chapters "Editing a Measurement Routine" and "Using the Edit Window" for complete information regarding the Edit window.

Moving Dialog Boxes

You can use the mouse to move a dialog box or window.

To move a dialog box or window:

1. Place the mouse pointer over the title bar.
2. Hold down the left mouse button.
3. Drag the dialog box or window to the desired position in the Graphic Display window.
4. Release the mouse button.

PC-DMIS moves the dialog box or window to its new location.

PC-DMIS stores the last position of the various PC-DMIS dialog boxes. When you re-open the dialog box, it opens the dialog box at the last used location, even across multiple monitors.

If you move PC-DMIS to another monitor, PC-DMIS resets the dialog box positions. This means it opens the dialog boxes in their default position on that monitor.

You can dock some dialog boxes and other interface elements inside the rest of the user interface. You may need to undock these items before you move them. For details on how to dock and undock UI elements, see "Docking and Undocking User Interface Elements".

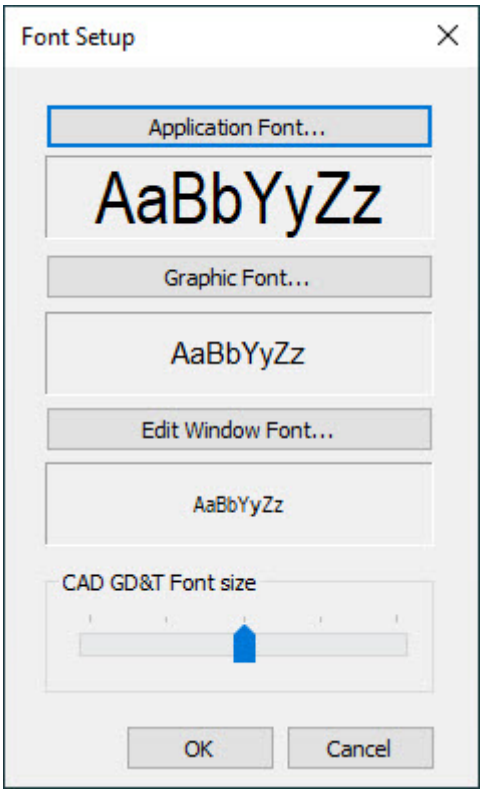
Customizing the User Interface

You can reorganize menus, add your own programs to menus, or create new menus and options altogether. PC-DMIS also allows you to link commands native to PC-DMIS and customized commands to toolbars. Instructions on how to modify the user interface are in the following topics:

- Restoring the Default User Interface
- Customizing User Interface Fonts
- Customizing Menus
- Customizing Toolbars
- Customizing Shortcut Keys

The organization of this documentation is based on the default user interface shipped with this version PC-DMIS. Be aware that customizing the user interface may make existing documentation difficult to follow.

Customizing User Interface Fonts



Font Setup Dialog Box

To modify font attributes, select the **Edit | Preferences | Fonts** menu option to open the **Font Setup** dialog box. Use this dialog box to change the font and its attributes (such as the font size and style) for these areas of the main PC-DMIS user interface:

- The Status Bar
- The Graphic Display window
- The Edit window

To change the font:

1. Click one of these buttons to open a standard **Font** dialog box:
    - **Application Font** - This changes the font of the Status Bar in the main application.
    - **Graphic Font** - This changes the font for text in the Graphic Display window. This affects feature labels, Dimension Info and Point Info text boxes, and so on. The **Color** list on the **Font** dialog box that appears sets the background color for CAD GD&T characteristic IDs. For information on these characteristic IDs, see "Working with CAD GD&T Callouts" in the "Editing the CAD Display" chapter.
    - **Edit Window Font** - This changes the font for the Edit window. For a recommended font for the Edit window, see the note below.
2. From the **Font** dialog box, use the lists and select your font changes.
3. Click **OK** to close the **Font** dialog box.
4. From the **Font Setup** dialog box, click **OK** to accept your change.

You can use any font available on your computer system; however, some fonts don't have a uniform spacing. This can make some components more difficult to read. For the Edit window text, we recommend that you use a monospace, fixed-width font, such as the *Courier New* font. Otherwise, characters, lines, and headings may not line up as expected.

CAD GD&T Font size

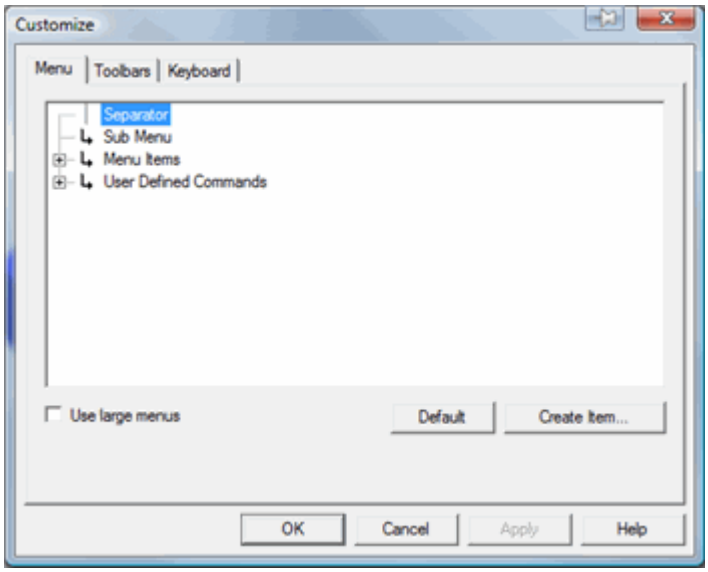
This slider scales the size of any GD&T CAD elements that appear in the Graphic Display window. Each increment above or below the midpoint increases or decreases the font by 10%. The font size changes dynamically as you adjust the slider. Click **OK** to keep the changed font size.

Customizing Menus

To customize the menus on the menu bar:

1. Access the **Customize** dialog box by selecting the **View | Toolbars | Customize** menu option.

2. Select the **Menu** tab.



Customize Dialog Box - Menu Tab

You can use this tab to add new menu items, move existing menu items, or remove menu items from the menu bar altogether.

You can use the **Use large menus** check box to show all menu items in a larger font. PC-DMIS will need to restart to apply the large menu sizes.

To Move a Menu Item

To move a menu item to a new location on the menu bar:

1. Select the **View | Toolbars | Customize** menu option to open the **Customize** dialog box, and then click the **Menu** tab.

2. Navigate to the menu item you want to move on PC-DMIS's actual menu bar (not the tree view menu list in the **Menu** tab).

3. Select the desired menu item.

4. Drag it to the new position. As you drag the item through the menu structure, PC-DMIS displays a small red arrow to indicate where you want to add the item.

5. Release the mouse button. The menu item is moved from its original location to the new location.

6. Click **OK** to accept your changes and close the **Customize** dialog box.

To Remove/Restore a Menu Item

To Remove a Menu Item from the Menu Bar:

1. Access the **Customize** dialog box by selecting the **View | Toolbars | Customize** menu option, and click the **Menu** tab.
2. Navigate to the menu item you want to remove on PC-DMIS's actual menu bar (not the tree view menu list in the **Menu** tab).
3. Select the desired menu item.
4. Drag it off of the menu bar area.
5. Release the mouse button, and the menu item is removed from the menu.
6. Click **OK** to accept your changes and close the **Customize** dialog box.

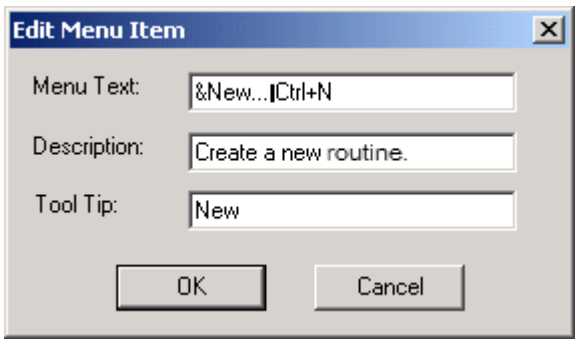
To Restore a Removed Menu Item:

1. Access the **Customize** dialog box by selecting the **View | Toolbars | Customize** menu option, and click the **Menu** tab.
2. Navigate in the **Menu** tree view list to the menu item you want to restore.
3. Select the menu item and drag it up onto PC-DMIS's actual menu bar. As you drag the item through the menu structure, a small red arrow will appear indicating where the item will be added when you release the mouse button.
4. Release the mouse button to insert the menu item.

To Edit an Existing Menu Item

You can edit existing menu items, including menu item names, descriptions, and tooltips. To do this:

1. Access the **Customize** dialog box by selecting the **View | Toolbars | Customize** menu option.
2. With the dialog box open, click on PC-DMIS's menu bar.
3. Select a menu and then right-click on the menu item you want to change on PC-DMIS's actual menu bar (not the tree view menu list in the **Menu** tab). The **Edit Menu Item** dialog box appears.



Edit Menu Item Dialog Box

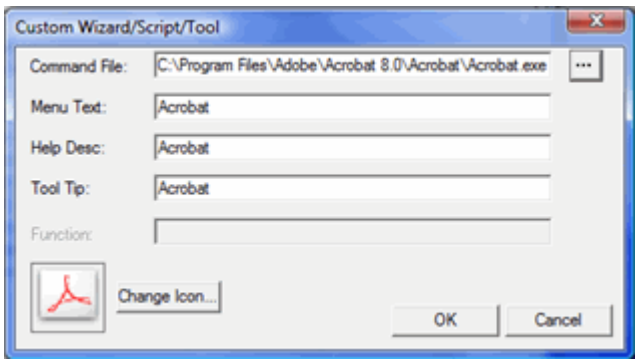
4. Modify the menu item using this dialog box and then click **OK**.
5. Click **OK** on the **Customize** dialog box.
6. Verify your change.

In the **Menu Text** box, the letter that follows the ampersand sign (&) indicates that the letter is used with the Alt key to quickly select that menu item. For example, when you press the key combination Alt + F + N, the **New Measurement Routine** dialog box opens from the **File | New** menu option. Note that you can also access this dialog box with the Ctrl + N key combination.

To Add a New Menu Item

You can create your own custom menu item and tie an external program or batch file to it. To do this:

1. Access the **Customize** dialog box by selecting the **View | Toolbars | Customize** menu option, and select the **Menu** tab.
2. Click the **Create Item** button. The **Custom Wizard / Script / Tool** dialog box appears.
3. Click the **'…'** button. An **Open** dialog box appears.
4. From the **Files of Type** list, select the type of file you want to insert.
5. Navigate to the directory containing the custom application, batch file, BASIC script, and so forth.
6. Select the file to insert and then click **Open**. The **Open** dialog box closes, and the **Custom Wizard / Script / Tool** dialog box displays the default information associated with the custom program you selected.



Example of a sample application in the Custom Wizard/Script/Tool dialog box.

Command File:
This box shows the pathway to the command.

Menu Text:
This box allows you to specify the name used on the menu for this item.

Help Desc:
This box allows you to define information that PC-DMIS displays in the Status bar when you move your mouse over the item.

Tool Tip:
This box allows you to specify the tooltip text displayed for this item when you hover your mouse over it. This only works if the custom item is added to a toolbar, not a menu.

Function:
This box remains unavailable for selection unless you are using a custom BASIC script. Once the box becomes enabled, you can use it to define the function or subroutine that runs from the loaded .bas file. Type the routine name without parentheses. For example, if you type **TestFunction**, PC-DMIS launches the TestFunction routine when the BASIC script is executed.

Change Icon:
This button allows you to change the icons displayed for this menu item.

7. Make any additional changes to this dialog box.
8. Click **OK** to accept your changes. PC-DMIS inserts the newly created command into the **User Defined Commands** tree view list in the **Menu** tab of the **Customize** dialog box.
9. Expand **User Defined Commands** tree view list.
10. Select the newly created command and drag it up onto PC-DMIS's actual menu bar. As you drag the item through the menu structure, a small red arrow will appear indicating where the item will be added when you release the mouse button.
11. Release the mouse button to insert the command.

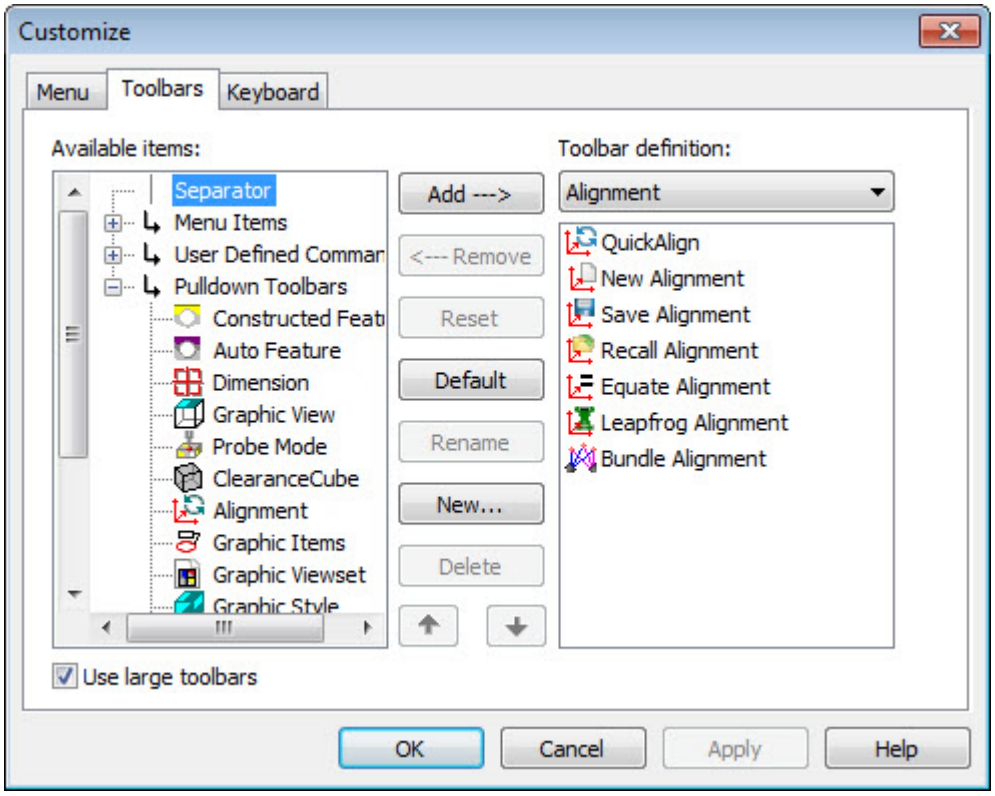
12. Close the **Customize** dialog box. The newly inserted menu item now resides in your menu bar.

Customizing Toolbars

To customize the toolbars that appear on the toolbar menu:

1. Select the **View | Toolbars | Customize** menu option to access the **Customize** dialog box.

2. Select the **Toolbars** tab.



Customize Dialog Box - Toolbar Tab

You can use this tab to add new toolbars and new toolbar icons, add new dropdown toolbars, remove custom toolbars, remove toolbar icons, and reorder toolbar icons on existing toolbars.

You can use the **Use large toolbars** check box to show all toolbar icons in a larger size. This change happens automatically when you click **OK** or **Apply**. PC-DMIS does not need to restart.

To Modify an Existing Toolbar

You can modify existing toolbars as described below. First, access the **Customize** dialog box by selecting the **View | Toolbars | Customize** menu option, and click the **Toolbars** tab.

To add a menu item to a toolbar:

1. Select the toolbar from the **Toolbar definition list**.
2. Find the item you want to add in the **Available items** list.
3. Select it, and click the **Add** button. The item appears on the desired toolbar.
4. Click **Apply** and then **OK** to accept your changes.

To remove a toolbar icon:

1. Select the toolbar from the **Toolbar definition** list.
2. Find the item in the list to remove (right side of dialog).
3. Select it and click the **Remove** button.
4. Click **Apply** and then **OK** to accept your changes.

> Existing toolbars must have at least one icon on them. If you remove the last icon and click **Apply** or **OK**, the icon still remains on the toolbar.

To erase any changes:

Click the **Reset** button. As long as the **OK** or **Apply** buttons haven't been clicked, the toolbar reverts to its previous state.

To remove all customized toolbars and restore the layout shipped with this version:

Click the **Default** button.

To create a new toolbar item:

Click **New**. The **Custom Wizard / Script / Tool** dialog box opens. Select an item to add.

This documentation covers the process of adding custom items in the "To Add a New Menu Item" topic above.

To rearrange the item order on a toolbar:

1. Select the toolbar from the **Toolbar definition** list.
2. Select the item that you wish to move.
3. Click the up arrow or down arrow button to move the item up or down respectively among the other toolbar icons in the list.

To rename a custom toolbar:

1. Select the toolbar from the **Toolbar definition** list.

2. Click **Rename**. A **New Toolbar Name** box appears.
3. Type a name in the box and click **OK**.

PC-DMIS also allows another way to rearrange or delete items from any custom toolbar on the fly. This is by using the Shift key. Consider the following:

To delete or rearrange a toolbar's icons:

1. Press and hold the Shift key.
2. Click and drag an icon. The icon becomes movable.
3. If *rearranging* the icon, drag it to a new spot on the toolbar.
4. If *deleting* the icon, drag it outside of the toolbar's boundaries.
5. Release the mouse button. The change is made.

Since existing toolbars must have at least one icon on them, if you remove the last icon in this fashion, it only remains removed until you restart PC-DMIS. After restarting, the icon reappears.

To add a separator:

1. Press and hold the Shift key.
2. Click and drag an icon to move it.
3. Drag it a small distance to the right (not far enough to rearrange its position).
4. Release the mouse button. The software places a separator to the left of the icon.

To delete a separator:

1. Press and hold the Shift key.
2. Click and drag the icon to the right of the separator. The icon becomes movable.
3. Drag it on top of the separator to its left.
4. Release the mouse button.

To Create a Custom Toolbar

1. Access the **Customize** dialog box by selecting the **View | Toolbars | Customize** menu option, and select the **Toolbars** tab.
2. Click **New** and select **Toolbar**. An input box appears requesting a toolbar name.

3. Type the name of the toolbar and click **OK**. Your new toolbar now appears in the **Toolbar Definition** list. You can now modify the toolbar to accept new toolbar icons (see "To Modify an Existing Toolbar").

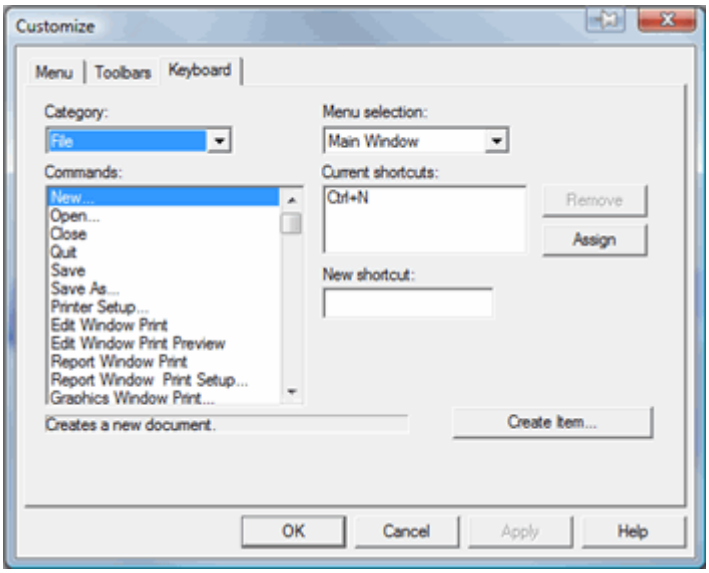
To Delete a Custom Toolbar

1. Access the **Customize** dialog box by selecting the **View | Toolbars | Customize** menu option, and select the **Toolbars** tab.
2. Select the toolbar from the **Toolbar Definition** list.
3. Click the **Delete** button.
4. Click **Apply** to apply your changes.

Customizing Shortcut Keys

To customize the shortcut keys used for menu items and commands in PC-DMIS:

1. Access the **Customize** dialog box by selecting the **View | Toolbars | Customize** menu option.
2. Select the **Keyboard** tab.



Customize Dialog Box - Keyboard Tab

You can use this tab to modify the shortcut keys used to call commands within PC-DMIS and add new shortcut keys for custom menu and toolbar items.

To Add Shortcut Keys to a Command

1. Access the **Customize** dialog box by selecting the **View | Toolbars | Customize** menu option, and select the **Keyboard** tab.

2. Select the command that you want to modify by using the **Category** and **Menu Selection** lists. Once you have selected a command in the **Commands** list, the current shortcut key(s), if any are assigned to that command, will be displayed in the **Current Shortcuts** box.
3. Highlight the command for which you will assign new shortcut keys.
4. Click in the **New Shortcut** box.
5. Type the keys you want to assign to this command. The keys you pressed appear as you type them.
6. Click the **Assign** button, and the new shortcut keys appear in the **Current Shortcuts** box with any other shortcut keys currently assigned to the command.
7. Click **Apply** to accept your changes.

As in the other tabs, you can use the **Create** button to first create a command and tie it to a custom program. You can then click **User Defined** from the **Menu Selection** list to select this command. All user-defined commands appear in the **Commands** list.

To Remove Shortcut Keys from a Command

1. To open the **Customize** dialog box, select the **View | Toolbars | Customize** menu option, and click the **Keyboard** tab.
2. Select the command you wish to modify with the **Category** and **Menu Selection** lists. Once you select a command in the **Commands** list, the software displays the current shortcut key or keys in the **Current Shortcuts** box if any are assigned to that command.
3. Select the command from which you want to remove the shortcut keys.
4. Select the shortcut key to remove.
5. Click the **Remove** button.
6. Click **Apply** to accept your changes.

Restoring the Default User Interface

To remove all intentional custom user interface changes at once, follow this procedure:

This removes changes you made with the **Customize** menu option. (**Customize** is visible when you right-click on the toolbar area.)

1. Close PC-DMIS.
2. Navigate to the directory where you installed PC-DMIS.
3. Access the directory that corresponds to your Windows user profile.
4. Delete the file named menu_xxx.dat where xxx refers to the three letter code for the language you're running. For English, delete menu_eng.dat.
5. Restart PC-DMIS. It will use the default user interface.

For information on how to customize menus, toolbars, and shortcut keys, see "Customizing Menus", "Customizing Toolbars", and "Customizing Shortcut Keys".

Docking and Undocking User Interface Elements

Some user interface elements (such as toolbars and some dialog boxes) can dock themselves into the Edit window or the toolbar area when you drag and drop the item on top of one of those areas. If you don't want this, hold down the Ctrl key while you release the mouse button. The toolbar or dialog box then hovers over the dockable background instead.

Some items, such as the Edit window, contain a right-click menu item (**Docking View**) that allows you to dock or undock that item. If the right-click menu item is not selectable, close any open dialog boxes and try again.

You may need to cascade (**Window | Cascade**) or tile (**Window | Tile Horizontally** or **Window | Tile Vertically**) your windows and then click and drag a window's title bar to float one over another.

Using Basic File Options

Using Basic File Options: Introduction

PC-DMIS provides you with many options to manipulate measurement routines and manage your essential files. As with most Windows-based programs, you can perform basic file management using standard Windows dialog boxes; these include creating, opening, copying, renaming, and deleting files. Additionally, through PC-DMIS you can perform more advanced operations, such as importing and exporting CAD data, or executing completed measurement routines.

This chapter specifically deals with Basic File Options. For more advanced options, see the "Using Advanced File Options" chapter.

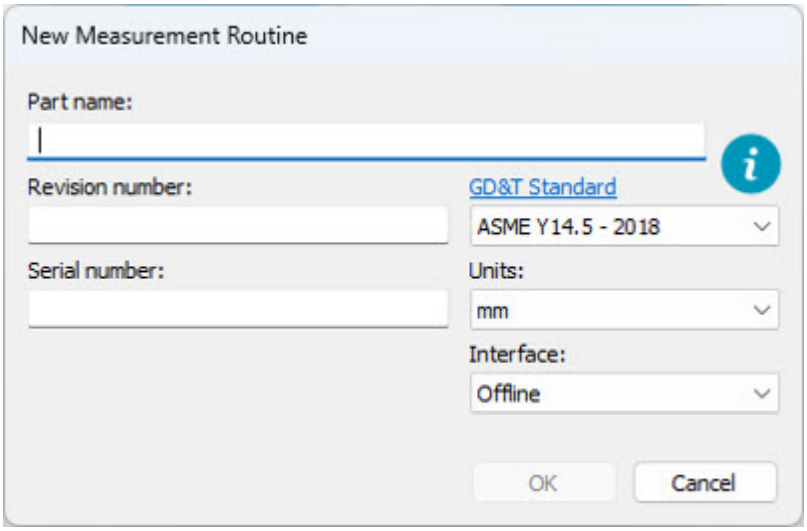
The options discussed in this chapter include:

- Creating New Measurement Routines
- Opening Existing Measurement Routines
- Saving Measurement Routines
- Working with Measurement Routine Archives
- Performing File Operations
- Connecting to Teamcenter
- Changing the Language
- Printing the Graphic Display Window
- Printing the Report Window
- Closing or Quitting a Measurement Routine
- Exiting PC-DMIS

Creating New Measurement Routines

If you don't have any existing measurement routines, you can create a new measurement routine with the **New Measurement Routine** dialog box. You can access this through the **File | New** menu option.

The **File | New** and **File | Open** menu options are unavailable while a probe change is in progress. This protects your hardware by preventing you from opening or creating a measurement routine that could power on a laser sensor and damage the probe mounted on the head.



New Measurement Routine Dialog Box

Here, you can create a new measurement routine. You can type a part name, revision number, serial number and select the GD&T standard, measurement units, and CMM interface type that you want to use. Once you click **OK**, PC-DMIS creates the measurement routine.

PC-DMIS only requires the **Part Name** box to have a value to create a new measurement routine. Information for the **Revision Number** and **Serial Number** boxes is optional.

By default, PC-DMIS selects the **ASME Y14.5 - 2018** standard from the **GD&T Standard** list. You can modify this to a different standard.

The GD&T standard affects Size or Geometric Tolerance commands in your measurement routine. The standard you select does not affect legacy dimensions. You can change the selected GD&T standard at any time from the **Geometric Tolerances** tab of the **Setup Options** dialog box. However, because the setting applies to the entire measurement routine, depending on the measurement routine's content at the time of change, it may behave differently.

For information on the **Geometric Tolerance** tab, see "Setup Options: Geometric Tolerances tab" in the "Setting Your Preferences" chapter.

For details on using Geometric Tolerances, see the "Using Geometric Tolerances" chapter in the PC-DMIS Core documentation.

For details on using legacy dimensions, see the "Using Legacy Dimensions" chapter in the PC-DMIS Core documentation.

You can also create new measurement routines from the Home page. You can even create measurement routines from templates so that the measurement routines come populated with those commands you use most frequently. You can also choose a destination folder for measurement routines that you create from a template. For information, see "The Home Page" and "Using Measurement Routine Templates" in the "Navigating the User Interface" chapter.

Creating a Measurement Routine Package

Select **File | Package** to create a .zip file that contains the measurement routine and its dependent files.

For more details about the Package Measurement Routine functionality, see the "Package Measurement Routine" chapter in the PC-DMIS Toolkit Module documentation.

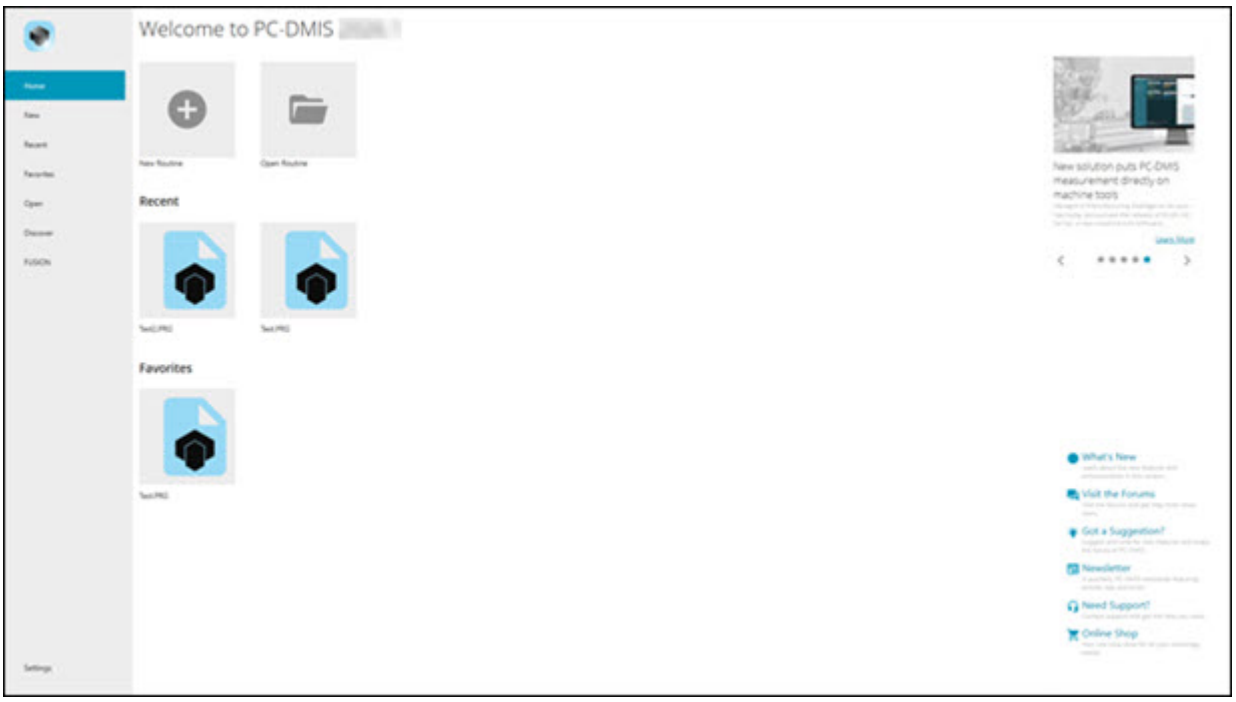
Opening Existing Measurement Routines

You can open measurement routines from the Home page or from the **File | Open** menu option.

The **File | New** and **File | Open** menu options are unavailable while a probe change is in progress. This protects your hardware by preventing you from opening or creating a measurement routine that could power on a laser sensor and damage the probe mounted on the head.

Using the Home Page

The Home page is discussed in the "Home Page" topic of the "Navigating the User Interface" chapter:

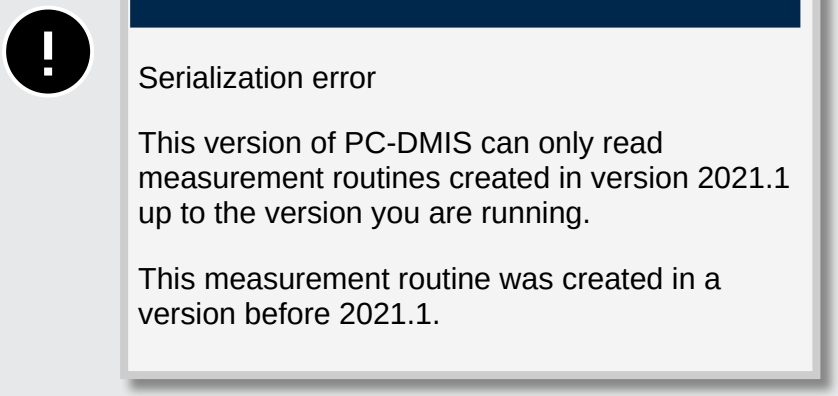


Home Page

Valid Versions

You can only open a measurement routine (.prg) made in valid versions of PC-DMIS. For this version of PC-DMIS, if you attempt to open a measurement routine created before PC-DMIS version 2021.1, PC-DMIS shows an error message.

Example error message when you try to open an invalid measurement routine file:



Using the File Open Dialog Box

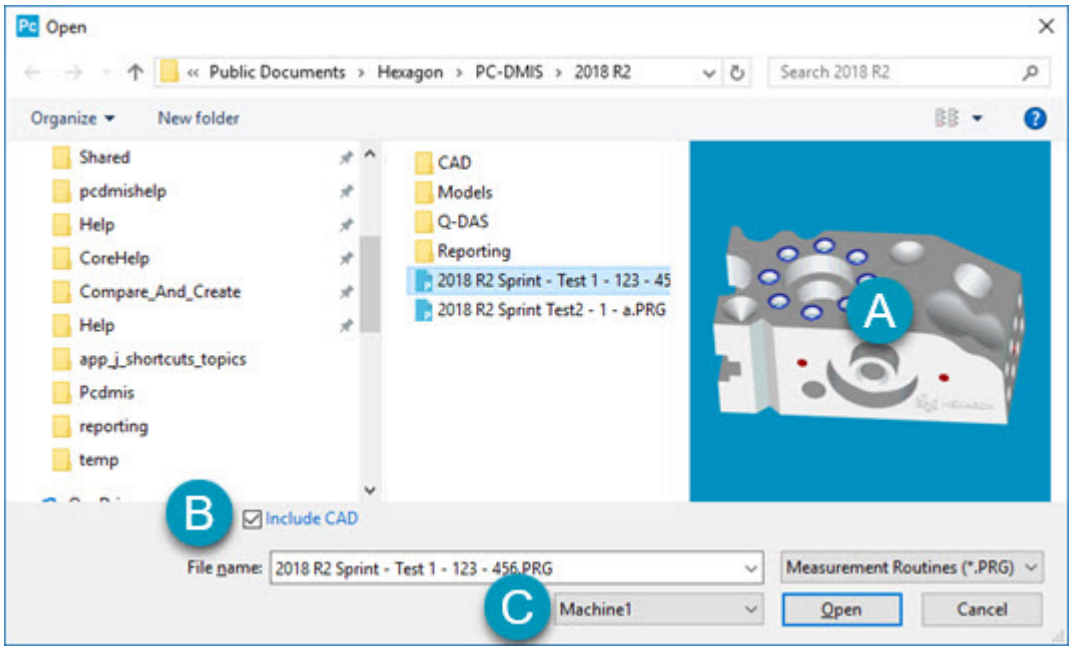
You can use the **Open** dialog box to locate and open a measurement routine.

To open the **Open** dialog box, select **File | Open**.

When you open a measurement routine that was created in a prior version, be aware of the following:

- If you quit the routine (**File | Quit**), any changes you made in this version are lost. The routine remains unchanged and you can still open it in the prior version of PC-DMIS.
- If you save (**File | Save**) or close (**File | Close**) the routine, or if you close PC-DMIS (close button in the top right of the application window), PC-DMIS saves the routine using this version's schema. Once that happens, it will no longer open in the prior version.
- If you wish to save your changes, and you need the routine to remain available in the prior version, choose **File | Save As** and be sure to select the prior version beneath the **Save as type** drop-down list. For more information, see "Save As".

This dialog box is a standard Windows **Open** dialog box with the following additions:



Open Dialog Box

A. **Preview** - This area of the dialog box shows the CAD image for the last view of your part in the Graphic Display window (without labels). If your part doesn't have the CAD data, the image displays measured geometry. If you set a thumbnail from "The Right Pane" of the Home page, PC-DMIS displays the thumbnail as the preview image.

B. **Include CAD** - This check box determines whether to load the CAD model when you open the measurement routine. If a CAD model is part of the measurement routine that you are opening, click the **Include CAD** check box. If you clear the check box, PC-DMIS does not load the CAD model when you open the measurement routine.

C. **Interface** - This list displays the online machines in your system as well as an **Offline** option.

- If PC-DMIS is running in Online mode, you can select the machine interface to use for this measurement routine (if you have multiple CMMs).
- If PC-DMIS is running in Offline mode, you can select the **Offline** machine option.

The **Open** dialog box automatically opens each time you start PC-DMIS so that you can open an existing measurement routine. However, if you want to turn off this feature, you can clear the **Show Startup Dialog** check box on the **General** tab of the **Setup Options** dialog box.

Probe Conversion Messages When Opening

When you open a measurement routine from a previous version, you may receive a warning message that asks you if you want to convert probe files for any probes used in the measurement routine to the latest format.

If you plan on using the probe with older versions of PC-DMIS, you may not want to update the probe file. However, note that until you update the probe file to the latest format, some newer functionality for that probe may not be available in this version of PC-DMIS.

If you continue to receive this message whenever you open your measurement routine, even after you click **Yes**, you should perform a **File | Save As** operation, and save the measurement routine so that it is compatible with this version of PC-DMIS. For more information, see the "Save As" topic.

Subroutine Names

If you open a measurement routine from a previous version that contains a subroutine with a name greater than 180 characters, the name of the subroutine is automatically shortened to the first 180 characters.

You can also open new measurement routines from the Home page. For information, see "The Home Page" in the "Navigating the User Interface" chapter.

Saving Measurement Routines

You can select the **File | Save** option to save any work that has been done in the current measurement routine. The first time you save a file, the **Save As** dialog box appears. This dialog box allows you to choose where to save your measurement routine (see the "Save As" topic for additional information).

If you have already saved a measurement routine to a previous version of PC-DMIS (from the **Save As** dialog box), PC-DMIS displays a message on subsequent saves. This

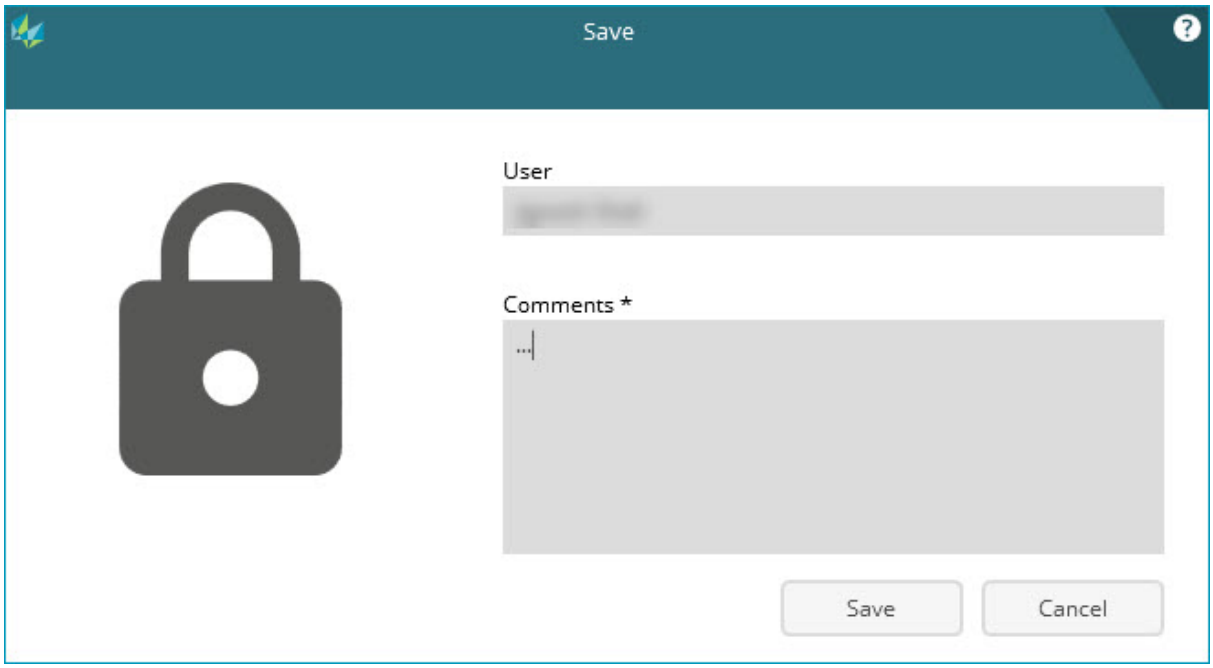
message asks if you want to save the measurement routine to the old version selected previously. You can choose these options:

- **Yes** - PC-DMIS saves the measurement routine to the old version.
- **No** - PC-DMIS saves the measurement routine to the current version.
- **Cancel** - PC-DMIS ends the save process without saving.

You cannot save a certified measurement routine to an older version of PC-DMIS.

If you want to stop displaying this message, see "Warnings" in the "Setting Your Preferences" chapter.

When you save a certified measurement routine, PC-DMIS displays the **Save** dialog box.



Save Dialog Box

The **Save** button saves all the changes that you made to the measurement routine with comments in the .protect file.

For information on certified measurement routines, see "Certify".

Your measurement routines are automatically archived during certain events. For more information, see "Working with Measurement Routine Archives".

Save As

When you select the **File | Save As** option, or save a measurement routine for the first time, the **Save As** dialog box appears.

- You can use the **File name** option in this dialog box to save the current measurement routine under a new file name.
- You can also save the measurement routine under an older version of PC-DMIS.

To save the measurement routine, click the **Save** button.

To close the dialog box without saving the measurement routine, click the **Cancel** button.

Certified Measurement Routine

When you click the **Save** button on the **Save As** dialog box to save a certified measurement routine to the current version of PC-DMIS, the software displays a message. The message asks if you want to keep the certification on the new measurement routine before the **Save As** dialog box closes.

You can choose these options:

- **Yes** - PC-DMIS saves the measurement routine and keeps the certification on the new measurement routine. It also generates a .protect file and continues to track the changes from the previous .protect file.
- **No** - PC-DMIS saves the measurement routine but doesn't keep the certification on the new measurement routine.
- **Cancel** - PC-DMIS ends the save as process without saving.

Saving to an Older Version of PC-DMIS

You cannot save a certified measurement routine to an older version of PC-DMIS.

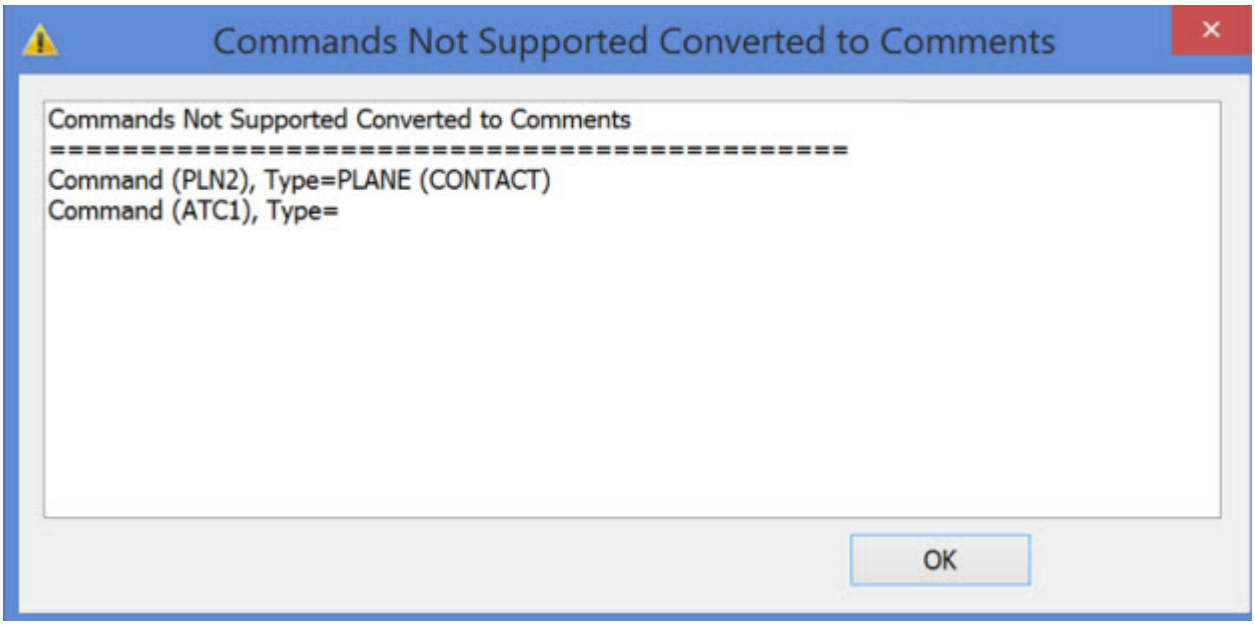
From the list of version numbers, you can choose to save the measurement routine in a format that the current version and previous versions of PC-DMIS can use. Available versions include 2021.1 and above.

- If you try to save a measurement routine to an older version of PC-DMIS, and if the measurement routine contains commands that the older version does not support, PC-DMIS displays a caution that it will convert those commands into comments.
- If you try to save a certified measurement routine to a previous version of PC-DMIS, PC-DMIS displays a message that you can only save certified measurement routines to the current version.

To cancel saving this measurement routine, click **Cancel**.

To continue to save the measurement routine to the older version, click **Save**.

PC-DMIS converts the non-supported commands into comments and displays the **Commands Not Supported Converted to Comments** dialog box. This dialog box lists the non-supported commands that PC-DMIS converted to comments. For example:



Commands Not Supported Converted to Comments Dialog Box

You must click **OK** to acknowledge that you have noted this message.

If the `SaveAsWarningLogEnabled` entry is enabled, PC-DMIS automatically creates a log file that contains the contents of the message. The log file is named:

<name>_Save_As_Log_<YYYYMMDDHHMMSS>.log

Where <name> is the name of the measurement routine, and <YYYYMMDDHHMMSS> is the date and time.

YYYY is the year.

MM is the month.

DD is the day.

HH is the hour.

MM are the minutes.

SS are the seconds.

The log file is in the same folder as the measurement routine.

You can disable the creation of the log file. For help, see the "SaveAsWarningLogEnabled" topic in the Settings Editor documentation.

About Schema Numbers and Saving to an Older Version

Each new version of PC-DMIS has new capabilities and stores new commands into a measurement routine that older versions cannot understand. Thus, each measurement routine has an internal schema number assigned to it that's associated with a specific version of PC-DMIS. By default, a measurement routine is assigned the current version's schema number when you choose **File | Save**. This number ensures that only that version (or a later version) can open that measurement routine.

For example, if you have a measurement routine that was saved in version 2011, it will have the schema number of 5008. If you try to load that measurement routine into version 2010, it will be incompatible because the older version cannot handle changes that were made in PC-DMIS 2011.

You can, of course, choose to save the measurement routine back to the version 2010 format. This drops the internal schema number for the measurement routine down to 4555, which enables you to then open it in version 2010. However, the newer commands won't be used. Instead, PC-DMIS stores the unsupported commands inside of DOCUMENT comments.

For more information, see "$$Document" in the "Using the Edit Window" chapter.

Custom reports, templates, label templates, and other reporting modifications are NOT backward compatible.

Saving a CAD File as a Reference

To save a CAD file as a reference to the original CAD file, select the **Save CAD as reference** check box. You can use this option to reference your CAD model instead of copying a new one. This action can help save disk space.

This option becomes available for selection whenever you have a CAD model loaded for your measurement routine and access the **Save As** dialog box.

If the software cannot find the original referenced CAD file when you try to open the measurement routine (due to a CAD file rename, deletion, or relocation), PC-DMIS prompts you to locate the original CAD file.

Working with Measurement Routine Archives

PC-DMIS provides some basic measurement routine archiving. This archiving replaces the automatic file save functionality that existed in some older versions of PC-DMIS.

Two copies of your measurement routine are automatically created in the background during these events:

- <name>.prg~ is created just before you save the measurement routine (where <name> is the measurement routine name).
- <name>.prg^ is created just before you load the measurement routine (where <name> is the measurement routine name).

> The above PRG~ and PRG^ backup files have the hidden attribute set and won't be visible in Windows Explorer unless the "Show hidden files" option is set.

If you try and open a corrupted measurement routine, PC-DMIS asks if you want to open the copy made before the last save (<name>.prg~). If you choose **Yes**, PC-DMIS renames the corrupt measurement routine to <name>.prg.tmp (by default, these files have the hidden attribute set to be hidden and won't be visible in Windows Explorer unless the "Show hidden files" option is set correctly). It renames <name>.prg~ to the current measurement routine name. If that backup was also corrupted, PC-DMIS asks if you want to restore from the backup that was made just before you loaded the measurement routine during your last session (<name>.prg^). It then follows the same process of renaming and copying.

> As with any backup/restore process, you may lose your latest changes when restoring.

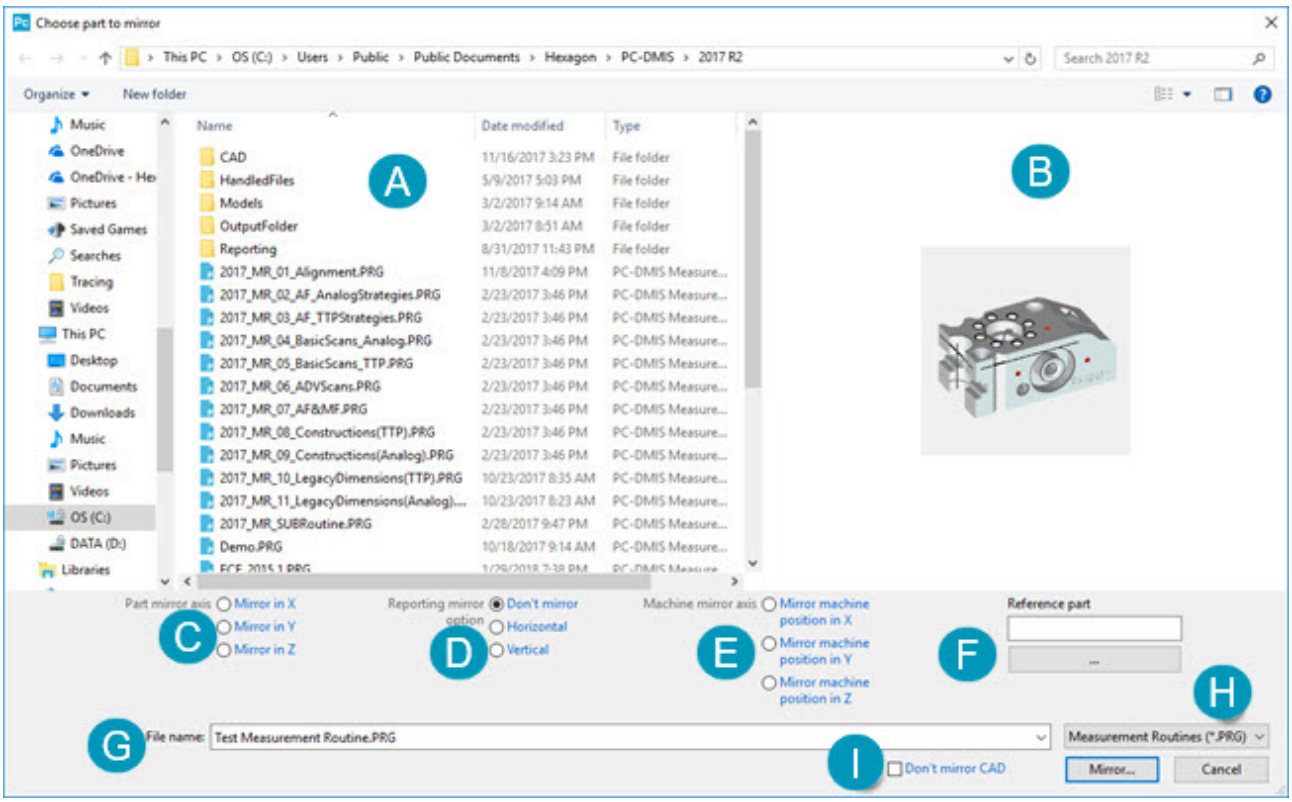
You can disable or enable this functionality by using the `DocumentRecovery` entry in the PC-DMIS Settings Editor.

Performing File Operations

Using PC-DMIS's file operations, you can mirror, copy, delete, rename, and certify measurement routine files.

Mirror

The **Mirror** command (**File | Operations | Mirror**) lets you create a mirror image copy in the X, Y, or Z axis of a measurement routine. The command opens the **Choose part to mirror** dialog box.



Choose part to mirror Dialog Box

You can only mirror measurement routine (.prg) and CAD files made in valid versions of PC-DMIS. For this version of PC-DMIS, if you attempt to mirror either of these file types created before PC-DMIS version 2021.1, PC-DMIS shows an error message.

Example error message when you try to mirror an invalid measurement routine file:

PC-DMIS Message

X Mirrored Copy of <measurement routine file> (Schema: 1215).

Serialization error

This version of PC-DMIS can only read measurement routines created in version 2021.1 up to the version you are running.

This measurement routine was created in a version before 2021.1.

Where <measurement routine file> is the name and location of the file you are trying to open.

The following description describes the items available for selection on the dialog box:

A. **Measurement Routines** - This area displays the available measurement routines in the current directory.

B. **Preview** - This area shows the CAD image for the last view of your part in the Graphic Display window (without labels). If your part doesn't have any CAD data, the image displays measured geometry. This area only shows images for .prg files.

C. **Part mirror axis** - This area defines the axis in which you want to mirror the measurement routine:

- **Mirror in X** - This option mirrors the part in the X axis.
- **Mirror in Y** - This option mirrors the part in the Y axis.
- **Mirror in Z** - This option mirrors the part in the Z axis.

D. **Reporting mirror option** - This area defines how PC-DMIS should mirror CAD images in reports:

- **Don't mirror** - This option does not mirror at all.
- **Horizontal** - This option mirrors CAD images horizontally.
- **Vertical** - This option mirrors CAD images vertically.

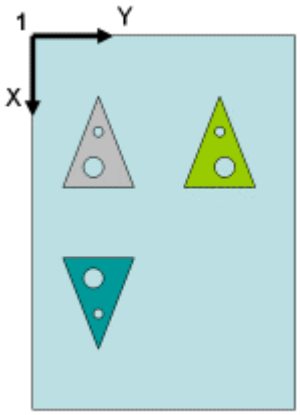
This area affects reporting objects, such as CadReportObjects, CadImageObjects, Analysis objects, and SectionCutObjects, as well as any defined viewsets in the measurement routine.

E. **Machine mirror axis** - This area defines the orientation of the mirrored part on the virtual machine:

- **Mirror machine position in X** - This option mirrors the virtual machine's X axis.
- **Mirror machine position in Y** - This option mirrors the virtual machine's Y axis.
- **Mirror machine position in Z** - This option mirrors the virtual machine's Z axis.

PC-DMIS mirrors the part at the same location as the original part. You can use the **Machine mirror axis** area to define the orientation of the mirrored part on the virtual machine. You only need to shift the part on the machine to the place it should get measured.

For a description of how these options position your part, consider this diagram:



1 - The machine's origin

- Original part

- Part mirrored in Y with mirror machine position in Y

- Part mirrored in Y with mirror machine position in X

F. **Reference part** - This box pulls out any quick fixture alignment data from the reference part and uses that information in the mirroring operation.

   If you use this area to define a reference part, then PC-DMIS does not use the **Machine mirror axis** area. Instead, the location and orientation of the mirrored part are loaded from the existing (and already mirrored) reference measurement routine.

   This option is especially useful if you have multiple measurement routines that belong to the same physical part and need to get mirrored. In this case, you would only need to define the location and orientation of the mirrored part in the first mirrored measurement routine. You could then select the first mirrored measurement routine as the reference part to mirror other measurement routines.

G. **File name** - This box defines the measurement routine to mirror.

H. This file type list filters the display of the current directory to only show measurement routine files (.PRG).

I. **Don't mirror CAD** - This check box determines whether the resulting CAD is mirrored. If you select this check box, the resulting CAD is not mirrored. The check box is initially cleared when you first start PC-DMIS. Afterward, this check box retains the state of what was applied in the last mirroring.

   You can use the PC-DMIS Settings Editor to change the `DoNotMirrorCAD` entry's value in the **Option** section.

To Mirror a Measurement Routine:

1. If you use an infinite wrist in the measurement routine, you should first set the `AlternateTipMirror` entry to TRUE. This entry is in the **USER_Option** section of the PC-DMIS Settings Editor. This entry helps PC-DMIS choose the correct AB angle in cases where the probe head offers more than one possible combination of AB angles to produce the mirrored tip vector.

2. Select **File | Operations | Mirror** to open the **Choose part to mirror** dialog box.

3. Select the measurement routine file to mirror.

4. From the **Part mirror axis** area, select the axis in which you want to mirror.

5. From the **Reporting mirror option** area, choose how you want to mirror CAD images in reports.

6. From the **Machine mirror axis** area, choose how you want to position the mirrored part on a virtual machine displayed in the Graphic Display window.
7. If you have an already mirrored reference part, use the **Browse** button in the **Reference part** area to select that part. This box pulls out any quick fixture alignment data from the reference part and uses that information in the mirroring operation.
8. Click the **Mirror** button to open the **Save mirrored part as** dialog box with the file name of the measurement routine that you selected to mirror.
9. Navigate to the directory where you want to save the measurement routine and click the **Save** button. PC-DMIS mirrors the measurement routine and saves it in that directory. Note that it may take a little while to copy the necessary files.

PC-DMIS also attempts to mirror your probe's AB tip angles. If your probe does not have the exact mirrored tip angles already defined and calibrated, PC-DMIS may choose the closest calibrated tip angles. It chooses closely-calibrated tip angles if the calibrated tip angles exist and are within the wrist angle amount specified in the **Wrist warning delta** box on the **Part/Machine** tab of the **Setup Options** dialog box. If no closely-calibrated AB tip angles exist, then PC-DMIS creates perfectly-mirrored yet non-calibrated AB tip angles. See the "Setup Options: Part/Machine tab" topic in the "Setting Your Preferences" chapter.

Copy

The **Copy** command allows you to copy all of the files that are associated with a measurement routine.

To copy a measurement routine, perform the following steps:

1. Select the **File | Operations | Copy** menu item to open the **Copy part files from** dialog box.
2. Navigate through the directory structure and select a measurement routine.
3. Click the **Copy** button to display the **Copy part files to** dialog box.
4. Click on the measurement routine that you want to copy so that its file name and extension appear in the **File name** box.
5. Navigate to the folder to which you want to copy the measurement routine.
6. Click the **Save** button.

These files are copied:

- .prg
- .cad

- Any file with the same base name and an extension in the range .001, .002, …, .999
- <*name of measurement routine*>.MiniRoutines.xml, if it exists
- <*name of measurement routine*>.QdasData.xml, if it exists

Delete

The **Delete** command allows you to delete all of the files that are associated with a measurement routine.

To delete a measurement routine:

1. Select the **File | Operations | Delete** menu item to open the **Delete part files** dialog box.
2. Choose the measurement routine to delete.
3. Click the **Delete** button. PC-DMIS asks if you are sure that you want to send the files to the Recycle Bin.
4. Click the **Yes** button.

These files are deleted:

- .prg
- .cad
- Any file with the same base name and an extension in the range .001, .002, …, .999.
- <*name of measurement routine*>.MiniRoutines.xml, if it exists
- <*name of measurement routine*>.QdasData.xml, if it exists

Deleted files are sent to the Recycle Bin.

Rename

The **Rename** command allows you to rename all of the files that are associated with a measurement routine.

You can only rename measurement routine (.prg), probe (.prb), and report (.rpt) files made in valid versions of PC-DMIS. For this version of PC-DMIS, if you attempt to rename any of these file types created before PC-DMIS version 2021.1, PC-DMIS shows an error message.

Example error message when you try to rename an invalid measurement routine file:

PC-DMIS Message

<measurement routine file>: Could not Rename File.

Unable to rename this Measurement Routine because it was created with a PC-DMIS version before 2021.1.

Where <measurement routine file> is the name and location of the file you are trying to open.

To rename a measurement routine:

1. Select the **File | Operations | Rename** menu item to open the **Rename part files from** dialog box.
2. Select the measurement routine to rename.
3. Click the **Rename** button to open the **Rename part files to** dialog box.
4. Type in the new name for the file in the **File name** box.
5. Click the **Save** button. The name change is applied immediately.

These files are renamed:

- .prg
- .cad
- Any file with the same base name and an extension in the range .001, .002, …, .999
- <*name of measurement routine*>.MiniRoutines.xml, if it exists
- <*name of measurement routine*>.QdasData.xml, if it exists

Certify

The **Certify** command lets you certify measurement routines and add related comments. You can select the **File | Operations | Certify** menu option, or from the **File Operations** toolbar, click the **Certify** button ( ).

A certified measurement routine is one validated by a programmer (a member of the PC-DMIS-Programmer group). This measurement routine meets internal requirements for use in production. The Protect Viewer application lets you control and track modifications to this measurement routine, such as:

- Any internal organizational requirements
- Specific externally imposed process certification requirements (such as ISO and FDA)

The Protect Viewer installer, included with the PC-DMIS installer, creates the **PC-DMIS-User** and **PC-DMIS-Programmer** groups in the **Local Users and Groups** folder on your computer.

- The **PC-DMIS-User** group's users can submit or cancel the submission of measurement routines to the programmer for certification. They can also edit measurement routines.
- The **PC-DMIS-Programmer** group's users can edit, certify, and reject measurement routines. They cannot edit the measurement routine created by the **PC-DMIS-User** group's users.

If you are not a member of either group, you can open, view, and execute certified measurement routines in Protected Mode. However, you cannot certify or edit certified measurement routines.

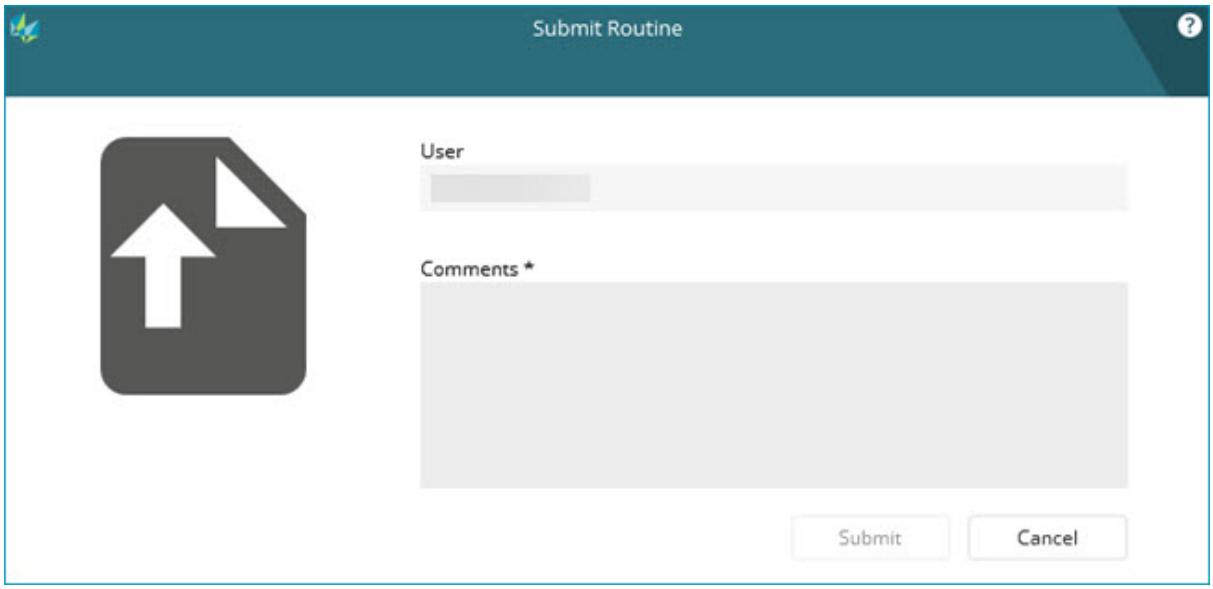
When the PC-DMIS Protect license option is enabled, operators (users who are not members of the PC-DMIS-Programmer or PC-DMIS-User group) can execute only certified measurement routines. To let operators also execute uncertified measurement routines, set the `RestrictCertifiedMRExecutionToOperators` entry in the **Option** section of the PC-DMIS Settings Editor to **FALSE**.

If you are a member of both the **PC-DMIS-User** and **PC-DMIS-Programmer** groups, PC-DMIS considers you as a user.

To modify the **PC-DMIS-User** or **PC-DMIS-Programmer** groups (such as adding or removing users), contact your computer administrator.

PC-DMIS-User Specific Dialog Boxes

- **Submit Routine** - This dialog box lets you submit a measurement routine and generate a .protect file. From the **File Operations** toolbar, click the **Submit** button ( ) to open the **Submit Routine** dialog box.



Submit Routine Dialog Box

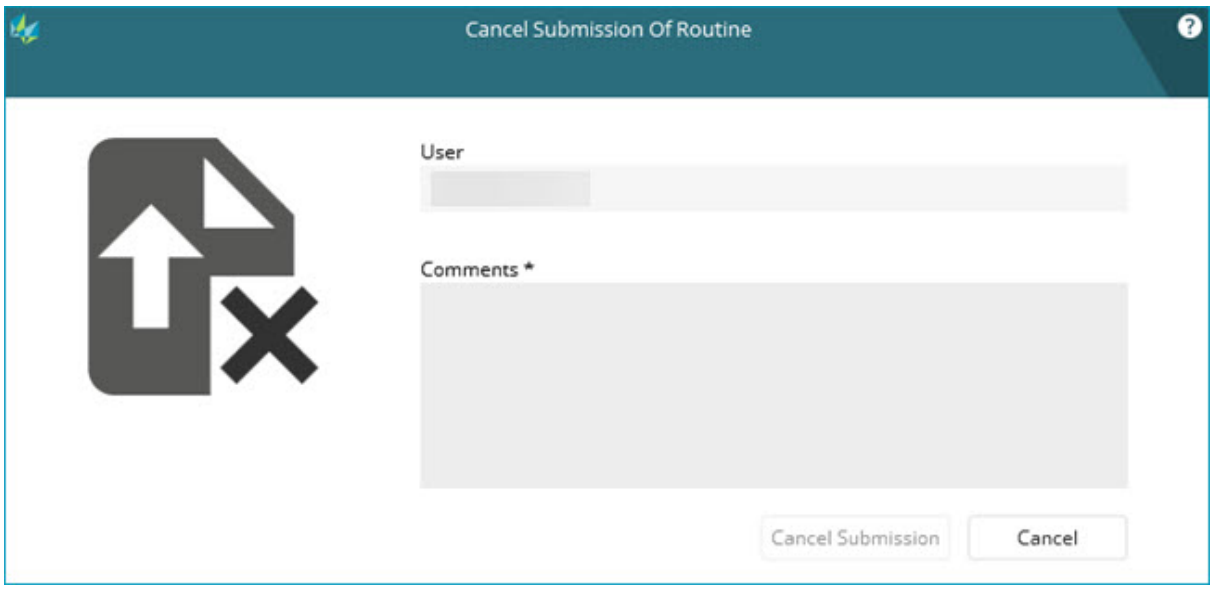
User - This box displays your network username.

Comments - This box lets you add comments before you submit a measurement routine for certification.

Submit - This button submits and saves the measurement routine, closes the dialog box, and generates a .protect file in the same folder as the measurement routine. The file name is <measurement routine file name>.PRG.protect, where <measurement routine file name> is the name of the measurement routine file. The default folder location is: "C:\Users\Public\Documents\Hexagon\PC-DMIS\2026.2".

Cancel - This button ignores any changes and closes the dialog box.

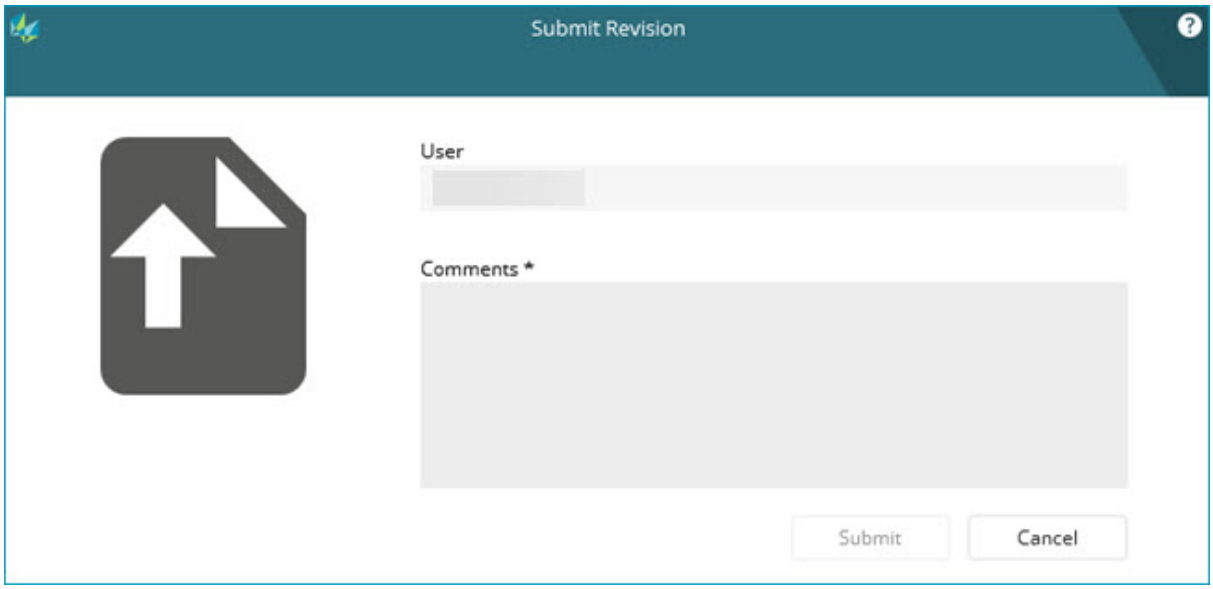
- **Cancel Submission Of Routine** - This dialog box lets you cancel the submission of a measurement routine. From the **File Operations** toolbar, click the **Cancel Submission** button ( ) to open the **Cancel Submission Of Routine** dialog box.



Cancel Submission Of Routine Dialog Box

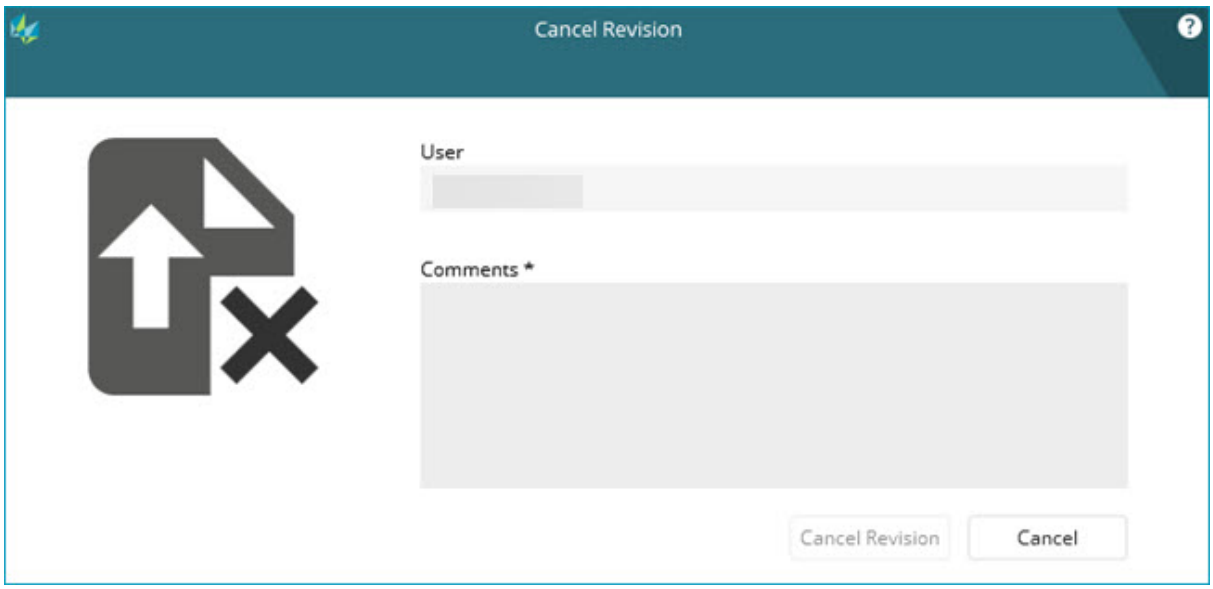
Cancel Submission - This button cancels the submission of the measurement routine. The user must resubmit the measurement routine for certification.

- **Submit Revision** - This dialog box lets you submit a revised certified measurement routine to a member of the PC-DMIS-Programmer group for recertification. From the **File Operations** toolbar, click the **Submit** button ( ) to open the **Submit Revision** dialog box.



Revision Dialog Box

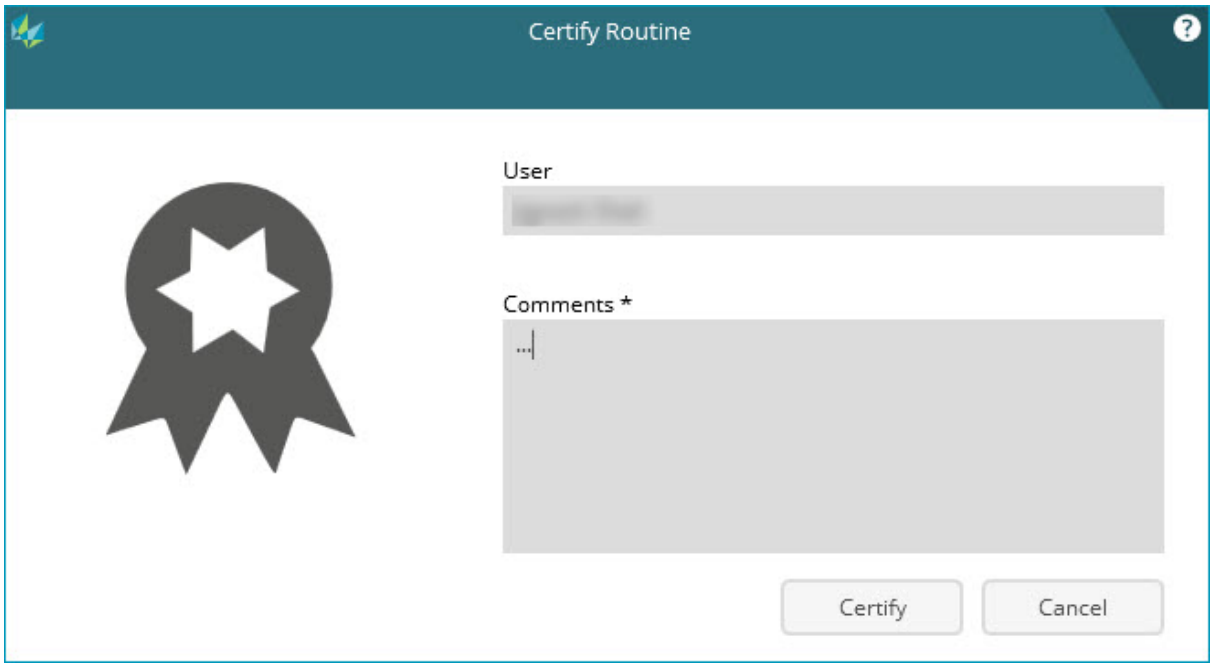
- **Cancel Revision** - This dialog box lets you cancel the submission of a revised measurement routine for recertification. From the **File Operations** toolbar, click the **Cancel Submission** button ( ) to open the **Cancel Revision** dialog box.



Revision Dialog Box

PC-DMIS-Programmer Specific dialog boxes

- **Certify Routine** - This dialog box lets you certify the measurement routine and generate a .protect file if you certify it without a submission from a user. Select the **File | Operations | Certify** menu option or, from the **File Operations** toolbar, click the **Certify** button ( ) to open the **Certify Routine** dialog box.



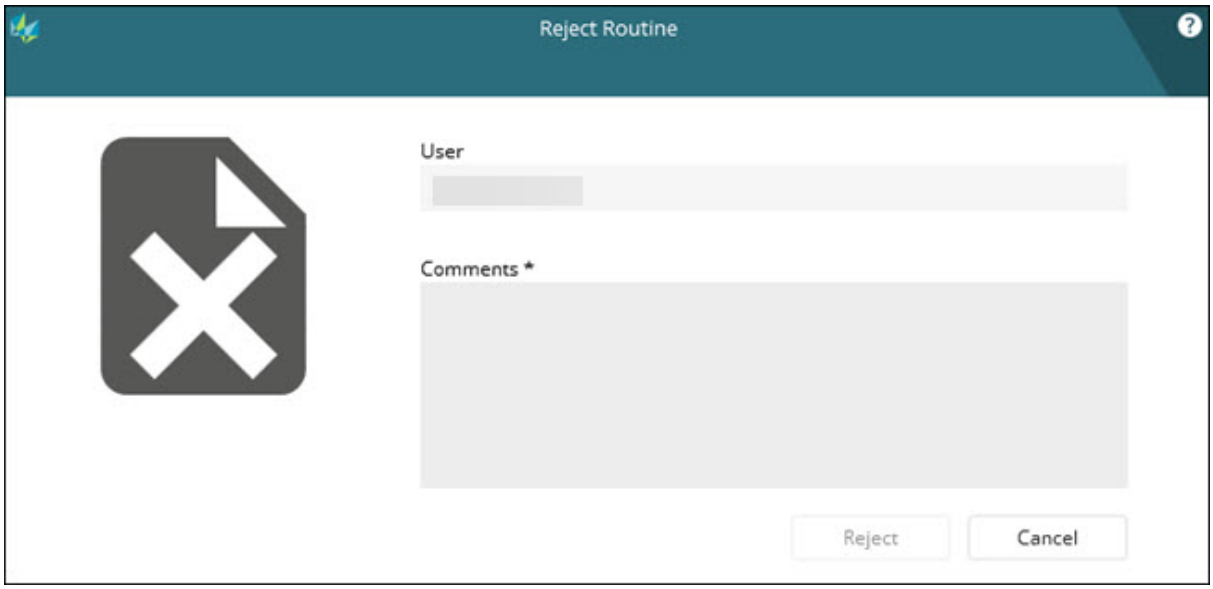
Certify Routine Dialog Box

Certify - This button certifies the measurement routine, saves it, and closes the dialog box. If you certify the measurement routine without a submission from the user, clicking this button generates a .protect file in the same folder as the measurement routine. The file name is <measurement routine file name>.PRG.protect, where <measurement routine file name> is the name of the

measurement routine file. The default folder location is: "C:\Users\Public\Documents\Hexagon\PC-DMIS\2026.2".

- **Reject Routine** - This dialog box lets you reject a submitted measurement routine.

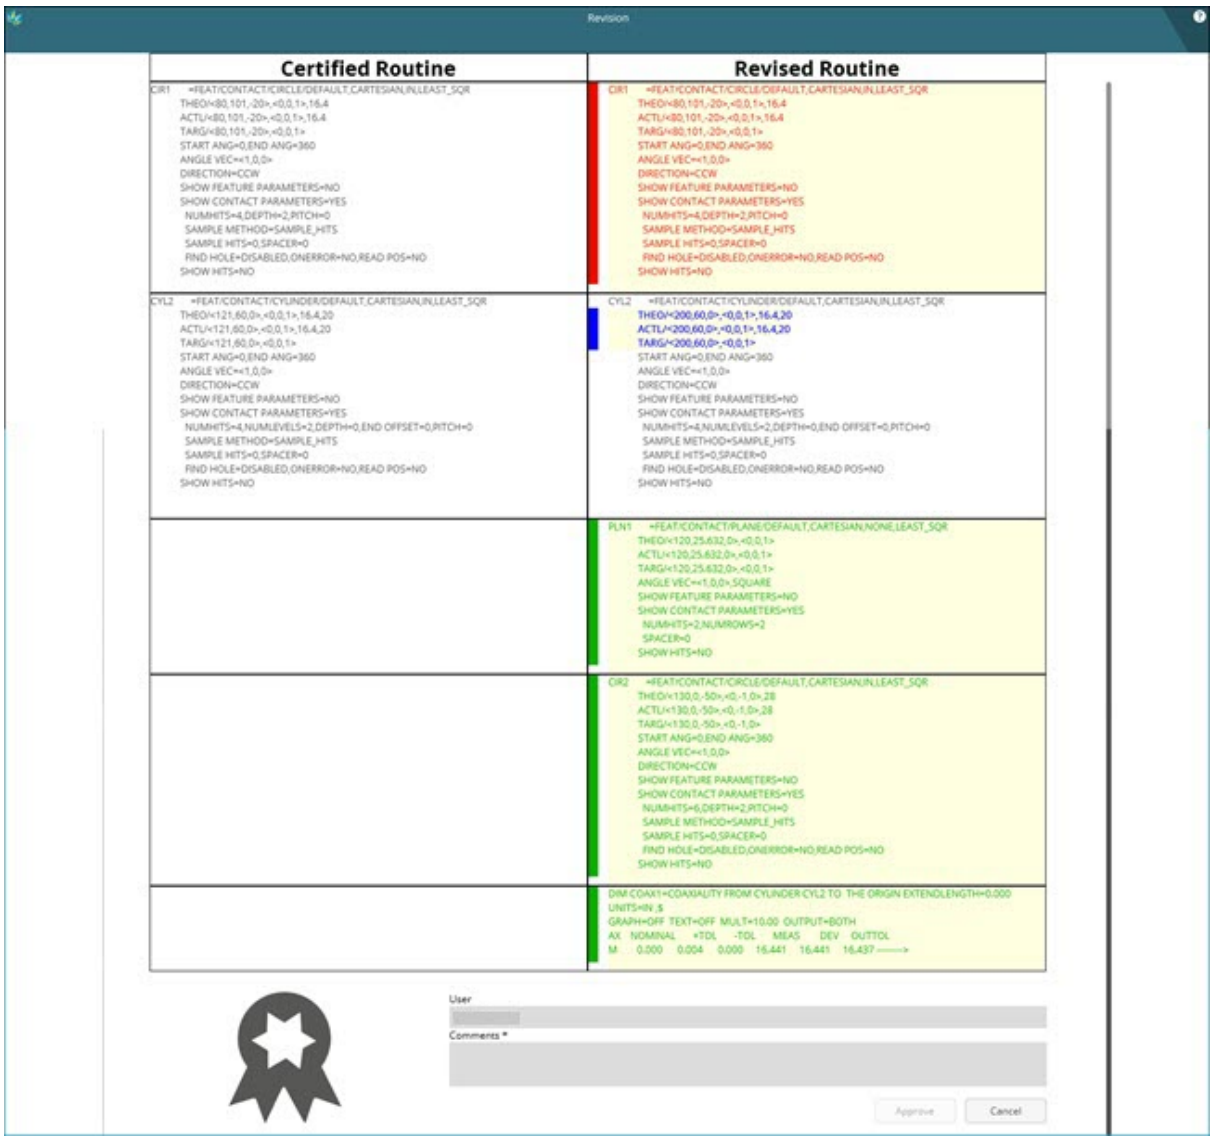
  From the **File Operations** toolbar, click the **Reject** button ( ) to open the **Reject Routine** dialog box. This button is only available when a user submits a measurement routine for certification.



Reject Routine Dialog Box

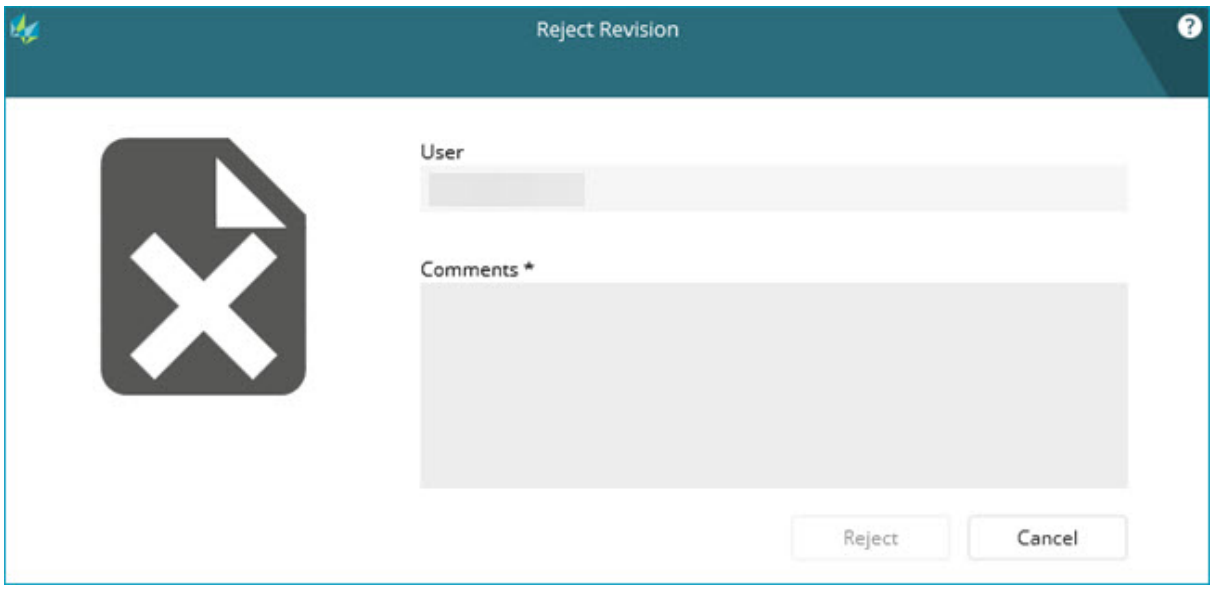
Reject - This button rejects the submission of the measurement routine. The user needs to resubmit the measurement routine for certification.

- **Revision** - This dialog box displays the **Certified Routine** and **Revised Routine** columns to review the changes made after certification. From the **File Operations** toolbar, click the **Recertify** button ( ) to open the **Revision** dialog box.



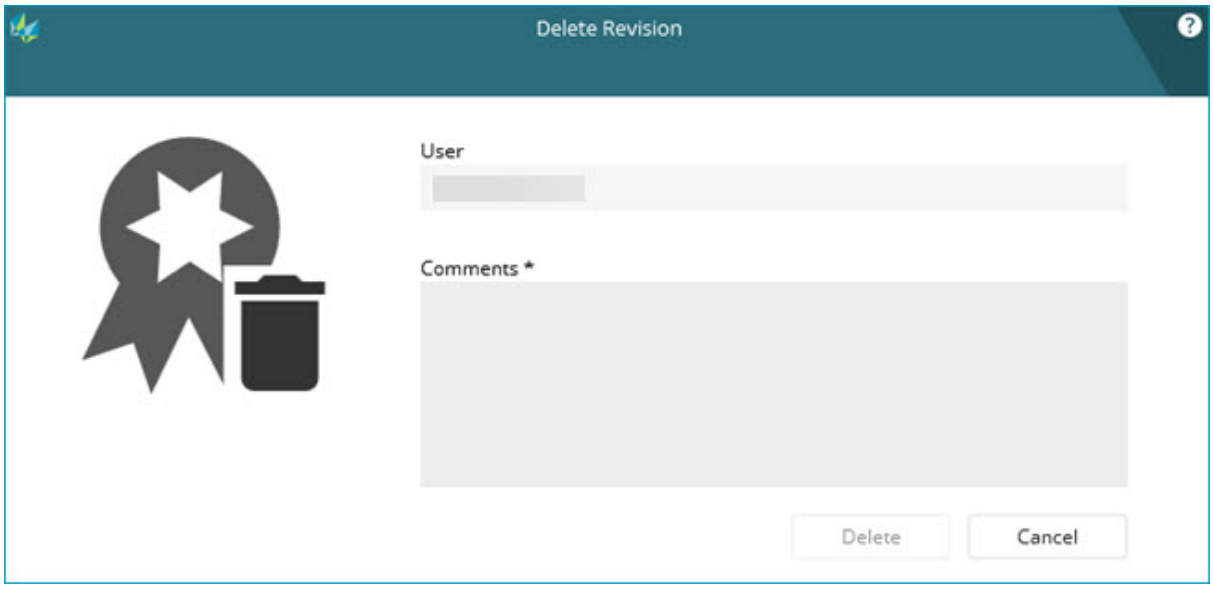
Revision Dialog Box

- **Reject Revision** - This dialog box lets you reject the changes made after the certification without deleting them. From the **File Operations** toolbar, click the **Reject** button ( ) to open the **Reject Revision** dialog box.



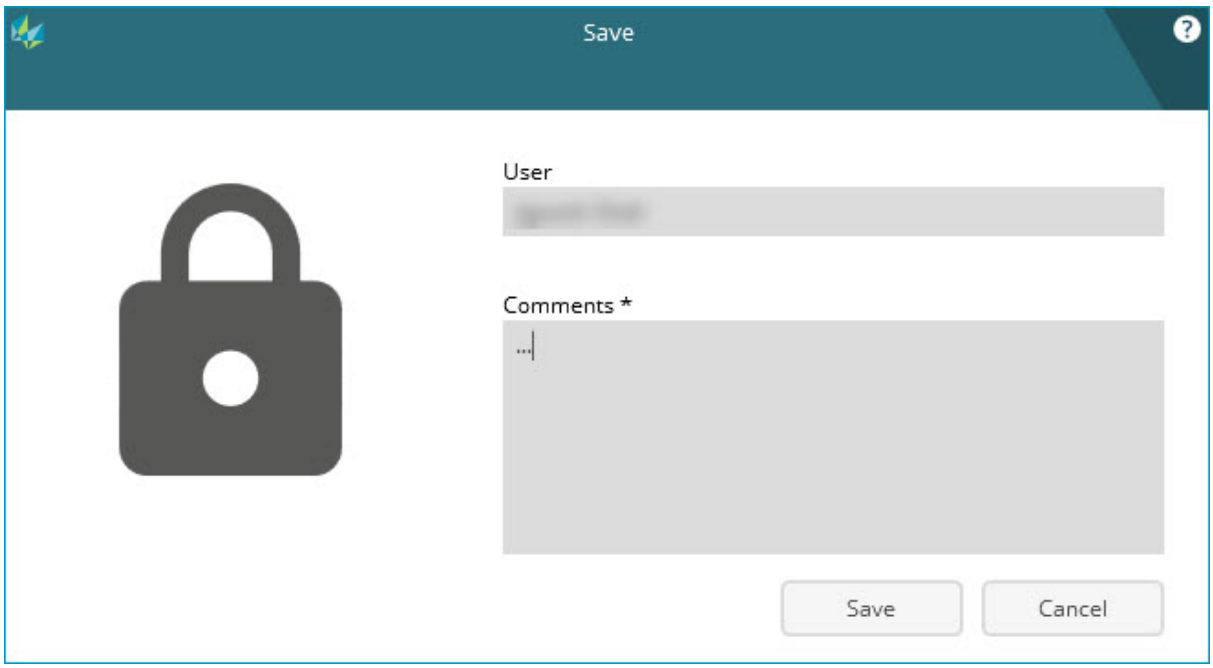
Revision Dialog Box

- **Delete Revision** - This dialog box lets you delete the changes made after the certification. From the **File Operations** toolbar, click the **Delete** button ( ) to open the **Delete Revision** dialog box.



Delete Revision Dialog Box

- **Save** - This dialog box appears only for the user who can edit the measurement routine after certification. After certification of the measurement routine, PC-DMIS displays the **Save** dialog box whenever you save any changes. This dialog box only appears if you want to save the changes to the measurement routine related to a feature or dimension.



Save Dialog Box

Save - This button saves the comments and changes to the .protect file.

When you open a certified measurement routine in PC-DMIS 2018 R2 and earlier, the certification is not available. The measurement routine opens like a usual measurement routine.

Adding a User or a Group to the PC-DMIS-Programmer Group

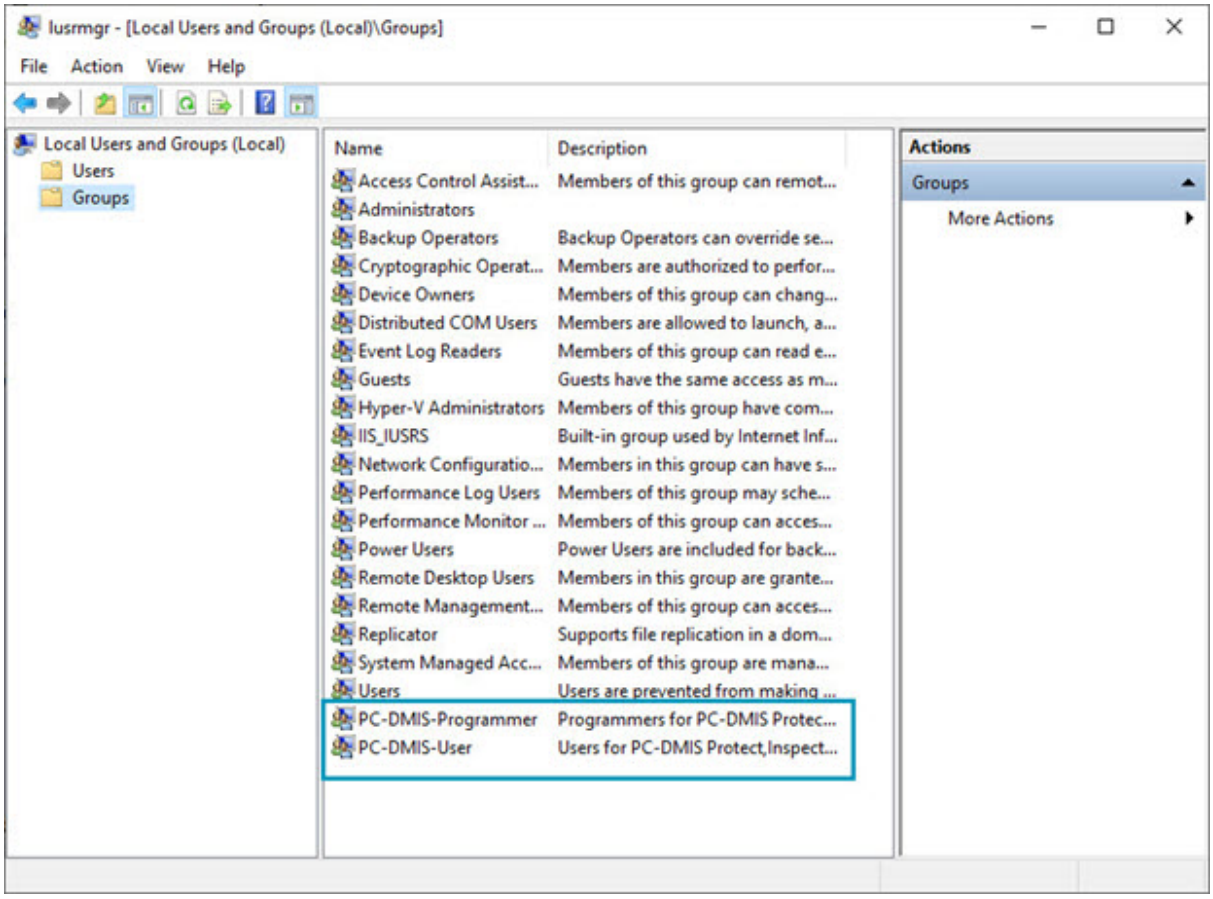
To add a user or a group to the PC-DMIS-Programmer group, follow these steps:

Adding a user or a group of users to the PC-DMIS-Programmer group makes them a metrology administrator.

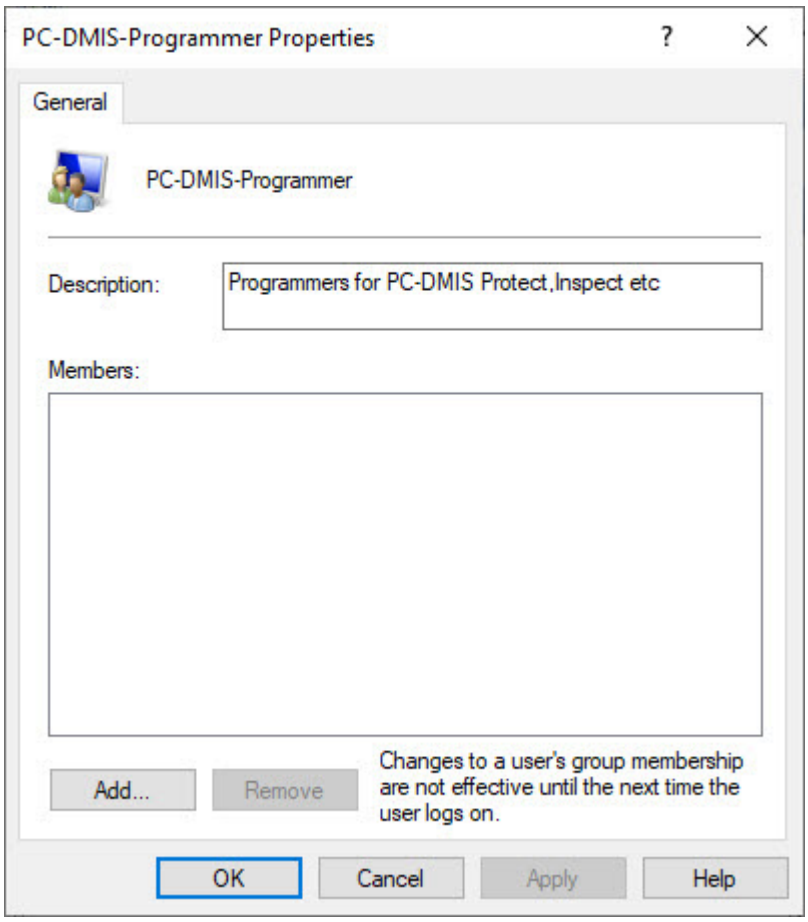
Prerequisites: Administrator access to the computer.

1. Install the Protect Viewer installer (included with the PC-DMIS installer). This creates the **PC-DMIS-User** and **PC-DMIS-Programmer** groups in the **Local Users and Groups** folder on your computer.
2. Open the **Edit local users and groups** dialog box. You can do this in two ways:
   - Type **local** in the search box on the taskbar and select **Edit local users and groups** from the results.
   - Press Windows + R key combination, type **lusrmgr.msc** in the **Run** dialog box, and click **OK**.

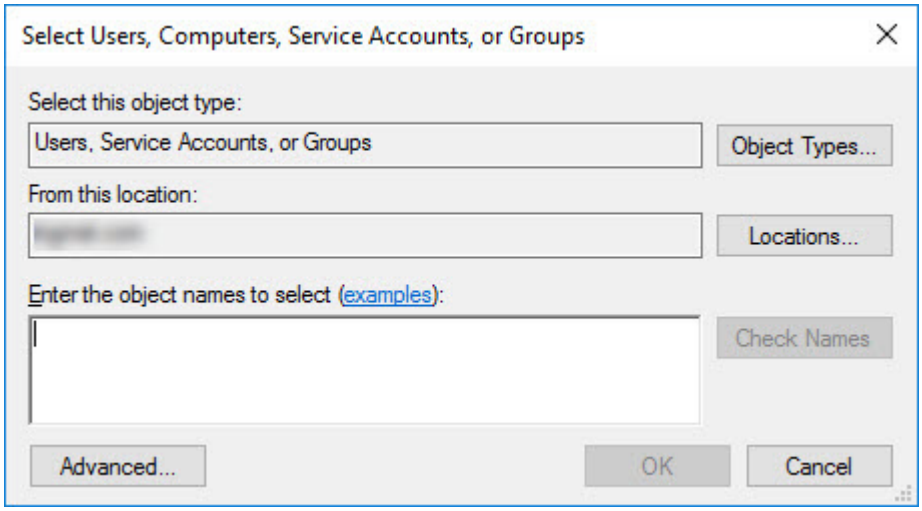
3. From the left pane, click **Groups** to display the list of groups on your computer, including the **PC-DMIS-User** and **PC-DMIS-Programmer** groups.



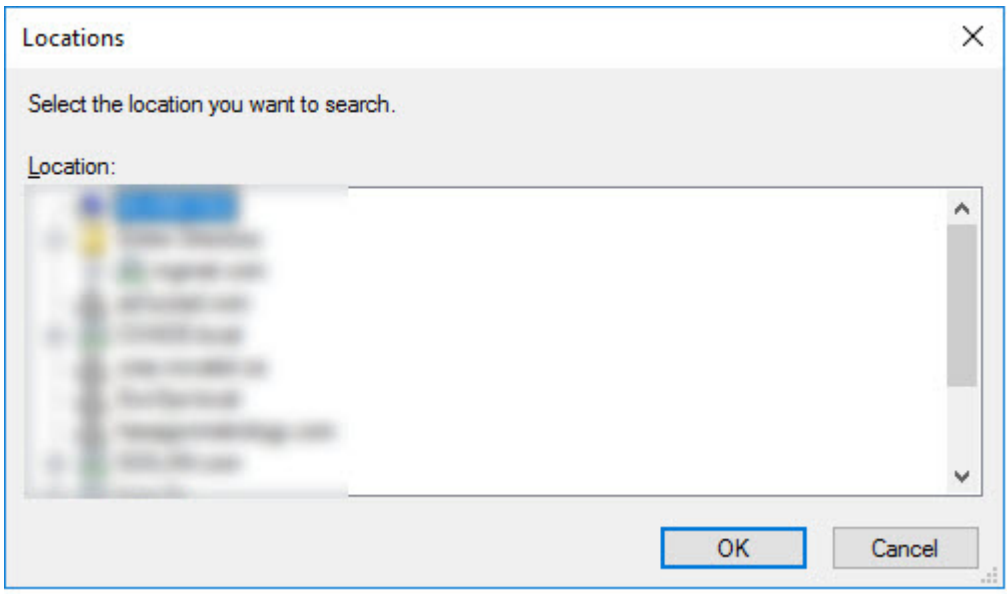
4. Double-click **PC-DMIS-Programmer** to open the **PC-DMIS-Programmer Properties** dialog box.



5. Click **Add** to open the **Select Users, Computers, Service Accounts, or Groups** dialog box.

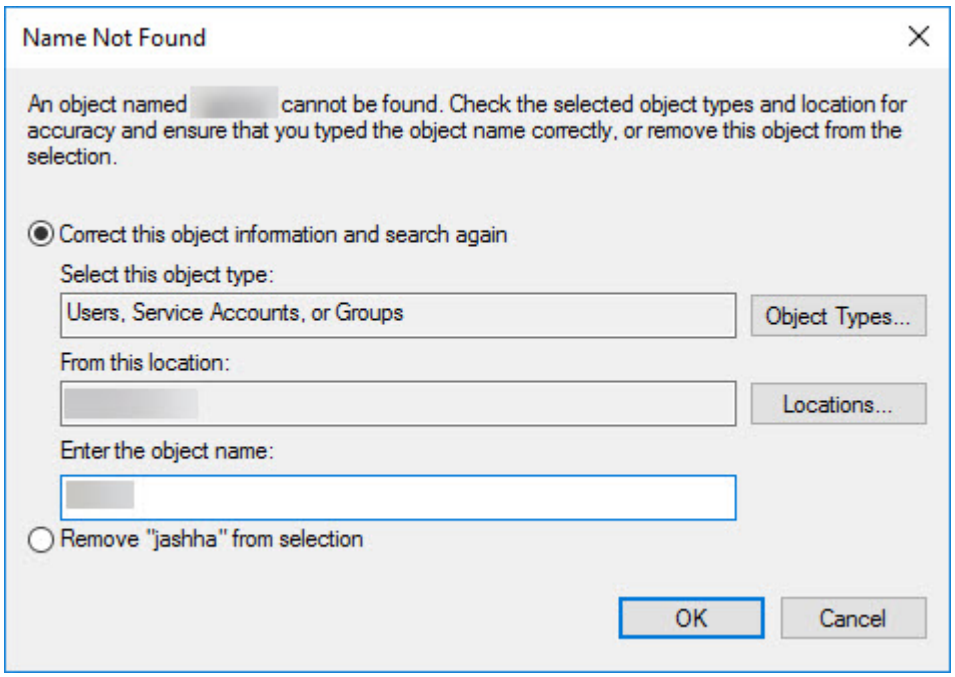


6. Click **Locations** to open the **Locations** dialog box. You can connect the account as a network user or a local user.



- To connect the account as a network user, select the network location and click **OK**.
- To connect the account as a local user, select the computer name and click **OK.**

7. In the **Enter the object names to select** box of the **Select Users, Computers, Service Accounts, or Groups** dialog box, type your user name and click **Check Names**. If the user account does not appear and your computer is part of a company network, verify your network connection. If you are outside of the company network, connect through a VPN.
   - If you are connected to a network, the box displays an entry with the network's name.
   - If you are not connected to a network, the **Name Not Found** screen appears.



> You can also add a local group or network group to the PC-DMIS-Programmer group. This adds all the members in that local or network group to the PC-DMIS-Programmer group.

8. Click **OK** to close the **Select Users, Computers, Service Accounts, or Groups** dialog box. The **Members** area in the **PC-DMIS-Programmer Properties** dialog box displays the user name or group that you added in step 6.
9. Click **OK** to close the **PC-DMIS-Programmer Properties** dialog box.
10. To apply the changes, you must sign out of Windows and sign back in.

You have successfully added the user or group to the PC-DMIS-Programmer group. You can follow the same steps to add a user or group to the PC-DMIS-User group.

> Whenever you make changes to the PC-DMIS-User or PC-DMIS-Programmer group, you must sign out of Windows and sign back in again to apply those changes. If you add a network group to the PC-DMIS User or PC-DMIS Programmer group, connect to the network to apply subsequent modifications.

Adding Azure AD (Microsoft Entra ID) Users to PC-DMIS-Programmer Group Offline

To add Azure AD (Entra ID) users to local groups without an Active Directory connection or VPN connection, open Windows PowerShell in administration mode and type this command: `net localgroup "PC-DMIS-Programmer" /add "AzureAD\user@domain.com"` .

One Level Authentication

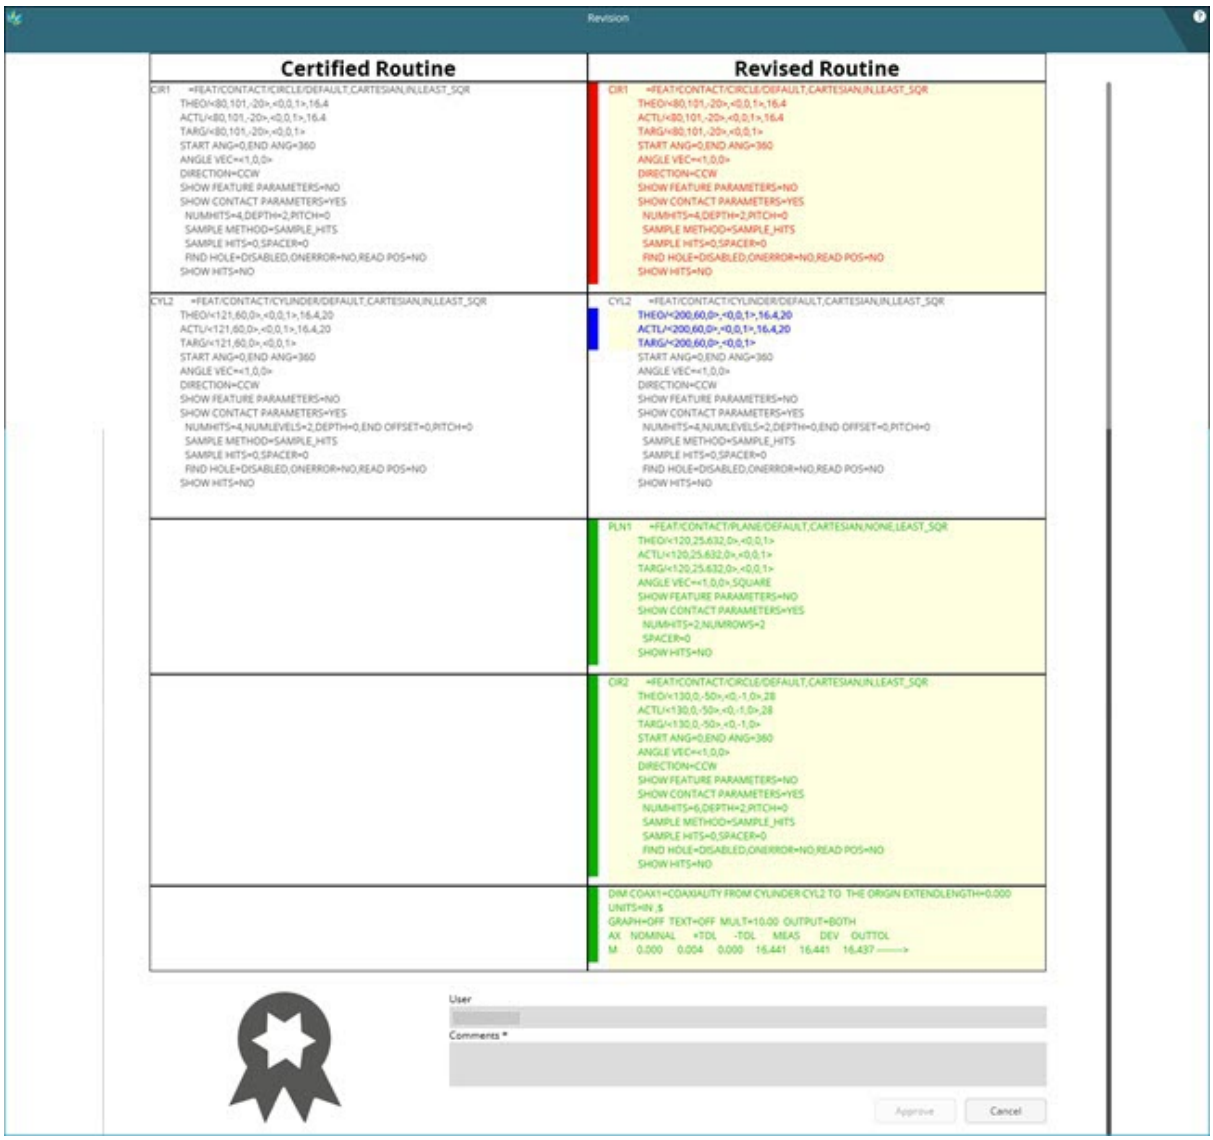
This procedure applies to members of the **PC-DMIS-Programmer** group.

To certify, edit, view, or recertify a measurement routine, follow these steps:

1. Create a measurement routine.
2. Add features, dimensions, and other necessary elements to the measurement routine.
3. From the **File Operations** toolbar, click the **Certify** button ( ) to open the **Certify Routine** dialog box.
4. In the **Comments** box, type your comments and click **Certify** to certify the measurement routine. PC-DMIS immediately opens the measurement routine in Protected Mode.

   > PC-DMIS displays a lock icon at the top of the Edit window, indicating that the measurement routine cannot be edited.

5. To edit the certified measurement routine, from the **File Operations** toolbar, click the **Edit Certified Routine** button ( ). PC-DMIS opens the measurement routine in Edit Mode.
6. Edit your measurement routine.
7. From the **File Operations** toolbar, click the **Recertify** ( ) button to open the **Revision** dialog box. This dialog box displays the **Certified Routine** and **Revised Routine** columns to review the changes made after the certification of the measurement routine.



Revision Dialog Box

8. After you review the changes, click **Approve** to recertify the measurement routine. PC-DMIS immediately adds the changes to the certified measurement routine and opens the recertified measurement routine in Protected Mode.

> After you submit a measurement routine for certification, PC-DMIS generates and assigns a .protect file to it. This file tracks changes and holds the current status of the measurement routine's certification process. If you move or delete the .protect file, you will lose all tracked changes, and no member of the PC-DMIS-Programmer group will be able to recertify the measurement routine.

Two Level Authentication

To certify a measurement routine, follow these steps:

1. As a member of the PC-DMIS-User group:
    a. Create a measurement routine.

b. Add features, dimensions, and other necessary elements to the measurement routine.

c. From the **File Operations** toolbar, click the **Submit** button ( ) to open the **Submit Routine** dialog box. In the **Comments** box, type your comments and click **Submit** to submit the measurement routine for certification.

> To cancel the submission, from the **File Operations** toolbar, click the **Cancel Submission** button ( ) to open the **Cancel Submission of Routine** dialog box. In the **Comments** box, type your comments and click **Cancel Submission**.

d. After you submit the measurement routine for certification, select the **File | Exit** menu option.

2. As a member of the PC-DMIS-Programmer group:

a. Open the submitted measurement routine.

b. Select the **File | Operations | Certify** menu option or from the **File Operations** toolbar, click the **Certify** button ( ) to open the **Certify Routine** dialog box.

c. In the **Comments** box, type your comments and click **Certify** to certify the measurement routine. PC-DMIS immediately opens the measurement routine in Protected Mode.

> After certification, PC-DMIS always opens the measurement routine in Protected Mode for all users.

To recertify a measurement routine, follow these steps:

1. As a member of the PC-DMIS-User group:

a. Open the certified measurement routine. PC-DMIS opens the measurement routine in Protected Mode.

b. From the **File Operations** toolbar, click the **Edit Certified Routine** button ( ) to open the measurement routine in Edit Mode.

If you are a member of the PC-DMIS-Programmer group and you open the same measurement routine, PC-DMIS displays a message stating that you are not the creator of the measurement routine and that the measurement routine has not been submitted to you for certification.

c. Edit the measurement routine.

d. From the **File Operations** toolbar, click the **Submit** button ( ) to open the **Submit Revision** dialog box. In the **Comments** box, type your comments and click **Submit Revision** to submit the measurement routine for recertification.

- To cancel the submission, from the **File Operations** toolbar, click the **Cancel Submission** button ( ) to open the **Cancel Revision** dialog box. In the **Comments** box, type your comments and click **Cancel Revision**.
- To view the certified measurement routine, from the **File Operations** toolbar, click the **View Certified** button ( ) to open the certified measurement routine in Protected Mode.

e. After you submit the measurement routine for recertification, click the **File | Exit** menu option.

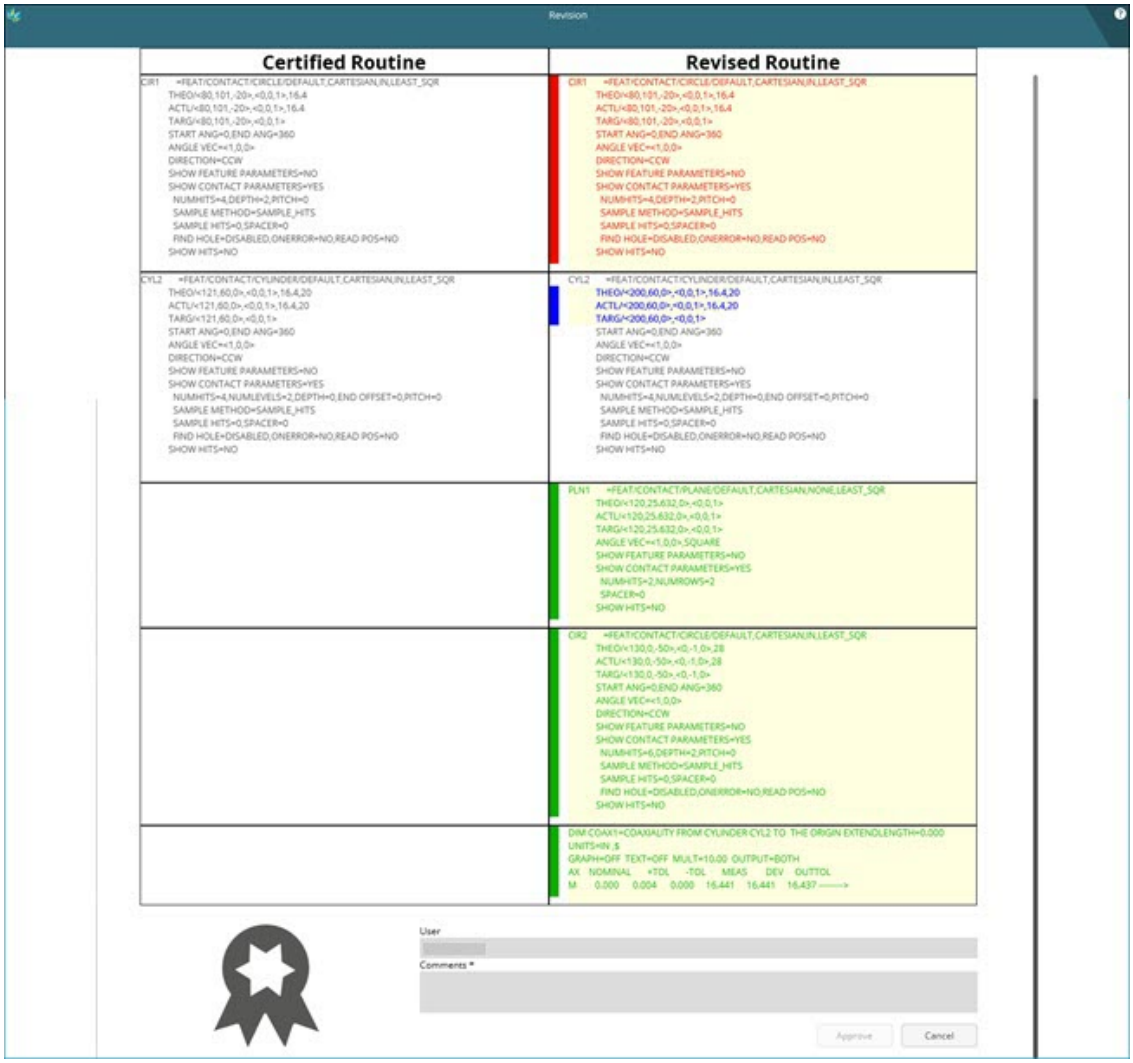
2. As a member of the PC-DMIS-Programmer group:

a. Open the measurement routine. PC-DMIS opens the measurement routine in Protected Mode.

b. From the **File Operations** toolbar, click the **Edit Certified Routine** button ( ) to open the measurement routine again in Protected Mode and to enable the **View Certified**, **Recertify**, **Reject**, and **Delete** options in the **File Operations** toolbar.

c. From the **File Operations** toolbar, click the **Recertify** button ( ) to open the **Revision** dialog box. The dialog box displays the **Certified Routine** and **Revised Routine** columns to review the changes made after the certification of the measurement routine.

- To reject the changes, from the **File Operations** toolbar, click the **Reject** button ( ).
- To delete all the changes after the last certification, from the **File Operations** toolbar, click the **Delete** button ( ).



Revision Dialog Box

d. After you review the changes, type your comments in the **Comments** box and click **Approve** to recertify the measurement routine. PC-DMIS immediately opens the measurement routine in Protected Mode.

After you submit a measurement routine for certification, PC-DMIS generates and assigns a .protect file to it. This file tracks changes and holds the current status of the measurement routine's certification process. If you move or delete the .protect file, you will lose all tracked changes, and no member of the PC-DMIS-Programmer group will be able to recertify the measurement routine.

Edit Certified Measurement Routines

Local Environment

You can edit certified measurement routines only if you are the creator of the measurement routine or a member of the PC-DMIS-User group.

To edit a certified measurement routine, follow these steps:

1. If you are a member of the PC-DMIS-User group and the creator of a certified measurement routine, PC-DMIS opens the certified measurement routine in Protected Mode.
2. From the **File Operations** toolbar, click the **Edit Certified Routine** button ( ) to open the measurement routine in Edit Mode.
3. Make the necessary edits to your measurement routine.

If you are a member of the PC-DMIS-Programmer group and you open the same measurement routine, PC-DMIS displays a message stating that you are not the creator of the measurement routine and that it has not been submitted to you for certification. However, if a member of the PC-DMIS-User group submitted the measurement routine for certification, clicking the **Edit Certified Routine** button ( ) opens the measurement routine in Protected Mode and enables the **Recertify**, **Reject**, and **Delete** buttons in the **File Operations** toolbar.

For members who are not part of either the PC-DMIS Programmer or PC-DMIS User group, PC-DMIS always opens the certified measurement routine in Protected Mode. In Protected Mode, you can only execute measurement routines. You cannot disable the mode. For information on Protected Mode, see the "Using Protected Mode to Protect Measurement Routines from Edits" topic in the PC-DMIS Core documentation.

Teamcenter Integrated Environment

> You can edit certified measurement routines only if you are a member of the PC-DMIS-Programmer group.

To edit a certified measurement routine, follow these steps:

1. Open the measurement routine. For information on how to open a measurement routine from Teamcenter, see the "Step 2 - Open a Measurement Routine" topic in PC-DMIS DCI documentation.
2. From the **File Operations** toolbar, click the **Edit Certified Routine** button ( ) to open the measurement routine in Edit mode.
3. Make the necessary edits to your measurement routine and do one of the following:
   - **Save Changes** – Click **File | Save** to save the changes. The measurement routine remains uncertified. To view or continue working with the saved changes, you must open the measurement routine in Edit mode.
   - **Re-certify the Measurement Routine**
     A. Click the **Recertify** button ( ) to open the **Revision** dialog box. Review the changes by comparing the **Certified Routine** and **Revised Routine** columns.
     B. Enter comments, if required, and click **Approve** to open the **Teamcenter Save As** dialog box.

        For information about the options in the **Teamcenter Save As** dialog box, see the "Step 4 - Save a Measurement Routine" topic in the PC-DMIS DCI documentation.
     C. Select the required fields and click **OK**.

Procedure to Certify and View the .protect File

The following procedure certifies a measurement routine and generates a .protect file. You can use the Protect Viewer application to view this file. For information about the Protect Viewer application, visit the PC-DMIS Help library page. Select your specific version of PC-DMIS help and then navigate to the Protect Viewer documentation.

Prerequisites:

- To certify a measurement routine, you must be a member of the PC-DMIS-Programmer group and have the Protect Viewer option in your license enabled.

- To view the .PRG.protect file, you must have the Protect Viewer application installed on your computer.

To certify and view the .PRG.protect file, follow these steps:

1. Create a measurement routine.
2. Select the **File | Operations | Certify** menu option or from the **File Operations** toolbar (**View | Toolbars | File Operations**), click the **Certify** button ( ) to open the **Certify Routine** dialog box.
3. Type your comments in the **Comments** box and click **Certify**.
   - **Local Environment** - PC-DMIS certifies and saves the measurement routine and generate a .PRG.protect file in the same folder as the measurement routine. The file name is <measurement routine file name>.PRG.protect, where <measurement routine file name> is the name of the measurement routine file. The default folder location is: "C:\Users\Public\Documents\Hexagon\PC-DMIS\2026.2".
   - **Teamcenter Integrated Environment** - PC-DMIS opens the **Teamcenter Save As** dialog box. Select the required options and click **OK**. PC-DMIS certifies and saves the measurement routine and generates the .PRG.protect file in the Teamcenter database.

     For information about the options in the **Teamcenter Save As** dialog box, see the "Step 4 - Save a Measurement Routine" topic in the PC-DMIS DCI documentation.

   Suppose the measurement routine file name is ABC.PRG, then the .protect file name is ABC.PRG.protect.
4. Navigate to the folder that contains the .protect file, double-click the file, or right-click and select **Open** to open the file in the Protect Viewer application.

Adding Watermarks to Certified Measurement Routine Reports

You can add a watermark to generated reports for certified measurement routines. The UseWaterMarkText Settings Editor entry controls whether the watermark appears, and WaterMarkText Settings Editor entry specifies the watermark text.

Changing the Language

The **File | Language** menu displays the languages that are supported by the product. A check mark indicates the current language. To switch to a new language, choose **File | Language** and select the desired language. PC-DMIS automatically saves your work, closes, and then restarts. Once restarted, PC-DMIS runs in the newly selected language.

Language Help Content

PC-DMIS automatically installs all the user interface resources for the supported languages during the main installation process. However, to show non-English offline help file content, you need to install that separately. Online help content is available over the Internet.

The offline language help files can be installed as needed by navigating to the language pack folder and running the appropriate language executable file.

To install a language help file:

1. Navigate to the language folder of the main PC-DMIS installer download. (<Product_Installer_Folder>\lang) .
2. Run the desired language pack executable to install the language help files.

This installs a **helpcenter** folder in the language directory under the PC-DMIS installation.

Connecting to Teamcenter

You can use the **File | Teamcenter** menu option to enable or disable a connection to the Teamcenter software. Teamcenter is a PLM (Product Lifecycle Management) database package developed by Siemens.

For the **File | Teamcenter** menu to appear, you must enable the Teamcenter option in your PC-DMIS license.

You can connect to Teamcenter by using either Service-Oriented Architecture (SOA) or the Shop Floor Connect (SFC) add-on. For information on SOA and SFC, see the "Teamcenter Connection Methods (SOA and SFC Connections)" topic in the PC-DMIS DCI documentation.

The **Teamcenter** menu includes these options:

- **On** - Select this option to establish a connection with Teamcenter. Once you select it, PC-DMIS displays the **Teamcenter Login** dialog box, where you can type your Teamcenter username and password. If the connection is successful, PC-DMIS displays a "Successfully connected to Teamcenter" message.

  A successful connection changes the standard **Save As** and **Open** dialog boxes to work with Teamcenter. If the connection fails, PC-DMIS defaults to **Off** and uses the standard **Save As** and **Open** dialog boxes.

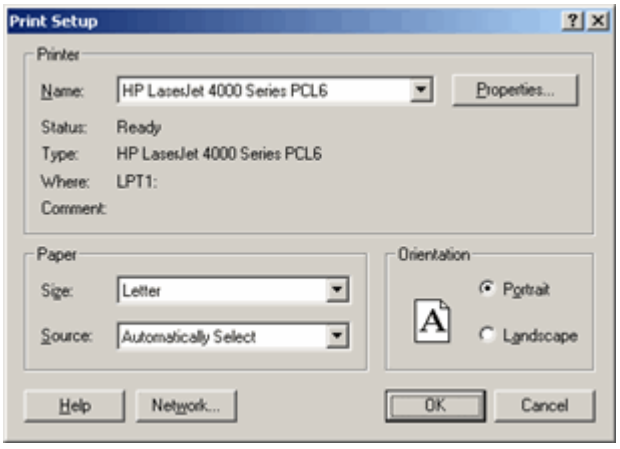
- **Off** - Select this option to disconnect PC-DMIS from Teamcenter. This reverts PC-DMIS to its standard **Save As** and **Open** dialog boxes.

- **Setup** - Select this option to open the **Teamcenter Setup** dialog box. For information on the **Teamcenter Setup** dialog box, see the "Teamcenter Setup Options" topic in the PC-DMIS DCI documentation.

For information on working with Teamcenter, see the "Using Teamcenter" topic in the PC-DMIS DCI documentation.

Setting Printer Options

The **Printer Setup** button and the **File Printing | Printer Setup** menu item access the standard Windows **Print Setup** dialog box. This dialog box lets you switch between available printers, choose paper size, page orientation, and access other printer properties. PC-DMIS then uses these options when printing the Edit window, the Inspection Report, or the Graphic Display window.



A Sample Print Setup Dialog Box

For information on this dialog box and the options available, consult the help file that came with your Windows operating system. For any advanced printer-specific properties, you may need to consult documentation specific to your printer.

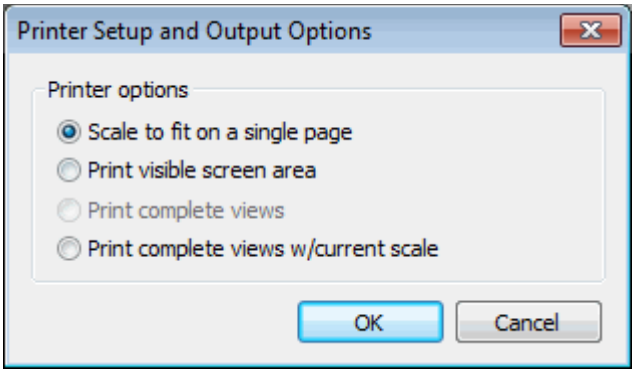
Printing the Graphic Display Window

PC-DMIS lets you send the current contents of the Graphic Display window to your printer. Select **File | Printing | Graphic Window Print** to display a Windows **Print Setup** dialog box. Click **OK** to send the report to the printer shown in the dialog box.

Before printing, you can set the output options, and preview your print job.

Setting Output and Printer Options for the Graphic Display Window

Select **File | Printing | Graphic Window Print Setup** to display the **Printer Setup and Output Options** dialog box.



Printer Setup and Output Options Dialog Box

Use this dialog box to set up your printer and various display options. The options available in the **Printer options** area enable you to select the type of graphical view to print. These include:

Scale to fit on a single page - This option scales any graphical image to fit on a single page.

Print visible screen area - This option prints only the currently visible screen area. If you're zoomed in on a feature, it only prints what's on the screen and not the entire part.

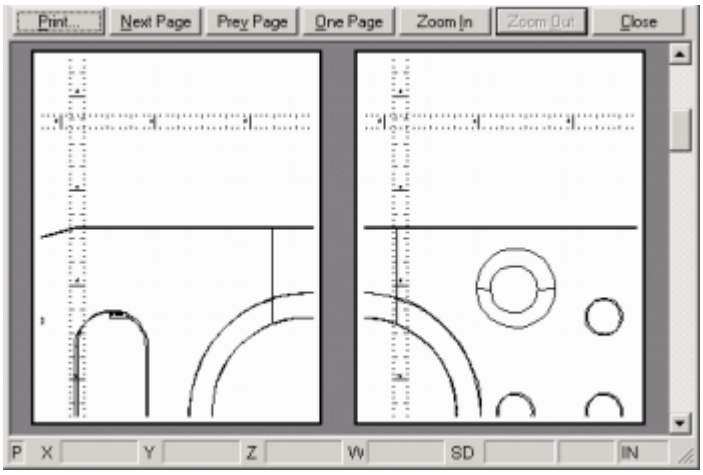
Print complete views - This option prints each view you have defined using the **Layout** area of the **View Setup** dialog box on its own page. For example, if you're showing the Z+ view and the Y- view of a part in your Graphic Display window, PC-DMIS prints two separate pages: one with the Z+ view and one with the Y- view.

Print complete views w/current scale - This option acts like the **Print complete views** option, except that it prints at the current scale. If you have zoomed in on the image, PC-DMIS still prints the entire view, but it splits the image among various pages.

To save any changes, click the **OK** button.

Previewing the Print Job

Select **File | Printing | Graphic Window Print Preview** to preview what is printed from the Graphic Display window. A Print Preview window appears.



Print Preview window showing the contents of the Graphic Display window.

The buttons at the top of the window perform these functions:

The **Print** button opens up a standard **Print Setup** dialog box so you can send the print job to the printer.

The **Next Page** and **Prev Page** buttons cycle through a print job that has multiple pages.

The **One Page** or **Two Pages** toggle button determines how many pages are displayed at one time in the Print Preview window.

The **Zoom In** and **Zoom Out** buttons allow you to take a quick closer look at a page in the Print Preview window. It doesn't affect the display of what's sent to the printer.

The **Close** button closes the Print Preview window.

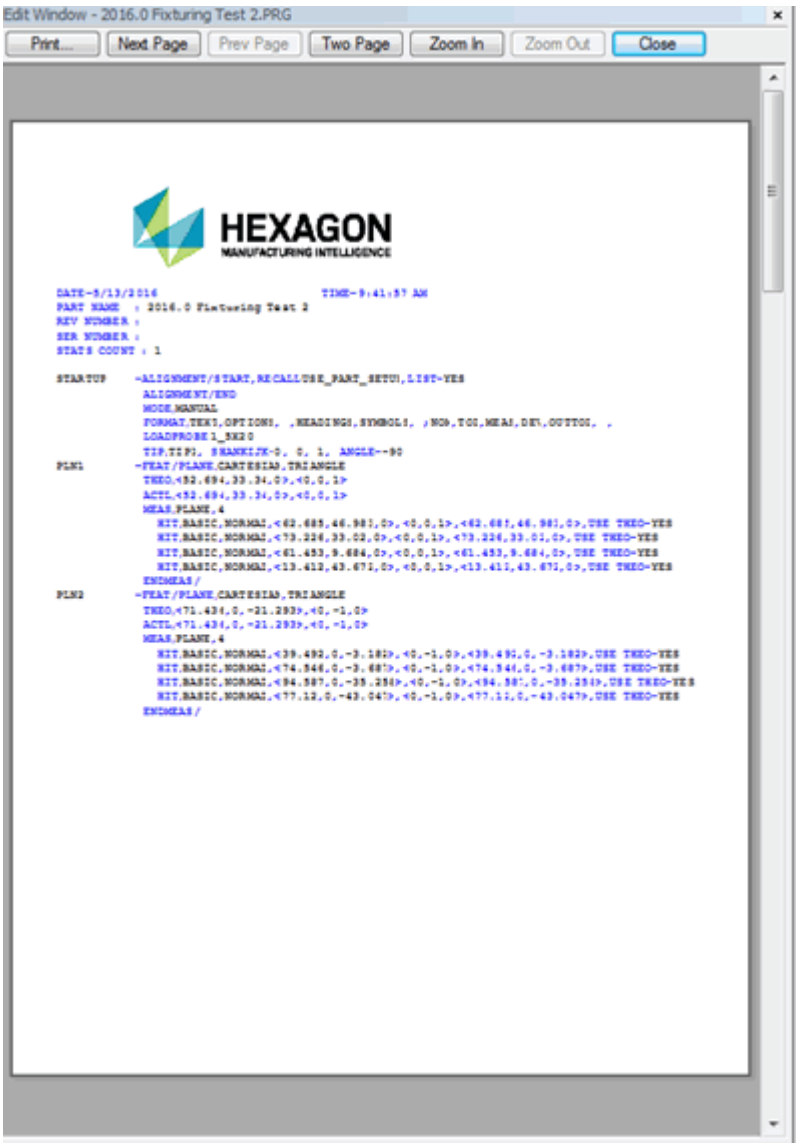
Printing the Edit Window

You can send the contents of the Edit window to your printer in these ways:

- Select **File | Printing | Edit Window Print**.
- Click the **Print** icon from the **Edit Window** toolbar.
- Press F4.

Previewing the Print Job

To preview what the printout will look like, select **File | Printing | Edit Window Print Preview**. A Print Preview window appears:



Print Preview window showing the contents of the Edit window.

The buttons at the top of the window perform these functions:

- The **Print** button opens a standard **Print Setup** dialog box that enables you to send the print job to the printer.
- The **Next Page** and **Prev Page** buttons cycle through a print job that has multiple pages.
- The **One Page** or **Two Pages** toggle button determines how many pages appear at one time in the Print Preview window.
- The **Zoom In** and **Zoom Out** buttons allow you to take a quick closer look at a page in the Print Preview window. It doesn't affect the display of what's sent to the printer.
- The **Close** button closes the Print Preview window.

When you print the Edit window's contents, you should use a TrueType font (such as Courier New). Otherwise, characters or lines may not line up as expected. To change the fonts used in the Edit window and in your reports, see "Customizing User Interface Fonts" in the "Navigating the User Interface" chapter.

Printout in Summary Mode

When you view the Edit window in Summary Mode, you get the printout exactly as you see in the Edit window. If a group is collapsed in the Edit window, the printout shows the group as collapsed.

Setting Output Options

You can set the output options for Edit window print tasks from the same **Output Configuration** dialog box that you use for the report's output. For information on the options in the **Output Configuration** dialog box, see "Setting Output and Printer Options for the Report Window".

To change printers, set page orientation, or modify other printer options, select **File | Printing | Printer Setup**. For more information, see "Setting Printer Options".

Printing the Report Window

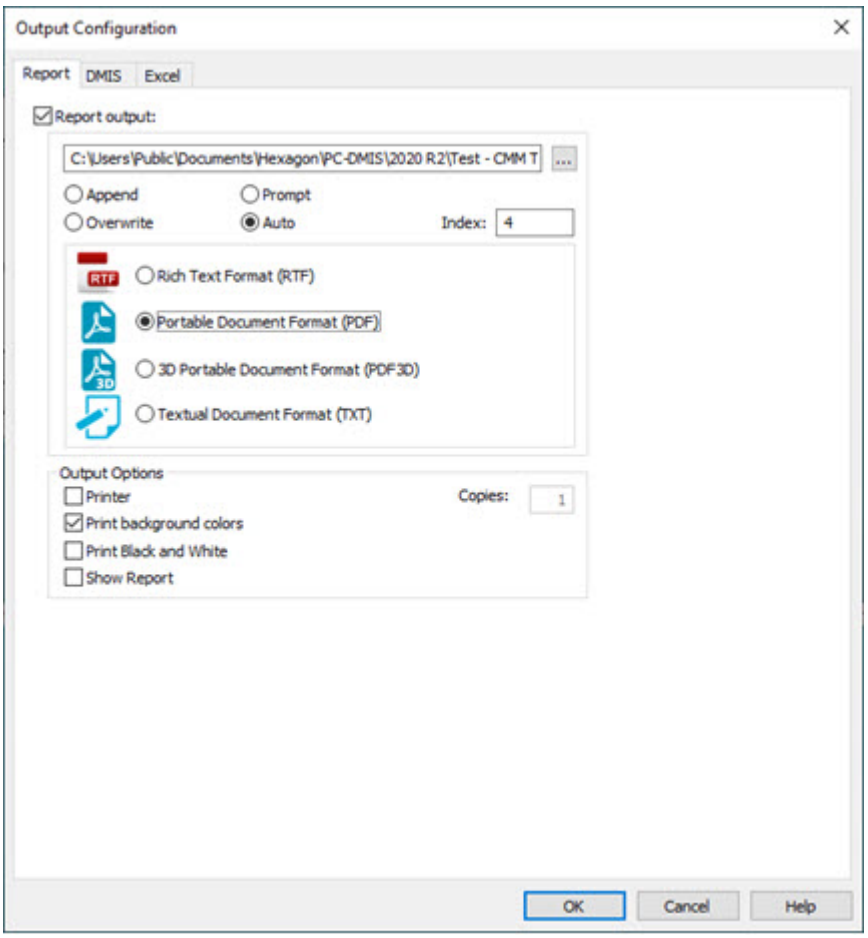
PC-DMIS lets you send the inspection report in the Report window to a variety of output devices or to a file. PC-DMIS supports a wide variety of printers and plotters. Please contact your PC-DMIS sales representative if you have any questions concerning hardware compatibility.

To print inspection reports, select the **File | Printing | Report Window Print Setup** menu option. Before printing, you can set the output options for your print job by choosing **File | Printing | Report Window Print Setup**.

When printing a text-only report, you should use a True Type font (such as Courier New). Otherwise, characters or lines may not line up as expected. If you need to change the font used in a text-only report, modify the **Font** property on the TextReportObject used in your report template.

Setting Output and Printer Options for the Report Window

Selecting the **File | Printing | Report Window Print Setup** menu option displays the **Output Configuration** dialog box.



Output Configuration Dialog Box

You can use this dialog box to tell PC-DMIS where to send the inspection report. The dialog box contains the following tabs that you can use to send the report to a file or printer, output it as a DMIS file or a Microsoft Excel file, or send to any combination of these:

Report - Sends the report output to a file (.rtf, .pdf, or .txt) or printer. For information about this tab, see "Output to an RTF, PDF, TXT or the Default Printer". For information about using this tab to output to a file using expressions, see "Output to a File Using Expressions".

DMIS - Sends the report output to a DMIS output file (.dmo). For information about this tab, see "Output to a DMIS File".

Excel - Sends the report output to an Excel file (.xls, xlsx, or .csv). For information about this tab, see "Output to an Excel File".

For information on viewing a saved inspection report, see the "Viewing an Inspection Report" topic in the "Using Other Windows, Editors, and Tools" chapter.

Setting Printing Options for Marked Sets

PC-DMIS also displays an instance of the **Output Configuration** dialog box whenever a marked set is created. This defines printing options *specific only to the newly created marked set*. Alternately, if you would rather use already defined print settings used by your

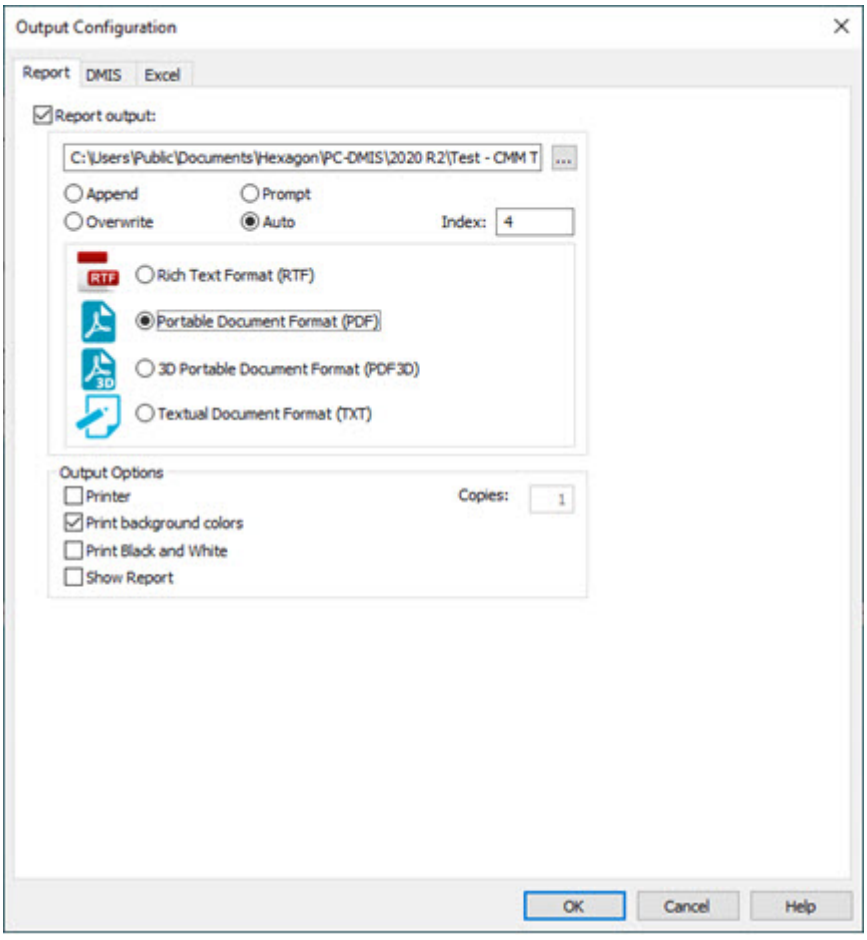
measurement routine at large, you can select the **Use Global Print Settings** check box. For information on using marked sets, see "Creating and Executing Marked Sets" in the "Editing a Measurement Routine" chapter.

To define printing options for existing marked sets, select the set in the Marked Sets window, and then select **File | Printing | Report Window Print Setup**.

Setting Image Ratio

The `MaxImageRatio` entry sets the maximum image ratio between the screen resolution and the printer resolution when printing the CAD drawing from the Report window. See the `MaxImageRatio` entry in the **Reporting** section of the PC-DMIS Settings Editor.

Output to an RTF, PDF, or TXT File or to the Default Printer



Output Configuration Dialog Box - Report Tab

In the **Output Configuration** dialog box (**File | Printing | Report Window Print Setup**), the **Report** tab defines whether to:

- Send the report's output to a printer
- Save the report as a separate file (.rtf, .pdf, or .txt)
- Do both of the above

The dialog box also provides options for the generated report.

Report Output

Report output - If selected, PC-DMIS sends the output to a file. It can be saved in either a text file (.txt), Rich Text Format (.rtf) or Portable Document Format (.pdf) file. This .pdf file can be a standard PDF file or a 3D PDF file.

The file name is initially generated and formatted to have the same name as the measurement routine plus an appended numerical index before the extension. Although PC-DMIS generates this initial file name, the name does not need to follow the default format and can be changed.

You can also type a variable name in the **Report output** box. As long as there's not a pathway already in the box, PC-DMIS interprets that variable's value for the filename.

Append - PC-DMIS adds the current data from the inspection report to the selected file. Note that the complete path *must* be specified; otherwise, PC-DMIS assumes the same directory as the measurement routine. Also, if the file does not exist, it is created when you generate the report.

Append Limitations:

For an RTF file, due to a limitation with how the RTF driver works with the PC-DMIS template approach to reporting, when *appending* to an RTF file, PC-DMIS only sends the contents of the **TextReporting** object, regardless of any other objects that may exist in your current report template.

Additionally, if you choose to append to an RTF file, it must be to a file that you have *always* used with the **Append** option. You cannot append to an RTF file that you first used with **Overwrite** or **Auto**.

For a 3D PDF file, PC-DMIS does not support the append functionality with that file format.

Overwrite - PC-DMIS overwrites the selected file with the current inspection report data. Note that the complete path must be specified; otherwise, PC-DMIS will assume the same directory as the measurement routine. Also, if the file does not exist, it is created when you generate the report.

Prompt - PC-DMIS displays the **Save As** dialog box through which you can choose the destination file for the report.

Auto - PC-DMIS generates the report file name automatically using the number in the **Index** box. The name of the generated file name will have the same name as the measurement routine appended by the numerical index and extension. Also, the generated file will be located in the same directory as the measurement routine. If a

file exists with the same name as the generated file name, the **Auto** option increments the index value until a unique file name is found.

After the report prints, PC-DMIS internally updates the value in **Index** to the next number. It also changes the file name in the **Print Options** dialog box so that it shows the newly-incremented file name.

Rich Text Format (RTF) - PC-DMIS generates the report using the Microsoft Rich Text Format (.rtf file) for interchanging documents. Images in RTF reports have a light border around them. By default, PC-DMIS generates RTF reports using an Amyuni RTF converter. This essentially orders information inside several text boxes inside the RTF file. This is needed for accurate positioning of report template elements inside the RTF report. To properly view the report, you should use Microsoft Word and set the document's view to **Print Layout**. If you find editing the report in this format difficult to work with, you may want to generate an old-style RTF report.

Generating an Old-Style RTF Report

PC-DMIS provides a way to generate an old-style RTF report, such as used in version 3.7 and earlier. To do this, follow this procedure:

1. Close down PC-DMIS.
2. Launch the PC-DMIS Settings Editor, and click **Connect**.
3. Inside the Settings Editor, expand the **USER_Printing** section, and find the `DoNotUseAmyuniRTF` entry.
4. Set the **Current Value** to **1**, click **Save Setting**, and click **OK**.

This setting only works if the RTF output is done using the **File | Printing | Report Window Print Setup** menu option. If you have inserted a PRINT/REPORT command (**Insert | Report Command | Print Command**) and you want that command to generate your RTF output, set the value to **2**.

5. Restart PC-DMIS.
6. Ensure that the Report window is set to print the report in a text-only format. To do this, right-click on the white-space at the end of the Report window and select the **Use Text Mode Dimension Reporting** check box. For more information, see "Changing the Report Window's Contents" in the "Reporting Measurement Results" chapter.

Changing Margin and Page Sizes for Old-Style RTF Reports

If the `DoNotUseAmyUniRTF` entry is set to 1 or 2, you can change the default margin and page sizes used for the RTF output by modifying these entries in the **Printing** section of the PC-DMIS Settings Editor:

`PcdmisRTFLeftMargin`

`PcdmisRTFRightMargin`

`PcdmisRTFTopMargin`

`PcdmisRTFBottomMargin`

`PcdmisRTFPaperHeight`

`PcdmisRTFPaperWidth`

Intended Uses of RTF Reports

As the RTF file type implies, an RTF report is primarily intended as a file format for interchange of text-based reports as shown below:

```
PART NAME  : Test Program
REV NUMBER : B5
SER NUMBER : 13579
STATS COUNT : 1

Active alignment changed to STARTUP

            START ANG=0,END ANG=0CYL1=CYLINDER MEASURED FROM 9 HITS
DIM LOC1= LOCATION OF CYLINDER CYL1  UNITS=MM
AX    NOMINAL       +TOL       -TOL       MEAS        DEV     OUTTOL
X      154.500      0.025      0.025    154.495     -0.005      0.000 ---#-----

```

Sample text-based report that uses the default .rtp report template.

RTF files containing graphical elements, such as those based off of the CADonly.rtp, TextOnly.rtp, and other similar templates, will take an extended amount of time to create, the files may become quite large, and the graphics may not look as good as with other file formats. For these reasons, the PDF format is recommended over the RTF format for graphical reports.

Portable Document Format (PDF) - PC-DMIS generates the report using the Adobe Portable Document Format (.pdf file) for electronic file sharing. Dimensions in PDF format do not have the default blue background color or display the dimension symbol.

If not already installed on your computer, you need to install the free Adobe® Acrobat® Reader™ in order to view .pdf files. You can download it from Adobe's website at: http://www.adobe.com/products/acrobat/readstep.html

3D Portable Document Format (PDF3D) - This also generates a .pdf file, but the main difference is that it also includes an embedded CAD object that you can manipulate within the .pdf file. For information and known limitations, see "Working with PDF 3D Files" in the "Reporting Measurement Results" chapter.

Textual Document (TXT) - PC-DMIS generates the report in a plain text format. You can view this type of report with any text editor. During report generation, PC-DMIS uses the default.rtp template, regardless of the actual template selected in the Report window. This textual report ignores any objects, such as images. For information on the default.rtp template, see "Viewing a Legacy Text Report" in the "Reporting Measurement Results" chapter. If you save your measurement routine to a version that doesn't support the .txt output, PC-DMIS uses the PDF output instead.

Use Global Print Settings - This check box becomes available if you first select a marked set from the Marked Sets window and then access this dialog box. The **Use Global Print Settings** check box determines whether or not PC-DMIS uses global output file parameters for the marked set. If you select this check box, PC-DMIS overrides the very specific default printing options used for marked sets with the measurement routine's global settings that give you greater control over the output. Select this check box to give you more control over the print-to-file naming schemes used with marked sets.

You can use the **Hyper Reports Inline** check box with the `REPORT/LEGACY` command. For more information, see "Embedding Reports or Report Templates in a Measurement Routine" in the "Reporting Measurement Results" chapter.

Output Options

Printer - Determines whether to send the report to the default printer.

Print background colors - Determines whether the report prints background colors.

By default, PC-DMIS marks this check box and prints the background colors. If you clear this check box, PC-DMIS does not print any background colors. If you want to clear or display the background color from a report already in the Report window, make sure you click the **Redraw the Report** button from the **Reporting** toolbar.

To change the default state of this check box, click the **Edit** menu, point to **Preferences**, and then click **Setup**. Then on the **General** tab, in the list of check boxes, mark or clear the **Print Background Colors** check box.

Sample report without background colors.

In certain cases, you may continue to see some background colors in your report even if you've turned off the display of background colors here. This is due to a special background color setting that exists inside certain report template objects and is not controlled by this check box. By default, the **TextReportObject** and the **Report** object that exist in PC-DMIS report templates have a faint light-green background color in their color scheme. For the **TextReportObject**, this exists to help show the limits of the object inside the template. If this background color poses a problem, access the **Color** property for these objects inside the report template, and change these objects' background colors to white. For more information on how to do this, see "Changing the Report's Text Colors" in the "Reporting Measurement Results" chapter.

Print Black and White - Determines whether text, lines, and the tolerance zone graphs print in black and white or use the defined colors.

This does not make every report a completely black and white report. Some elements are not affected by this check box (for example, the Graphic Display window, images, and elements in some OCXs are not affected).

Sample report in color.

Show Report - Determines whether to open the report that PC-DMIS sent to a .pdf or an .rtf file. If you select this option, the report opens in whatever application you have associated with the .rtf or .pdf file types after you generate the report.

Copies - Determines the number of copies to send to your printer. This option is only enabled if you mark the **Printer** option.

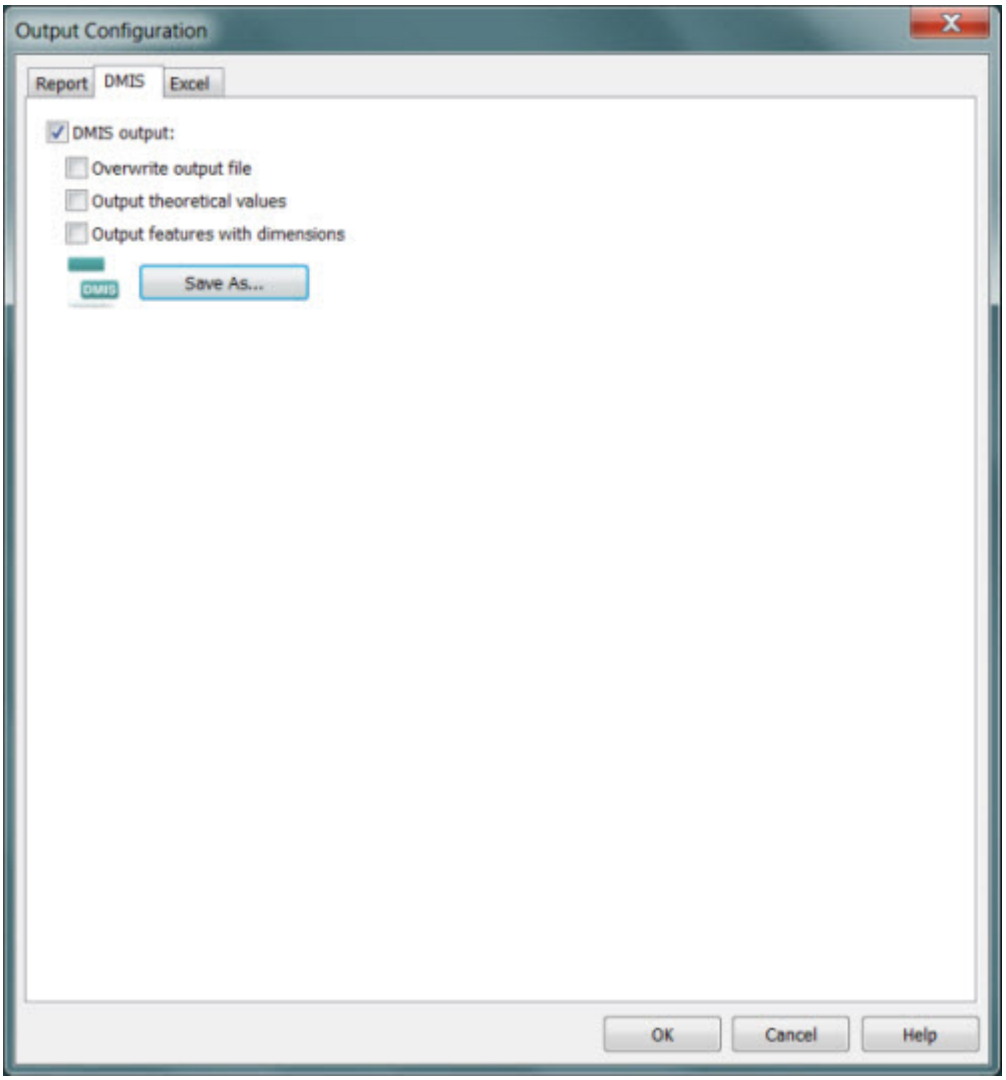
Controlling File Size by Changing the Print Resolution

If your report contains images of your part model, PC-DMIS, by default, prints these images at your printer's highest resolution capacity. This means reports showing part models and sent to a file may have a larger file size than expected.

You can control the resolution, and in turn control the report's file size, by changing the value of the `MaxPrintResolution` entry in the **USER_Printing** section of the PC-DMIS Settings Editor. For information on how to change entries, see "Modifying Setting Entries".

The `MaxPrintResolution` entry defines the dots per inch (dpi) that your printing device generates when printing CAD images. You can change this value to define the proper balance between file size and image quality to suit your needs. The default value is 1,000,000 dpi, thereby effectively using any printer's maximum print resolution capacity. If you define a value less than your printer's maximum print resolution, you will see a decrease in file size. For example, if your printer can print up to 500 dpi but you change the entry to a smaller value, like 70 dpi, you will notice a decrease in the size of the file.

Output to a DMIS File



Output Configuration Dialog Box - DMIS Tab

In the **Output Configuration** dialog box (**File | Printing | Report Window Print Setup**), on the **DMIS** tab, if you mark **DMIS output** check box and execute the measurement routine, PC-DMIS saves the inspection report's information as a DMIS output file with the same base file name as your measurement routine, with a .dmo file extension. PC-DMIS saves the file in the same directory where your measurement routine resides.

The **Overwrite output file**, **Output theoretical values**, and **Output features with dimensions** check boxes and **Save As** button become available. By default, PC-DMIS automatically generates the output file whenever you execute the measurement routine. It increments the number on the file name each time.

Overwrite output file

- If you select this check box, PC-DMIS overwrites the old output file with the new one. If you clear this check box, PC-DMIS automatically increments the file name specified in the **Save As** dialog box without overwriting any previous file.

For example, if you previously selected "test.dmo" as your output file, and **Overwrite output file** was not selected, the next time you execute the measurement routine, PC-DMIS saves a new file as "test1.dmo". New executions of the measurement routine increment the number in the saved file name in this manner.

- If you place **Overwrite output file** in its third state (a solid blue color), PC-DMIS opens the specified file in append mode. This follows the DMIS convention where you can enable, disable, and enable again the output to the same file. In PC-DMIS, this functions correctly only if you initially open the file with the **Overwrite output file** check box selected.

Output theoretical values

- If you select this check box, PC-DMIS outputs all theoretical values along with the measured values to the output DMIS file. If you clear this check box, the report does not include any theoretical values.

- If you place the **Output theoretical values** check box in its third state (a solid blue color), only those theoretical values that the original DMIS routine explicitly output are included in the report. This third state is useful when a DMIS import process creates the measurement routine, and you need to maintain the same DMIS output format.

Output features with dimensions

- If you select this check box, PC-DMIS keeps the measured features and associated tolerances together in the output file. PC-DMIS writes the measurement results immediately before their associated tolerance results for each dimension associated to the feature itself.

  If a feature is not associated with any tolerance, PC-DMIS does not generate any output.

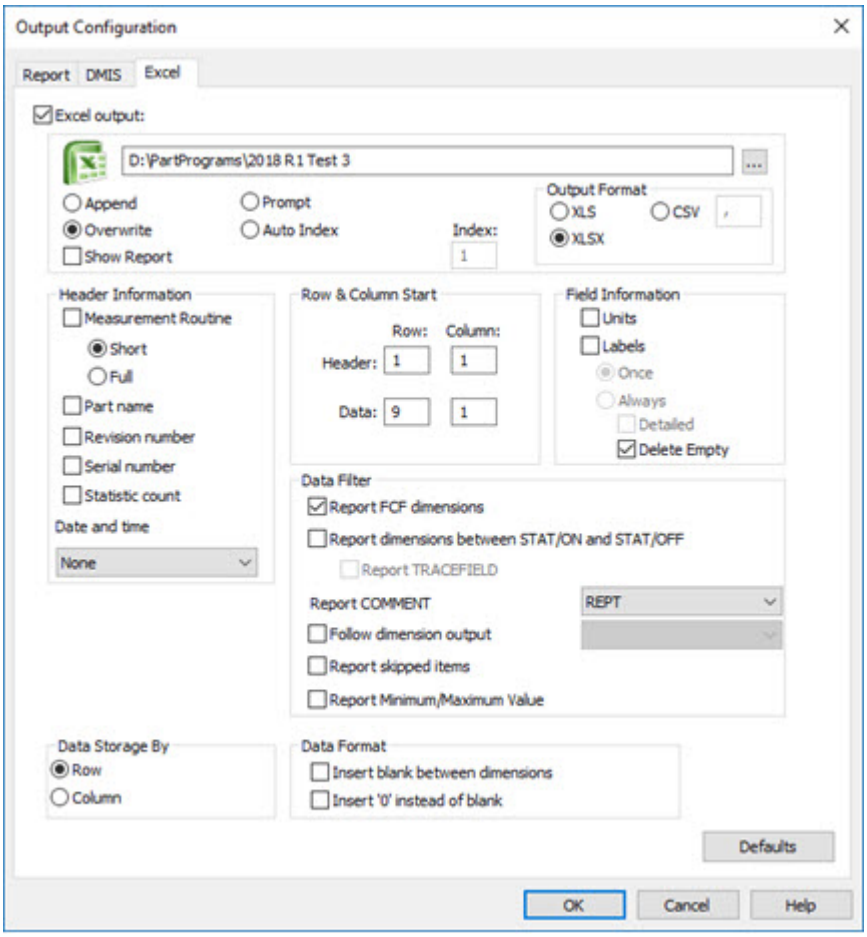
- If you clear this check box, the measurement results are written exactly when the feature is measured and not later when PC-DMIS executes the associated dimensions.

Save As

This button opens a **Save As** dialog box. This saves the inspection report to a file and directory of your choice in the DMIS output format (.dmo). PC-DMIS does not save the file once you click **Save** from the **Save As** dialog box. Instead, it creates the output file with the specified name the next time you execute the measurement routine.

The numeric portion of the file name should not exceed more than 10 digits. Otherwise, you run the risk of overwriting older output files.

Output to an Excel File



Output Configuration Dialog Box - Excel Tab

In the **Output Configuration** dialog box (**File | Printing | Report Window Print Setup**), the **Excel** tab outputs the report to an Excel file.

PC-DMIS follows the mode of the Report window:

- If you select the **View Report Mode** on the Report window's toolbar, the report output is generated from beginning to end.
- If you select the **View Last Execute Report Mode** on the Report window's toolbar, the report output is generated by following the execution list.

  For more details, see "Reporting Toolbar".

To output a report in an Excel format, do the following:

1. Click the **Excel** tab on the **Output Configuration** dialog box (**File | Printing | Report Window Print Setup**).
2. Select the **Excel output** check box to enable the tab's options.
3. Make your selections in the dialog box as needed and then click **OK**.

PC-DMIS saves the inspection report's information in the Excel file format that is selected in the **Output Format** area. The default is the same base file name as your measurement routine with a .xlsx file extension. The default location is in the same directory as your measurement routine. The available Excel file format options are:

- The latest Excel .xlsx format
- The older Excel .xls format
- The comma-separated value (.csv) format

Configuring the Excel Options

When the **Excel output** check box is selected, the following options become available:

Excel output - Displays the file name and the path where the report is saved. The file name defaults to the name of the measurement routine. You can enter a new file name and pathway, or click the "**...**" browse button to locate and select an existing file name and pathway.

You can also type a variable name in the **Excel output** box. As long as there's not a pathway already in the box, PC-DMIS interprets that variable's value for the filename.

Append - If the file name already exists in the targeted location, the current report information automatically appends to the end of the existing file.

Overwrite - If the file name already exists in the targeted location, the existing file is automatically overwritten with the current report content.

Prompt - If the file name already exists in the targeted location, you are prompted if you want to overwrite the existing file with the current report content or update the file name.

Auto Index - Used in conjunction with the **Index** box, this value updates the file name by appending an incremented numerical value by the index value. For example, if **XLS** is selected in the **Output Format** area, the initial file name is "FileName001.xls". The file names from then on are "FileName002.xls", "FileName003.xls", etc.

Index - A non-editable field that represents the increment value for the **Auto** option used when automatically naming the output file (see the **Auto** option above).

Show Report - The Excel report automatically opens for review once you generate it.

Output Format - Defines the output type. It contains these options:

XLS - Sends the output to the legacy Excel formatted file type.

XLSX - Sends the output to the latest Excel formatted file type.

CSV - Sends the output to a plain-text comma-separated value (CSV) file. You can choose a different delimiting character in the box next to **CSV**. This box is enabled when the CSV option is selected; it determines the separator, or delimiting character, to use when you export to a CSV file. The default is the comma character.

Header Information - Determines how the header data for the measurement routine is written to the output file.

Measurement Routine - Includes measurement routine names in the output file.

Short - The file name is a shortened format and shows only the file name (not the full path).

Full - The file name includes the full path.

Part name - Includes the part name in the output file.

Revision number - Includes the revision number in the output file.

Serial number - Includes the serial number in the output file.

Statistic count - Includes the number of transactions or runs in the output file.

Date and time - Specifies if the date and time appear in the output file and the format. It has these options:

None - Does not include the date and time in the output file.

System - Formats the date and time according to your computer's current format. This is the default.

24 Hour - Formats the date and time according to a 24-hour format.

Row & Column Start - Determines how the dimensional data appears in the output.

Header Row and **Column** - Define the starting location where you want the header information to appear. For example, values of 2 and 2 mean that it begins in the second row down and second column to the right.

Data Row and **Column** - Define the starting location where you want the dimensional data to appear. For example, values of 9 and 2 mean that it begins in the ninth row and second column.

Field Information - Determines how the information is formatted when you save it.

Units - Determines whether the measurement units used by each dimension are included in the export. For example, angle measurements show DEG for degrees, and size measurements show MM for millimeters or IN for inches.

Labels - Determines whether labels appear next to data fields in the output. If marked, the following options become enabled:

Once - Field labels appear only once after the heading information and before all the dimensions are listed.

Always - Field labels appear before each dimension.

Detailed - If you mark **Always**, this check box becomes available. Select this check box if you want all field labels to appear in the report.

The labels that appear if this check box is selected are: DIMENSION, DESCRIPTION, FEATURE, AXIS, SEGMENT, NOMINALS, MEAS, +TOL, -TOL, BONUS, DEV, OUTTOL, DEVANG, Datum Shift Effect, Unused Zone, Shift X, Shift Y, Shift Z, Rotation X, Rotation Y, and Rotation Z.

If the check box is not selected, only these labels appear: DIMENSION, DESCRIPTION, AXIS, NOMINALS, MEAS, +TOL, -TOL, DEV, and OUTTOL.

Delete Empty - Deletes any empty field from the report.

Data Storage By - Determines how the report is presented: either by row or by column.

Row - Dimensions are laid out horizontally.

Column - Dimensions are laid out vertically.

Data Filter - Determines how the data filters in the output report.

Report FCF dimensions - PC-DMIS passes the Feature Control Frame commands to the Excel file. See the "Using Geometric Tolerances" chapter.

Report dimensions between STATS/ON and STATS/OFF - If you select this check box, you *must* include dimension (or Feature Control Frame dimension) commands between the `STATS/ON` and `STATS/OFF` commands in your measurement routine; otherwise, the data does not export to the Excel file. If you clear this check box, all dimension commands export into the Excel file. See the "Tracking Statistical Data" chapter. The following option becomes enabled:

Report TRACEFIELD - PC-DMIS includes data from `TRACEFIELD` commands in your Excel report if the `TRACEFIELD` commands are within the `STATS/ON` and `STATS/OFF` commands. For more information, see the "Using Tracefields" chapter.

Report COMMENT - Determines whether PC-DMIS includes comments in your Excel report. It has these options:

None - PC-DMIS does not send comments to the Excel report.

REPT - PC-DMIS only sends report comments (`COMMENT/REPT` commands) to the Excel report.

Display on report - PC-DMIS sends all report comments (`COMMENT/REPT` commands), as well as any comment that has its **Display on report** check box marked to the Excel report.

For information on comments, see "Inserting Programmer Comments" in the "Inserting Report Commands" chapter.

Follow dimension output - PC-DMIS filters the data so that the Excel report only includes dimensions that have their outputs set to match whatever you select from this list:

- REPORT
- STATS
- BOTH

For example, if you choose **REPORT**, and you have a Location dimension set to OUTPUT=STATS, it is not included in the Excel report.

For more information on dimension outputs, see these topics:

- For legacy dimensions, see "Output To" in the "Using Legacy Dimensions" chapter.
- For geometric tolerances, see the **Output** area discussed in the "Reporting tab" topic of the "Using Geometric Tolerances" chapter.

Report skipped items - PC-DMIS processes items that the operator skips during execution and includes them in the report. If you clear this check box, PC-DMIS ignores the skipped items. Note that commands are skipped if the operator manually skips them or if an On Error command tells PC-DMIS to skip them. For more information on **Skip**, see "Using the Execution Dialog Box". For information about On Error branching, see "Branching on an Error".

Report Minimum/Maximum Value - Displays the maximum and minimum deviation values from the points that make up the dimension. While you can report the MaxMin for any dimension, it only makes sense for Line Profile and Surface Profile dimensions. For an example of this, see the "Parameter Settings: Dimension tab" topic in the "Setting Your Preferences" chapter.

Data Format - Determines how the output report shows the data:

Insert blank between dimensions - Inserts a blank row or column after each dimension.

Insert '0' instead of blank - Inserts a '0' (zero) for any blank data.

Defaults - Creates a "defaults" file (ExcelDefaults.p2xfile) that stores this dialog box's settings. When you click this button, PC-DMIS automatically updates the contents of the "defaults" file without showing a message.

PC-DMIS uses this defaults file in these cases:

- For new measurement routines
- For the current measurement routine if PC-DMIS cannot locate the routine-specific settings file. (Note that PC-DMIS creates a routine-specific .p2x file in the same directory as the measurement routine whenever you click **OK**.)

PC-DMIS saves the ExcelDefaults.p2xfile here: C:\ProgramData\Hexagon\PC-DMIS\2026.2\. You can view this file in any text editor.

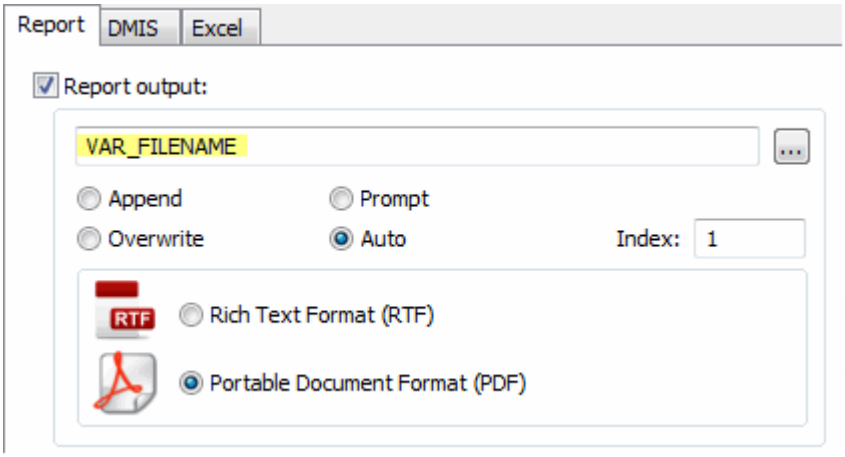
Output to a File Using Expressions

In the **Output Configuration** dialog box (**File | Printing | Report Window Print Setup**), from the **Report** tab, you can use expressions in the **File** box. With this functionality, you can use your measurement routine code along with the **Output Configuration** dialog box to dynamically change the destination directory for the output file.

For example, suppose two users, John and Amy, want to send the same measurement routine's inspection report to an existing subdirectory based on the user name. Instead of opening the **Output Configuration** dialog box for each user and changing the destination directory and the name of the report, you can have the user type their name into a Comment and then use assignment and flow control commands to store the different destination directories and report names in a variable, like this:

```
C1          =COMMENT/INPUT,YES,Type your name:
             IF/C1.INPUT=="John"
                 ASSIGN/VAR_FILENAME="C:\\inspectionreports\
\John\\John.rtf"
                 COMMENT/OPER,NO,VAR_FILENAME
             END_IF/
             ELSE_IF/C1.INPUT=="Amy"
                 ASSIGN/VAR_FILENAME="C:\\inpectionreports\
\Amy\\Amy.rtf"
                 COMMENT/OPER,NO,VAR_FILENAME
             END_ELSEIF/
             ELSE/
                 ASSIGN/VAR_FILENAME="C:\\inspectionreports\
\"+C1.INPUT+".rtf"
                 COMMENT/OPER,NO,VAR_FILENAME
             END_ELSE/
```

Then inside the **File** box, on the **Report** tab of the **Output Configuration** dialog box, you can type the `VAR_FILENAME` variable as shown here:



Example showing VAR_FILENAME in File box.

Thereafter, whenever you execute the measurement routine, if John is the user, PC-DMIS saves the report *John.rtf* to his directory; if Amy is the user, PC-DMIS saves *Amy.rtf* to her directory; if another user types his or her name, it goes to the default *C:\Inspectionreports* directory.

- For information on comments, see the "Inserting Programmer Comments" topic in the "Inserting Report Commands" chapter.
- For information on expressions and variables, see the "Using Expressions and Variables" chapter.
- For information on flow control statements, see the "Branching by Using Flow Control" chapter.

Closing or Quitting a Measurement Routine

- To save and close the active measurement routine, select **File | Close**. If you have never saved the measurement routine, you are prompted to name and save your file.

  You can only save measurement routine (.prg) files to valid versions of PC-DMIS.

  For PC-DMIS 2026.2, the furthest you can save back to is PC-DMIS version 2021.1.

- To quit the current measurement routine, select **File | Quit**. If you have unsaved data, a message appears and asks if you want to quit the measurement routine without saving. To save the measurement routine, choose **NO** in the message box, and choose **File | Save** or **File | Save As** (for more information, follow the instructions under "Saving Measurement Routines").

If you close down all open sub-windows in the software (the Report window, the Edit window, and the Graphic Display window) by clicking on each window's X, PC-DMIS immediately saves the measurement routine and then closes it. If you use the **View** menu to hide the windows, the measurement routine remains open.

Exiting the Software

To quit the current measurement routine and exit PC-DMIS, choose the **File | Exit** command. When you choose **File | Exit**, PC-DMIS automatically saves the current measurement routine before exiting.

Using Advanced File Options

Using Advanced File Options: Introduction

PC-DMIS provides you with many options to manipulate measurement routines and manage your essential files. As with most Windows-based programs, you can perform basic file management using standard Windows dialog boxes; these include creating, opening, copying, renaming, and deleting files. Additionally, through PC-DMIS, you can perform more advanced operations, such as importing and exporting CAD data or executing completed measurement routines.

This chapter specifically deals with advanced file options. For more basic options, see the "Using Basic File Options" chapter.

The options discussed in this chapter include:

- Importing CAD Data or Feature Data
- Exporting CAD Data or Feature Data
- Using Direct CAD Interfaces
- Setting Import Options
- Executing Measurement Routines

These options and commands are described in detail throughout this chapter.

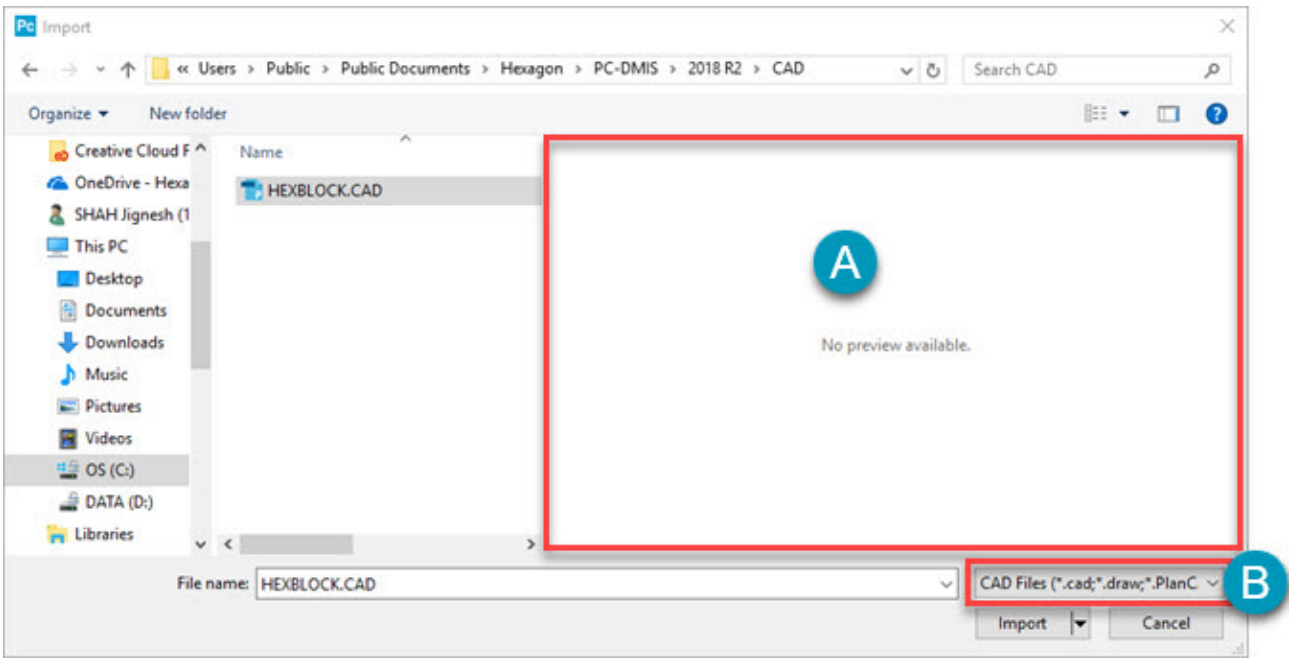
Importing CAD Data or Feature Data

When you select **File | Import**, PC-DMIS displays a submenu of data types that you can import into the current measurement routine. Data types are either:

- CAD data that the software can import into the CAD file in the Graphic Display window or
- Feature data that the software can import into the measurement routine

Once you select a menu item, the software displays an **Import** dialog box so that you can choose the file to import.

The dialog box is a standard Windows **Import** dialog box with the following additions:



Example of the Import dialog box for CAD.

A. **Preview** - This area of the dialog box shows the CAD image for .prg files. This area remains blank for all the other types of files.

B. This file type list displays the various file types that you can import. You can import any of these file types:

- **CAD Data** - ACIS, CAD, CAD by Reference, CATIA, Creo, DES, DXF, EDGECAM, IGES, Inventor, JT, Parasolid, QIF, Solid Edge, SolidWorks, STEP, STL, NX, VDAFS, Wavefront, or XYZ
- **Feature Data** - ASCII, Chorus DMIS, Datalog, DMIS, Pointcloud, MeasureMax, Inspection Plan, CSV, or XYZ. PC-DMIS imports the data into the measurement routine in the PC-DMIS format.

> With DMIS data, the data is imported into the measurement routine in PC-DMIS format, eliminating the need for a separate file.

PC-DMIS imports CAD data as CAD entities into the Graphic Display window.

- PC-DMIS keeps track of the CAD data as a separate file. This file has the same file name as the measurement routine and has a ".cad" extension.

> If you have a measurement routine with a file name of test.prg, once you add CAD data to this measurement routine, PC-DMIS creates a CAD file named test.cad and stores it in the same directory.

- You can use PC-DMIS to import existing .cad files for multiple measurement routines. For information, see "Importing a CAD by Reference".

PC-DMIS imports feature data as feature commands in the Edit window.

Importing CAD Data

PC-DMIS can import CAD data into the Graphic Display window.

These translators are supported:

- ACIS
- CAD
- CAD by Reference
- CATIA DCT (V4, V5, or V6)
- Creo DCT
- DES
- DXF/DWG
- EBM
- EDGECAM
- IGES
- Inventor
- JT
- MetIL
- NX DCT
- Parasolid DCT
- QIF
- Solid Edge DCT
- SolidWorks DCT
- STEP
- STL
- From Teamcenter

- VDAFS
- VISI
- Wavefront Object
- XYZ

If you want to use the CATIA, Parasolid, Creo, SolidWorks, NX, QIF, or VISI translators, your PC-DMIS license must have these applicable DCT license options enabled: **CATIA V4 DCT, CATIA V5 DCT, CATIA V6 DCT, NX DCT, PRO-E DCT**, **Parasolid DCT**, **QIF-DCT**, or **VISI DCT**.

General Import Procedure

The general procedure below imports the CAD data through an **Import** menu. However, you may find it easier to drag and drop the files directly into the Graphic Display window to start the import process. Drag and drop import functions if you run PC-DMIS as a standard user. If you run PC-DMIS as an administrator, this is not allowed, due to Windows UAC security restrictions.

To import CAD data into the Graphic Display window of your inspection plan, follow this general procedure. You can find specifics for your CAD type in the topics below:

1. Select the **File | Import | <CAD File Type>** menu item to open the **Import** dialog box.
2. From the file type list, select the file type that filters the current folder.
3. From the **Import** dialog box, navigate to the folder that contains the file to import. Then select the file.
4. Click **Import** to import the file. If you already have a CAD model in the Graphic Display window, PC-DMIS asks if you want to replace the existing CAD data or merge the CAD data together.
    - To *add* the new imported data without deleting the existing data, click the **Yes** option.
    - To *replace* the existing data with the new imported data, click **No**.
    - To return to the **Import** dialog box, click **Cancel**.

Some imported file types automatically replace old existing CAD data with the imported data. In those cases, you won't be presented with the **Merge Import Data** dialog box.

If a Model View is active, and you merge an imported CAD file, PC-DMIS adds all the visible geometry of the imported CAD model into the active Model View.

For details on CAD Model View, see "Working with CAD Model Views" in this documentation.

5. PC-DMIS starts to import the CAD data with any accompanying GD&T dimension information.

6. If PC-DMIS detects a reference to the GD&T standard to which your CAD model was designed, PC-DMIS compares the CAD model's GD&T standard to the measurement routine's GD&T standard (see "Creating New Measurement Routines" and "Setup Options: Geometric Tolerances" tab). If the CAD model's GD&T standard differs from that of the measurement routine, PC-DMIS displays this message:

   Your measurement routine GDT standard (ASME Y14.5 - 2018) does not match the imported CAD standard (ISO 1101). Click OK to set the measurement routine to ISO 1101 or Cancel to keep the current routine standard.

   - If you click **OK**, PC-DMIS changes the measurement routine's GD&T standard to match that of the CAD model.
   - If you click **Cancel**, PC-DMIS leaves the measurement routine's GD&T standard unchanged. You are responsible for managing any GD&T discrepancies.

7. If your model contains embedded GD&T callouts, PC-DMIS asks if you want to make the first CAD model view that contains GD&T to be active and to show it in the Graphic Display window.

   - If you click **Yes**, PC-DMIS activates the first CAD model view that contains GD&T and turns on the **Show GD&T** option in the **Operation | Graphic Display Window | CAD Items** menu.
   - If you click **No**, PC-DMIS turns off the **Show GD&T** menu option in the **Operation | Graphic Display Window | CAD Items** menu.

For additional information on CAD GD&T callouts, see "Working with CAD GD&T Callouts".

If you re-import the original CAD model file, PC-DMIS removes any modifications to the GD&T CAD callouts in the Graphic Display window.

In some supported CAD model formats, the **Cancel** and **Stop** buttons are available:

During the import process, you can cancel or stop the import.

- **Cancel** - This button cancels the import altogether. If you already had a CAD model loaded before the import, PC-DMIS retains the previous CAD model.
- **Stop** - This button stops the import, but keeps any imported CAD elements up to that point.

If you import both a part model and a machine model into the Graphic Display window, and you don't have any outstanding manual machine offsets or rotations, PC-DMIS automatically positions the part model to the machine model's table.

If you have manual x,y,z, offsets or rotations from the **Part/Machine** tab of the **Setup Options** dialog box, you need to use that tab's **Auto Position** button to position the part model to the machine table. For more information on the **Auto Position** button, see the "Part Setup area" topic in the "Setting Your Preferences: Introduction" chapter.

Importing Multiple CAD Files

PC-DMIS allows you to import multiple CAD files at the same time.

If you have a wireframe and a solid model of the same part, you can import both into your measurement routine.

You can choose to import a .cad, .draw, or .PlanCAD file.

You can press Ctrl and then click on different files to select multiple files at the same time.

If a Model View is active, and you merge an imported CAD file, PC-DMIS adds all the visible geometry of the imported CAD model into the active Model View.

For details on CAD Model View, see "Working with CAD Model Views" in this documentation.

Importing an ACIS File

ACIS files come from the 3D ACIS Modeler, which is a CAD software package developed by Spatial Corporation (formerly Spatial Technology). You can import ACIS files up to v2016 1.0.

You can choose to import a .sat, .asat, or .sab file.

Importing a CAD File

To import a CAD file, perform the following steps:

You can choose to import a .cad, .draw, or .PlanCAD file.

Your file to import should have the same measurement units as the measurement routine that takes the import. If the files don't have the same measurement units, you can still import the file, but the measurement routine ends up with incorrect information. For example, if you have a circle with an X value of 4 inches in the file to import, the software imports it as 4 millimeters if the measurement routine that takes the import expects millimeters.

You can reference one CAD file from more than one measurement routine. For more information on how to reference the CAD file, see the "Importing a CAD by Reference" topic.

Importing a CAD by Reference

You can have multiple measurement routines reference a single CAD model. If you use large CAD models, to save disk space, you can reference just one .cad file for multiple measurement routines.

You can choose to import a .cad, .draw, or .PlanCAD file.

- If you import a .PlanCAD file, the software imports both the plan features and the embedded CAD model.

- If PC-DMIS detects changes in the original .PlanCAD file that you're referencing, it asks if you want to use the Change Manager to handle those changes. For information on the Change Manager, see "Updating Inspection Plans with the Change Manager".

The software only reloads the CAD model if the original .plancad file is modified.

> You cannot have circular references to .cad files. These result in error messages. For example, an error occurs if you create a measurement routine, import an IGES file, save the measurement routine, and then later attempt to import its own .cad file.

Once imported, you can use the **View | CAD Info** menu option to view information about a CAD element and display the file path for the referenced CAD file. For information, see "View | CAD Info" in the "Editing the CAD Display" chapter.

> Be aware that modifications made to the CAD model, either the original CAD model or a referenced CAD model, are made to all other measurement routines based on that CAD model. For example, if you make changes to the original CAD model, any models referenced from the original are also changed. Conversely, if you make changes to a referenced model, then the original model also has the same changes made.

Importing CATIA Files

PC-DMIS allows you to translate various CATIA file types and import the file type into a PC-DMIS measurement routine. This type of import differs from interfacing directly with the CATIA CAD file. For information on directly interfacing with CAD models, see the "Direct CAD Interface" documentation.

You can choose to import **CATIA 4 Files**, **CATIA 5 Files**, **and CATIA 6 Files**.

- If you select **CATIA 4 Files**, you can import files with .mod, .exp, .iso, and .cat filename extensions.
- If you select **CATIA 5 Files**, you can import files with .CATPart and .CATProduct filename extensions.
- If you select **CATIA 6 Files**, you can import files with .3dxml filename extensions.

CATIA v5 Assemblies

CATIA v5 assemblies can contain embedded CATIA v4 model files. When you use the CATIA v5 DCI or DCT to import a CATIA v5 assembly, PC-DMIS uses the CATIA v4 DCT to translate any embedded CATIA v4 model files. As such, your PC-DMIS license must be programmed for the CATIA v4 DCT. Otherwise, the embedded CATIA v4 model files are

not translated. For information on assemblies, see "Working with Assemblies of Parts" in the "Editing the CAD Display" chapter.

CATIA v5 Model Views

PC-DMIS supports CATIA v5 CAD model views. For more information, see "Working with CAD Model Views".

Importing a Creo File

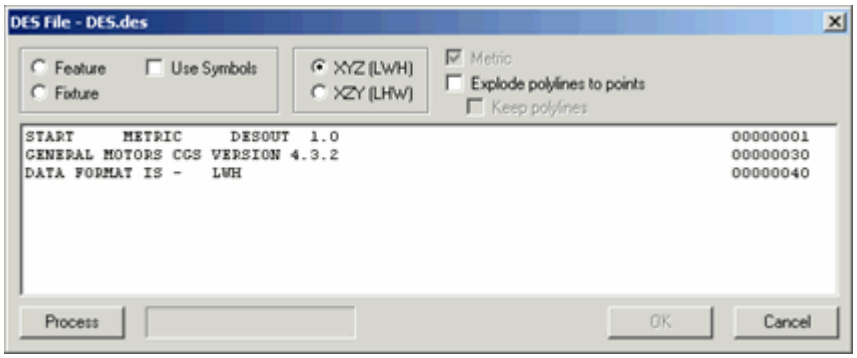
PC-DMIS allows you to translate a Creo (previously Pro/ENGINEER) file and import it into a PC-DMIS measurement routine. This type of import differs from interfacing directly with the Creo CAD file as described in the "Installing and Using Creo Direct CAD Interface" topic in the "Direct CAD Interfaces and Translators" documentation.

You can choose to import a .prt, .asm file, .xar, or .xpr file.

Importing a DES File

You can choose to import a .des file.

When you click **Import**, PC-DMIS displays the **DES File** dialog box.



DES File Dialog Box

Feature or **Fixture** - This option specifies what type of data you want to import. If you select **Feature**, you can select the **Use Symbols** check box to use feature labels.

XYZ (LWH) or **XZY (LHW)** - This option specifies the orientation for the imported data.

Metric - Use this check box if the needed units are not specified in the DES file.

Explode polylines to points - This check box converts imported lines into points. Additionally, you can select the **Keep polylines** check box to keep the imported polylines.

Process - This button imports the DES file.

OK - This button accepts the processed file.

Once you import the DES file you can create features similar to other CAD formats. For more information, see "DES Input" in the "Working in Offline Mode" appendix.

Importing a DXF or DWG File

You can choose to import a .dxf or .dwg file.

PC-DMIS stores the units of DXF files in the measurement property inside the DXF file. The measurement property is indicated by the text "$MEASUREMENT" in the DXF file.

Fixing a Missing Measurement Property

Some DXF files may omit the measurement property. In these cases, PC-DMIS assumes that the DXF file is in inch units. If the units of the DXF file should be millimeter, and you import the DXF file into PC-DMIS, PC-DMIS scales the CAD model too large by a factor of 25.4.

To fix this problem, you can use the **CAD Transform** dialog box to scale the model by a factor of 1/25.4:

1. Choose **Operation | Graphic Display Window | Transform** to access the **CAD Transform** dialog box.
2. In the **Scale** box, type **1/25.4**.
3. Click **OK** to scale the model down by that factor.

For more information on the **CAD Transform** dialog box, see "Transforming a CAD Model" in the "Editing the CAD Display" chapter.

Fixing an Incorrect Measurement Property

Some DXF files may have an incorrect measurement property. For example, the measurement property may indicate inch units but the intended units are millimeters. If you import the DXF file into PC-DMIS, PC-DMIS scales the CAD model too large by a factor of 25.4.

To fix this problem, you can edit the DXF file in a text editor:

1. Open the DXF file in a text editor, such as Notepad.
2. Search for the text "$MEASUREMENT" in the file.

   For example, the text could look something like this:

   ```
   $MEASUREMENT

   70

   0

   0
   ```

This measurement property defines the drawing units. The first number that follows group code 70 defines the drawing units for the CAD model. It can be 0 or 1 and signifies the following:

0 = inch

1 = millimeters

3. Modify the drawing units to the intended units: 0 for inch or 1 for millimeter.

   So, in the above example, to change the CAD model units to millimeter, change the drawing units property from 0 to 1, like this:

```
$MEASUREMENT
70
1
0
```

4. In your text editor, save your changes to the DXF file.
5. In PC-DMIS, import the modified DXF file.

Importing an EBM File

The EBM file type is a text file that defines features and dimensions. When you import an EBM file, PC-DMIS creates features and dimensions. PC-DMIS creates the features and dimensions based on their parameters in the EBM file. For those parameters not explicitly defined in the EBM file, PC-DMIS uses previously defined default parameters.

To show the plus and minus dimension tolerance values as they appear in the EBM file, you must select the **Minus Tols Show Negative** check box. You can find this in the **Output options** area on the **Dimensions** tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**).

When you import this file type, PC-DMIS performs these error checks:

- Corrupted file
- File format and syntax errors
- Unsupported input feature types

If the software finds an error, it displays a message with a brief description of each error.

EBM File Import

File Name: D:\EBM_Files\EBM_TestFile_01.ebm

Line 13: Ignored the command REFERENTIELLE (NOM="CAISSE")

LINE 41: Ignored the command PT_GEOM_SUR_ (NOM="9802PR31G_Z121"

LINE 123: Wrong or missing fields in the command CERCLE (NOM="9802PR_XY9")

LINE 137: Wrong or missing fields in the command OBLONG (NOM="9802PR_X6")

Imported 107 features

Importing an EDGECAM File

For a general procedure, see "Importing CAD Data".

You can import geometry information from an EDGECAM file (.ppf) into the Graphic Display window.

You can choose to import a .ppf file.

Importing an IGES File

You can choose to import .igs or .iges files.

If you want to manipulate a 2D CAD drawing three-dimensionally, thereby creating desired 3D levels, you can use CAD-level functionality. If you do this, your original data should be defined in a single plane parallel to the Z (= 0) plane. For complete information on CAD levels, see the "Working with CAD Levels" topic in the "Editing the CAD Display" chapter.

For information about the different input file formats, see the "Working in Offline Mode" section.

Importing an Inventor File

You can choose to import a .ipt file (CAD file) or a .iam (CAD assembly). They are the Autodesk Inventor model filename extensions.

Importing a JT File

The JT file format is a relatively light-weight file format capable of containing large assemblies of parts with faceted data, lighting, textures, curves and surfaces; product and manufacturing information (GD&T callouts); and other information. It is useful for visualization and collaboration.

You can choose to import a .jt file.

Importing a MetIL File

MetIL files come from the Metrology Mentor, which is a part of the Nexus platform. MetIL files are in a .json format that contains measurement instructions. For each Metrology Mentor measurement plan, there are two files:

<planname>.metil.json and <planname>.analysis.json, where <planname> is the name of Metrology Mentor plan.

MetIL Converter

PC-DMIS MetIL Converter converts MetIL instructions into PC-DMIS commands. You need to add alignment to the measurement routine.

To convert MetIL instructions into PC-DMIS commands:

1. Create a Metrology Mentor measurement plan.
2. From the measurement plan, generate a program to create the MetIL and Analysis files.
3. Download the MetIL and Analysis files.
4. Open PC-DMIS.
5. Create a measurement routine in inch or mm units.

   In the **New Measurement Routine** dialog box, you must select the **ASME Y14.5 - 2009/2018** option from the **GD&T Standard** list.

6. Import the same CAD file that you used to create the MetIL file.
7. From the PC-DMIS menu, select **File | Import | MetIL**.
8. Navigate to the folder where you stored the MetIL files.
9. Select a <planname>.metil.json file.

PC-DMIS starts the conversion and display the commands in the Edit window.

Importing an NX File

PC-DMIS allows you to translate an NX (previously Unigraphics) file and import it into a PC-DMIS measurement routine. This type of import differs from interfacing directly with the NX CAD file described in the "Direct CAD Interfaces" documentation.

You can choose to import a .prt file.

If you have an NX model with global tolerances, PC-DMIS applies those tolerances to non-basic dimensions without tolerances during the model import.

Importing a Parasolid File

You can choose to import a .x_t, .x_b, .xmt_txt, or .xmt_bin file.

Importing a QIF File

You need a license to use this option.

PC-DMIS allows you to translate Quality Information Framework (QIF) file types and import them into a PC-DMIS measurement routine. The QIF file type conforms to the ISO standard for the CAD neutral file format and 3D CAD files that contain Product Manufacturing Information (PMI).

You can import .qif file types the same way you import any file type into PC-DMIS from the **File | Import** menu option.

PC-DMIS only supports QIF version 3.0.0.

Importing a Solid Edge File

PC-DMIS allows you to translate Solid Edge file types and import them into a PC-DMIS measurement routine. Solid Edge is a CAD modeler that is similar to SolidWorks, NX, Creo, and CATIAv5.

You can choose to import a .par, .asm, .psm, or .pwd file.

Importing a SolidWorks File

PC-DMIS allows you to translate SolidWorks file types and import them into a PC-DMIS measurement routine.

You can choose to import a .sldprt or .sldasm file.

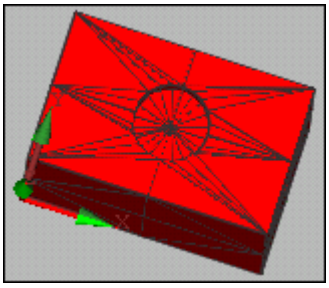
Importing a STEP File

This is a 3D model file formatted in STEP (Standard for the Exchange of Product Data).

You can choose to import a .stp, .step, or .stpZ file.

Importing an STL File

The stereolithography (STL) format, an ASCII or binary file used in manufacturing, provides a list of the triangular facets that describes a computer generated solid model. This format is the standard input for most rapid prototyping machines.



Example of an imported STL file.

You can choose to import a .stl or .stla file.

Importing from Teamcenter

Teamcenter is a PLM (Product Lifecycle Management) database package developed by Siemens. You can import CAD models stored in the Teamcenter database.

For information on how to import CAD models, see "Step 3 - Load Supported Models" in the "Using Teamcenter" chapter of the PC-DMIS DCI documentation.

Importing a VDAFS File

You can choose to import a .vda file.

A Note on Importing Point Data from PSET (Point Set) Objects

If the .VDA file you are importing contains point data within PSET Objects, PC-DMIS may create a .cad file with fewer CAD entities than what actually appears on the screen.

To get a number of CAD entities equivalent to the number of displayed points on the Graphic Display window, follow this workaround:

1. Close PC-DMIS.
2. Start the PC-DMIS Settings Editor.
3. Expand the **ImportSettings** section.

4. Set the `ExplodePolylines` entry to TRUE.
5. Set the `KeepPolylines` entry to FALSE.
6. Save your changes to the JSON file, close PC-DMIS Settings Editor, and restart PC-DMIS.
7. Import the .vda file again.

For information on how to modify entries, see the "Modifying Setting Entries" section.

Importing a VISI File

You can import geometry information from a VISI file (.wkf) file into the Graphic Display window. VISI modeling is a surface and solid modeling system that is based around the Parasolid geometric modeling kernel.

You can choose to import a .wkf file.

Importing a Wavefront Object File

For a general procedure, see "Importing CAD Data".

You can import geometry information from a Wavefront object (.obj) file into the Graphic Display window. The .obj file is an open 3D model format that many 3D graphics applications use.

You can choose to import a .obj file.

Importing an XYZ File as CAD Data

An XYZ file is a simple text file with a .xyz extension. It can contain feature information in the form of xyz coordinates with or without a vector. You can use any standard text editor to view the values in an .xyz file.

You can choose to import a .xyz file.

When you click **Import**, PC-DMIS interprets the data in the .xyz file and imports it into the Graphic Display window as separate CAD entities.

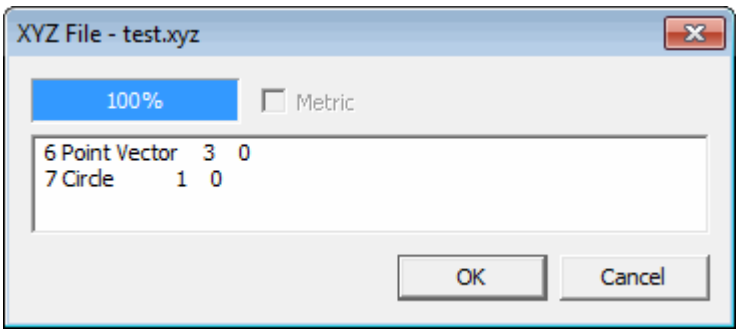
The software creates each feature based on how many comma-separated numbers are on each line. PC-DMIS reads the rows of the .xyz data file and converts the points to the following CAD entity depending on the amount of numbers per row:

Numbers per Row	Description	CAD Entity Generated
3	First number = X value Second number = Y value Third number = Z value	Point with no vector
4	First number = X value Second number = Y value Third number = Z value Fourth number = diameter	CAD circle with a workplane based vector
5	First number = X value Second number = Y value Third number = Z value Fourth number = nothing Fifth number = nothing	Point with no vector
6	First number = X value Second number = Y value Third number = Z value Fourth number = I value Fifth number = J value Sixth number = K value	Point with a vector

7	First number = X value Second number = Y value Third number = Z value Fourth number = I value Fifth number = J value Sixth number = K value Seventh number = diameter	Circle with vector
8+	First number = X value Second number = Y value Third number = Z value Fourth number = I value Fifth number = J value Sixth number = K value Seventh number = nothing Eighth number = nothing	Point with a vector

If your XYZ file contained a line with 25,280,750,25, PC-DMIS would create a circle with the center at x=25, y=280, and z=750 with a diameter of 25.

After you select the file to import, PC-DMIS displays the features constructed from the XYZ file in the **XYZ File** dialog box.



XYZ File Dialog Box

Be aware that the order in which the features are created in the .xyz file and the order in which they are generated inside PC-DMIS may not be the same.

After you click **OK**, if you imported the file into the Graphic Display window, PC-DMIS displays the created CAD elements there. If you imported the file into the measurement routine, the features appear in the Edit window.

Notes on XYZ Files

PC-DMIS can read in an .xyz text file that contains XYZ (and possibly IJK) data. The file should contain the nominal (theoretical) inspection points that need to be measured.

The file must follow these rules:

1. Columns 1 - 6 in the first line of the file must contain the characters "XYZIJK" (without quotes). PC-DMIS uses this sequence of characters as a keyword to distinguish this file type from DES and IGES files. *It must be in capital letters*.

   In the first line of the file:

   Col. 1 = X

   Col. 2 = Y

   Col. 3 = Z

   Col. 4 = I

   Col. 5 = J

   Col. 6 = K

2. If the file contains metric data, columns 11 - 16 of the first line must contain the word METRIC. That is:

   Col. 11 = M

   Col. 12 = E

Col. 13 = T

Col. 14 = R

Col. 15 = I

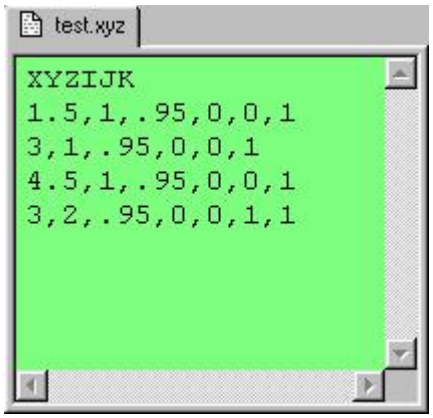
Col. 16 = C

The default, if the METRIC keyword is not present, is INCH.

The rest of the first line should be blank.

3. Each line thereafter *must* contain three to eight floating point numbers *separated by a comma*.

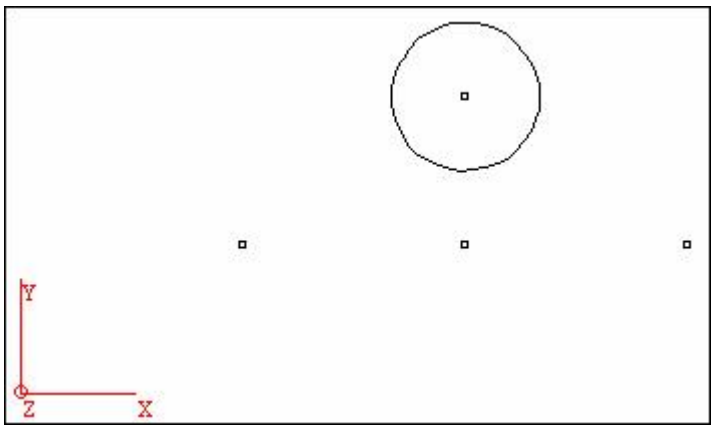
   For example, suppose your XYZIJK file looked like this sample:



Example of a XYZIJK file in a text editor.

   - Line 1 contains the XYZIJK keyword, and since the keyword METRIC isn't on columns 11 through 16, this defaults to INCH.
   - Line 2 produces a point with a vector.
   - Line 3 produces a point with a vector.
   - Line 4 produces a point with a vector.
   - Line 5 produces a circle with a vector and a diameter.

   Once imported, it produces this result in the Graphic Display window:



Example showing the Graphic Display window with data imported from the XYZIJK file.

Importing Feature Data

You can import feature data stored in another file into your measurement routine. This adds additional feature commands into the measurement routine:

It does not affect any CAD model entities displayed in the Graphic Display window.

Importing an ASCII File

ASCII files are text files that contain measurement routine information output from virtually any third party CMM software. To import these file types into PC-DMIS, select **File | Import | ASCII** to automatically create a measurement routine.

> For this menu item to appear, your PC-DMIS license must be programmed to support the **IP Measure** module.

PC-DMIS's Generic Parser (GP) is designed to parse the ASCII output from other CMM systems. The ASCII output (file) may contain file header, comments, feature commands, file footer, etc. As long as the info is written line by line in the ASCII file, GP can parse it according to the user-defined rules provided through the Rule Set Wizard. After parsing it, GP translates all the filtered-through info (like feature commands) and imports it into the active measurement routine.

> Nine PC-DMIS feature types are supported by GP. The supported features are: POINT, EDGEPOINT, LINE, PLANE, CIRCLE, CYLINDER, SPHERE, SQSLOT (Square Slot) and RDSLOT (Round Slot). See "Step 3: Feature Type Mapping and Field Assignment" topic.

To import an ASCII file as an inspection plan, follow these steps:

1. Select **File | Import | ASCII File** to open the **Import** dialog box.

2. From the file type list, select the file type that filters the current folder. If you select **ASCII Files**, you can choose to import any supported file.
3. From the **Import** dialog box, navigate to the folder that contains the file to import. Then select the file.
4. Click **Import** to import the file into the Graphic Display window. PC-DMIS displays the **Importing** dialog box. You can use this dialog box to create new rule sets, add existing rule sets, and start the import process. For more information, see "Using the Importing Dialog Box".
5. From the list of rule sets in the **Importing** dialog box, check to see if the needed rule set for your ASCII file is already visible. This rule set defines how to import the chosen ASCII file.
    - If you have an existing rule set but it isn't already added into the **Importing** dialog box, click **Add** to add it into the dialog box.
    - If you don't have a rule set defined, click **Create** to create a new rule set. These topics describe how to create a rule set.

        Rule Set Wizard - Step 1: Excluding Data

        Rule Set Wizard - Step 2: Defining Delimiters

        Rule Set Wizard - Step 3: Feature Type Mapping and Field Assignment

        Rule Set Wizard - Step 4: Handling Labels, Conflicts, and Point Offsets

        Creating a Rule Set - Previewing the ASCII File
6. Select the rule set to use for importing the ASCII file.
7. Once you have your rule set defined and selected, choose how you want to import the ASCII file:
    - **Directly** - This imports the file without showing the Rule Set Wizard first.
    - **By Wizard** - This opens the selected rule set in the rule set wizard so you can preview and modify any rules before importing the file.
8. Click **Import to Measurement Routine** to parse and import the ASCII file. Follow any on-screen instructions.

Using the Importing Dialog Box

The **Importing** dialog box allows you to create, edit, add, or delete rule sets that you can use to evaluate your ASCII file.

The selected rule set determines which information PC-DMIS imports into your measurement routine. Use the following options to select and apply rules for parsing your ASCII file.

Create - This option opens Step 1 of the Rule Set Wizard. See "Rule Set Wizard - Step 1: Excluding Data". PC-DMIS displays the values of the selected Rule Set, but if you do not select a Rule Set, PC-DMIS does not display any values.

Edit - This option allows you to edit the rule set selected from the **Rule Set List**.

Add - This option opens an **Open** dialog box that allow you to navigate to and select a preexisting rule set. PC-DMIS copies the rule set file into the designated rule file directory and then displays a new entry in the list box

Delete - This option removes the selected rule set from the **Rule Set List**.

Set as default - This option sets the highlighted rule set in the **Rule Set List** as the default. PC-DMIS then uses this rule set until you select another rule set later. If you do not select a new rule set, PC-DMIS sets the last used rule set as the default and highlights it in the list box. The next time that you import an ASCII file, PC-DMIS highlights the default rule set.

Import to Measurement Routine - PC-DMIS imports the opened ASCII file into the current measurement routine:

- **Directly** - Select this option if you want to import the ASCII file using the selected rule set *without* using the Rule Set Wizard.
- **By wizard** - Select this option if you want to open Step 1 of the Rule Set Wizard. When you click finish on Step 3, PC-DMIS imports the file using any newly specified rules.

Cancel - Select this option to abort the ASCII Import process

PC-DMIS stores all rule set files in the same directory designated by the GP. The directory is named "AscImportRules", where the rule set files are named "*.ascimportrule".

Rule Set Wizard - Step 1: Excluding Data

This step of creating a rule set helps you exclude unwanted lines of data from the import.

The **Rules for parsing lines** provided in this step determines which lines of your ASCII file will included for importing into your measurement routine. This appears when you click **Create...** from the **Importing** dialog box. Use the following options to exclude data from import:

Skip file header - When this option is selected, the specified **Number of lines** from the top of the ASCII file will be skipped. Therefore, they will not be evaluated or imported into your measurement routine.

Skip file footer - When this option is selected, the specified **Number of lines** from the bottom of the ASCII file will be skipped. Therefore, they will not be evaluated or imported into your measurement routine.

For lines containing - Lines containing the text specified to the right will be evaluated on the following criteria:

Qualifying search text is CASE specific

- **Skip the entire line** - Entire line is excluded from being evaluated if qualifying text is present.
- **Truncate the strings after** - Anything after the qualifying text will be excluded from being evaluated.
- **Truncate the strings before** - Anything before the qualifying text will be excluded from being evaluated.
- **Truncate the strings until** - Anything after the first qualifying text and prior to the text specified to the right of this option will be excluded from being evaluated.

Use the **Add>>** and **<<Remove** buttons to update the criteria to the table on the right side of this dialog box. Multiple criteria can be used to evaluate your ASCII file.

Preview and Refresh - See the "Rule Set Wizard - Previewing the ASCII File" topic.

Next - Continue with Step 2.

Cancel - Returns to the **Importing** dialog box.

Rule Set Wizard - Step 2: Defining Delimiters

This step of creating a rule set helps you determine how you want to parse the data in the ASCII file, by column or by a delimiting character. You can also define the measurement units to use.

The **Delimiter** information provided in this step determines the columns for each of the parsed lines. Use the following options to parse your data.

By column - Use this option for ASCII files that use fixed lengths for fields. This allows you to separate each field based on the length of the field. This may require a little trial and error to define the correct lengths for each field.

- **Add** - Specify the **Beginning** and **Ending** characters of the field and click **Add**. The next column number will be assigned with the **Beginning** and **Ending** values. Continue this process of adding columns until all the needed data is included in the appropriate columns.
- **Remove** - Select the column you need to remove and click **Remove**. The column is removed from the list.
- **Change** - Select the column you need to change, alter the **Beginning** and **Ending** values for the column and click **Change**. The column is updated with the new information.

By character - Use this option for ASCII files where fields are separated by tabs, spaces, commas or other characters. Select the separating character, tab or space.

- **Specific character** - Select this option and specify the one or more **Specific characters** that separate the fields in your ASCII file. Type the desired character and click **Add** to add it to the **Character List**. Select a character from the **Character List** and click **Remove** to remove a character.
- **Tab**- Select this option and click **Add** if the fields of your ASCII file are separated by tabs. **Tab** is added to the character list.
- **Space(s)** - Select this option and click **Add** if the fields of your ASCII file are separated by one or more spaces. **Space** is added to the character list.

The **Units** area specifies the measurement units to use for the imported values:

- **MM** - Millimeter
- **CM** - Centimeter
- **DM** - Decimeter
- **Inch** - Inch

Preview and Refresh - See the "Rule Set Wizard - Previewing the ASCII File" topic.

Back - Returns to Step 1.

Next - Continue with Step 3.

Cancel - Returns to the **Importing** dialog box.

Rule Set Wizard - Step 3: Feature Type Mapping and Field Assignment

This step of creating a rule set helps you to map feature types to the features in your ASCII file. Additionally, you can assign the field names to the delimited columns.

Feature Type - Select the check box(es) of the feature type(s) that are to be imported. All of the available feature types are provided in the **Feature Type** list.

To map the feature type name:

1. If a feature type exists in your ASCII file, highlight the line in the **Feature type** area.
2. Click in the list box under the heading "In ASCII file" on the same highlighted line.
3. Type the feature type name exactly as it appears in the ASCII file in the edit box.

If there are multiple feature types in the ASCII file, but a feature type name is not defined in the file, the parser doesn't have a way to differentiate which feature is a point, circle, and so forth. However, if there is only one feature type in the ASCII file, you don't need to define the feature type name. You only need to mark the check box to the left of the feature type.

Feature Fields - The available fields for the selected **Feature Type** are displayed for assignment. Each field represents a valid PC-DMIS value for the selected feature type.

To assign feature fields to the columns of the ASCII file:

1. Select a **Feature Type**.
2. Select the needed field name(s) from the **Field List**. To select consecutive fields, click the first item, press and hold down SHIFT, and then click the last item. To select nonconsecutive fields, press and hold down CTRL, and then click each item.
3. Click **Add** to add the field name to the list box on the right.

You may also ADD or REMOVE fields by double-clicking the item in the **Field List** or the list box on the right.

4. Use the **UP** and **DOWN** arrows to ensure that the field values appear in the order that the corresponding values appear in the ASCII file.
5. Select any unneeded field(s) from the list on the right and click **Remove** to remove that field name(s). To select consecutive fields, click the first item, press and hold down SHIFT, and then click the last item. To select nonconsecutive fields, press and hold down CTRL, and then click each item.

PC-DMIS may not accept certain fields in the ASCII file that may be proprietary to a third-party CMM system provider's software. For such a field, the user can add the field called "Skip" to inform the GP to skip the column that contains this field.

Preview and Refresh - See the "Rule Set Wizard - Previewing the ASCII File" topic.

Back - Returns to Step 2.

Next - Continue with Step 4.

Cancel - Returns to the **Importing** dialog box.

Rule Set Wizard - Step 4: Handling Labels, Conflicts, and Point Offsets

This step of creating a rule set helps you define how your features are handled as they're imported. You can define the feature labels, what to do if imported feature names conflict with existing feature names, and whether or not points are offset by a defined amount in XYZ.

Feature Label - If you want to define the base name for the features to import, mark **Use base name** and then type the name of the feature. For example, if you're importing point features, you might want to type "PNT" or "Point".

- **Use base name** - Mark this to define the base name for the imported features. If this is cleared, PC-DMIS uses the feature type as the base name.
- **Base name** - Type the base name the process uses for the imported features if **Use base name** is marked.

Creation Confliction - Use this area to determine how to handle conflicts with existing features of the same name.

- **Update existing nominals** - This updates existing features with the imported data. During import, the process checks the current measurement routine's existing feature names and attempts to update matching features with the information contained in the ASCII file. If you have more than one feature in the measurement routine with the same ID, only the top-most feature in the measurement routine is updated. When the import process updates the nominal values of an existing feature, a dialog box appears showing all the features that had nominal values updated.
- **Create new feature with a -1 extension** - This adds an underscore and a number to the feature ID to make it unique. So, if PNT1 was a duplicate, this would be changed to PNT1_1. If there was another PNT1, it would be renamed to PNT1_2 and so on.

Point Offset - This area lets you offset imported points by a specified location.

- **Offset the points** - If marked, points are offset by the distance in the offset boxes below. If cleared, no offset takes place.
- **X offset** - This defines the offset distance in the X direction.
- **Y offset** - This defines the offset distance in the Y direction.

- **Z offset** - This defines the offset distance in the Z direction.

Back - Returns to Step 3.

Cancel - Returns to the Importing dialog box.

Finish - This button functions according to how the Rule Set Wizard was started.

- If you started by clicking **Create**, the Rule Set Wizard is closed and a Create new rule set dialog box appears. Type the name of the new rule set in the Rule set name box and click OK. A message box informs you that the rule file is saved.
- If you started by clicking **Edit**, the Rule Set Wizard is closed, and any changes are applied to the edited rule set file.
- If you started by clicking **Import to Measurement Routine** (By wizard), The rule set is applied, and the parsed ASCII file is imported into PC-DMIS as an Inspection Plan. If any changes have been made to the rule set, then you will also be prompted to save your changes.

Rule Set Wizard - Previewing the ASCII File

As you make changes in each step of the Rule Set Wizard, you can preview the affect that the rules has on your ASCII file by using these items at the bottom of the wizard.

Preview - Marking this check box displays the results of the evaluated file in a preview drop-down pane.

Refresh - Updates the view of your file based on the changes that you made to the evaluation criteria.

No Rule Set Applied

Below is an example preview of an ASCII Inspection Plan file where no rules have been applied. Any ASCII file that contains features can be used to import.

The file used as an example is an Inspection Plan from SolidWorks with a .ip extension. The Generic Parser can work with any ASCII file with any extension.

ASCII File with Step 3 Rules applied

Importing a ChorusNT File

The migration path from ChorusNT to PC-DMIS is based on PC-DMIS's ability to import a Chorus DMIS file, converting the original DMIS file into equivalent PC-DMIS commands that make up a PC-DMIS measurement routine file, a file with a .prg filename extension.

PC-DMIS converts most DMIS commands into PC-DMIS commands to maximize the automatic conversion and minimize the manual modifications needed after the automatic import.

To begin the import process of ChorusNT extensions, perform the following steps:

1. Select **File | Import | Chorus DMIS** to open the **Import** dialog box.

2. From the file type list, select the file type that filters the current folder. If you select **Chorus DMIS Files**, you can choose to import a .dmi, .dms, or .dmis file.
3. From the **Import** dialog box, navigate to the folder that contains the file to import. Then select the file.
4. Click **Import** to import the file into the Graphic Display window. PC-DMIS displays the **Dmis Import Setup** dialog box.

You can use this dialog box to set the following required information during the import phase:

- Specify the probe file name used for each arm
- Enable the warning dialog at the end of the import phase
- Enable some options relating to specific customers and hardware configurations

Taking the basic steps in the following topics can help you correctly import and translate your DMIS file into a PC-DMIS measurement routine file.

Step 1: Configure PC-DMIS

Verify PC-DMIS's setup, and check if the standard settings in PC-DMIS correspond to ChorusNT settings. For example, verify the CMM axis conventions and probe head Orientation and Top Speed (CMM max move speed) value.

Use the PC-DMIS Settings Editor to set the following entries in the **DMIS** section:

- `DMISMaxMeasurementVelocityMMPS` - Define your maximum measurement speed.
- `DMISFedratPcntOfMaxMachineSpeed` - Set this to 0.

For information on setting entries, see the "Modifying Setting Entries" appendix.

Step 2: Create and Calibrate the Probe File Inside PC-DMIS

- Create a new measurement routine and, when prompted, define a new probe (**Insert | Hardware Definition | Probe**). Name it MYPROBE.PRB and specify in the **Probe Utility** dialog box the components according to your specific needs.
- Import the Chorus qualification program. Use as your probe, the previously created MYPROBE.PRB file. PC-DMIS imports each SNSDEF statement and adds the corresponding TIP angles. Note that Chorus identifies each tip with the DMIS label that looks something like this: a tip with roll = 0 and pitch = 0 is named S(**R**000**P**000T1). PC-DMIS names this as T1A0B0.

- If in ChorusNT you used a self-calibrated probe, import into PC-DMIS a simple DMIS routine that contains the definition of the "Chief" probe. It needs to have the right label (the same used in the SNSLCT/S(label),90,90 for example) and Pitch and Roll equal to 0.
- After you import the DMIS file, your MYPROBE.PRB probe file contains all the needed tips. In PC-DMIS these AB tip angles will show an asterisk symbol ‘*’ to indicate that they are not yet calibrated.
- Calibrate the tips in one of the following ways:
  - Execute the measurement routine.
  - Click the **Measure** button from the **Probe Utilities** dialog box.

Step 3: Create the PC-DMIS Measurement Routine File and Import the DMIS File

- Create a new PC-DMIS measurement routine.
- Import the ChorusNT measurement routine, specifying the MYRPOBE.PRB probe file created in the previous step.
- Usually Chorus measurement routine contain SNSLCT/ S(label) or SNSLCT/ SA(label) statements. For self-calibrated wrists, you can explicitly specify roll and pitch angles in the SNSLCT label.

After PC-DMIS imports the DMIS file, the final PC-DMIS measurement routine will have at the beginning the `LOADPROBE/MYPROBE.PRB` command, and for each SNSLCT statement the corresponding `TIP` command will appear with the correct A and B angles.

Step 4: End of Automatic Import Phase

PC-DMIS completes the Import phase, showing you a report in the **Warning** window.

For example, you might see something like this:

```
L42: ---: DECL/CHAR,O_D_L[11]

L56: ---: DECL/
REAL,TX,TY,TZ,MISX,MISY,MISZ,CXT,CYT,CZT,VX,VY,VZ

L57: ---: DECL/REAL,INVCXT,INVCYT,INVCZT

L112: !MAJOR :MMEDIA/ON,'C:\myfile.exe'

L150: !MAJOR :MRRPCS/D(MRR),0,1,0

L213: ERROR: !UNITS

L253: ERROR: !SNSLCT/S(S_103)
```

These messages are explained here:

- **L##** - This represents the *line number* for that statement in the original DMIS routine (## represents the number). For example L42 would indicate that on line 42 of the DMIS routine, the DMIS statement is found.
- **---:** - This symbolizes that the statement was ignored, that is it was not converted into a corresponding PC-DMIS command because there is no equivalent PC-DMIS command. For example, you will find that PC-DMIS always ignores the DECL statement because PC-DMIS doesn't need explicit variable declaration.
- **!MAJOR** - This means that the specified DMIS statement (Major DMIS Word) is not supported.
- ERROR - This means the specified command was not correctly imported.

Step 5: Manual Verification of the PC-DMIS Measurement Routine

Be sure to manually verify that the translation into PC-DMIS functions properly. Look through the measurement routine in Command Mode. Errors appear in red text.

Try executing the measurement routine in Offline Mode then try using the CMM in Online Mode at low speed to verify that the measurement routine imported without problems.

Things to Watch for and Some Helpful Tips and Suggestions

ChorusNT and PC-DMIS are different measuring systems, and some intrinsic characteristics need to be carefully considered. The following list contains some tips and suggestions:

Automatic Measuring Cycle

The DMIS Standard states that in a MODE/AUTO section the features are measured with the automatic cycle, ignoring any eventually present PTMEAS.

Since ChorusNT supplies automatic cycle for POINT, CIRCLE, SPHERE, and SLOT (CPARLN), all these cases are translated into the corresponding AUTO feature. However, due to the intrinsic differences between Chorus and PC-DMIS, you should carefully verify their execution.

In SLOT (round slot) automatic cycle, ChorusNT takes the first two points on one of the straight sides. PC-DMIS however, takes the points on the rounded ends of the slot.

STAR TIP Probes

PC-DMIS recognizes the ChorusNT SNSDEF extension that defines a star probe. Be careful that the PC-DMIS setup for the Probe Head orientation corresponds to the ChorusNT SNSMNT specification.

CW43, CW43L, and IW42 Wrist Mounting conventions

ChorusNT and PC-DMIS conventions for the roll angle are different. While PC-DMIS can correctly adjust it during the import of a Chorus DMIS measurement routine, you must be careful to safely execute the imported measurement routine the first time.

Theoretical values in FEAT statements

PC-DMIS always uses both Theo and Actual values, which should be correct (not too much off a deviation from actual values). If the deviation is great, you may have problems, especially with features used in alignments. This is because PC-DMIS defines two matrices for each alignment:

- First, the CADTOPART matrix. Based on the theoretical values, this converts feature THEO values.
- Second, the MACHINETOPART matrix. Based on actual measured values, this converts the actual measured values in features.

Since ChorusNT doesn't have the CADTOPART matrix, it always uses the actual measured values. If you have the wrong nominal values, you only become aware of them if you execute an OUTPUT statement on that feature. To verify correctness, you should add them into the original DMIS routine OUTPUT statements for your features, especially for the alignment features.

FILNAM

FILNAM in ChorusNT specifies the name of the output file when using the `DISPLY/STOR` command. PC-DMIS recognizes it but this command must appear after the DISPLY in the DMIS routine. Consult your DMIS manual for more information.

VFORM

The ChorusNT vendor format statement is V(label)=VFORM/ALL which translates into the PC-DMIS `FORMAT/TEXT` command that has the following information:

- MEASURED
- NOMINAL
- DEVIATION
- UP_TOL
- LO_TOL
- CRIT/OOT

The final PC-DMIS `FORMAT` command will look like this:

```
FORMAT/
TEXT,OPTIONS,ID,HEADINGS,SYMBOLS,SD;MEAS,NOM,DEV,TOL,OUTTOL, ,
```

DEFGRF

DEFGRF statement is a Chorus extension that lets you define dialog boxes with buttons and input fields. PC-DMIS imports this command and creates a script using the BASIC language (Cypress Enable). Due to different screen resolutions, it’s possible that the resulting dialog box may need some adjustment. You can modify the Basic Script file using PC-DMIS's Basic Script Editor. For details, see the PC-DMIS Basic documentation.

FROM and GOHOME

ChorusNT's conventions move the head center not the tip's ball center. While the PC-DMIS import can make the necessary offsets, you should use a low feed the first time you execute the imported ChorusNT routine inside PC-DMIS.

MRRPCS

In ChorusNT this command defines the reference system to be used in a routine created with ChorusNT's MIRROR Utility. PC-DMIS does not support the import of Chorus mirrored routines. You should instead use PC-DMIS's more powerful and complete mirror utility on a .prg file created by importing the "left side" Chorus routine.

GAUGE

In ChorusNT this statement defines and measures a sphere gauge, specifying the name: G(label), the diameter, and the stem direction. It also optionally specifies the center position, the incidence angle, and the number of points used to measure it.

```
GAUGE/SPHERE,G(label), diam, i, j, k, [angle, x, y, z,
npoints]
```

Because of the different parameters, PC-DMIS translates these two commands: `AUTO/SPHERE` and `CALIBRATE ACTIVE`.

F(label)= AUTO/SPHERE

The `AUTO/SPHERE` command uses the same name, diameter, and direction as the GAUGE statement. If the center position was not specified and during execution you manually select the first point on the top of the pole, then init=1 and perm=1, otherwise init=0 and perm=0.

PC-DMIS can also adjust the orientation, angle_vec, and normal_vec values accordingly.

```
CALIBRATE ACTIVE TIP WITH FEAT_ID=F(label),
QUALTOOL_ID=label,MOVED=YES
```

CALIB

In ChorusNT this statement calibrates the specified probe using the specified sphere gauge, G(label), and angle:

```
CALIB/SENS, S(probe),G(label), [angle]
```

PC-DMIS translates this statement into these three commands:

```
TIP/ T1A..B..
```

The tip command will have the same AB angles as the S(probe)) statement.

```
F(label)=AUTO/SPHERE
CALIBRATE ACTIVE TIP WITH FEAT_ID=F(label),
QUALTOOL_ID=label, MOVED=NO
```

Importing a Datalog File

Datalog programs are text files containing feature information that is stored in a proprietary format used by Chrysler.

The **File | Import | Datalog** menu item imports the information stored in the Datalog text file into your measurement routine. This functions much like importing an Inspection Plan file. Also, the **Change Management** dialog box discussed in "Updating Inspection Plans" topic of the "Using Inspection Plans in PC-DMIS" section also supports the Datalog file type.

Importing DMIS Files

PC-DMIS can import generic DMIS files and DMIS routines created using extensions from specific vendor environments.

> Extensions may include non-standard commands, or added or modified parameters of standard DMIS commands.

To import a DMIS routine file, follow these steps:

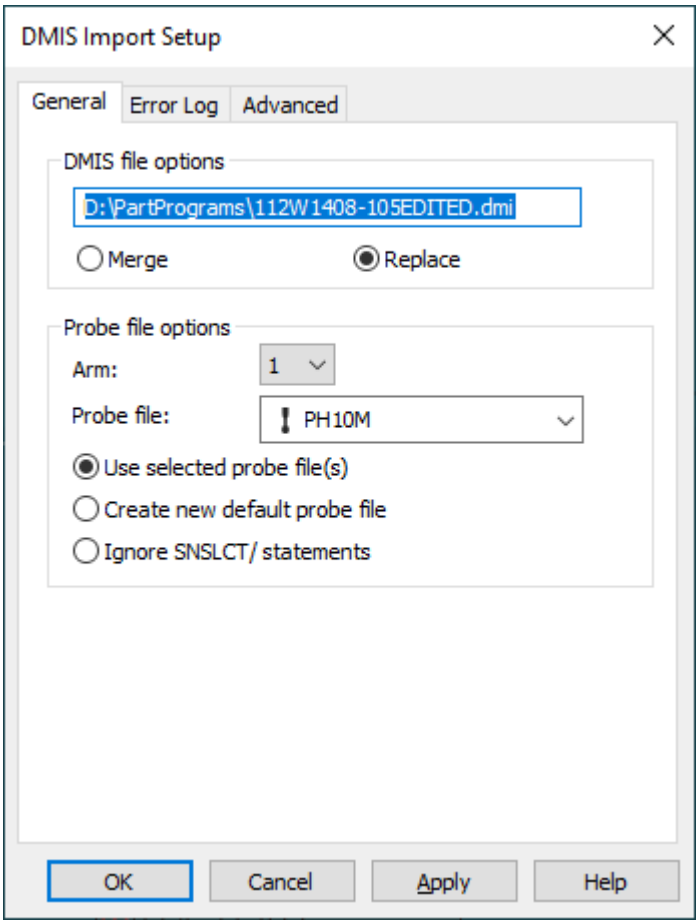
1. Select **File | Import | DMIS** to open the **Import** dialog box.
2. From the file type list, select the file type that filters the current folder. If you select **Chorus DMIS Files** or **DMIS Files**, you can choose to import a .dmi, .dms, or .dmis file.

   > Chorus NT programs follow the DMIS 3.0 Standard with extensions and are better managed. In most cases, you should choose **Chorus DMIS Files** over normal **DMIS Files**. For notes on how to translate ChorusNT DMIS files into a PC-DMIS measurement routine, see "ChorusNT to PC-DMIS Translation Notes".

3. From the **Import** dialog box, navigate to the folder that contains the file to import. Then select the file.
4. Click **Import** to import the file into the Graphic Display window. A progress bar appears and indicates the progress.
5. PC-DMIS makes a first-pass translation of the input file. Once it completes this pass, the **DMIS Import Setup** dialog box appears. You can use this dialog box to select many options that are useful during the actual import phase.
6. Select the necessary options from the **DMIS Import Setup** dialog box. For information on how to use this dialog box, see the topics below.
7. Click **OK**. PC-DMIS finishes the importation process.

PC-DMIS inserts an `RMEAS/LEGACY` command into the imported measurement routine. You can modify the `DMISRmeasImport` entry to change the default value for RMEAS commands on future imported DMIS files. For information on this command, see "Setting Up Relative Measure (RMEAS)".

DMIS Import Setup - General tab



DMIS Import Setup Dialog Box - General Tab

The **General** tab of the **DMIS Import Setup** dialog box (**File | Import | DMIS**) allows you to control probe file translation for the imported DMIS measurement routine. The controls used on this tab are described here:

DMIS file options - This box specifies the DMIS file to import. It automatically contains a pathway to the file selected from the **Open** dialog box described in the DMIS import procedure above.

Merge and **Replace** - These options specify whether or not PC-DMIS replaces existing commands with the imported DMIS commands or merges the new commands with the existing commands.

- **Replace** - This option replaces the existing commands in the currently loaded measurement routine with new PC-DMIS commands during the import process.
- **Merge** - This option appends PC-DMIS commands created during the import process at the end of the currently loaded .PRG file.

Arm - This list specifies the arm to use from a multiple arm system.

Probe File - This list specifies an existing probe file.

Use selected probe file(s) - This option uses an existing probe file selected from the **Probe file** list.

1. From the **Arm** list, select the arm that will use the displayed probe file from the drop-down window.
2. Select the probe file from the list.
3. Click **Apply**. PC-DMIS adds any tips (sensors) referenced in the DMIS measurement routines that are not already in the probe file.

Create new default probe file - This option creates a new probe file based on the SNSDEF statements in the DMIS measurement routine file. PC-DMIS generates a new probe file and gives it the same name as the DMIS measurement routine filename and a ".prb" extension. The created probe configuration defaults to a PH9 wrist with a TP2 connection with a TIP2BY20MM tip. However, if no SNSDEF statements are detected in the DMIS measurement routine, a probe configuration will not be created.

Ignore SNSLCT/ statements - This option ignores SNSLCT statements in the DMIS measurement routine during the import process.

If the default probe configuration does not match the probe configuration of your machine, you should construct a probe file with the correct probe configuration using PC-DMIS *prior to* importing a DMIS measurement routine file. Then, select the created probe file from within this tab and click **Apply** and then **OK**. This allows the translator to select the most appropriate tip or tips during translation of the SNSDEF statements.

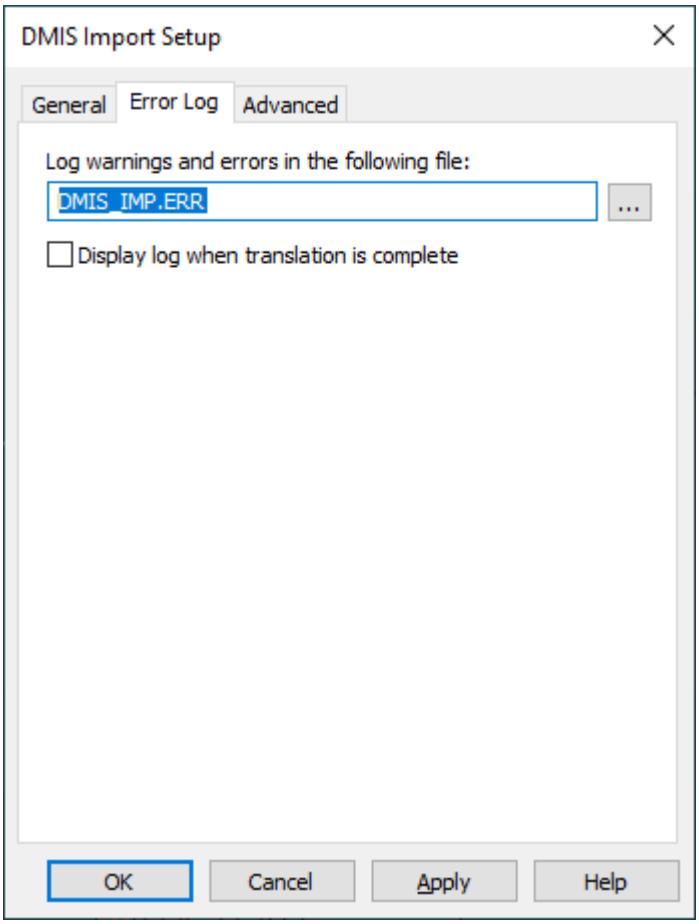
DMIS Import Setup – Error Log tab

DMIS Import Setup – Advanced tab

DMIS Import Setup - Error Log tab



DMIS Import Setup Dialog Box - Error Log Tab

The **Error Log** tab of the **DMIS Import Setup** dialog box (**File | Import | DMIS**) causes PC-DMIS to store any warnings or errors at the end of the import process in a text file of your choice. To select a text file, click the Browse button.

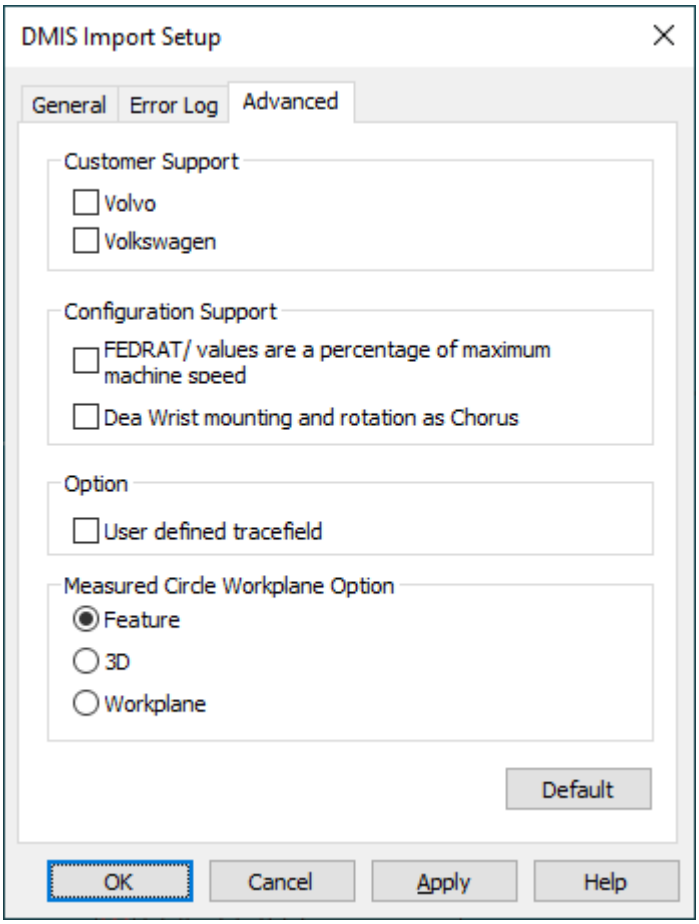
If you want PC-DMIS to automatically display this error log at the end of the import process, click the **Display log when translation is complete** check box. The text file opens in a **DMIS Import Results** dialog box.

Related Topics:

DMIS Import Setup – General tab

DMIS Import Setup – Advanced tab

DMIS Import Setup – Advanced tab



DMIS Import Setup Dialog Box – Advanced Tab

The **Advanced** tab of the **DMIS Import Setup** dialog box (**File | Import | DMIS**) allows you to import specific customer requests and configurations. These requests may include non-standard commands or added / modified parameters of standard DMIS commands. When you import Chorus DMIS files, PC-DMIS disables unnecessary options and enables needed ones.

For information on the controls on this tab, see the descriptions here:

Customer Support - This area contains specific check boxes for DMIS vendors. If your DMIS files are created using software from these companies, select the appropriate check box to enable extension support specific to those vendors. These include the following:

- Volvo
- Volkswagen

Configuration Support - This area contains check boxes that allow you to select different DMIS configurations. These include the following:

FEDRAT/ values are a percentage of maximum machine speed

DMIS commands don't automatically specify whether imported FEDRAT/ commands (commands that control the machine's speed) refer to maximum machine speed or maximum touch speed.

- *If you select this check box*, imported FEDRAT/ statements are a percentage of the *maximum machine speed*.
- *If you deselect this check box*, imported FEDRAT/ statements are a percentage of the *maximum touch speed*.

DEA Wrist mounting and rotation as Chorus

If you're using a DEA CMM equipped with an IW42, CW43, or CW43L wrist and you select this check box, PC-DMIS follows Chorus conventions and adjusts the B rotation angle during the import of the SNSLCT statement.

This option is automatically selected when you import Chorus DMIS files.

Option - This area contains a **User Defined Tracefield** check box. This check box determines whether certain imported DMIS commands are transferred into user-defined tracefields.

According to the DMIS standard, you can query the operator for the following information during measurement routine execution with these DMIS commands:

Info	DMIS Command
Part Name	PN(label) = 'text'
Part Serial Number	PS(label) = 'text'
Manufacturing Device	MD(label) = 'text'
DME Name	DI(label) = 'text'
Operator Name	OP(label) = 'text'

Suppose the DMIS file you are to import has these DMIS commands:

```
PN(label1) = PARTID/' part number'

PS(label2) = PARTSN/'2345'

MD(label3) = MFGDEV/'BRAVO1'

DI(label4) = DMEID/'PC-DMIS'

OP(label5) = OPERID/'My Name'
```

If you select the **User Defined Tracefield** check box, PC-DMIS supports the same functionality required by the DMIS standard and it imports DMIS commands into TRACEFIELD commands, like this:

```
TRACEFIELD/DISPLAY,LIMIT=15 ; PN(LABEL1) : part
number

TRACEFIELD/DISPLAY,LIMIT=15 ; PS(LABEL2) : 2345

TRACEFIELD/DISPLAY,LIMIT=15 ; MD(LABEL3) : BRAVO1

TRACEFIELD/DISPLAY,LIMIT=15 ; DI(LABEL4) : PC-DMIS

TRACEFIELD/DISPLAY,LIMIT=15 ; OP(LABEL5) : My Name
```

Then when you execute our measurement routine, PC-DMIS provides a small dialog box for each TRACEFIELD command, so that you can type this information.

If you do not select the **User Defined Tracefield** check box, by default, PC-DMIS inserts these DMIS commands into normal comment report commands, like this:

```
COMMENT/REPT,"PN(LABEL1)=' part number'"

COMMENT/REPT,"PS(LABEL2)='2345'"

COMMENT/REPT,"MD(LABEL3)='BRAVO1'"

COMMENT/REPT,"DI(LABEL4)='PC-DMIS'"

COMMENT/REPT,"OP(LABEL5)='My Name'"
```

Measured Circle Workplane Option - A measured circle is a 2D feature that is relative to the normal vector. This area contains options that define how PC-DMIS handles the normal vector for measured circles in DMIS files during a DMIS file import.

Feature - A plane feature defines the normal vector. The plane feature needs to be immediately above the circle feature in the DMIS file.

If your DMIS file doesn't have a plane feature, your circle feature will still import, but there will be an empty feature reference in the circle feature. In this case, after import, you can define a plane feature in the Edit window and then select it in the measured circle feature.

3D - PC-DMIS uses the feature's nominal vector to define the normal vector. This is the traditional method to define the normal vector.

Workplane - PC-DMIS uses the current workplane as the normal vector.

Default - This button sets your selection as the default to use when importing DMIS files.

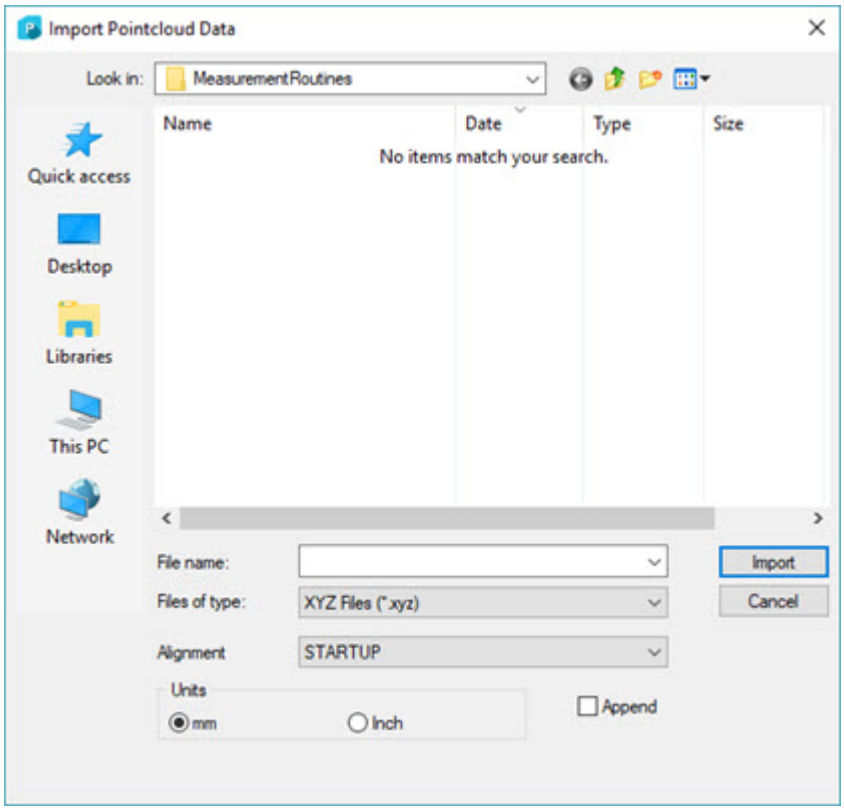
DMIS Import Setup – Error Log tab

Importing Pointcloud files

To import a Pointcloud file, perform the following steps:

1. Select **File | Import | Pointcloud** to open the **Import Pointcloud Data** dialog box.



Import Pointcloud Data Dialog Box

2. Choose the appropriate Pointcloud type from the **Files of Type** list at the bottom of the dialog box. PC-DMIS lists files ending with extensions according to what you selected.

- If you select the **XYZ Files** option, PC-DMIS lists files with a .xyz extension.
- If you select the **PSL Files** option, PC-DMIS lists files with a .psl (Polyworks) extension.
- If you select the **STL Files** option, PC-DMIS lists files with a .stl extension.
- If you select the **NSD Files** option, PC-DMIS lists files with a .nsd (3DReshaper) extension.

3. Mark the **Append** check box if you want to add the new COP data onto existing COP data.
4. Navigate to the appropriate directory and select the desired pointcloud file from the list.
5. Click **Import** to load the Pointcloud file into your measurement routine.

Importing from Planner (.plancad, .planxml, .xml)

You can import the Inspection Plan from Planner into PC-DMIS by importing a .planxml or .xml file exported from Planner. The .planxml or .xml file contains XML elements with the inspection plan information.

To import a .plancad, .planxml, or .xml file:

1. Select **File | Import | Inspection Plan** to open the **Import** dialog box.
2. From the file type list, select the file type that filters the current folder. If you select **All Plan Files**, you can import a .plancad, .planxml, or .xml file.
   - If you import a .PlanCAD file, the software imports both the plan features and the embedded CAD model.
   - If PC-DMIS detects changes in the original .PlanCAD file that you're referencing, it asks if you want to use the Change Manager to handle those changes. For information on the Change Manager, see "Updating Inspection Plans with the Change Manager".

   Your file to import should have the same measurement units as the measurement routine that takes the import. If the files don't have the same measurement units, you can still import the file, but the measurement routine ends up with incorrect information. For example, if you have a circle with an X value of 4 inches in the file to import, the software imports it as 4 millimeters if the measurement routine that takes the import expects millimeters.

3. Click **Import** to import the inspection plan and create a measurement routine from it. For .plancad and .planxml files, once you click **Import**, the software opens the **Sensor Mapping** dialog box so that you can map features to sensors. For more information, see the "Mapping Features to Sensors" topic.

PC-DMIS uses entries to determine the settings for the imported features. You can use the Measurement Strategy Editor or the **Auto Feature** dialog box to modify these settings.

Importing a Legacy Planner Inspection Plan (.ip)

To import a Planner Inspection Plan as an .ip file, perform the following tasks first:

- Define Parameters and Rules
- Perform an optimization step on the imported plan
- Ensure that the probe won't collide with the part by inserting proper move commands

Once you have completed these tasks, you can then execute your imported inspection plan as a newly-created PC-DMIS measurement routine.

If you have problems using the PC-DMIS Planner commands inside PC-DMIS, ensure that there is an *InsPlan.dll* file located in the directory where you installed PC-DMIS.

Inspection Plan Default File (.ipd)

You must have an Inspection Plan Default file or .ipd to import a .ip file into PC-DMIS. The "Legacy Planner Parameters" topic provides more information on this file.

Once you've performed the above preparatory steps, you can import the legacy inspection plan and any rules by importing an inspection plan's .cad file that has the inspection plan embedded in it or by importing a previously-exported inspection plan.

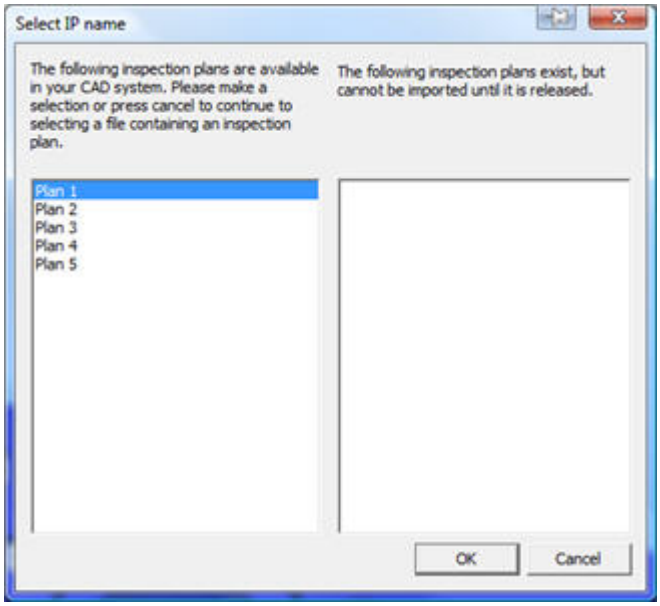
To import an embedded Inspection Plan from a CAD file:

1. Select **File | Import | CAD**. The **Open** dialog box appears.

When importing a CAD file using the **CAD by Reference** menu option, PC-DMIS updates the file accordingly if any changes were made to the IP CAD file by the legacy PC-DMIS Planner application.

2. Browse to and select the needed IP CAD file, and click **Import**. PC-DMIS imports the IP CAD file.

3. Select **File | Import | Inspection Plan**. The **Select IP name** dialog box appears.



Select IP name Dialog Box

4. Select the needed Inspection Plan, and click **OK** or click **Cancel** to browse to and select an exported Inspection Plan via the **Open** dialog box.

5. Follow any on-screen instructions.

    - Select the **IPD** file that will be applied to the imported Inspection Plan if you have not previously selected it. See the "Legacy PC-DMIS Planner Parameters and Rules" topic for more information.

    - If the insertion point is not at the end of the measurement routine, you are prompted to move the cursor to the end of the measurement routine before continuing.

    - If the CAD file comes from a CATIA v5 model, any comments associated with a feature in the eTool data of the CATIA model are imported as Feature Locator Text for the feature. Note that eTool is a proprietary format used by Chrysler. For information on Feature Locator Text, see the "Providing and Using Feature Locator Instructions" topic in the PC-DMIS CMM documentation.

    - Specify the **Optimize Path** options and click **OK**, or click **Skip** to ignore this step. See "Optimizing the Path" for more information.

    - Specify the options for "Inserting Clearance Moves Automatically" and click **OK** to complete this process or click **Cancel** to skip this step.

To import an Inspection Plan from an exported .ip text file:

1. Select **File | Import | Inspection Plan**. An **Import** dialog box appears.

2. Browse to the directory containing your file with an .ip filename extension.

3. Select the inspection plan, and click **Import**.

4. Follow any on-screen instructions.

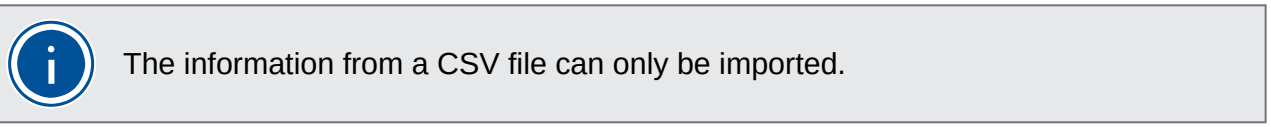
    - Select the **IPD** file that will be applied to the imported Inspection Plan if you have not previously selected it. See the "Legacy PC-DMIS Planner Parameters and Rules" topic for more information.
    - If the insertion point is not at the end of the measurement routine, you are prompted to move the cursor to the end of the measurement routine before continuing.
    - Specify the **Optimize Path** options and click **OK**, or click **Skip** to ignore this step. See "Optimizing the Path" for more information.
    - Specify the options for "Inserting Clearance Moves Automatically" and click **OK** to complete this process or click **Cancel** to skip this step.

Once you've imported your inspection plan, the imported commands are preceded by a start comment that provides the following basic information for the imported inspection plan:

- Date and time
- The .ip file name with path
- The .ipd file name and path

An end comment indicates the end of the imported inspection plan.

Importing a CSV File



Select **File | Import | CSV** to import information from a CSV file.

Each row in the CSV file represents a feature and a feature command that PC-DMIS creates during the import. If tolerance values are specified, a location dimension command is also added.

The first row of the CSV file contains the format designators. This designator row indicates the data for each column. There are predefined column headers. Columns that do not include a format designator or that have an unrecognized column header are ignored. Columns can be in any order. If the "Type" column is missing or if there is no feature type specified for a row of data, PC-DMIS treats this row of information as a "Point" feature.

If a row has only an asterisk in the first column with no other information in the row, this signals that the next row is a format designator row. This lets you switch formats inside a single CSV file.

File Format...

A CSV file is a **C**omma **S**eparated **V**alues file created by many software packages, including Microsoft Excel. Here is an example of an Excel table used to create a CSV file:

TYPE	NAME	X	Y	Z	X2	y2	z2	D	A	L
Point	PNT1	67.98	89.88	13.99						
Line	LIN1	51.75	0	-13.1	62.25	0	-13.1			
Plane	PLN1	100.25	0	-25.6						
Circle	CIR1	124	50	0				60.5		
Ellipse	ELL1	179.9	10	0						14.125
SlotR	SLTR1	191.05	72.998	0				7.02		33.045
SlotS	SLTS1	69.7	23.35	0				11.041		12.018
SlotN	SLTN1	76.5	6	0				6		12
Polygon	POL1	26.35	49.5	15				22		
Cylinder	CYL1	124	50	0				60.5		
Cone	CON1	69	90	14					30	14
Sphere	SPH1	188.5	45.65	0				12.75		

Example of a spreadsheet table used to create a CSV file (continued below).

D	A	L	W	i	j	k	I2	J2	K2	+ TOL	- TOL
				0	0	1				0.05	0.05
				1	0	0				0.05	0.05
				0.707	0.707	0				0.05	0.05
60.5				0	0.707	0.707				0.05	0.05
		14.125	7.23	0.707	0	0.707	1	0	0	0.05	0.05
7.02		33.045	12.8	0.707	0	0.707	1	0	0	0.05	0.05
11.041		12.018	4.2	0.707	0	0.707	1	0	0	0.05	0.05
6		12	3.5	0.707	0	0.707	1	0	0	0.05	0.05
22				0.707	0	0.707	1	0	0	0.05	0.05
60.5				0.707	0	0.707				0.05	0.05
	30	14		0.707	0	0.707				0.05	0.05
12.75				0	0	1				0.05	0.05

Example of a spreadsheet table used to create a CSV file (continued).

Download the above CSV example file here: CSV_Example_File.csv

Another example of a spreadsheet table used to create a CSV file is shown below:

TYPE	NAME	X	Y	Z	+TOL	-TOL
Point	X48a001	68	90	14	0.05	0.05
Point	X48a002	74	85	12	0.05	
Point	X48a006	76	84	11		
Point	X48a011	79	83.5	10.75	0.035	0.035
Point	X48a021	85	83.25	10.67	0.035	0.035
Point	X48a022	88	2.375	10.5	0.035	0.035
Point	X48a029	97	82.125	10.375	0.05	0.05

Example of a spreadsheet table used to create a CSV file.

Row two defines a point feature with both +TOL and -TOL. PC-DMIS adds the point feature command and the location dimension command based on this row.

The first row (TYPE, NAME, X, Y, Z, +TOL, -TOL) is the format designator row.

Neither +TOL nor -TOL is specified in the point feature in row four. Only a feature command is added. A location dimension command is not added.

Format Designators

The very first line (or row if viewed in Excel) in a CSV, is the format designator line. It determines what type of data is expected in the subsequent lines. The following is a list of valid format designators allowed when a CSV file is imported.

TYPE – This is the feature type. The legal entries for this column are: **Point**, **Line**, **Plane**, **Circle**, **Ellipse**, **SlotR**, **SlotS**, **SlotN**, **Polygon**, **Cylinder**, **Cone** and **Sphere**.

NAME – Feature name

X : Feature’s nominal X value

Y : Feature’s nominal Y value

Z : Feature’s nominal Z value

X2 : Feature’s second nominal X value

Y2 : Feature’s second nominal Y value

Z2 : Feature’s second nominal Z value

D : Feature’s nominal diameter

A : Feature’s nominal angle in degrees

L : Feature’s nominal length

W : Feature’s nominal width

i : Feature’s nominal i vector

j : Feature’s nominal j vector

k : Feature’s nominal k vector

i2 : Feature’s second nominal i vector

j2 : Feature’s second nominal j vector

k2 : Feature’s second nominal k vector

+TOL : Feature’s plus tolerance

-TOL : Feature’s minus tolerance

Asterisk (*) Character for Multiple Format Designators

An asterisk character (*) in the very first position of a comma delimited row indicates that this is the end of the data for the current format designator. The asterisk character also indicates that the next row is a new format designator row. This lets you have features of multiple types in the CSV file with simpler format designator rows:

	A	B	C	D	E	F	G
1	TYPE	NAME	X	Y	Z	+TOL	-TOL
2	Point	PNT1	3	5	10	0.05	0.05
3	Point	PNT2	6	5	10	0.05	0.05
4	*						
5	TYPE	NAME	X	Y	Z	D	
6	Circle	CIR1	3	50	10	25	
7	Circle	CIR2	3	100	10	25	
8							

*The * in row 4 instructs PC-DMIS to use the new format designator in row 5 for the two circle features.*

File Import Sequence

The following describes the sequence of events that occur when you import a CSV file:

1. Each row of data is read into PC-DMIS from the CSV file.
2. The information is matched with the previously defined column headers to determine the meaning of each item of information.
3. Based on the feature type, PC-DMIS uses the information to create a feature command.
4. If one or both tolerance values are specified, PC-DMIS adds a location dimension command.

Importing XYZ Feature Data into the Measurement Routine

An XYZ file is a simple text file with a .xyz extension. It can contain feature information in the form of xyz coordinates with or without a vector. You can use any standard text editor to view the values in an .xyz file.

To import an XYZ file into the Edit window, follow these steps:

1. Select **File | Import | XYZ into Measurement Routine** to open the **Import** dialog box.
2. From the file type list, select the file type that filters the current folder. If you select **XYZ Files**, you can choose to import a .xyz file.
3. From the **Import** dialog box, navigate to the folder that contains the file to import. Then select the file.
4. Click **Import** to import the file. PC-DMIS interprets the XYZ data and imports it into the Edit window as separate feature commands.

For information on how the software interprets the XYZ data in the file, see "Importing an XYZ File as CAD Data".

Importing a Direct CAD File

Direct CAD Interfaces (DCI) allow you to connect directly to your CAD software. As the CAD file is updated in your CAD software, the corresponding changes are reflected in PC-DMIS.

Instead of translating CAD data into the internal CAD format of PC-DMIS, the Direct CAD file types are accessed directly. That is, the CAD data of these file types remains in its native format after being imported. Routines native to the CAD type are used for all calculations done on the CAD data. Accessing the CAD data directly eliminates problems that can occur because of translation inaccuracies or limitations.

PC-DMIS supports the use of the following DCIs:

- CATIA 5
- Creo (previously Pro/Engineer)
- Solidworks
- NX (previously Unigraphics)

When you select the **NX** option, the NX file name appears in the **Layers to Import** dialog box.

For more information on how to import Direct CAD files, see the "Direct CAD Interfaces" documentation.

Tessellating a Part without a CAD License

You can tessellate the image of a Direct CAD Interface part even if you do not have its CAD license currently available. The method for accessing this functionality varies by the Direct CAD Interface. In general, however, you need to access your Direct CAD Interface program. PC-DMIS will then display the part, but some functionality will not be available. For example, you cannot create a measured vector point on the part.

Importing a MeasureMax Project

PC-DMIS can import a MeasureMax project, converting it to work in a PC-DMIS measurement routine.

To import a MeasureMax project, follow these steps:

1. Select the **File | Import | MeasureMax Project** to open the **Import** dialog box.
2. From the file type list, select the file type that filters the current folder. If you select **MeasureMax Files**, you can choose to import a .vbp file.
3. Click **Import**. PC-DMIS automatically converts the project and inserts the PC-DMIS commands at the end of your measurement routine.
4. Follow any on-screen prompts to import the MeasureMax project into PC-DMIS.

Importing an Inspection Plan File

Inspection plans are created using the Planner application. Planner shares many similarities to PC-DMIS. Instead of an all-inclusive metrology application, Planner focuses on taking a part model and creating inspection plans of specified features. Inspection plans determine which features of the geometry and GD&T/dimension to use in the inspection process.

PC-DMIS 2019 R1 was the last version that included Planner.

A Planner user can then export these inspection plans from Planner as a .plancad, a .planxml, or an .xml file. These files contain both the underlying CAD model and the inspection plan data serialized together into a single file.

The **File | Import | Inspection Plan** menu item discussed here lets you then import the inspection plan file into PC-DMIS. The import process supports the old legacy PC-DMIS Planner .ip file or the newer .plancad, .planxml, or .xml file types.

- Your file to import should have the same measurement units as the measurement routine that takes the import. If the files don't have the same measurement units, you can still import the file, but the measurement routine ends up with incorrect information. For example, if you have a circle with an X value of 4 inches in the file to import, the software imports it as 4 millimeters if the measurement routine that takes the import expects millimeters.
- As part of the import, PC-DMIS runs an optimizing routine, which automatically adds measurement and motion commands in an optimal order for the imported features.

For additional information on importing inspection plans, see "Importing a Legacy Planner Inspection Plan" and "Importing from Planner" in the "Using Inspection Plans in PC-DMIS" chapter.

Exporting CAD Data or Feature Data

Similar to importing data, PC-DMIS can also export CAD data or feature data from your measurement routine into one of these file formats:

Alignment:

- PolyWorks Text
- GDS (.gds)

Part model:

- AS3 (.as3)
- CAD Mesh (.cad or .draw)
- PDF 3D (.pdf)
- STL (.stl)
- Wavefront (.obj)
- STEP (.stp or .step)
- XAML (.xamlsolid or .xamlwireframe)

Pointcloud:

- XYZ (.xyz) - Exports the pointcloud to an XYZ file type.
- IGES (.igs) - Exports the pointcloud to an IGES file type.
- PSL (.psl)

Other file types:

- DES (.des)
- DXF or DWG (.dxf or .dxg)
- Generic text (.txt)
- IGES (.igs) - Exports the PC-DMIS measurement routine to an IGES file type.
- STEP AP203 (.stp or .step)
- STEP AP214 (.stp or .step)
- VDAFS (.vda)
- XYZ (.xyz) - Exports the PC-DMIS measurement routine to an XYZ file type.
- BASIC (.bas)
- Datalog (.txt)
- DMIS (.dmi or .dms)
- Microsoft Excel (.xls)
- Inspection Plan (.ip)
- XML (.xml)

When you export your measurement routine as CAD data, PC-DMIS does not export previously imported CAD part models. Instead, PC-DMIS generates a CAD file from the feature commands in your measurement routine.

To export data from the current measurement routine:

1. Select the **File | Export** menu option and the export type (or select an appropriate submenu and then the export file type) to open an **Export** dialog box.
2. From the file type list, select the desired file type. PC-DMIS displays the available files for the indicated type.

3. In the **File Name** box, type the name you want to give the exported file, or select an existing file from the list. If you select an existing file, PC-DMIS replaces the current data in that file with the information generated by the **Export** operation.

4. Click **Export** to close the **Export** dialog box. (Depending on your data type, PC-DMIS may display another dialog box that asks you for additional input. For more information, see the topics below.) PC-DMIS generates the exported data file in the selected directory and gives it the extension from the file type list.

Exporting to a PolyWorks Text File

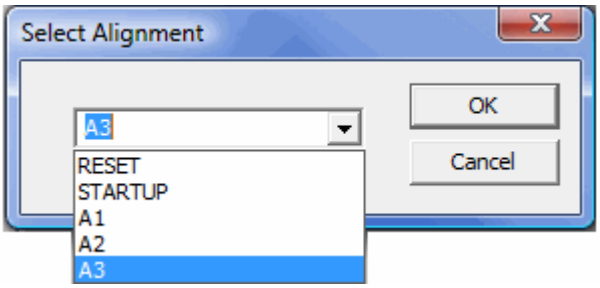
Using the **Export | Alignment | PolyWorks Text** menu item, PC-DMIS exports an alignment from the measurement routine into a PolyWorks text file. This allows you to use the exported PC-DMIS alignment in software applications that support the exported format (such as ScanWorks™) using the same coordinate reference frame as PC-DMIS.

Exporting to a Gds File

Using the **Export | Alignment | Gds** menu item, PC-DMIS can export an alignment from the measurement routine into a .gds file format. The .gds format is the Romer France file format for alignments. Romer France's portable arms can then use this small alignment file. It is also used to interface with other software packages, such as 3DReshaper.

By default, when you export to a .gds file, PC-DMIS exports the most recent alignment of the active measurement routine.

To export a specific alignment, from the **Setup Options** dialog box, first select the **Select Alignment to Export** check box. Then, when you export to a .gds file, the **Select Alignment** dialog box opens so that you can select an alignment.



Select Alignment Dialog Box

For more information on the **Select Alignment to Export** check box, see the "Select Alignment to Export" topic in the "Setting Your Preferences" chapter.

The .gds file name defaults to index.gds. PC-DMIS saves the file to the armdata folder of the G-Scan software. If you don't have the ROMSOFT software installed, a common **Export** dialog box opens so that you can select where to export the .gds file.

Exporting to an AS3 File

You can easily export your CAD model to DataView's .AS3 file format and then load this information into DataView to view your CAD model.

To export to the AS3 DataView file format:

1. Select **File | Export | Part Model | Wavefront** and then choose the directory where you want to export the file.
2. Type a file name.
3. Click **Export**.
4. PC-DMIS creates the .OBJ file at the specified location.

Exporting a CAD Mesh File

With the **File | Export | Part Model | CAD Mesh** menu option, you can export your CAD model as a lightweight mesh (as a .cad or .draw file). This export saves the model's surfaces as triangle meshes instead of the mathematical surface definitions. This essentially strips the model to its bare essentials that you can then use for visualization or collision detection. For a size comparison, after export a 2.9 MB .iges model file exported as a CAD mesh file takes up only 458 KB of space.

You may also find this menu option a useful solution to create a lightweight model for things like quick fixtures and other components.

A CAD mesh file is not an alternative for a true CAD model file. For example, with a mesh file, you lose the ability for PC-DMIS to use QuickFeatures or to do one-click Auto feature selection.

Exporting to a PDF 3D File

You can export your CAD model to a PDF 3D file format. This type of format stores your CAD model in a .pdf file. You can manipulate the CAD model in the .pdf file.

To export to a PDF 3D file:

1. Select **File | Export | Part Model | PDF 3D**, and then choose the directory where you want to export the file.
2. Type a file name.
3. Click **Export**.
4. PC-DMIS creates the .pdf file at the specified location.

For more information, see "Working with PDF 3D Files" in the "Reporting Measurement Results" chapter.

Exporting to an STL (Stereolithography) File

You can easily export your CAD model to DataView's .STL file format and then load this information into DataView to view your CAD model.

To export to DataView:

1. Select **File | Export | Part Model | STL** and then choose the directory where you want to export the file.
2. Type a file name.
3. Click **Export**.
4. PC-DMIS creates the .STL file at the specified location.

Exporting to a Wavefront Object File

You can export your CAD model to the Wavefront .obj file format and then load this information into applications that support .obj files to view your CAD model. The .obj file is an open 3D model format used by many 3D graphics applications.

To export to a Wavefront .obj file,

1. Select **File | Export | Part Model | Wavefront**, and then choose the directory where you want to export the file.
2. Type a file name.
3. Click **Export**.
4. PC-DMIS creates the .obj file at the specified location.

Exporting to a STEP File

You can export your CAD model as a STEP file with the application Protocol 214. This type of format stores your CAD model as a .stp file. You can then import the file back into PC-DMIS or use it with other CAD systems.

To export your CAD model to a STEP file, you must use the STEP AP214 option:

1. Select **File | Export | Part Model | STEP | STEP AP214** and then choose the directory where you want to export the file.
2. Type a file name.

3. Click **Export**.
4. PC-DMIS creates the .stp file at the specified location.

When you export your CAD model as a STEP file, PC-DMIS includes only the original part geometry. It does not modify or transform the internal CAD geometry based on any applied transformations.

Exporting to an XAML Model File

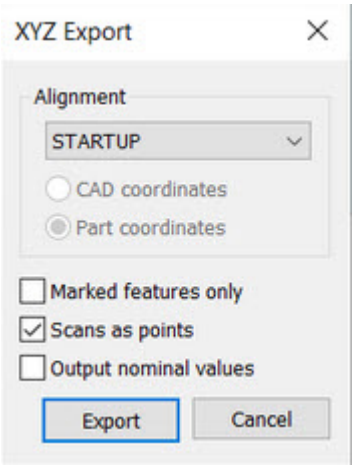
Using the **File | Export | Part Model | XAML** sub menu, you can choose to export your part model as one of these file XMAL model types:

- **Solid** - (*.xmalsolid)
- **Wireframe** - (*.xamlwireframe)

XAML is typically used as a markup language to define user interfaces. PC-DMIS, however, uses an extension that exports a subset of XAML used for specifying CAD data. This results in a 3D graphical display comparable to the PC-DMIS CAD format but weighing in at about half the size of the PC-DMIS CAD format. This light-weight graphics file is used in DataPage+.

Exporting to an XYZ File

When you click the **Export** button during the XYZ export process (**File | Export | XYZ**), PC-DMIS displays the **XYZ Export** dialog box.



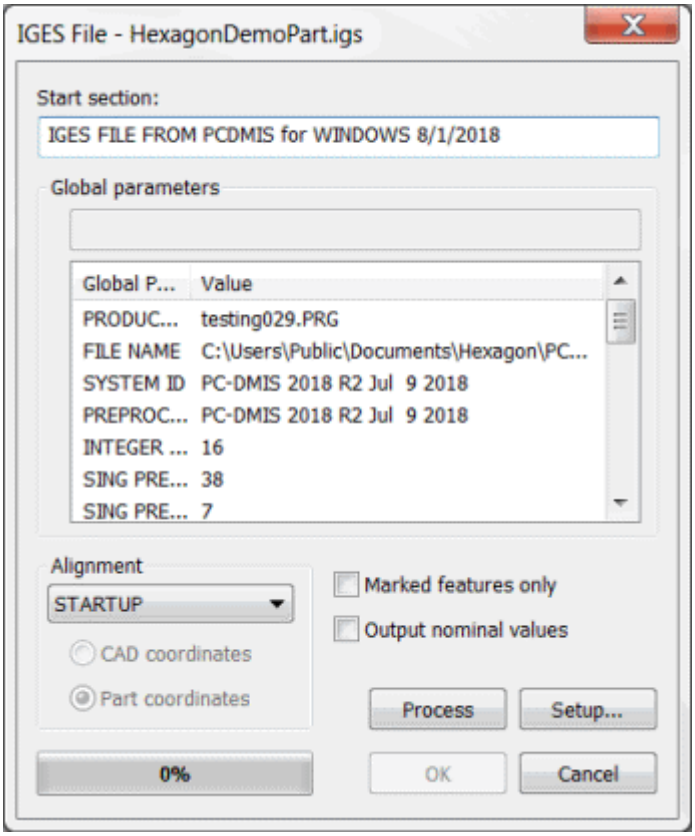
XYZ Export Dialog Box

The **XYZ Export** dialog box allows you to select options for your XYZ export. This exports your measurement routine as an .xyz file. This file type is readable inside standard text editors. For information on the .xyz file type, see the "Importing an XYZ File as CAD Data" for a discussion of this file's characteristics.

This dialog box has the exact same options as the **STEP Export** dialog box. For information, see "Exporting a STEP File".

Exporting an IGES File

When you click the **Export** button during the IGES export process (**File | Export | IGES**), PC-DMIS displays the **IGES File** dialog box.



IGES File Dialog Box

The **IGES File** dialog box displays information about your selected IGES export in the **Start section** and **Global parameters** areas. It also allows you to select additional options for your IGES export.

To export an IGES file, do the following:

1. Select an alignment in the **Alignment** list.
2. You can export an IGES CAD model with measured features.
    - If the features are not measured with an alignment, PC-DMIS exports them according to the selected option (**CAD coordinates** or **Part coordinates**).
    - If the features are measured with more than one alignment, the **CAD coordinates** and **Part coordinates** options become available. Select the desired option.

3. To alter the display of the exported image, click the **Setup** button and then complete the **IGES Write Setup** dialog box. For help, see "Altering the Display of Exported IGES CAD".

4. To export only the marked features, select the **Marked features only** check box.

5. To cause PC-DMIS to create the export file from the nominal values in your measurement routine, select the **Output nominal values** check box. If you clear this check box, PC-DMIS exports the measured feature results.

6. Click the **Process** button to output the IGES data from the selected measurement routine. PC-DMIS indicates when the file is 100% processed.

7. Click the **OK** button to export the IGES file.

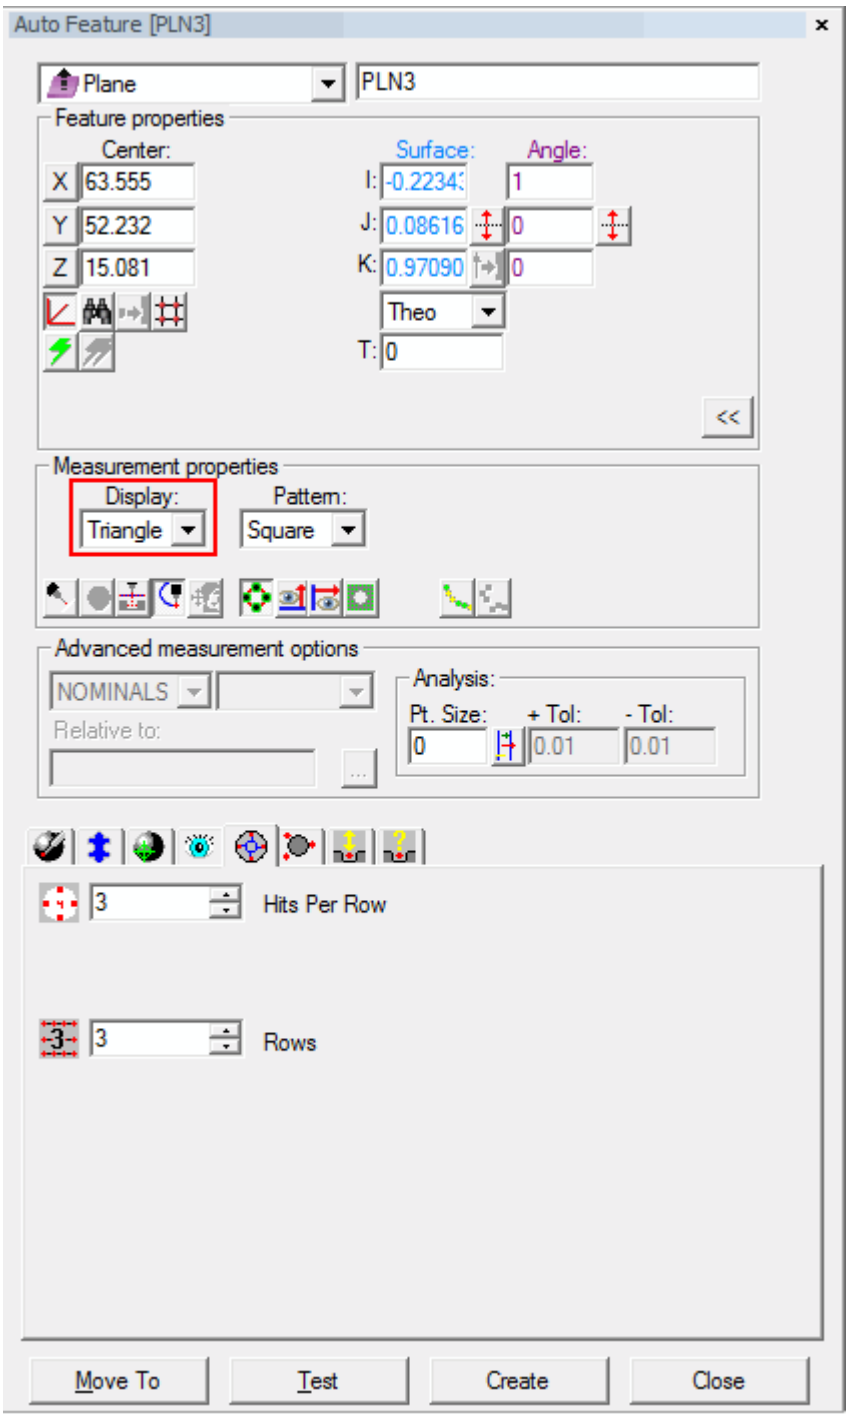
Exporting Plane Features in IGES

Plane features are exported in IGES the way they appear in the Graphic Display window. If the triangle representation of the plane is selected from the **Display** area of the dialog box, it is exported as a triangle bounded plane. If the outline is selected, the plane is exported as a convex polygon.

For an example of these display types, see "Using the Display Area" under the "Constructing a Plane Feature" topic.

The following sub-topics show the locations of the **Display** areas in each of the plane feature dialog box types:

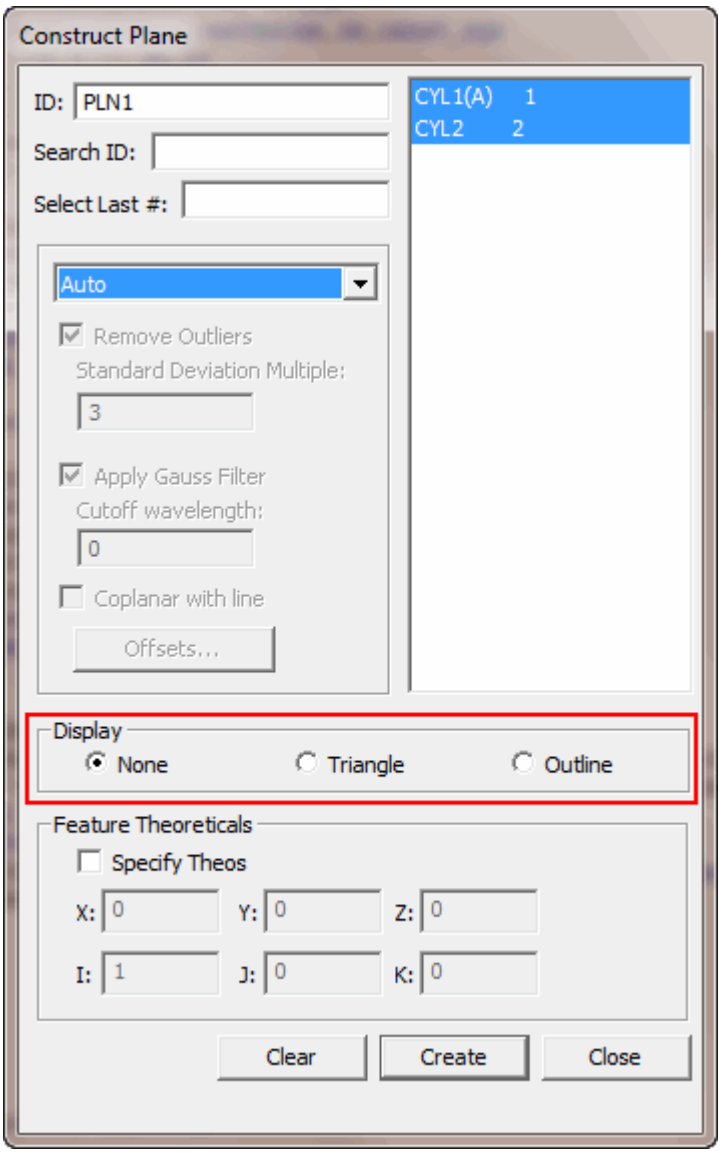
Auto Plane Feature Dialog Box



Auto Plane Feature dialog box emphasizing the Display section

For information, see the "Creating Auto Features" chapter.

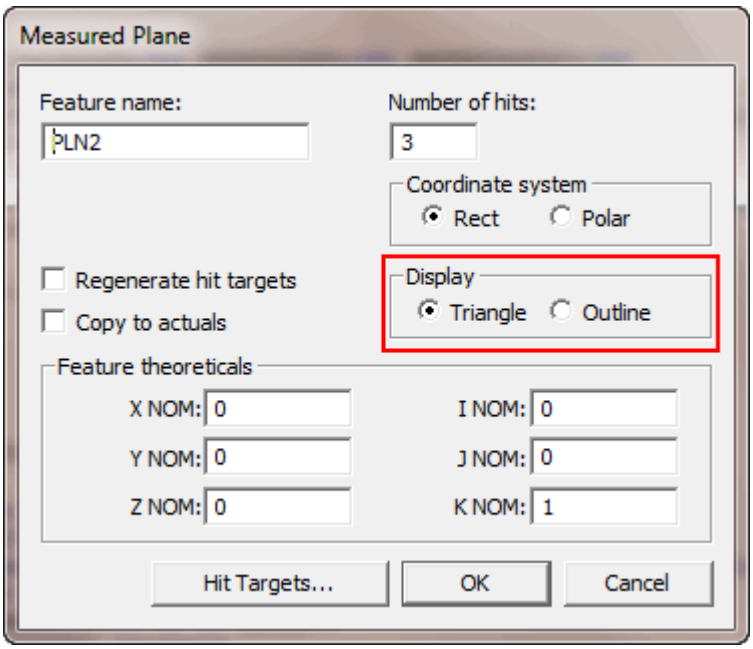
Construct Plane Feature Dialog Box



Construct Plane dialog emphasizing the Display section

For information, see the "Constructing New Features from Existing Features" chapter.

Measured Plane Feature Dialog Box



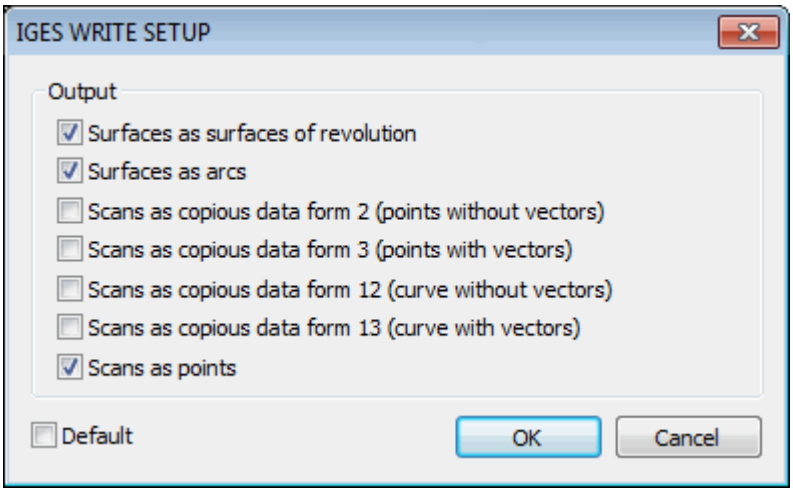
Measured Plane Feature dialog box emphasizing the Display section

For information, see the "Creating Measured Features" chapter.

The display type can also be changed in the Edit window in the plane feature's settings.

Altering the Display of Exported IGES CAD

The **IGES Write Setup** dialog box allows you to alter how the IGES/DMIS image displays in the exported file.



IGES Write Setup Dialog box

To access this dialog box and alter how the IGES/DMIS image displays, do the following:

1. Begin to export your CAD file (see "Exporting an IGES File").
2. When the **IGES File** dialog box appears, click the **Setup** button.

3. Select the desired check boxes in the **IGES Write Setup** dialog box.
4. Click the **OK** button.

PC-DMIS draws the selected CAD image with the requested features.

Understanding the Available Output Options

The **IGES Write Setup** dialog box, accessible from the **Setup** button in the **IGES File** dialog box (**File | Export | IGES**), provides these options that control how PC-DMIS exports IGES entities:

Surfaces as surfaces of revolution check box - Select this check box to export cones, cylinders, and spheres as surfaces of revolution entities.

Surfaces as arcs check box - Select this check box to export cones, cylinders, and spheres as arcs.

- PC-DMIS exports a cone as a circle at its base and a point at its vertex.
- PC-DMIS exports a cylinder as two circles: one at the top and one at the bottom.
- PC-DMIS exports a sphere as a circle about its equator.

To export cones, cylinders, and spheres as both surfaces of revolution and arcs, select both the **Surfaces as surfaces of revolution** and **Surfaces as arcs** check boxes. If you clear both check boxes, PC-DMIS doesn't export cones, cylinders, or spheres.

Scans as copious data form 2 (points without vectors) check box - Select this check box to export scans as copious data IGES entities in form 2. This format includes point data without vectors.

Scans as copious data form 3 (points with vectors) check box - Select this check box to export scans as copious data IGES entities in form 3. This format includes both point and vector data. The various forms control the format of the copious data entities.

Scans as copious data form 12 (curve without vectors) check box - Select this check box to export scans as copious data IGES entities in form 12. This format represents the data as a piecewise-linear curve without vectors. The various forms control the format of the copious data entity.

Scans as copious data form 13 (curve with vectors) check box - Select this check box to export scans as copious data IGES entities in form 13. This format represents the data as a *piecewise-linear curve with vectors*. The various forms control the format of the copious data entity.

Scans as points check box - Select this check box to export scans as multiple point entities.

To export scans as both copious data and points, select both the **Scans as copious data** check box (such as form 2, 3, 12, or 13) and the **Scans as points** check boxes. If you clear both the check boxes, PC-DMIS doesn't export scans.

Exporting a Pointcloud PSL File

You can easily export your CAD model to a Pointcloud .PSL file format and then load this information into DataView to view your CAD model.

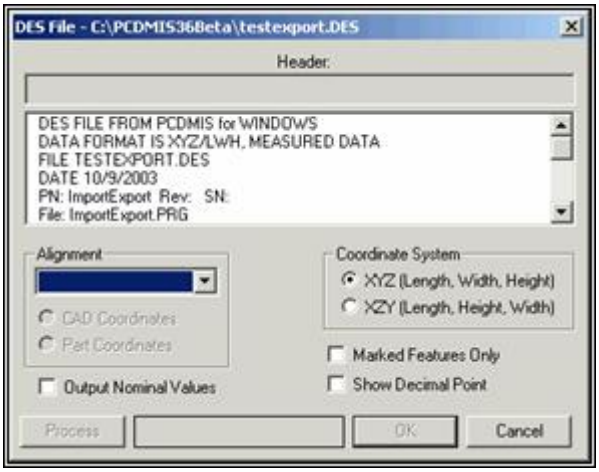
To export to DataView,

1. Select **File | Export | Part Model | PSL** and then choose the directory where you want to export the file.
2. Type a file name.
3. Click **Export**.
4. PC-DMIS creates the .PSL file at the specified location.

Exporting a DES File

You can export your measurement routine as a DES file. A DES file is a proprietary GM format used by GM's internal applications.

To export this file, select **File | Export | DES**. Choose where you want to place the file, and click **Export**. PC-DMIS displays the **DES File** dialog box.



DES File Dialog Box

The **DES File** dialog box displays information on your selected DES export in the **Header** area; it also allows you to select additional options for your DES export.

1. Select an alignment from the **Alignment** list.
2. Select a coordinate system from the **Coordinate System** area.

3. If desired, select the **Marked Features Only** check box to export only the marked features.

4. If desired, select the **Show Decimal Point** check box to show the decimal point in the exported data.

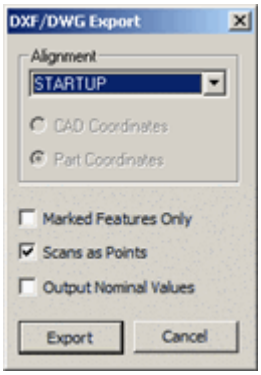
5. If desired, select the **Output Nominal Values** check box to cause PC-DMIS to create the export file from the nominal values in your measurement routine. If you don't select this check box, PC-DMIS exports the measured feature results.

6. Click on the **Process** button in the **DES File** dialog box to output the DES data from the selected measurement routine. PC-DMIS indicates when the file is 100% processed.

7. Click the **OK** button to finish exporting the DES file.

Exporting a DXF or DWG File

When you click the **Export** button during the DXF or DWG export process (**File | Export DFX** or **File | Export | DWG**), PC-DMIS displays a **DXF/DWG Export** dialog box.



DXF/DWG Export Dialog Box

The **DXF/DWG Export** dialog box allows you to select additional options for the export of these file types.

1. Select an alignment from the **Alignment** list.

2. If desired, select the **Marked Features Only** check box to only export the marked features.

3. If desired, select the **Scans as Points** check box to cause scan data to get converted to its scanned points.

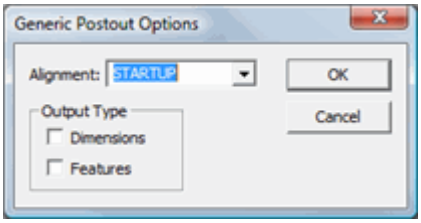
4. If desired, select the **Output Nominal Values** check box to cause PC-DMIS to create the export file from the nominal values in your measurement routine. If you don't select this check box, PC-DMIS exports the measured feature results.

5. Click the **Export** button to finish exporting the DXF or DWG file.

Exporting to a Generic Text File

Using the **File | Export | Generic** menu option, PC-DMIS can export your measurement routine's feature and dimension data to a simple text file as comma separated values. You can then import this data into other software applications, such as Microsoft Excel, as needed.

After choosing where to export the file and clicking the **Export** button, PC-DMIS displays a dialog box asking for you to choose the alignment to use when exporting the data and the type of data to export:



Generic Postout Options Dialog Box

Alignment is a drop-down list of alignment options you can choose from to apply to the data when exported.

Output Type area is where you select the type of data to export, either Dimensions, Features, or both.

An Example Exported Circle Feature:

```
CIR1, 93.486348, 19.488589, -1.269350, 0.000000, 0.000000,
1.000000, 14.997670

CIR1 HITS, 85.984616, 19.473057, -1.279984, 0.999998,
0.002070, 0.000000

CIR1 HITS, 93.479917, 11.992677, -1.287909, 0.000858,
1.000000, 0.000000

CIR1 HITS, 100.988033, 19.458504, -1.285809, -0.999992,
0.004010, 0.000000

CIR1 HITS, 93.486169, 26.984522, -1.265512, 0.000024,
-1.000000, 0.000000
```

The format for the first line of the feature is:
[Feature Label], [X], [Y], [Z], [I], [J], [K], [D]

The format for the hits lines, lines 2 - 5, is:
[Hits Label], [X], [Y], [Z], [I], [J], [K]

Only Auto feature hits data exposed in the Edit window can be exported to a generic text file.

An Example Exported Location Dimension:

```
LOC1 AX:X, 93.485000, 0.010000, 0.010000, 93.486348,
0.001348, 0.000000

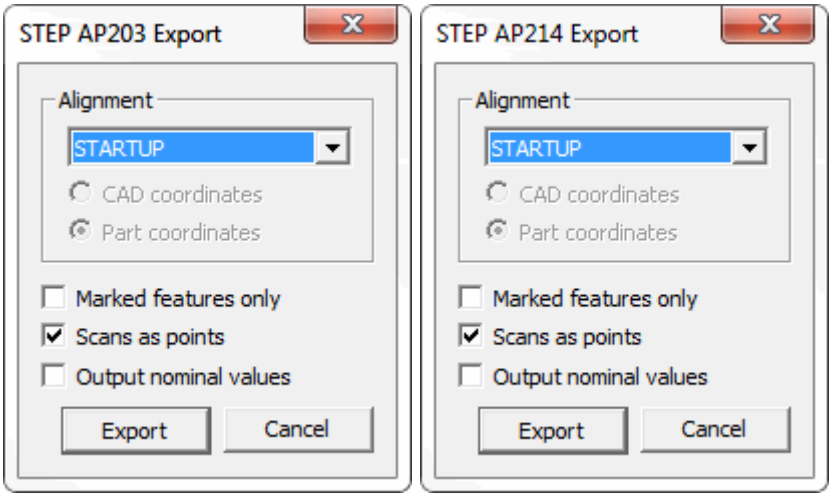
LOC1 AX:Y, 19.500000, 0.010000, 0.010000, 19.488589,
-0.011411, 0.001411

LOC1 AX:D, 15.000000, 0.010000, 0.010000, 14.997670,
-0.002330, 0.000000
```

The format for the lines is:
[Dim Label]AX:[Axis Indicator], [Nominal], [+ Tol], [- Tol], [Measured], [Deviation], [Out of Tol]

Exporting a STEP File

Exporting a STEP file is done by clicking **File | Export | STEP** from the main menu and, from the pull out list, choose either the **AP203** or **AP214** option. The corresponding **STEP Export** dialog box opens, as shown below.



STEP AP203 and AP214 Export Dialog Boxes

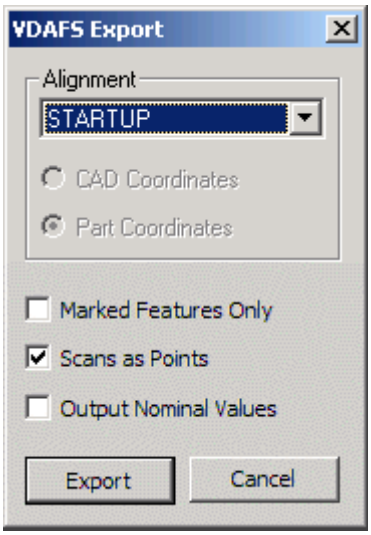
The **STEP Export** dialog box allows you to select additional options for your STEP export.

1. Select an alignment from the list in the **Alignment** area.
2. Select a coordinate system from the **Alignment** area.

3. If desired, select the **Marked Features Only** check box to only export the marked features.
4. If desired, select the **Scans as Points** check box to cause scan data to get converted to its scanned points.
5. If desired, select the **Output Nominal Values** check box to cause PC-DMIS to create the export file from the nominal values in your measurement routine. If you don't select this check box, PC-DMIS exports the measured feature results.
6. Click the **Export** button to finish exporting the STEP file.

Exporting a VDAFS File

When you click the **Export** button during the VDAFS export process (**File | Export | VDAFS**), PC-DMIS displays the **VDAFS Export** dialog box.



VDAFS Export Dialog Box

The **VDAFS Export** dialog box allows you to select options for your VDAFS export. This dialog box has the same options as the **STEP Export** dialog box. For information on these options, see "Exporting a STEP File".

Exporting to a BASIC File

PC-DMIS provides you with tools that help you to automate PC-DMIS. Exporting your measurement routine as a BASIC script (*.BAS file) allows you to then automate that measurement routine using any external application that supports the BASIC language. For more information on how to automate PC-DMIS, see these documentation topics:

- PC-DMIS BASIC Language Reference documentation.
- "Inserting BASIC Scripts" in the "Adding External Elements" documentation.

Exporting to a Datalog File

The **File | Export | Datalog** menu item exports your measurement routine's feature and dimension data to a simple Datalog text file. Datalog is a proprietary Chrysler format used by Chrysler's internal applications.

When you choose to export the file, a **Datalog Export** dialog box appears. Choose a location to store the exported text file, and click **Save**. You can view the resulting file by opening the file inside of a text editor such as Notepad.

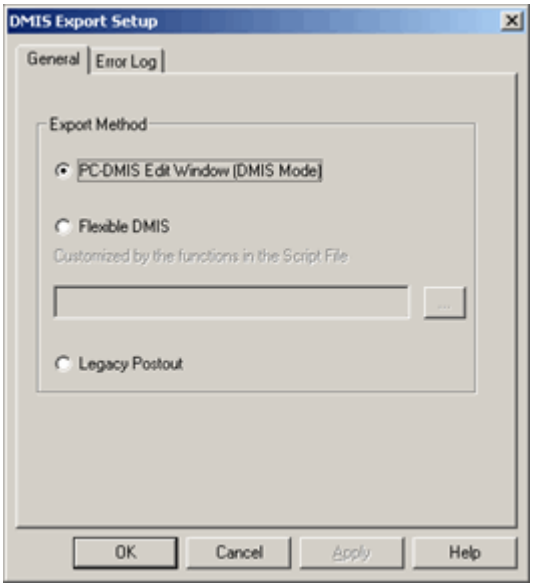
Exporting to a DMIS File

DMIS files adhere to the DMIS standards for DMIS commands. You can execute DMIS files on other applications that use the DMIS language.

To export your PC-DMIS measurement routine file as a DMIS file, follow these steps:

1. Select **File | Export | DMIS**. This action opens the **Export** dialog box.
2. In the **Export** dialog box, choose a file name and click **Export** to open the **DMIS Export Setup** dialog box. This dialog box contains the **General** tab and the **Error Log** tab.
3. After you choose your options on these tabs, click **OK** to complete the export process.

General tab



DMIS Export Setup Dialog Box - General Tab

The **General** tab lets you choose one of three methods to convert your PC-DMIS measurement routine into a DMIS file.

- **PC-DMIS Edit Window (DMIS Mode)** - This method exports a DMIS file exactly as the measurement routine looks in the Edit window when you are in DMIS Mode.

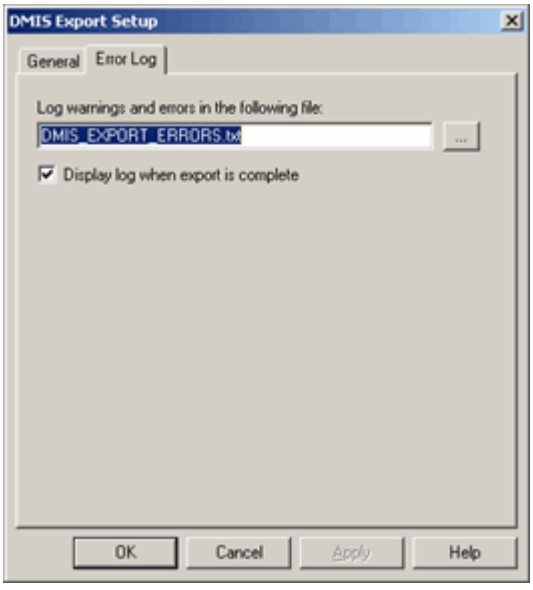
- **Flexible DMIS** - This method allows you to customize the exported file to match your specific DMIS version, measurement methods, or supported DMIS statements. When you select this option, a file selection box becomes enabled that allows you to browse to and select a specific BASIC script file (*.bas extension). You can create your own script file, or modify an existing script file to control exactly what PC-DMIS should export.

  PC-DMIS provides you with three ready-to-use .bas files that reside in your PC-DMIS installation directory. These files customize your export so that it uses a defined subset of supported DMIS statements for a specific DMIS version. The files are PCD2DMIS030.BAS, PCD2DMIS040.BAS, and PCD2DMIS050.BAS (for DMIS 3.0, 4.0, and 5.0 respectively). The commands that are not customized in the .bas file are exported as they are for the **PC-DMIS Edit Window (DMIS Mode)** option.

  If a function in the BASIC script returns an error when you use this option, then the exported file gets written as if you had selected the **PC-DMIS Edit Window (DMIS Mode)** option above.

- **Legacy Postout** - This method exports the file as it used to do in older versions of PC-DMIS.

Error Log tab



DMIS Export Setup Dialog Box - Error Log Tab

The **Error Log** tab lets you view or save errors encountered during an export phase so that you can correct them in your script file or take some other appropriate action. PC-DMIS displays errors or warnings in these instances:

- When a function in the BASIC script returns a logical error, meaning you have a problem somewhere in your script that's causing an automation logic error. In this

case, the BASIC Script function returns a text string with this header: `$$ LOGERR |` .

- When a parameter in a PC-DMIS command cannot be converted into DMIS code. In this case, the BASIC Script function returns a text string with this header: `$$ DMISERR |`

Click the **...** button to locate and select an existing text file to which PC-DMIS should send the errors.

Click the **Display log when export is complete** check box to display the text file in a text editor once PC-DMIS finishes the export process.

SuppressDMESWComandOutput Entry

A `SuppressDMESWComandOutput` entry lets you suppress `DMESW/COMAND` statements in the output file with the $$ comment marker prefix if you use the **Flexible DMIS** export method discussed above. For more information, see the "SuppressDMESWComandOutput" topic in the PC-DMIS Settings Editor documentation.

Exporting to Excel

PC-DMIS allows you to export your measurement routine's results as text data to a Microsoft Excel template. To do this, select **Insert | Report Command | Excel Form Report** to open the **Excel Form Report** dialog box.

For more information, see the "Using the Excel Form Report Command" section of the PC-DMIS Toolkit Modules documentation.

Exporting to an Inspection Plan

Inspection plans determine which features of the geometry and GD&T/dimension to use in the inspection process. Usually, inspection plans are created using Planner, an application that shares many similarities to PC-DMIS. However, you can also use the **File | Export | Inspection Plan** menu option in PC-DMIS to export your measurement routine as an inspection plan.

- **Planner XML (*.planxml, *.xml)** - PC-DMIS can import this default file type into an open measurement routine. Planner can do the same into an open inspection plan. In addition, third-party applications can potentially parse and use the data contained inside this widely-used tagged format. This is the format used by Planner.
- **Planner IP File (*.ip)** - Both PC-DMIS and the legacy PC-DMIS Planner can import this older proprietary format. This is the format used by the legacy PC-DMIS Planner.

You can then import the IP into a measurement routine (see "Importing an Inspection Plan File") or load the plan into PC-DMIS Planner for further development.

PC-DMIS 2019 R1 was the last version that included Planner.

Exporting to an XML File

You can use the **File | Export | XML** menu item to export your PC-DMIS measurement routine's measurement data into an XML (.xml) file. You can then share the file or store the data on a database server.

From the **Export Measurement Routine to XML** dialog box, type or select a filename from the list and click **Save** to complete the export process.

Using Direct CAD Interfaces

Direct CAD Interfaces (DCI) allow you to connect directly to your CAD software. As the CAD file is updated in your CAD software, PC-DMIS reflects the corresponding changes.

Instead of translating CAD data into the internal CAD format of PC-DMIS, the Direct CAD file types are accessed directly. That is, the CAD data of these file types remains in its native format after being imported. Routines native to the CAD type are used for all calculations done on the CAD data. Accessing the CAD data directly eliminates problems that can occur because of translation inaccuracies or limitations.

For detailed information, see the "Direct CAD Interface" documentation.

PC-DMIS supports the use of the following DCIs:

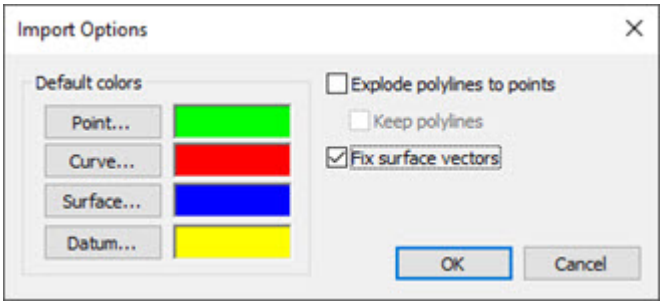
- ACIS
- CATIA 5
- Creo
- Solidworks
- NX

Your PC-DMIS license must have the following options enabled: **CATIA V5 DCI**, **NX DCI**, **PRO-E DCI**, and **Solidworks DCI**.

Setting Import Options

You can easily set import options to determine the default colors for certain imported entity types, as well as how PC-DMIS displays imported curves.

To perform these manipulations, select the **Edit | Preferences | Import Options** menu item. This menu item displays the **Import Options** dialog box.

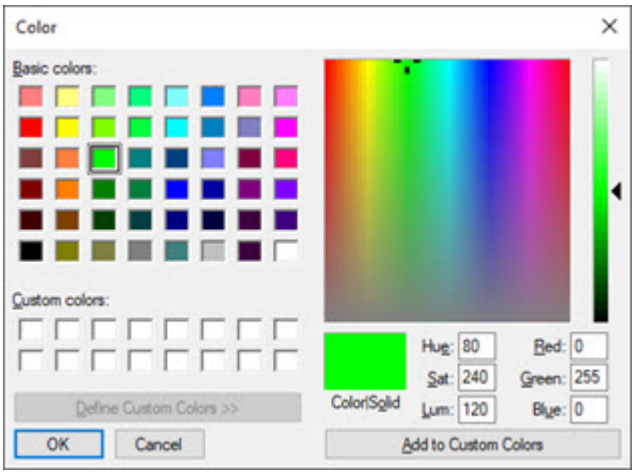


Import Options Dialog Box

This dialog box contains the **Default Colors** area as well as some check boxes.

Default Colors

This area lets you change the default colors for imported Points, Curves, Surfaces, and Datum entity types. If the entity types don't already have a defined color, it uses this default color. To change a color, simply click on a button in this area. A standard **Color** dialog box appears, allowing you to select a new color.



Color Dialog Box

When you import the next feature, PC-DMIS uses the newly-defined colors.

Check Boxes

Explode polylines to points

Usually, when you import curves entities, they appear as individual curves. In reality, however, each curve is really a polyline, a bunch of lines connected by a series of points. Selecting this check box makes imported polyline curve entities appear as a series of points, one point for each polyline vertex. Clearing this check box makes imported curves appear as normal.

Keep polylines

Selecting this check box allows the image to continue to display the original polyline along with the points when you select the **Explode polyline to points** check box. Clearing this check box only shows the series of points.

Fix Surface Vectors
If you want your surface vectors to be correct and always point away from the surface, mark the **Fix surface vectors** check box. This is helpful for pointcloud and laser scanning operations, but it does increase the import processing time. If you don't use laser scanning, you can clear this check box.

PC-DMIS uses these settings for all future import operations.

Executing Measurement Routines

With PC-DMIS, you can easily execute an entire measurement routine or perform partial executions. This topic describes how to perform both full and partial executions. It also explains how to use the **Execution** dialog box to execute your measurement routines and how to resize the dialog box.

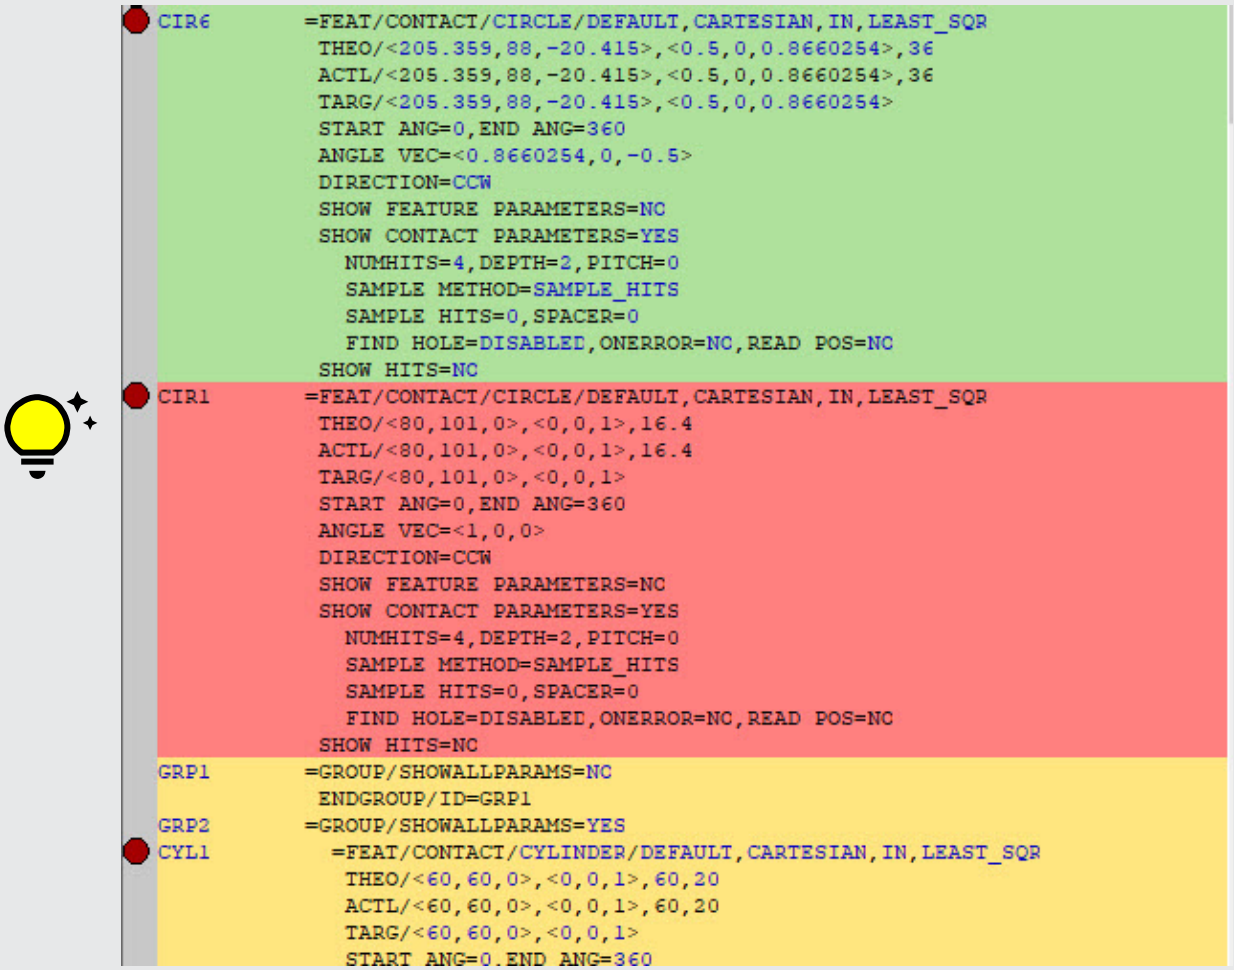
When you execute some or all of your measurement routine, select **File | Execute** or a menu item from the **File | Partial Execution** submenu to open the **Execution** dialog box. Also, if you don't have breakpoints in your measurement routine, PC-DMIS displays a different layout of the screen display called the "execution layout". This layout initially hides the Edit window and expands the Graphic Display window, to show more of the part. It also displays the Probe Readouts window. You can change what windows appear during execution by pausing the execution and showing or hiding a window. Subsequent executions use your updated execution layout.

When execution finishes, the screen layout returns to the learn time layout. Any window you show or hide during learn time becomes part of the learn time layout.

When the PC-DMIS Protect license option is enabled, operators (users who are not members of the PC-DMIS-Programmer or PC-DMIS-User group) can execute only certified measurement routines. To let operators also execute uncertified measurement routines, set the `RestrictCertifiedMRExecutionToOperators` entry in the **Option** section of the PC-DMIS Settings Editor to **FALSE**. For information on certified measurement routines, see the "Certify" topic.

If you execute a measurement routine with breakpoints, PC-DMIS continues to display the Edit window during execution:

In Command Mode, PC-DMIS highlights the current command to execute in red.



Example of colors used in Command Mode during execution with a breakpoint

Execute

To execute all marked commands of the entire measurement routine, select the **File | Execute** option.

Execute Feature

To execute only the feature or operator comment command on which the cursor rests, select the **File | Partial Execution | Execute Feature** option.

PC-DMIS displays the **Execution** dialog box.

If PC-DMIS is set to Manual Mode (mode = MANUAL), automatic machine motion does not occur. Instead, PC-DMIS prompts you to move the machine to take the necessary hits.

If PC-DMIS is set to DCC Mode (mode = DCC), it automatically moves the probe based on the parameters set in the dialog box.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

To maintain good execution speeds, PC-DMIS does not generate a report in the Report window if using the **Execute Feature** functionality. However, you can still view report-like information inside the Status window.

Execute From

To resume a previous cancelled execution, use the **File | Partial Execution | Execute From** menu option. This command executes the feature listed until the end of the measurement routine. This menu option is only available when you have canceled a prior execute command by using the Execution dialog box.

If during a measurement routine execution, you click the **Cancel** button while measuring feature CIR1, the Execute From menu becomes available so that you can continue inspecting the part beginning at CIR1.

Execute From Cursor

To execute the measurement routine from the current cursor location, select the **File | Partial Execution | Execute From Cursor** menu option. The measurement routine begins execution at the cursor's current location.

Use the Execute From Cursor option only for troubleshooting, not for full executions after you thoroughly test the measurement routines. This command retains data from the previous execution by design, and prolonged use may impact system performance.

To skip specific commands, such as the manual features in a measurement routine, you can use the Mark option. For information on how to use the Mark option, see the "Mark" topic in the PC-DMIS Core documentation.

Execute Block

To execute a block of commands, select the commands you want to execute, and then with the commands still selected, choose the **File | Partial Execution | Execute Block** menu command. PC-DMIS will execute only the selected block of commands.

Execute From Start Points

To begin execution at a specified start point, first set the start point by right-clicking inside Command Mode and selecting **Set Start Point** from the shortcut menu, and then choose the **Execute from Start Points** menu command.

> Be aware when the current tip for that location in the measurement routine does not match the current orientation of the probe head. The software does not execute the previous tip command in order to change the tip orientation.

Mini Routines

Mini routines enable you to measure a selected dimension or group of dimensions from a long measurement routine.

Because mini routines can execute partial measurements in a measurement routine, you must ensure that there will be no collisions when you execute a partial measurement routine. You are responsible for creating such a measurement routine. For details, see "Mini Routines" in the PC-DMIS Core documentation.

Dynamic Inspection

To execute Dynamic Inspection, select the **File | Partial Execution | Dynamic Inspection** menu option or click the **Dynamic Inspection** icon from the **Execute** toolbar to open the **Dynamic Inspection** dialog box. This dialog box displays the characteristics that O-QIS selected to measure the next part. Select the appropriate options and click **Execute** to execute the measurement routine.

For more information, see the "Dynamic Inspection" chapter in the PC-DMIS Toolkit Modules documentation.

Any Order Execution

You can execute manually-measured features in the measurement routine in any order. This is useful for portable arm machines.

This functionality becomes possible if the following conditions are met:

- It only applies to features measured with manual hits.
- The measurement routines cannot have any branching or loops.
- The features that you measure out of order must use the same alignment and probe as the features initially defined to measure in the current measurement routine. PC-DMIS does not search across `LOAD PROBE` or `ALIGNMENT` commands.
- Out of order execution only works for features measured after a complete alignment. The initial alignment must be measured in order.

How It Works

When you execute your measurement routine, PC-DMIS prompts you to take the first hit on the first feature. You can decide to take your first hit on a different feature instead. When you do this, PC-DMIS determines if you took that hit within a tolerance of the hit PC-DMIS expected. If your hit is more than a specified tolerance (usually 10 mm) away from the feature, then PC-DMIS searches backwards and forwards through the measurement routine for the closest feature that has an initial hit that matches the initial hit that you took. You can define the tolerance on the **General** tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**).

If you take a hit that is not in tolerance for any feature in your entire measurement routine, the arm sounds a beep alert, and PC-DMIS ignores the hit. PC-DMIS shows an error message in the **Execution** dialog box. You should take a different hit closer to a measurement routine feature to continue.

When PC-DMIS finds the appropriate feature, it passes your first hit into the feature and then moves the arrow to indicate where to take the next hit for the new feature. PC-DMIS only checks the tolerance on the first hit of the feature. After that, it assumes that you will continue taking hits until you finish measuring that feature.

Once you finish measuring a feature out of order, PC-DMIS attempts to go back to its initial order. It continues to prompt you to measure the original feature each time you finish measuring something else out of order until you either skip the original feature or measure it. PC-DMIS tracks the features you measure out of order so that they aren't remeasured when PC-DMIS resumes its regular execution route.

If you remeasure a feature, PC-DMIS recomputes everything that uses that feature up until the current execution location.

Reset Execution List

As execution progresses, PC-DMIS maintains an internal list containing all the commands that have been executed. This is called the execution list. PC-DMIS uses the execution list for generating reports in the Report window. This list is saved with the measurement routine and restored when the measurement routine is loaded.

PC-DMIS always clears out the information in this list whenever you perform a full measurement routine execution.

However, if you perform a partial execution (using execution menu items from the **File | Partial Execution** sub menu), it does not clear out the execution list. For example, if you perform a full execution, followed by a partial execution, the information from the full execution remains in your execution list and shows up in your report along with the partial execution information.

If you don't want this, the **File | Reset Execution List** menu item immediately clears out the execution list.

The `ClearExecutionListPriorToProgramExecution` entry is available to modify how the Execution List is cleared out. Details can be found in the **Reporting** section of the PC-DMIS Settings Editor.

Additionally, the `SaveExecuteList` entry in the **Reporting** section in the PC-DMIS Settings Editor controls this behavior. It defaults to 1, meaning the list is saved and restored as described. If you don't want PC-DMIS to save or restore the list, change this setting to 0.

Reporting a Dimension Using a Feature Skipped During Execution

If you skip a feature when you execute a measurement routine, PC-DMIS displays dimensions in red when the input feature was set to:

- SKIPPED_DURING_EXECUTION - This occurs when you get the PC-DMIS prompt "Read new probe position" and you press **No** to skip.
- SKIPPED_DURING_EXECUTION_BECAUSE_INPUT_SKIPPED - This occurs from a constructed feature type that has a skipped feature as one of its inputs.

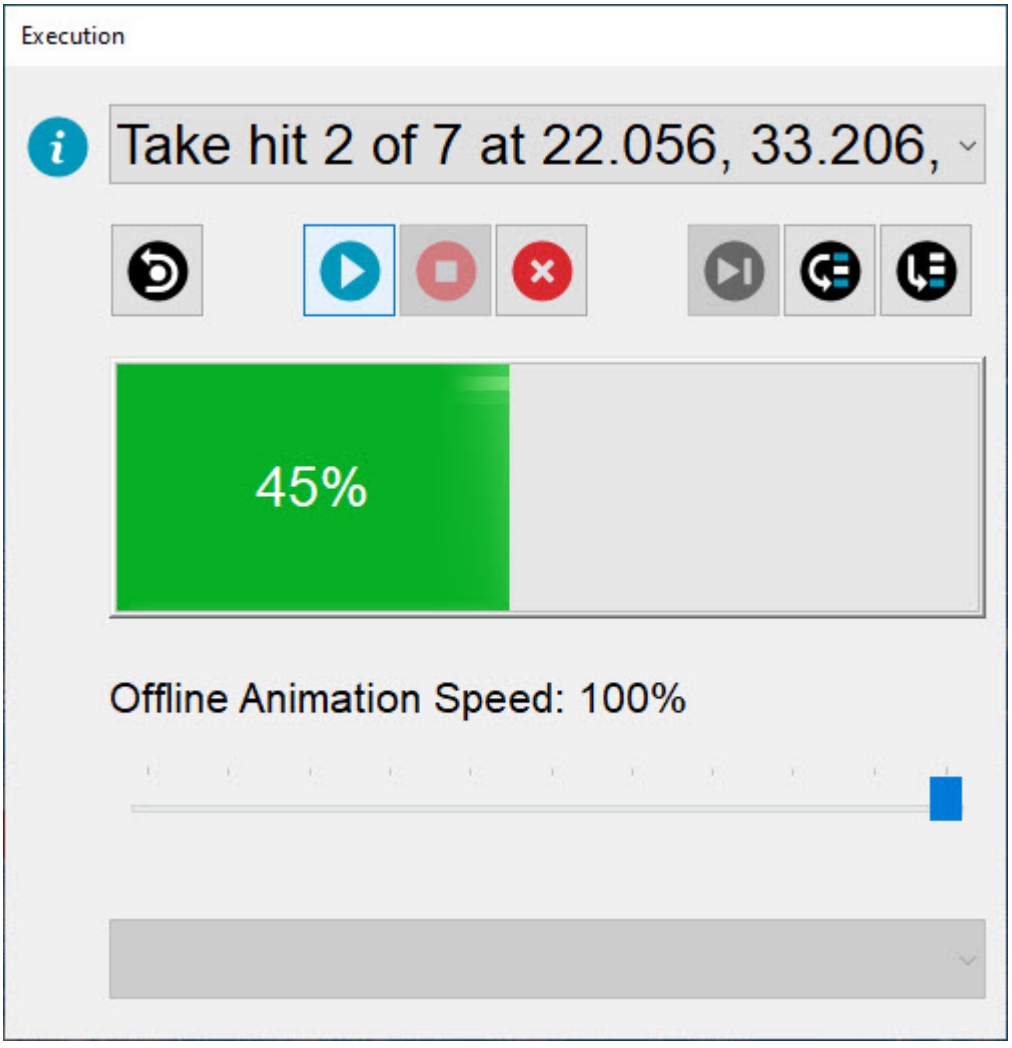
Previously, PC-DMIS was not refreshing dimensions that use a skipped feature during measurement routine reporting. When you create a new dimension that uses a skipped feature, it will have a different result than it would after you execute the measurement routine. Now, PC-DMIS marks the dimensions in red to highlight that it too is skipped because an input was skipped during execution. This "red" state is only present after execution. If you close and re-open the measurement routine, it returns to the original text colors.

Using the Execution Dialog Box

You can use the On Error command to tell PC-DMIS to skip commands that generate certain machine errors during the execution of a measurement routine. For information about On Error branching, see the "Branching on an Error" topic.

You can use the Check Calibration Limits command to check for probe calibration errors and raise alerts during execution. You can combine this command with the On Error command to control the execution. For information about the Check Calibration Limits command, see the "Creating a Check Calibration Limits Command" topic in the PC-DMIS Toolkit Modules documentation.

To begin all execution operations, open the **Execution** dialog box (**File | Execute** or **File | Partial Execution**).



Execution Dialog Box

Once the **Execution** dialog box appears, PC-DMIS attempts to execute all marked commands in the current measurement routine.

- If PC-DMIS is in Manual Mode, PC-DMIS requests that you manually move the probe to the feature and take hits with the probe.
- If PC-DMIS is in DCC Mode, PC-DMIS automatically begins the measurement process. It moves to and probes each feature and takes the needed number of hits.

> **WARNING:** When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

These items are available in the **Execution** dialog box:

Machine Commands - Displays the current action to perform.

These include any moves and hits for the current feature (the feature about to be measured). These commands are only available if the measurement routine is stopped during execution, from an error, from the operator, or if the execution takes place in Manual Mode. If this takes place in DCC Mode, you can resume the measurement routine execution by highlighting the desired hit or move from the **Machine Commands** list and clicking **Continue**.

> Suppose a clearance move command was programmed with the wrong X, Y, or Z values. During the execution of that move, you might get a motion error. To continue, you would do the following:
>
> 1. Select the **Machine Commands** list.
> 2. Select the command following the offending move.
> 3. Click **Continue**.

Erase Hit - Removes the currently-highlighted hit in the **Machine Commands** list.

Most CMM jog boxes also have a button assigned to erasing the last hit. Pressing that button on the CMM's jog box while in Execute mode, produces the same result as clicking the **Erase Hit** button on the dialog box.

New Row - Starts a new row for the manual scan being executed (or learned).

This button is only available when a manual scan is executed.

To use the **New Row** command button:

1. Press **Stop** to pause the scan.
2. Click **New Row** . This indicates a new row to scanned.

Or

1. Click **New Row** first. PC-DMIS automatically pauses the scan.
2. Move the probe to the next row.
3. Click **Continue** .
4. PC-DMIS scans the new row.

Continue - Resumes the execution of a measurement routine halted by a CMM motion error, or the **Stop** button.

You can choose the specific location within the current feature where the probe is to resume measuring the part. The default location is displayed in the **Machine Commands** list. To select another location, click the list and select the desired line. PC-DMIS continues the measurement process at that location once you click **Continue**.

The software does not know why you chose to pause an execution. Therefore, to safely resume a paused execution, check to ensure that the probe has a clear lane of travel to its next point. A message box reminds you to do this in these circumstances:

- The probe is already inside the ClearanceCube.
- The probe is outside the ClearanceCube but the first target position exists within the ClearanceCube.
- Anytime the first movement intersects with the ClearanceCube.

For information on the ClearanceCube, see "Using the ClearanceCube" in the "Editing the CAD Display" chapter.

Stop - Halts the probe at its current position and suspends execution of the measurement routine.

> This button does not stop the measurement routine execution if the current move is a PH9 orientation change. The measurement routine stops after the PH9 stops.

The topic "Manually Controlling a Feature's Measurement" discusses using **Stop** to switch to Manual Mode during the execution process.

Cancel - Stops the execution and closes the dialog box.

Scan Done - Stops collecting data in a manual scan and processes the data for finding nominals, vector compensation, and other data.

This is only available if a manual scan is executed (learned).

As you execute the scan, PC-DMIS gathers data from the CMM. Simultaneously, PC-DMIS filters (or reduces) the data according to the scan method (**Fixed Time**, **Fixed Distance**, **Fixed Time / Distance**, and other methods) you provide. PC-DMIS excludes data that does not satisfy the criteria (such as **Fixed Time** or **Distance** increments) and keeps data that does satisfy the criteria.

Step Next - Continues the measurement process by stepping through each new command that moves the CMM.

This pauses the CMM between each step, which requires you to click **Step Next** to continue to step through the routine. This puts PC-DMIS into Step Mode. When PC-DMIS is in Step Mode, you can insert hits into features and insert new features between existing features or commands. If you insert a new feature, PC-DMIS displays a dialog box that enables you to do the following:

- **Skip** to the `HIT /BASIC` command of the new feature.
- **Remeasure** the new feature.
- **Continue** to step through the measurement routine, and ignore the new feature entirely.

You can also simulate Step Mode offline.

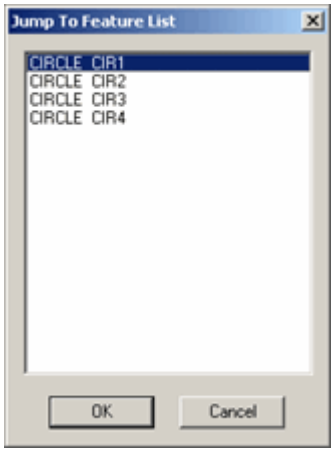
Step Next appears in the dialog box when PC-DMIS pauses execution for a breakpoint (see "Using Breakpoints" in the "Editing a Measurement Routine" chapter).

Skip - Skips the next command displayed in the **Machine Commands** list. It also skips commands that depend on the skipped command.

For details on how PC-DMIS reports dimensions that use skipped features during execution, see the "Reporting a Dimension Using a Feature Skipped During Execution" topic in this documentation.

Jump - Stops execution so that you can jump to a new feature.

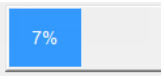
This displays the **Jump to Feature List** dialog box. From this list, you can select the next feature to execute and deviate from the automatically-generated execution path.



Jump to Feature List Dialog Box

After you select a feature from the list and click **OK**, PC-DMIS executes the selected feature. After PC-DMIS executes that feature, it returns to the pre-defined path and attempts to execute the next non-measured feature until you click **Jump** again and select a new feature.

Suppose you have seven circles labeled CIR1 through CIR7, and they are programmed to execute in that order. If after CIR1, you click **Jump** and select CIR6, PC-DMIS immediately measures CIR6. When finished, PC-DMIS returns and measure circles CIR2 through CIR5, and then it finishes by measuring CIR7.



Progress Bar - Indicates the percentage of the measurement routine that has finished executing.

The percentage is derived from the amount of executed commands and hits taken compared against the total number of marked commands and hits to take. The progress bar updates as it progresses through the measurement routine. You may

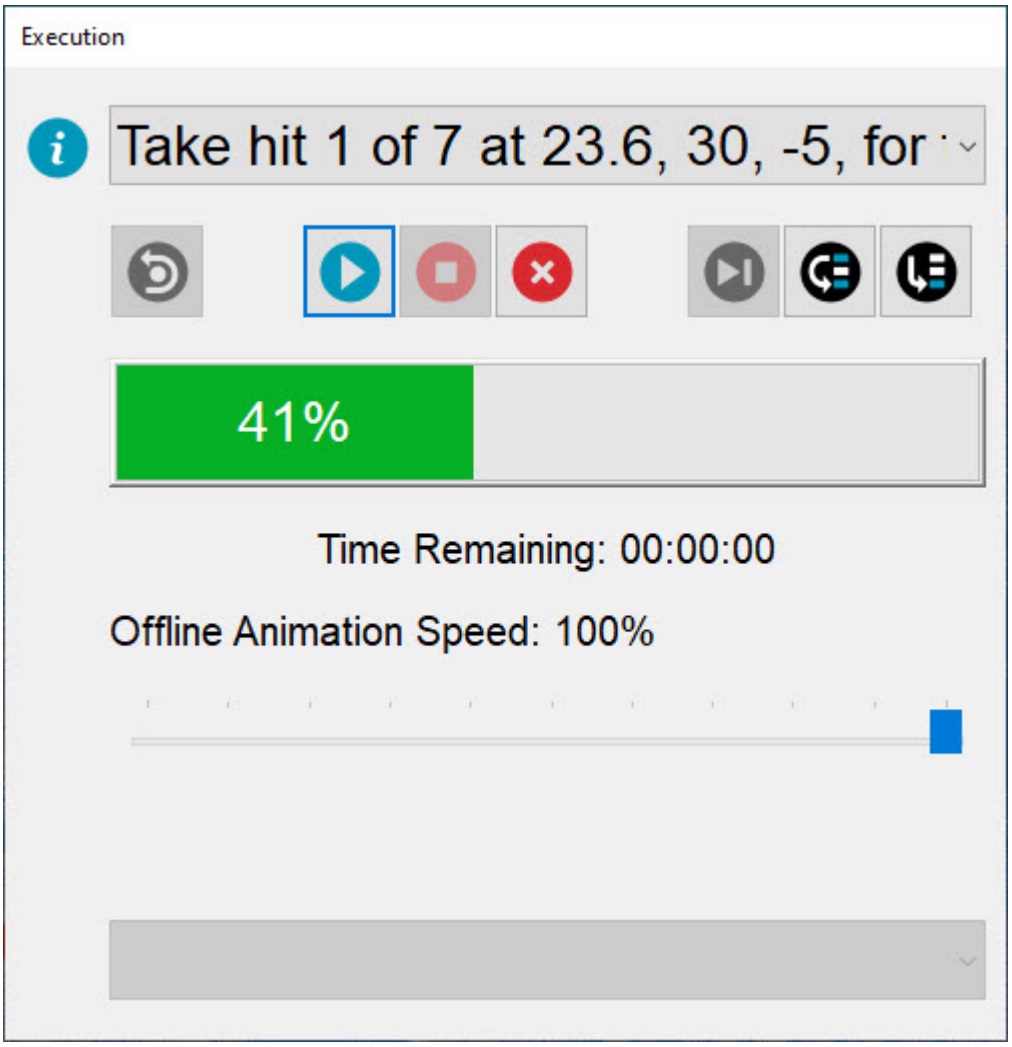
find this useful when you have a large measurement routine and want a general idea of how long it takes to complete.

> This functionality does not factor in individual scan hits or alterations to the number of executed items due to flow control statements.

Machine Errors - Displays any errors that occur during the execution of the measurement routine.

Some possible errors are an unexpected probe hit or an unexpected end of move. You can view the errors by clicking this list.

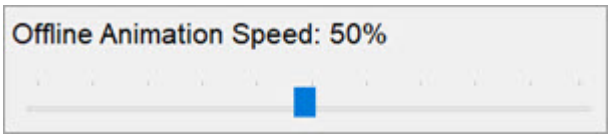
Time Remaining - Displays the execution time (in <hours>:<minutes>:<seconds>) that remains for a measurement routine or mini routine if the **Record and display execution time** check box in the **Execution** area on the **General** tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**) is selected. For example:



Example of the Execution dialog box with remaining time.

If the **Add to execution time (seconds)** check box in the **Execution** area is also selected, PC-DMIS adds the number of seconds that are entered in the box to the measurement routine or mini routine execution time when the execution finishes.

Offline Animation Speed slider - The **Offline Animation Speed** slider is only available when you run your measurement routine in Offline mode. The slider allows you to adjust the speed of the execution of the measurement routine in Offline mode as a percentage of the **Max animation speed** value. The default value is 100%.



The **Offline Animation Speed** slider on the **Execution** dialog box is directly linked to the **Animation speed %** slider option on the **Animation** tab of the **Setup Options** dialog box. The value you set the slider to on the **Execution** dialog box, for example, is also set for the slider on the **Animation** tab of the **Setup Options** dialog box. When you close and then reopen the measurement routine, the slider value in both locations is set back to the default value of 100%.

For details on measurement routine animation setup options, see the "Execution area" section of the "Setup Options: Animation tab" topic in the PC-DMIS Core documentation.

When you execute a measurement routine for dual arms in Offline mode, PC-DMIS shows two **Execution** dialog boxes, each with an **Offline Animation Speed** slider. The sliders are synchronized so, if you adjust one slider, the other slider adjusts to the same percentage value.

Note the following:

- PC-DMIS records the remaining time for only the DCC portion of a measurement routine.
- PC-DMIS stops recording the remaining time when the measurement routine or mini routine pauses due to attention required by the user. For example, the execution may pause when a comment is executed, a message appears, or an error appears, and the execution stops.
- PC-DMIS does not record the remaining time if the execution does not get completed or if it is suspended (see **Stop** above).

Manually Controlling a Feature's Measurement

To manually control the measurement of a feature:

1. From the **Execution** dialog box (**File | Execute**), click **Stop** .

2. From the **Probe Mode** toolbar, click the **Manual Mode** icon . You are given control for measuring the current hit.

Once you finish measuring the current feature in MANUAL mode, PC-DMIS then automatically returns the system to DCC Mode and continues to measure the part under computer control. You can click the **DCC Mode** icon to go back to DCC Mode at any time.

PC-DMIS does *not* replace the original hits with any of the new hits. If a measurement value needs to be altered, it must be done in the Edit window.

At the end of manual measurement of some Auto features, the software may prompt for you to save the new location of the feature as the target for future executions of the measurement routine. If you click **YES** in response to this prompt, the software saves the currently measured position as the new target.

Re-sizing the Execution Dialog Box

You can re-size the **Execution** dialog box (**File | Execute** or **File | Partial Execution**):

1. Place the pointer on the outer edge of the dialog box. The arrow icon for the pointer changes to a double arrow icon.

2. Drag the pointer to the desired location and release the mouse button to resize the dialog box.

You may find this capability useful when you need a larger dialog box in order to read the data better from a distance or if you want to use larger icons.

Setting Your Preferences

Setting Your Preferences: Introduction

PC-DMIS allows you to set personal preferences that tailor the form and function of PC-DMIS to meet individual specifications. Using this chapter, you will be able to control output format, screen graphics, machine parameters, and other options.

The main topics in this chapter include:

- Selecting Setup Options
- Modifying Report and Motion Parameters
- Setting Up the Edit Window
- Setting Up the Probe Readouts Window
- Setting Up Multiple Arms
- Defining the Rotary Table
- Setting Up Probe Changer Options
- Managing Multiple Probe Changers
- Loading the Active Probe
- Examples of Working with Single and Multiple Probe Changers
- Setting Up the Machine Interface
- Compensating for Temperature
- Using Simplified Temperature Compensation
- Temperature Gage
- Editing Part Materials and Coefficients
- Specifying Search Paths
- Changing OpenGL Options
- Using the Measurement Strategy Editor
- Setting Up Sensor Mapping

- Setting Import Options
- Understanding File Locations
- Understanding Data Files
- Defining Default Environment
- PC-DMIS FUSION Settings

The following paragraphs describe the various system options and their functions.

A Note on Storing Settings for Multiple Users

Switching Between Machine Profiles

A Note on Storing Settings for Multiple Users

PC-DMIS now stores all changes made to the software's settings, parameters, or user-interface customizations for each user. This is controlled internally by using Windows user permissions. When you log onto the operating system with your specific user name, the system automatically recalls your settings. The system stores your settings inside named sub directories where you installed PC-DMIS.

Switching Between Machine Profiles

Your license must have the **IP Measure** option for the **Save Machine Profile** and **Recall Machine** menu items to appear.

These two menu items let you easily switch between machine profiles when you create measurement routines in Offline mode.

Edit | Preferences | Save Machine Profile - This menu item displays a **Save As** dialog box that asks for a file name. It records all the current settings for the virtual machine in a file with an "mpl" file name extension. PC-DMIS saves the following into the file for later recall:

- Loaded machine model
- Loaded tool changer model
- Rotary table settings
- Mount orientation for the probe
- Starting default probe component (PH10, CW43, and so on)
- Active probe file

- Any "fixed" quick fixture components
- Machine's speed settings and limits

Edit | Preferences | Recall Machine - This menu item lets you restore a machine's settings that were stored in an .mpl file. PC-DMIS displays an **Open** dialog box. Once you select the file to open, PC-DMIS restores the settings.

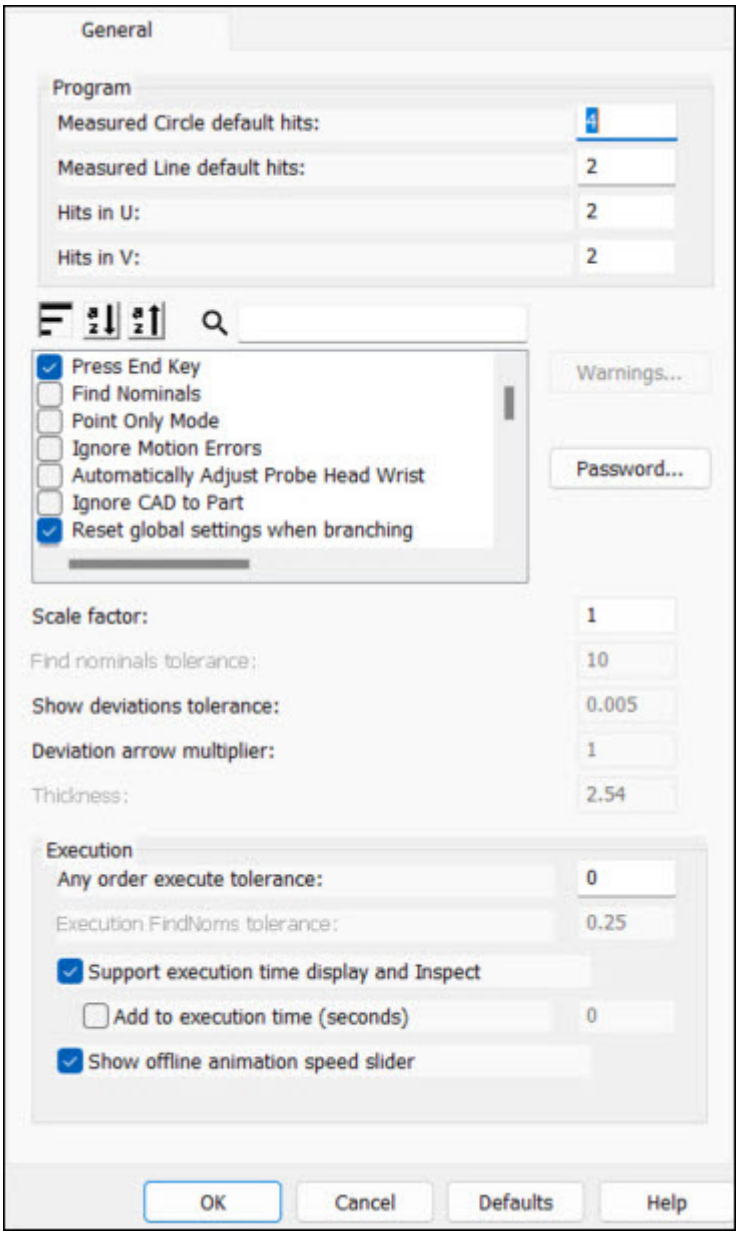
Selecting Setup Options

Selecting the **Edit | Preferences | Setup** menu option accesses the **Setup Options** dialog box. Use the tabs in this dialog box to alter the form and function of PC-DMIS. The tabs include the following:

- Setup Options: General tab
- Setup Options: Part/Machine tab
- Setup Options: Dimension tab
- Setup Options: Geometric Tolerances tab
- Setup Options: ID Setup tab
- Setup Options: Laser Sensor tab
- Setup Options: Sound Events tab
- Setup Options: Animation tab

For information on how the **OK** and **Defaults** buttons work, see the Command Buttons topic in the "Navigating the User Interface" chapter.

Setup Options: General tab



Setup Options Dialog Box - General Tab

To access the **General** tab, open the **Setup Options** dialog box (**Edit | Preferences | Setup**) and select the **General** tab. You can use this tab to change various functions that control the measurement process.

Program Area

The edit boxes in the **Program** area of the **General** tab allow you to edit the following options:

Measured Circle default hits

The **Measured Circle default hits** box allows you to set the default number of hits PC-DMIS takes while learning circles using CAD data. The minimum number of hits that you can type in is three. It only changes the number of hits for circles about to be programmed, not for circles that have already been programmed.

The entry in the PC-DMIS Settings Editor for this option reads: **AutoCirHits= [number of hits]**. For information on modifying entries, please view the "Modifying Setting Entries" chapter.

Measured Line default hits

The **Measured Line default hits** box allows you to set the default number of hits PC-DMIS takes while learning lines using CAD data. The minimum number of hits that you can type in is two. It only changes the number of hits for lines about to be programmed, not for lines that have already been programmed.

The entry in the PC-DMIS Settings Editor for this option reads: **AutoLineHits= [number of hits]**. For information on how to modify entries, please view the "Modifying Setting Entries" chapter.

Hits in U

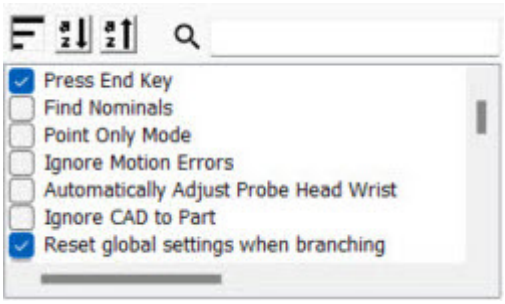
The **Hits in U** box indicates the minimum number of rows that must be taken when scanning.

Hits in V

The **Hits in V** box indicates the minimum number of hits per row that must be taken when scanning.

The **Hits in U** and **Hits in V** scanning options are only active when you use them with the Curves and Surfaces options.

Check Boxes for the General tab



The **General** tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**) lets you turn various options on or off. This allows you to customize the PC-DMIS Setup options to fit your specific needs.

You can use these options to sort or search the list:

Sort Default button - Click this button to display the list in the default order as it appears when you open the dialog box.

Sort A to Z button - Click this button to sort the list in alphabetical order (A - Z).

Sort Z to A button - Click this button to sort the list in reverse alphabetical order (Z - A).

Search box - Type any text in this box to filter the list and display only the options that contain the entered string.

Press End Key

The **Press End Key** check box controls whether or not PC-DMIS waits for you to press the END key before it accepts the last hit taken. Selecting this check box allows you to preview the last hit before you accept it. If you don't select this check box, the current hit that you take with the jog box is not stored in the hit buffer, but automatically becomes the last hit for the feature, even if you take the hit at the wrong spot.

Find Nominals

The **Find Nominals** check box controls how PC-DMIS treats hits. When selected, PC-DMIS will then automatically consider each probe touch, finding the closest CAD nominal for that touch. It continues to accumulate hits until you press the End key. PC-DMIS then calculates the feature type and applies the CAD nominals.

Once selected, the **Find Nominals Tolerance** box becomes available. See "Find Nominals Tolerance".

Point Only Mode

The **Point Only Mode** check box controls how PC-DMIS responds to each probe hit. When selected, PC-DMIS automatically considers each probe hit to be a single point measurement and automatically creates an Auto Vector Point. If the check box is not selected, PC-DMIS will accumulate probe hits until the END key is pressed. Only then will it determine the type of feature just measured.

When you select this check box, the **Thickness for Point only Mode Points** check box becomes available. See "Thickness for Point Only Mode Points".

Edge Point Only Mode

The **Edge Point Only Mode** check box controls how PC-DMIS responds to each set of probe hits. In this case, a set is defined as two singular probe hits. The first hit should always be taken on the surface. The second hit should always be taken on the edge. When you select this check box, PC-DMIS automatically considers each set of probe hits to be a single point measurement and automatically creates an Auto Edge Point. If you do not select the check box, PC-DMIS accumulates probe hits until you press the End key. Only then does PC-DMIS determine the type of feature you measured.

PC-DMIS uses the options as displayed in the **Hits**, **Auto**, and **Misc** areas of the **Edge Point** dialog box when you create an Edge Point (see the "Creating Auto Features" chapter).

PC-DMIS applies the CAD nominals if you marked the **Find Noms** check box option.

Ignore Motion Errors

Select **Insert | Parameter Change | Probe | Ignore Motion Errors** to access the **Ignore Motion Errors** option.

This option does not apply to all machine types. Some machines can utilize this option, while on others it will have no effect. For those machine types where it does have an effect, the exact nature of the effect may also depend on the machine type.

Selecting the **Ignore Motion Errors** check box tells PC-DMIS to try to avoid stopping from a motion error during movement when the ignore request is active. If you select this check box and click **OK**, PC-DMIS inserts an `IGNOREMOTIONERRORS/ON` command into the Edit window.

When PC-DMIS executes the `IGNOREMOTIONERRORS/ON` command, the command enables a state where PC-DMIS will try to avoid stopping due to motion errors, if possible, when it enters DCC motion. The exact manner of implementation may vary by machine type.

On traditional CMMs with contact probes, the most common implementation is through disabling the probe. However, if PC-DMIS disables the probe during a move, normally it does need to re-enable the probe to take a measurement. This may result in a repeating

sequence where PC-DMIS disables the probe for transitional moves between measurements but then re-enables the probe when it actually takes the measurement.

You can use this command to prevent problems from spurious vibration or acceleration-induced triggering, or both.

Automatically Adjust Probe Head Wrist

If you select the **Automatically Adjust Probe Head Wrist** check box, then during execution when the software reaches a TIP command, it will, based on the geometry, automatically select the tip for which the IJK of the tip shank most closely approximates the IJK on the TIP command. The IJK on the TIP command is relative to part coordinates so the tip actually selected can vary based on the part alignment.

WARNING: If you want PC-DMIS to recalculate the wrist angles in the face of a change in the workpiece alignment, you must ensure that the **Automatically Adjust Probe Head Wrist** check box is selected before you execute the measurement routine.

The TIP commands in the measurement routine will be updated with the new angles at each execution.

How it Works with Non-Mapped Wrists

For non-mapped wrists, PC-DMIS returns the closest theoretical position. If there is a calibrated tip that matches this theoretical position, PC-DMIS uses that calibrated tip. If PC-DMIS can find calibrated tips that fall within the angle tolerance defined in the **Wrist warning delta** box on the **Part/Machine** tab, it'll use those tips over non-calibrated tips that have closer angle matches. (For more information about the tab, see "Setup Options: Part/Machine tab").

If PC-DMIS cannot find what it thinks is a theoretical match, it gives the error "Illegal TIP command or TIP not qualified".

If PC-DMIS found a good theoretical match but that tip doesn't exist or isn't yet calibrated, it will wait until the machine catches up to the TIP statement, so that no machine motion is in progress. The software then asks you if it should use the closest calibrated tip.

- If you select **YES**, PC-DMIS uses the calibrated tip.
- If you select **NO**, PC-DMIS adds a tip object to match the best theoretical fit and halts, but does not cancel, the execution. A message appears on the PC-DMIS Status bar to press continue when you're done calibrating the new probe. At this point, you should access the **Probe Utilities** dialog box (**Insert | Hardware Definition | Probe**), perform any calibration work as needed, and then click **Continue**.

If you select the **Automatically Adjust Probe Head Wrist** check box and click the **Mark Used** button in the **Probe Utilities** dialog box, PC-DMIS may not select all the probe tips for calibration. For more information about the **Mark Used** button, see the "Mark Used" topic in the "Defining Hardware" chapter.

How it Works with Mapped Wrists

With an infinite wrist that is actually mapped (and therefore calibrated), PC-DMIS automatically returns the best matching tip position and proceeds using that position.

Other Notes

If you want PC-DMIS to continue to use the original tips during any execution of the measurement routine, then clear the **Automatically Adjust Probe Head Wrist** check box.

Ignore CAD to Part

Each time you create an alignment (saved or otherwise), PC-DMIS creates two transformation matrices:

1. **Machine to part transformation matrix** - Computed from the input features' measured values stored internally in machine coordinates.
2. **CAD to part transformation matrix** - Computed from the input features' theoretical values stored internally in CAD coordinates.

When you don't have available CAD data, theoretical data usually comes from the measured values of the learned features. It is difficult to get consistent results using theoretical values. This can happen when some of these values are edited, while others are not.

If you select the **Ignore CAD to Part** check box when you save an alignment, PC-DMIS ignores the *CAD to part* matrix and instead only saves the *machine to part* alignment. All theoretical values are then in the same coordinate system.

Generally, if you are not using CAD data, select this check box.

Effects on CAD Equals Part

If you want to execute an alignment from features measured without CAD data in DCC Mode, and you use the **CAD Equals Part** menu option (or **CAD = Part** button), be sure to select the **Ignore CAD to Part** check box prior to setting the CAD equal to the part. For information on setting the CAD equal to the part, see the "Equating CAD to Measured Part Data" topic in the "Creating and Using Alignments" chapter.

Theoretical Values for Copied Features

- *If you clear this check box and copy a feature to a new location in the Edit window*, the theoretical values of the feature are associated with the alignment at the feature's original location.
- *If you select this check box and copy a feature to a new location in the Edit window*, the theoretical values of the feature are associated with the alignment at the feature's new location.

See "Changing Alignment Nominal Values" in the "Creating and Using Alignments" chapter.

Reset global settings when branching

If you select the **Reset global settings when branching** check box, PC-DMIS resets the global values for state commands after encountering a branching statement. See the list of affected commands below. (For information on branching, see the "Branching by Using Flow Control" chapter.) PC-DMIS does not execute any state commands jumped over because of a branching statement. This allows you to skip over sections of the measurement routine without having these settings change.

For example, suppose your measurement routine has the following:

```
TIP /T1A0B0

MYLABEL=LABEL/
```

Measurements etc...

```
TIP/T1A90B90

GOTO/MYLABEL
```

If you mark the check box, when PC-DMIS reads the `GOTO` statement, it jumps to `MYLABEL`. It then searches up, using the first encountered `TIP/` command: `TIP/T1A0B0`

When returning from subroutines, any global setting modified by the subroutine is not affected by the **Reset global settings when branching** flag. See "Pass Back Settings from Subroutine" for more information.

If you clear the check box, when PC-DMIS reads the `GOTO` statement, it jumps to `MYLABEL`. PC-DMIS does not reset global settings when encountering a branching statement. Instead, it uses the last executed `TIP/` command: `TIP/T1A90B90`

PC-DMIS defaults to marking the check box.

Commands Reset After Branching:

- Start/align
- Recall/align
- Mode/
- Rmeas /
- Workplane/
- Tip/
- Loadprobe/
- Retract/
- Check/
- Touchspeed/
- Movespeed/
- Polarvectorcomp/
- AutoTrigger/
- Triggerplane/
- TriggerTolerance/
- Videosetup/
- Displayprecision/
- ManRetract/
- Scanspeed/
- Prehit/
- Clamp/
- Clearp /
- Format/
- 132column/
- Gaponly/
- Retrolinearonly/

- Probecom/
- Array_indices/
- Fly/
- Positivereporting/
- Ignoremotionerrors/

Move Feature to Reference Plane

If you select the **Move Feature to Reference Plane** check box, PC-DMIS automatically projects the measured feature to the workplane. In general, this works for any of the following feature types as long as they use the best fit functionality internally:

- Circles
- Ellipses
- Lines
- Polygons
- Slots

For a detailed explanation on reference types, see the description of "Reference Feature area" in the "Using the Quick Start Dialog Box" topic in the "Using Other Windows, Editors, and Tools" chapter.

Show Extended Sheet Metal Options

If you select the **Show Extended Sheet Metal Options** check box, PC-DMIS displays all of the available Sheet Metal options in the **Auto Features** dialog box. (See the various extended sheet metal topics in the "Creating Auto Features" chapter.)

For this option, the `ShowExtendedSheetMetal` entry in the PC-DMIS Settings Editor reads 0 or 1. For information on modifying entries, see the "Modifying Setting Entries" appendix.

Fixed Dialog Positions

If you select the **Fixed Dialog Positions** check box, PC-DMIS displays dialog boxes in their default positions. If this check box is cleared, PC-DMIS displays each dialog box where it was last positioned.

The `DialogFixedPosition` entry in the PC-DMIS Settings Editor for this option is set to 0 or 1. For information on modifying entries, see the "Modifying Setting Entries" appendix.

Lock Marked Sets

If you select the **Lock Marked Sets** check box, PC-DMIS will prevent users from accidentally deleting or otherwise modifying the current mark set configurations. PC-DMIS will only allow you to execute and activate marked sets. You must clear this check box to add or delete features from a marked set.

Automatically Scale to Fit

If you select the **Automatically Scale to Fit** check box, PC-DMIS automatically scales the screen every time you measure a feature.

For this option, the `AutoScaleToFit` entry reads 0 or 1 in the PC-DMIS Settings Editor. For information on how to modify entries, see the "Modifying Setting Entries" chapter.

Show Hit Deviations

If you select the **Show Hit Deviations** check box, PC-DMIS will draw an arrow whenever a hit is taken to show the measured value minus the nominal deviation.

Use Circular Moves on Round Features

If you select the **Use Circular Moves on Round Features** check box, and if you are "learning" a measurement routine by taking hits on the part, PC-DMIS automatically places circular move commands into the inside circular features as well as into the outside of circular features. This includes Circles, Cylinders, Cones, and Spheres. This state, however, is only relevant in Learn mode. Once the circular or move commands are present inside features, they remain there unless directly removed by the user.

The `UseCircularMoves` entry in the PC-DMIS Settings Editor for this option is set to either 0 or 1. For information on modifying entries, please view the "Modifying Setting Entries" chapter.

Thickness for Point Only Mode Points

When you select this check box, you can apply thickness to points created with Point Only Mode. Selecting this check box makes the **Thickness** box in this same dialog box available for editing. You can then type a thickness and apply that thickness to points created using Point Only Mode.

For additional information, see "Point Only Mode" and "Thickness".

Allow fine tuning of Alignment

Whenever you change an alignment, PC-DMIS asks if it should update the commands below with the changed alignment. If you have this check box selected, and you click the **NO** button at this prompt, PC-DMIS changes the MACHINETOPART transformation if required. If deselected, the MACHINETOPART transformation does not change.

Use CAD Provided IDs for Features

The **Use CAD Provided IDs for Features** check box allows you to import feature IDs from a CAD file. When you select this check box, PC-DMIS automatically inputs the given CAD ID into the **Auto Feature** dialog box when the CAD feature is selected with a left mouse click. If you decide to keep this value, then the feature created will have the given ID.

Find Nominals During Execution

If you select the **Find Nominals during Execution** check box, new nominals are found for both Surface and Vector points during measurement routine execution. See "Execution FindNoms Tolerance" to define the tolerance values PC-DMIS will use. Also, see "Find Nominals Tolerance".

Auto Continue Execution if FindHole Fails

If you select the **Auto Continue Execution if FindHole Fails** check box, PC-DMIS allows you to automatically continue executing a part if the **Find Hole** option found on the **Auto Feature** dialog box fails to find a hole.

In the past, when the **Find Hole** option failed, PC-DMIS prompted you to place the probe in the center of the hole to continue running the measurement routine. However, with the **Auto Continue Execution if FindHole Fails** check box selected, PC-DMIS automatically prints an error message to the report and continues running the remaining measurement routine.

For more specific information on Find Hole, see the "Working with Contact Find Hole Properties" topic in the "PC-DMIS CMM" documentation.

Show Startup Dialog

The **Show Startup Dialog** check box allows you to determine whether or not PC-DMIS shows the **Open File** dialog box each time you start PC-DMIS. This dialog box shows a listing of available measurement routines to open.

When you clear the check box, PC-DMIS will disable this startup dialog.

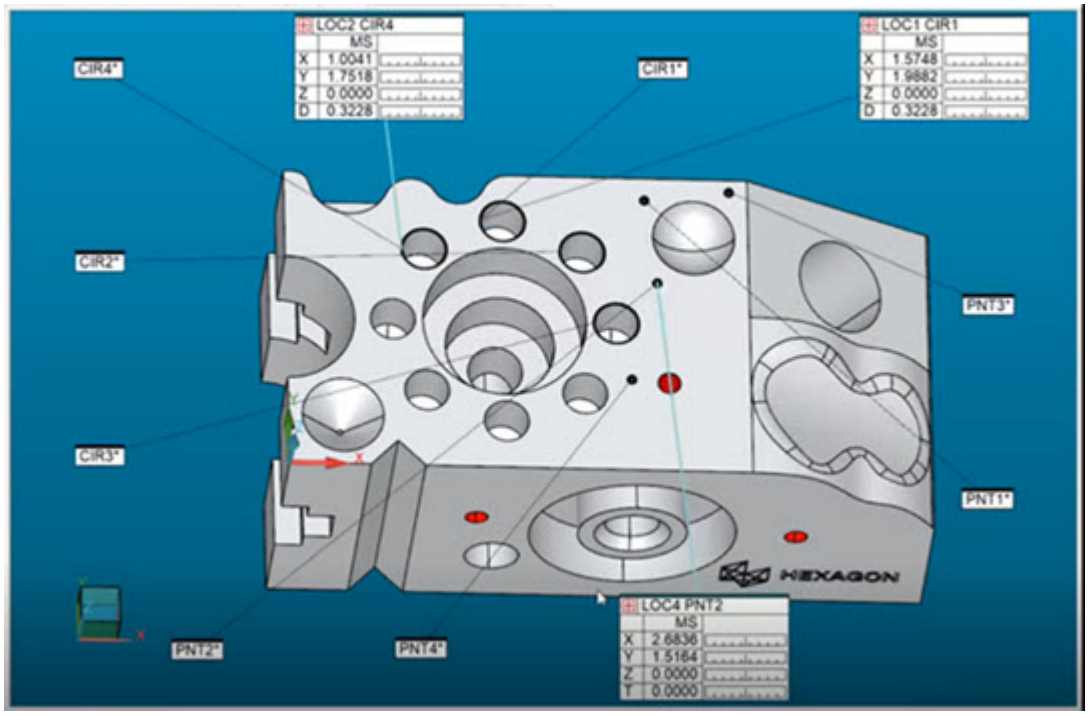
See "Opening Existing Measurement Routines" in the "Using Basic File Options" chapter for additional information on the **Open File** dialog box.

Automatic Label Positioning

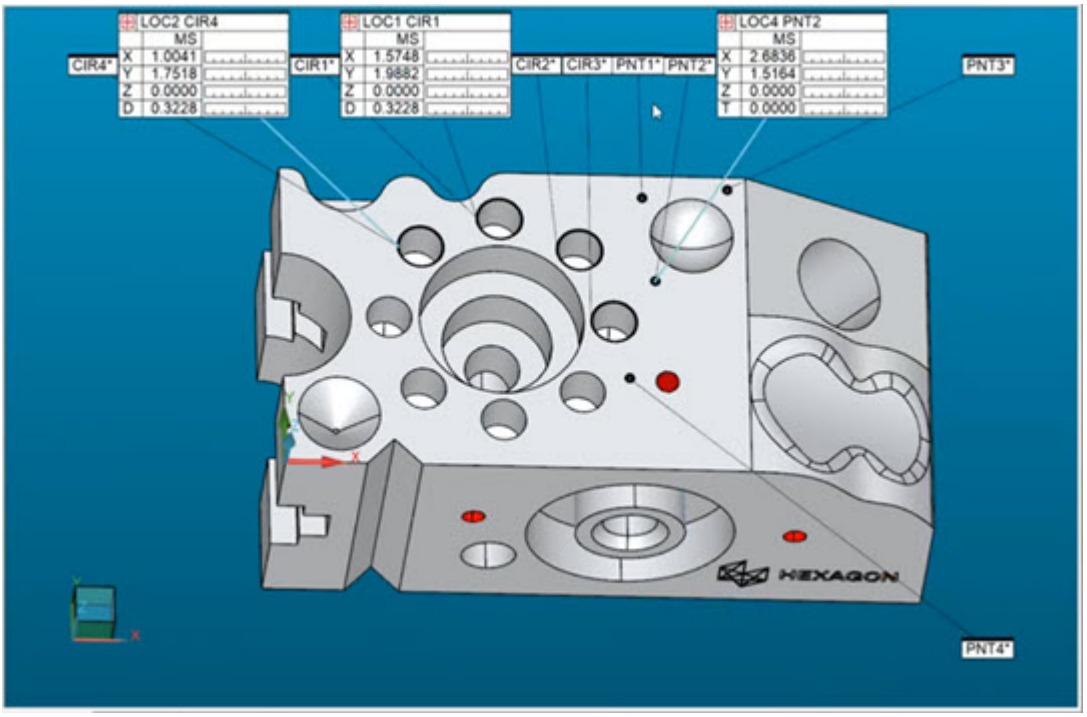
The **Automatic label positioning** check box allows PC-DMIS to automatically position the feature labels. When you select this check box, PC-DMIS repositions the feature ID labels whenever you pan, zoom, or rotate the part model.

You can also enable Automatic Label Positioning from the Graphic Display window. Right-click a feature ID label and select **Automatic Label Positioning**, and then choose one of the following options:

- **Spread-out** - When you select this option, PC-DMIS positions the labels around the Graphic Display window.



- **Near to Edge** - When you select this option, PC-DMIS positions the labels close to the nearest edge of the Graphic Display window.



Animate Probe during Program Mode

The **Animate probe during Program Mode** check box activates probe animation during Program Mode. When you select this check box, the probe will animate the taking of hits in the Graphic Display window as the hits are generated from CAD.

Show Icon in Text Boxes

The **Show icon in text boxes** check box allows you to determine if icons depicting the feature or dimension type should appear in text boxes and inside feature ID labels. The text boxes include feature ID, dimension info, and point info text boxes.

For information on text boxes see "Text Box Mode" in the "Editing the CAD Display" chapter.

Save Measurement Routine on Execute

The **Save Measurement Routine on Execute** check box tells PC-DMIS to automatically save the current measurement routine whenever it's executed.

Use DMIS Button in Edit Window

The **Use DMIS Button in Edit Window** check box determines whether or not PC-DMIS displays the **DMIS Mode** icon on the **Edit Window** toolbar.

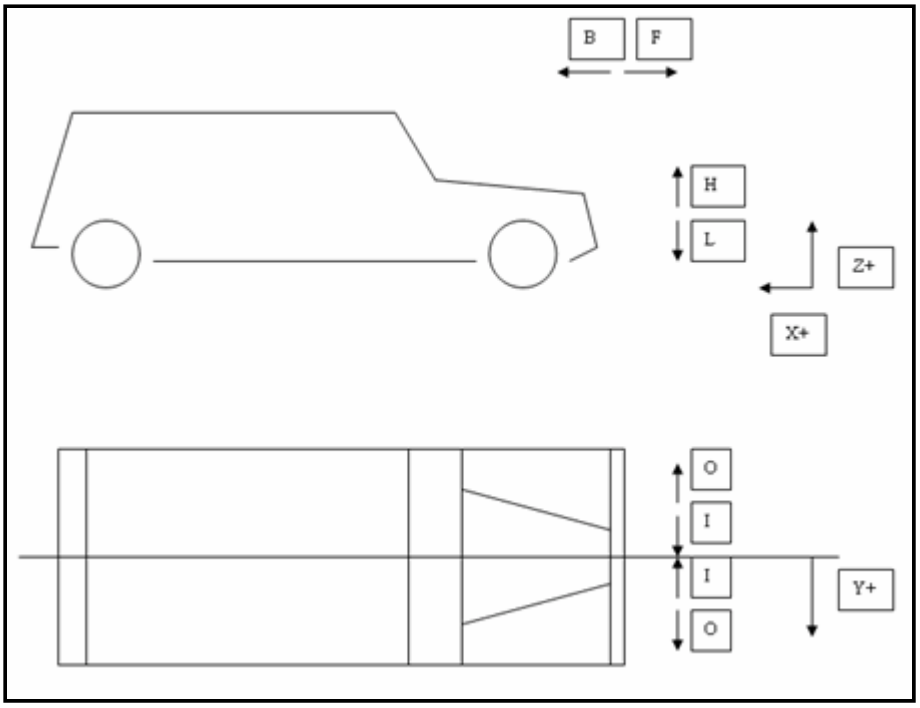
Patch Scans Maintain Last Increment

The **Patch Scans Maintain Last Increment** check box forces each new line of the patch scan to use the last increment from the previous line. If you deselect this check box, the scan will revert to the minimum scan increment when taking the first hit on each line.

Use Automotive Deviation Letters

The **Use Automotive Deviation Letters** check box causes PC-DMIS to add a letter after the deviation number in Location and Position dimension reports. PC-DMIS inserts the letter

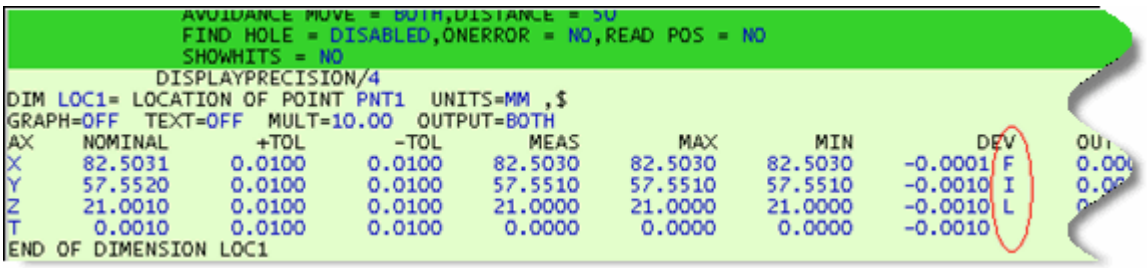
- **F** when the feature deviates in the direction of the front of the car.
- **B** when the feature deviates in the direction of the back of the car.
- **I** when the feature deviates towards the centerline of the car (meaning the car is too narrow).
- **O** when the feature deviates away from the centerline of the car (meaning the car is too wide).
- **H** when the feature deviates towards the top of the car.
- **L** when the feature deviates towards the bottom of the car.



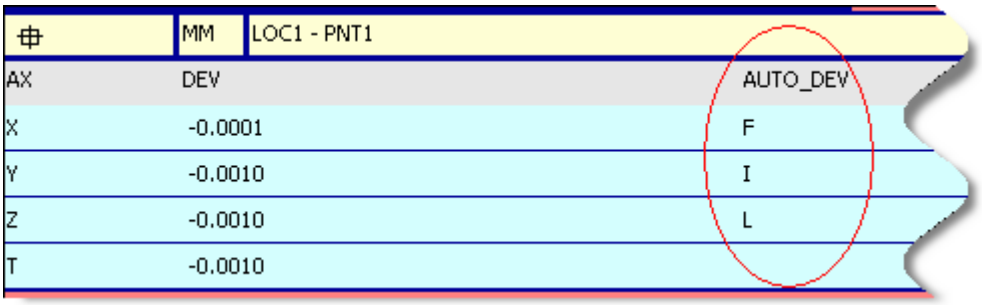
Map of Automotive Deviation Letters

These letters are added to the Location and Position dimensions just following the deviation numbers reported. These deviation letters also appear inside the Report window for the appropriate dimensions.

Automotive Deviation Letters in Command Mode



Automotive Deviation Letters in Report Window



Use Find Nominals Override for Scans

The **Use Find Nominals Override for Scans** check box allows you to override found nominals when searching for nominal values for a scan's measured points when it executes.

> The execution must fail to find at least one of the measured nominal point values for you to override the found nominals.

See "Overriding Found Nominals" in the "Editing a Measurement Routine" chapter.

Use ONLY Priority Surfaces for the Find Nominals During Scans

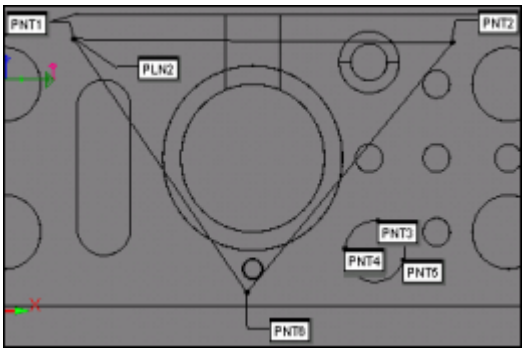
The **Use ONLY Priority Surfaces for the Find Nominals During Scans** check box causes PC-DMIS (during measurement routine execution) to search for nominal values for a scan's measured points on only the priority surfaces set in the **Edit CAD Elements** dialog box.

See "Editing CAD" in the "Editing the CAD Display" chapter.

Display Outline of Plane

The **Display Outline of Plane** check box determines whether or not PC-DMIS, when it creates new measured or constructed plane features, displays actual plane outlines in the Graphic Display window instead of the small symbolic triangle symbol typically used.

For example, if you select this check box and measure three points to construct a plane, the symbolic triangle for the plane is sized so that its vertices are exactly where the measured points are.



Example showing a constructed plane feature when you select the check box.

Whether you select or clear this check box, *existing* outlines aren't redrawn; this only affects planes created from that point. To change existing outlines, you have to do it manually.

To switch the display of existing planes:

1. Access the Edit window.
2. Place it in Command Mode.
3. Go to the command for the plane's display that you want to change. For example:

   ```
   PLN1 = FEAT/PLANE,RECT,TRIANGLE
   ```

4. Press the Tab key until you highlight the `TRIANGLE` or `OUTLINE` field.
5. Press F7 or F8 to switch between the available values for this field.
   - `TRIANGLE` displays the plane as a triangle.
   - `OUTLINE` displays the plane as an actual outline of the points that make up the plane.
   - `NONE` hides that specific drawing of the plane.

   See "Using the Display Area" under the "Constructing a Plane Feature" topic for an example of these display types.
6. Press the Tab key to see the result in the Graphic Display window.

You can also right-click and choose **Edit** to open the plane's dialog box to make the change.

This setting corresponds with the `DisplayOutlineOfPlane` entry in the **Option** section of the PC-DMIS Settings Editor.

Treat Theo Values As if Stored in Part Coordinates

The **Treat theo values as if stored in part coordinates** check box causes PC-DMIS to treat theoretical values as if they're stored in part coordinates. This check box was added for cases where measurement routines perform loops and the alignments are changing within the looping code.

The offset parameters of the LOOP/START command take care of this issue automatically. This is for looping measurement routines that don't use the LOOP/START and LOOP/END commands, such as a WHILE - END/WHILE loop.

Consider this sample pseudo measurement routine:

```
ASSIGN/COUNT=4
ASSIGN/I=1
WHILE/I<4
   LOOPALIGN=START/ALIGN
      ALIGN/TRANSLATION OFFSET,X,50
      END/ALIGN
   MYCIRCLE=MEAS/CIRCLE
      THEO/0,0,0
ASSIGN/I=I+1
END_WHILE/
```

You would expect that each time through the loop the X value would shift by 50 since the alignment is shifting by 50 each time. However, since PC-DMIS doesn't store feature data in part coordinates but in CAD and Machine coordinates, the effect is that the feature doesn't actually move in this situation even though the alignment is changing each time through the loop. This is because the CADTOPART and PARTTOMACHINE transform matrices of the alignment are both altered in the same way, the net effect is that the CADTOMACHINE transform remains unchanged. This means, by default (when this check box is not selected), PC-DMIS ends up measuring in the same spot all four times through the loop.

If PC-DMIS stored coordinates in part coordinates internally, then this would work as expected. This is where this check box comes into play. When you select this check box, PC-DMIS keeps track of the alignment that was used during the initial measurement. On subsequent measurements of a feature, it checks to see if the current alignment differs from the alignment used on the first pass. If it does, then PC-DMIS calculates the differences and shifts the feature by that difference, causing this to function as expected.

Rather than changing how PC-DMIS does things internally, this functionality was provided as a check box to preserve existing measurement routines.

Update Theoretical Values in While Loops

When you use a while loop to measure features multiple times in your measurement routine, during the execution, the software creates multiple copies of those features. The **Update theoretical values in while loops** check box updates the theoretical values for the copied features, so that even if the CAD to part coordinate system changes during execution, the features' CAD values are modified so that they are in the original part coordinate frame used before execution.

Make Variables Globally Visible

Usually, when a subroutine is called, all variables go "out of scope" and are unavailable. The **Make Variables Globally Visible** check box makes any variable globally "visible", or usable, throughout the entire measurement routine.

By default, this check box isn't selected. This means variables in a subroutine won't replace data stored in variables with the same name in the main measurement routine.

```
>ASSIGN/V1=1
>C1=CALLSUB,MYSUB
>.
>.
>.
>SUBROUTINE/MYSUB
>COMMENT/OPER,V1
>END/SUB
```

- If you clear this check box, variables are not globally visible. In the example above, with this check box cleared, the OPER comment shows a value of 0. This is because V1 cannot be seen from inside the subroutine.
- If you select this check box, variables are globally visible. In the example above, with this check box marked, the OPER comment shows a value of 1. This is because V1 can be seen from inside the subroutine.

For information on variables, see the "Using Expressions and Variables" chapter.

Use DMIS Polar Convention

With this option selected, polar angles will follow standard DMIS Polar Convention.

- XY Plane (PLUS Z or MINUS Z) coordinate 'a' is the angle from the x-axis towards the y-axis.

- YZ Plane (PLUS X or MINUS X) coordinate 'a' is the angle from the y-axis towards the z-axis.
- ZX Plane (PLUS Y or MINUS Y) coordinate 'a' is the angle from the z-axis towards the x-axis.

Pass Back Settings from Subroutine

This check box determines whether or not global settings applied within a subroutine are changed permanently for the remainder of the measurement routine when the execution flow returns out of the subroutine.

- If you select this check box, any global settings within the subroutine are "passed back" and used for the remainder of the measurement routine.
- If you clear this check box, any global settings within the subroutine only apply while within that subroutine. When the execution flow returns out of the subroutine, the previous settings are restored.

For example, suppose you have a `SCANSPEED/10` statement before your subroutine and a `SCANSPEED/5` statement somewhere within your subroutine. If you select this check box, when the execution flow leaves the subroutine, the scan speed of 5 is passed back and used for the remainder of the measurement routine. If you don't select this check box, the scan speed will automatically return to its original value of 10 after the execution flow leaves the subroutine.

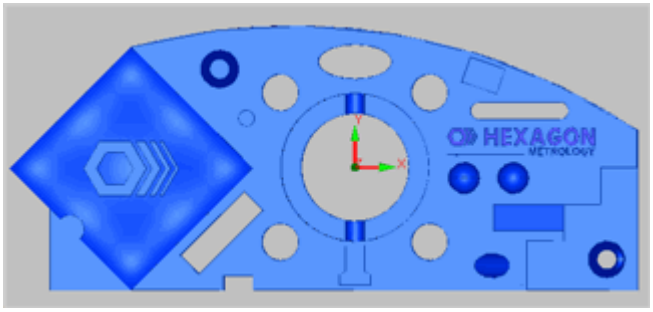
Use Program Layout for Execution

Selecting this check box lets you use the same window layouts at execution time as you have for program time.

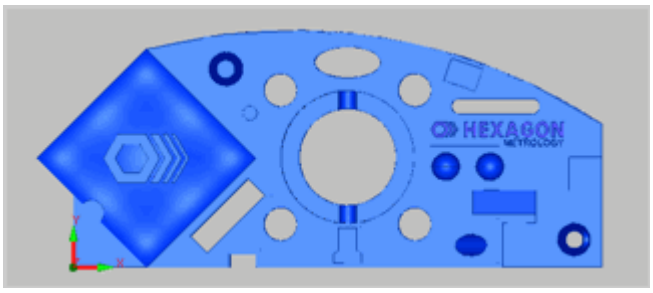
Force Part Alignment in Car Body

The **Force Part Alignment in Car Body** check box forces your alignment to be in car body alignment. If you select this check box, no matter what alignment method you choose, the alignment will always match that of the CAD. Selecting this check box acts as a secondary transformation after the initial alignment.

For example, if you translate to the center hole on the Hexagon test block and select this check box, the origin will still be in the corner, but when you report on that hole, it will be perfect since you used it to set your origin.



Example showing the alignment before using the check box.



Example showing the alignment after using this check box.

Keep Existing Dimension's Axes

The **Keep Existing Dimension's Axes** check box keeps existing axes for dimensioned features from getting updated even if you switch a dimensioned feature to a different feature type. If you don't select this check box, the related dimension axes will update according to the selected feature.

By default, this is not selected.

Select Alignment to Export

This check box determines whether PC-DMIS displays a dialog box to select the alignment to export as a .gds file.

> If you select this check box, PC-DMIS lets you choose an alignment to export to a .gds file.
>
> If you don't select this check box, PC-DMIS exports the last used alignment automatically.

For more information on how to export to a .gds file, see the "Exporting to a Gds File" topic in "Using Advanced File Options".

Gap Only

This check box sets the default value for the **Gap Only** check box used in new Location dimensions for the current measurement routine.

- If you select **Gap Only** then, when the measurement routine next starts, the `GAPONLY/ON` command gets added into the Edit window. In addition, the **Feature Location** dialog box (**Insert | Dimensions | Location**) for Location dimensions automatically has its **Gap Only** check box selected by default whenever you create a new Location dimension.
- If you deselect **Gap Only** then the **Feature Location** dialog box has its **Gap Only** check box also deselected whenever you create a new Location dimension.

Show tracker parameters in offline

If you use a portable Leica Tracker device in Online mode to generate feature commands, PC-DMIS automatically inserts the following information into the Edit window inside those feature commands:

- **RMS** - Root Mean Squared value of each hit.
- **Probe Type** - The type of probe you use to measure the feature.
- **Time Stamp** - The time that PC-DMIS executed or learned the feature. PC-DMIS only updates this time stamp when it actually measures a feature in Online mode.
- **Environmental Conditions** - Information such as temperature, pressure, and humidity.

In Offline mode, PC-DMIS behaves differently. These Leica Tracker items only appear after you select the **Show tracker parameters in offline** check box, and they only appear for new feature commands inserted into the measurement routine after you selected this option. Previously-measured features remain unaffected except for a permanent structure change that added an empty Tracker Parameter group into each feature command.

If you select this check box, PC-DMIS permanently changes your measurement-routine structure for inserted feature commands regardless of whether or not you later clear this check box. For example, if you clear this check box after you've already used it for some features, newly-inserted features still contain a Tracker Parameter group, although that group does not contain any group items.

For information on where and how these items appear in the feature commands, see the PC-DMIS Portable documentation.

Update Report During Execution

This determines whether PC-DMIS creates the report in the Report window during measurement routine execution.

- When marked, the Report window sends update requests during execution, and PC-DMIS generates the report as the execution progresses.

- When cleared, the Report window does not send update requests during or at the end of execution unless you do any of the following:
  - From the Report window's toolbar, click **Redraw the report**. This generates the report in the Report window with the latest data.
  - Choose **File |Printing| Report Window Print**. This generates a report if you configured a file or printer output.
  - Insert a `PRINT/REPORT` command. This generates a report at the time it executes the command if you configured a file or printer output.

Update Summary Mode During Execution

This determines whether or not the Summary Mode should be updated during execution or after execution has been completed. When disabled, the Edit window's Summary Mode will not send requests to be updated during execution.

If marked, information that is typically updated during execution are measured values, deviations, out of tolerance and so forth on dimensions.

Clearing this check box may help speed up report generation.

Suppress Vision Load Probe Dialogs

This setting is only used with optical machines. See the "Available Vision Setup Options" topic in the "PC-DMIS Vision" documentation.

Focus Along Camera Vector

This setting is only used with optical machines. See the "Available Vision Setup Options" topic in the "PC-DMIS Vision" documentation.

Auto Edge Strength

This setting is only used with optical machines. See the "Available Vision Setup Options" topic in the "PC-DMIS Vision" documentation.

Clear Input on Execution

When checked, every time the measurement routine is executed, any input field that is displayed will be empty. If this feature is not checked, any input field that is displayed will display the contents from the previous input.

Do Not Display Plane

When you add measured or constructed plane features, PC-DMIS has the option of displaying a shaded plane as either an outline of the hits comprising the plane or as a triangle. You can mark this check box to hide the drawn shaded plane at creation so that it doesn't clutter up the Graphic Display window. This only hides the drawn plane; PC-DMIS still creates the actual plane feature. This setting corresponds with the `DoNotDisplayPlane` entry in the **Option** section of the PC-DMIS Settings Editor.

Print Background Colors

This **Print Background Colors** check box determines the default state of the **Print background colors** check box in the **Output Configuration** dialog box. See "Output to the Default Printer" for additional information. This setting corresponds to the `PrintBackgroundColors` entry in the **Printing** section of the PC-DMIS Settings Editor.

Use Legacy Profile 2D

Selecting this option toggles between the legacy version of Profile 2D (selected) and the latest version of Profile 2D (de-selected).

The legacy Profile 2D has the options of **Matching Edge and Under Scan** which are no longer available in the latest version of Profile 2D.

For more information on using the Legacy Profile 2D functionality, see the vision topic "**Vision Profile 2D**".

Move to focus position

This check box controls the stage motion at the end of a focus measurement.

- If this check box is selected, the machine will move back to the focus position at the end of the focus scanning motion.
- If this check box is cleared, the machine will not move to the focus position if there is a move or measurement following the focus measurement. Instead, it will move from the top of the focus scan directly to the next machine position.

ClearanceCube uses Tip Vector for Start/End Face

If this check box is selected, new features inserted into the measurement routine will use the probe tip's vector as the default ClearanceCube start face and end face. Otherwise, the ClearanceCube start face or end face is determined by the feature's vector.

Start Points Always Track Execution

The **Start Points Always Track Execution** check box enables start points to always track the execution of a measurement routine. Specifically, it determines if you created the start point or if PC-DMIS created it because the **Cancel** button in the **Execution** dialog box was selected.

If the check box is selected:

- If you select **Cancel** to stop the execution, PC-DMIS adjusts the insertion point in the Edit window to be at the lowest arm number start point that it inserted.
- If you do not select **Cancel**, and the execution successfully completed, PC-DMIS checks the start points. If PC-DMIS inserted them because **Cancel** was previously selected, PC-DMIS clears them. In this case, it restores the insertion point back to where it started from before you executed the measurement routine.
- If you select **Cancel**, PC-DMIS inserts the start point.

If the check box is cleared:

- If you select **Cancel** to stop the execution, and PC-DMIS inserted the start points, PC-DMIS adjusts the insertion point to be at the lowest arm number start point that it inserted.
- If you do not select **Cancel**, and the execution successfully completed, PC-DMIS checks the start points. If PC-DMIS inserted them because **Cancel** was previously selected, it clears them. In this case, the insertion point is restored back to where it started from before you executed the measurement routine.
- If you select **Cancel**, PC-DMIS inserts the start point if there are no start points on an arm, or if it inserted them because **Cancel** was previously selected. If you inserted the start point, PC-DMIS does not adjust it.

For more information about start points, see "Setting Start Points".

Use Scanning Strategies for QuickAlign

The **Use Scanning Strategies for QuickAlign** check box determines whether or not the DCC Mode features during a QuickAlign operation are created using the scanning strategy that is defined in the .ipd (inspection plan defaults) file. However, if you modify that Auto feature type and choose a new strategy prior to generating the alignment, it remembers and uses the newer strategy and no longer uses the defaults in the .ipd file.

The scanning strategies are used for a QuickAlign operation, if the following conditions are true:

- This check box is marked.

- The features in the manual alignment are Auto features.
- The probe type is a scanning probe.

If this check box is unmarked, PC-DMIS uses the default touch trigger strategy.

For information on strategies, see "Working with Measurement Strategies" in the PC-DMIS CMM documentation.

For information on QuickAlign, see "About QuickAlign" in the "Creating and Using Alignments" chapter.

Open report file when generated

The **Open report file when generated** check box determines whether or not any generated .pdf, .rtf, or xls report files are opened once the measurement routine finishes executing. If marked, PC-DMIS marks the **Show Report** check boxes on both the **Report** and **Excel** tabs of the **Output Configuration** dialog box. For more information on the **Output Configuration** dialog box, see the "Printing the Report Window" topic and its sub topics.

Send skipped items to statistics

The **Send skipped items to statistics** check box determines whether or not features that are skipped during execution are sent to any defined statistics database or output files. By default, this is marked and the software sends the skipped features to the database and output files.

Looped Analysis Commands use same CAD Alignment

You may have one or more `ANALYSISVIEW` commands inside of a `LOOP/START` and `LOOP/END` command block. This check box determines if those `ANALYSISVIEW` commands all use the same alignment.

If marked, the commands use the same alignment.

If cleared, the commands may use different alignments based on your measurement routine.

Suppose your measurement routine has this sequence of commands:

```
A1 ALIGNMENT

CIR1

CIR2

CIR3

DIM1

DIM2

DIM3

LOOP/START 1 to 3

    A2 ALIGNMENT

    ANALYSISVIEW, DIM1, DIM2, DIM3

LOOP/END
```

Suppose the loop runs three times. Also, suppose that with each loop, A2 changes the origin to reference a different circle. So that:

- Loop #1 - A2 uses CIR1
- Loop #2 - A2 uses CIR2
- Loop #3 - A2 uses CIR3

If you mark this check box, the `ANALYSISVIEW` command uses the alignment that points to CIR1. It does this for all three iterations.

If you clear this check box, the `ANALYSISVIEW` command uses the three different alignments.

Auto Insert Temperature Compensation in New Routine

You can choose to either automatically insert the `TEMPCOMP` temperature compensation command into a measurement routine or not insert it. For details, see "Automatic Insertion of Temperature Compensation Command".

Use Characteristic ID Naming

This check box determines how PC-DMIS names features that you import from embedded CAD GD&T callouts (PMI).

- If you mark this check box, PC-DMIS uses the characteristic IDs from the native CAD model for the feature naming. PC-DMIS also assigns the characteristic IDs to features and dimensions during the OCR feature creation workflow.
- If you clear this check box, PC-DMIS uses its default feature naming.

For information on importing CAD GD&T callouts, see "Importing CAD GD&T Callouts" under "Working with CAD GD&T Callouts" in the "Editing the CAD Display" chapter.

Don't confuse this characteristic ID naming with characteristic IDs used by **Show Characteristic IDs** on the **Graphic Items** toolbar. The IDs from the toolbar come from an entirely different source. For information on the **Graphic Items** toolbar, see "Graphic Items Toolbar" in the "Using Toolbars" chapter.

Use Measurement Strategy Widget

This check box determines whether the measurement strategy widget appears when you create a QuickFeature or a feature for a GD&T callout. By default, PC-DMIS marks this check box for CMM configurations. For portable configurations, PC-DMIS clears this check box.

- If you mark this check box, the widget always appears when you click on the feature.
- If you clear this check box, the widget does not appear when you click on the feature. PC-DMIS still creates the feature, but it does not show the widget.

For more information on this measurement strategy widget, see "Using the Measurement Strategy Widget" in the "Creating Auto Features" chapter.

Use Measurement Strategy Editor

This check box determines whether to enable or disable the Measurement Strategy Editor (MSE) application. By default, PC-DMIS marks this check box for CMM configurations. For portable configurations, PC-DMIS clears this check box.

- If you mark this check box, the MSE appears when you select the **Edit | Preferences | Measurement Strategy Editor** menu.
- If you clear this check box, the **Edit | Preferences | Measurement Strategy Editor** menu turns gray and you can no longer select it.

For more information on the Measurement Strategy Editor, see "Using the Measurement Strategy Editor" in this chapter.

Show Home Page

This check box determines whether to show the Home page if you don't load any measurement routines. If you clear this check box, the Home page does not appear, and it shows the gray screen from versions before 2019 R2.

For more information on the Home page, see "The Home Page" in the "Navigating the User Interface" chapter.

Show Peek Window

This check box determines whether to enable or disable the Peek window. The Peek window is enabled by default.

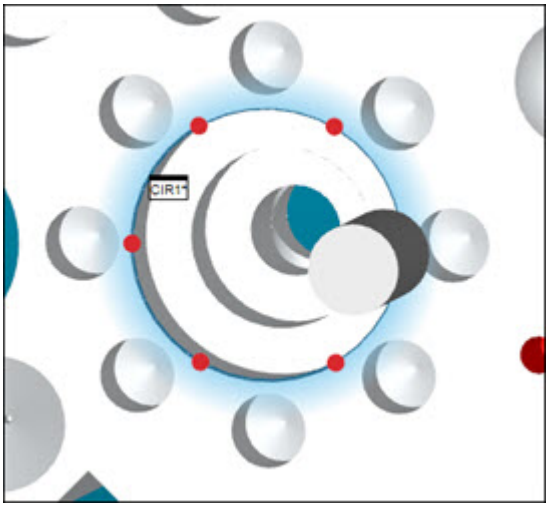
- If you mark this check box, the Peek window displays a command's information when you point to the command in the Edit window in Summary Mode.
- If you clear this check box, the Peek window does not display a command's information when you point to the command in the Edit window in Summary Mode.

For more information on the Peek window, see "Using the Peek Window" in the "Using the Edit Window" chapter.

Auto Scale manual feature during execution

This check box determines whether PC-DMIS automatically rotates the view of the part and zooms to manual features in the Graphic Display window during execution. The rotation is slightly isometric. This option essentially provides a visual guide of what feature you need to measure next with your device. This only works for features that follow a `MODE/MANUAL` command.

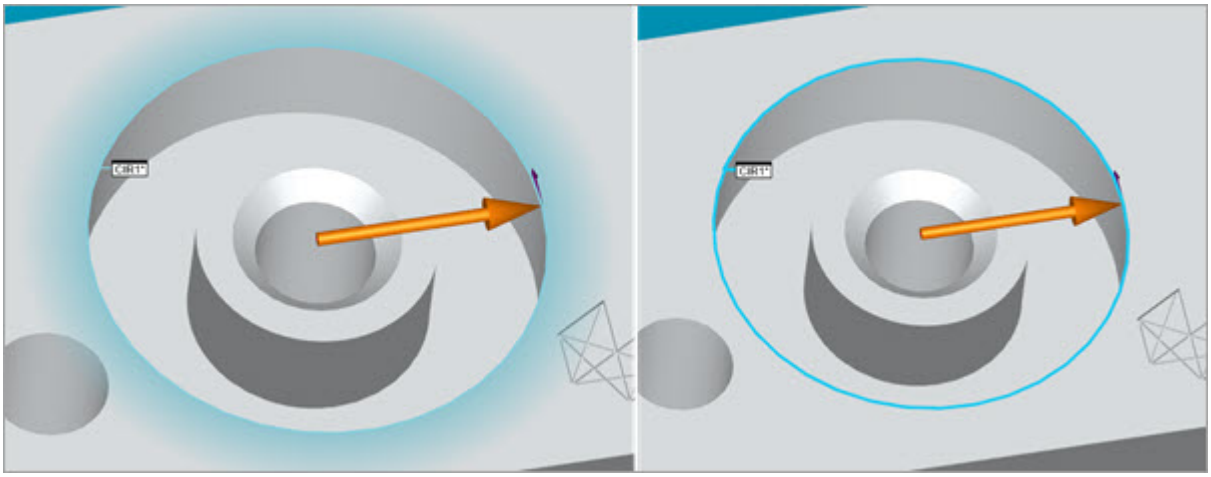
For example, an Auto Circle on the top surface of the Hexagon block looks like this during execution:



For the rotation and scaling to function, you must have a part alignment before manual features.

Enable 2D feature glow

This check box allows you to turn the glow effect for 2D features on and off. PC-DMIS marks this check box by default to allow the glow effect for 2D features.



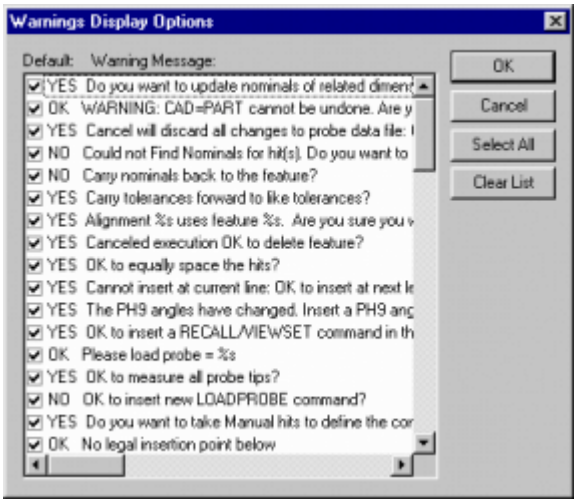
Examples that shows the Enable 2D feature glow option set to On (left) and Off (right).

Here's how this option works:

- If you mark this check box and click the **OK** button on the dialog box, PC-DMIS applies this effect on 2D features only in the currently opened measurement routine. PC-DMIS uses the `Enable2DFeatureGlow` setting in the Settings Editor on all new measurement routine you create to determine whether to apply the effect or not. For details, see "Enable2DFeatureGlow" in the PC-DMIS Settings Editor documentation.
- If you mark this check box and click the **Defaults** button on the dialog box, PC-DMIS applies this effect on 2D features in the currently opened measurement routine and any new measurement routines you create. PC-DMIS sets the Settings Editor entry `Enable2DFeatureGlow` to **TRUE**.
- If you clear this check box and click the **OK** button on the dialog box, PC-DMIS does not apply this effect on 2D features in the currently opened measurement routine. PC-DMIS uses the `Enable2DFeatureGlow` setting in the Settings Editor on all new measurement routines you create to determine whether to apply the effect or not.
- If you clear the check box and click the **Defaults** button, PC-DMIS does not apply this effect on 2D features in the currently opened measurement routine or any new measurement routines you create. PC-DMIS sets the Settings Editor entry `Enable2DFeatureGlow` to **FALSE**.

Warnings

The **Warnings** button on the **General** tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**) displays the **Warnings Display Options** dialog box.



Warnings Display Options Dialog Box

You can use this dialog box to tell PC-DMIS to re-display warnings that you have already switched off as well as change the default actions for warning messages that are turned off. By default, this dialog box is empty. When a warning message appears, PC-DMIS gives you the option of not receiving that warning again. When you choose to not receive the warning, the warning ends up in this dialog box.

If you need information on specific warnings, consult the "Warn(Option)" topic in the **Option** section of the PC-DMIS Settings Editor documentation.

Warning messages only appear in this interface in the **Warnings Display Options** dialog box once you have turned them off. If no warnings have been turned off, the dialog box remains empty.

To start receiving a warning message again:

1. Access the **Warnings Display Options** dialog box. It shows any warnings that you have turned off.
2. Select the warning and clear its check box.
3. Click **OK** to remove the warning. PC-DMIS starts displaying that warning message again.

The **Clear List** button clears all the check boxes for all items, thereby returning PC-DMIS to its default mode of displaying all the warning messages.

To change the default action for a warning message:

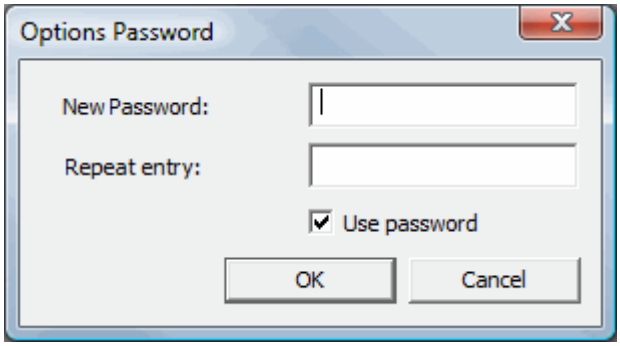
1. Make sure you have clicked the **Don't ask me again** check box when the warning appears. This causes it to go to the **Warnings Display Options** dialog box.
2. Access the **Warnings Display Options** dialog box. It shows any warnings you have turned off.
3. Double-click on the warning message whose default action you want to change. PC-DMIS displays the warning so that you can select the new default action.
4. Select the new default action to update the list with the new action.
5. Click **OK** to save your choice.

Password

The **Password** button allows you to password protect access to the **Setup Options** dialog box.

To password protect your setup options:

1. Access the **Setup Options** dialog box (**Edit | Preferences | Setup**).
2. Select the **General** tab.
3. Click the **Password** button. The **Options Password** dialog box appears.

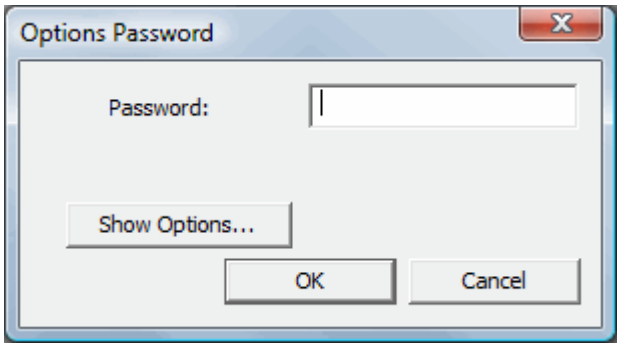


Options Password Dialog Box

4. In the **New Password** box, type the desired password.
5. In the **Repeat entry** box, re-type the same password to confirm your entry.

6. Select the **Use Password** check box.
7. Click **OK**.

The next time you attempt to access the **Setup Options** dialog box, you will be asked to type the password before proceeding. The password is case-sensitive.



Even if you don't have password access to edit the settings, you can always view the available settings by using the **Show Options** button. This displays the **Setup Options** dialog box, but you are unable to make any changes.

> The Protected Mode password supersedes and overwrites any other password you have defined. This means if you have password protection enabled for the **Setup Options** dialog box or for an .ipd file, you need to use the password defined when Protected Mode was enabled.

Other Edit Boxes for the General tab

Use the other boxes on the **General** tab to edit the following options:

Scale factor box

The **Scale factor** box scales the measured data by whatever factor is entered. For example, if a circle is measured and has a diameter of 1.0 inches and the scale factor is 0.95, then the measured value will be reported as 0.95 inches.

Find nominals tolerance box

This box becomes available when you first select the **Find Nominals** check box. See "Find Nominals".

Use the **Find nominals tolerance** box to type the amount of tolerance that PC-DMIS uses when finding the nominals. The default is 10 mm.

When you initially set this value and click **OK** (and whenever you perform a find nominals operation in learn mode), PC-DMIS checks this value against the active tip's radius. If this

value is less than the tip's radius, PC-DMIS will change it to match the diameter of the active tip.

Show deviations tolerance box

Use the **Show deviations tolerance** box to type the amount of tolerance that PC-DMIS uses when PC-DMIS is showing hit deviations. This option is only available when you first select the **Show Hit Deviations** check box.

Deviation arrow multiplier box

The **Deviation arrow multiplier** box is only available when you first select the **Show Hit Deviations** check box. An arrow appears in the Graphic Display window marking each hit taken, showing the deviation. The larger the value you enter in this box, the greater the size of the arrow.

Thickness box

The **Thickness** box works with the **Thickness for Point Only Mode Points** check box. If you select the **Thickness for Point Only Mode Points** check box, the thickness in this box will be applied to each point created by Point Only Mode.

See "Point Only Mode" and "Thickness for Point Only Mode Points" for additional information.

Execution Area

Use the items in the **Execution** area of the **General** tab to edit the following options:

Any order execute tolerance

In the **Any order execute tolerance** box, define the tolerance that the hit must be within for PC-DMIS to measure that feature when executing your measurement routine in any order execute mode.

If your initial hit is more than the specified tolerance away from the feature, PC-DMIS searches backwards and forwards through the measurement routine for the closest feature whose initial hit matches your initial hit and executes that feature instead. For more information, see "Any Order Execution" in the "Using Advanced File Options" chapter.

PC-DMIS stores the tolerance value with your measurement routine. This enables you to have different search zones for different measurement routines if desired.

Execution FindNoms tolerance

In the **Execution FindNoms tolerance** box, type the amount of tolerance that PC-DMIS uses when finding the nominals during measurement routine execution.

This box becomes available when you first select the **Find Nominals during Execution** check box. For more information, see "Find Nominals During Execution".

Support execution time display and Inspect

If you select the **Support execution time display and Inspect** check box, PC-DMIS displays the remaining execution time for a measurement routine or mini routine in the **Execution** dialog box. The time is recorded only for the DCC portion of the execution.

The Inspect software uses this option to display how long it takes to execute a routine. This check box also give Inspect the ability to execute subsets of routines known as "dimension sets". (Inspect is a software built specifically for operators. It runs PC-DMIS in the background and is available with PC-DMIS.)

This check box is not available for Portable machines (the execution time applies only to DCC measurements).

Every time you execute a measurement routine or mini routine, PC-DMIS records and stores its execution time. The next time you start the execution, the last time that was recorded appears in the **Execution** dialog box. This way, if you add or delete features, or decide to decrease or increase speeds in your measurement routine or mini routine, PC-DMIS records the change in execution time.

PC-DMIS records the execution time in the *<name of measurement routine>*.MiniRoutines.xml file. This file is located in the same folder as the measurement routine. If a measurement routine is executed when the file does not exist, then PC-DMIS creates the file. For more information about this file, see "Mini Routines".

You can decide to not record and display the execution time in the **Execution** dialog box. For example, the execution time for a machine that operates only in Manual Mode does not need to be recorded and displayed. To not record and display the execution time, clear the **Record and display execution time** check box.

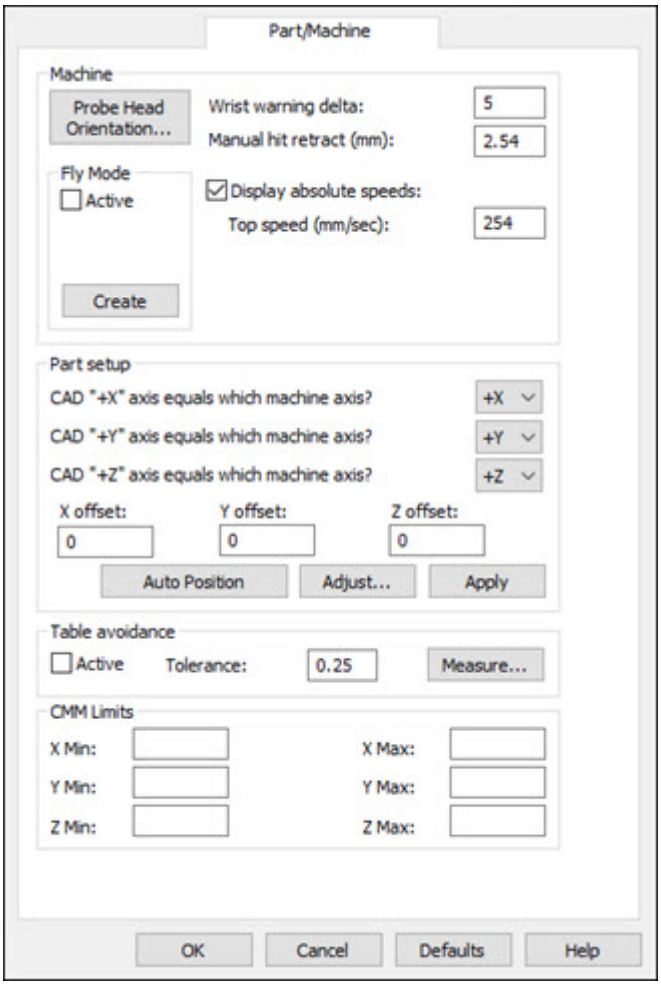
Add to execution time (seconds)

The time required to complete a measurement routine may include other actions in addition to executing the measurement routine or mini routine, such as printing the measurement results. If you select the **Add to execution time (seconds)** check box and enter the time in seconds, PC-DMIS adds the seconds to the actual execution time. The next time you execute the measurement routine or mini routine, the remaining time that appears in the **Execution** dialog box includes this additional time.

Show offline animation speed slider

If you select the **Show offline animation speed slider** check box, PC-DMIS displays the **Offline Animation Speed** slider in the **Execution** dialog box. This slider lets you adjust the execution speed of the measurement routine in Offline Mode as a percentage of the maximum animation speed value.

Setup Options: Part/Machine Tab



Setup Options Dialog Box - Part/Machine Tab

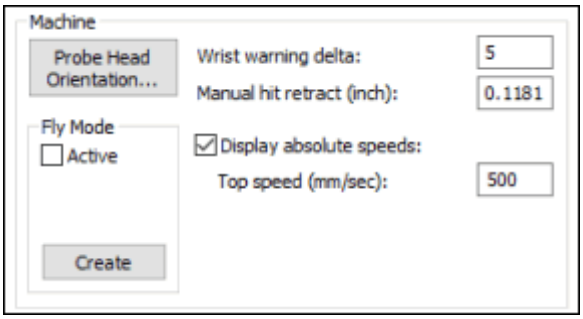
The **Part/Machine** tab lets you define the part setup on the CMM (or Machine) by changing the CAD axes relationship to the machine axes. To access this option, click on the **Part/Machine** tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**).

This capability is needed when you use PC-DMIS to create a measurement routine, and the CAD coordinate system differs from the CMM part setup.

A part is set up on the machine with its X+ CAD axis pointing in the same direction as the CMM's Z+ axis. The Z+ CAD axis is pointing in the same direction as the CMM's X- axis. You can use this function to create the proper relationships.

To equate the CAD setup to the part's setup, select the appropriate axes from the drop-down lists. Once you establish this relationship, it becomes easier to create a measurement routine for the part because PC-DMIS properly displays the probe in relation to the part.

Machine area



Machine Area

Probe Head Orientation button

The **Probe Head Orientation** button allows you to configure the probe head wrist AB angles for multiple arms.

To configure the AB wrist angles for multiple arms:

1. Access the **Setup Options** dialog box (**Edit | Preferences | Setup**).
2. Select the **Part/Machine** tab.
3. Click the **Probe Head Orientation** button. The **Probe Head Wrist Angle Configuration** dialog box appears.
4. Select the appropriate axes for the AB angles for the Arm1 and Arm2 arms (if applicable).
5. Click the **OK** button.

Fly Mode area

The **Fly Mode** area provides a way to move the probe around the part in a smooth and non-stopping motion. You must insert a move point into the measurement routine before you use this option. (See "Inserting a Move Point Command" in the "Inserting Move Commands" chapter.) The `Fly` command can only be inserted before or after any feature in the measurement routine.

To use the Fly Mode:

1. Scroll to the location in the Edit window where you want the Fly command.
2. Select the **Active** check box.
3. Click the **Create** button.

   The Fly mode is automatically placed in the current measurement routine at the designated location. The Edit window command line for this option reads: `FLY/TOG1` . The TOG1 toggle field switches between either `ON` or `OFF` . If `ON` , PC-DMIS activates the command. If `OFF` , PC-DMIS skips the command.

In DMIS mode, the Edit window command line that activates the command is: `FLY/1`

If you have selected an illegal position, a message informs you that PC-DMIS cannot insert the command at the current line. The message then asks if it should insert the command at the next legal position.

- If you click the **Yes** button, PC-DMIS moves the `Fly` command down to the end of the current feature in the Edit window.
- If you click the **No** button, PC-DMIS cancels the `Fly` command and returns you to the **Part/Machine** tab.

Wrist warning delta box

This is a numerical value that defines the minimum change in the wrist angle required before PC-DMIS proposes a change to the current wrist position. This affects users with a DCC CMM with all auto wrists.

Manual hit retract box

The **Manual hit retract** box allows you to type the retract distance the CMM automatically travels after you take a manual hit. This value corresponds to the unit type of the measurement routine (inches or millimeters).

If you change the manual hit retract value from either the default or from the last-used value, PC-DMIS places a retract command (shown as `MANRETRACT/` and then the value) in the current measurement routine's Edit window at the cursor's location. As manual hits are taken, the CMM retracts by the new value stated on this command.

For example, if you change the manual hit retract value from the default value of 0.1 to 0.003, PC-DMIS shows the command `MANRETRACT/0.003` in the Edit window.

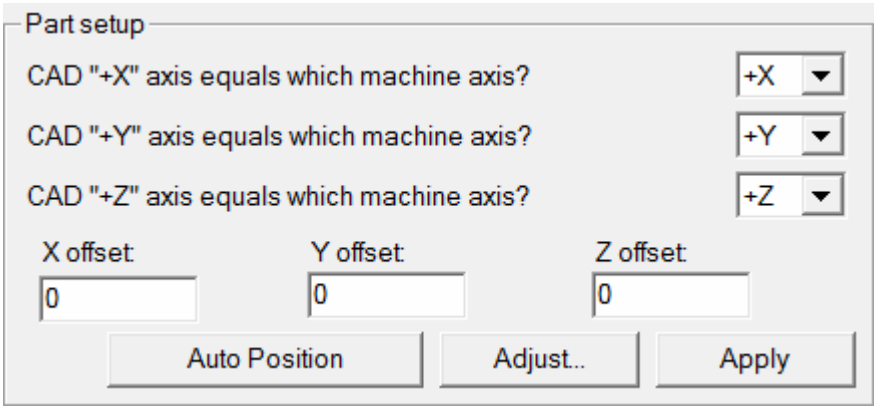
Display absolute speeds box

If you select the **Display absolute speeds** check box, PC-DMIS displays the speed values in other dialog boxes as an absolute value instead of a percentage. This value corresponds to the unit type of the measurement routine (inches or millimeters).

Top speed (mm/sec) box

The **Top speed (mm/sec)** box allows you to reset the top speed that the machine can travel. The value that you specify cannot exceed the machine's designated top speed. The value works with the **Move speed** option.

Part Setup area



Part Setup Area

The **Part Setup** area of the **Part/Machine** tab is useful when you create a measurement routine and the CAD coordinate system differs from the CMM part setup.

CAD "+X" axis equals list

This drop-down list allows you to set the relationship between the CAD X+ axis and the machine axis.

CAD "+Y" axis equals list

This drop-down list allows you to set the relationship between the CAD Y+ axis and the machine axis.

CAD "+Z" axis equals list

This drop-down list allows you to set the relationship between the CAD Z+ axis and the machine axis.

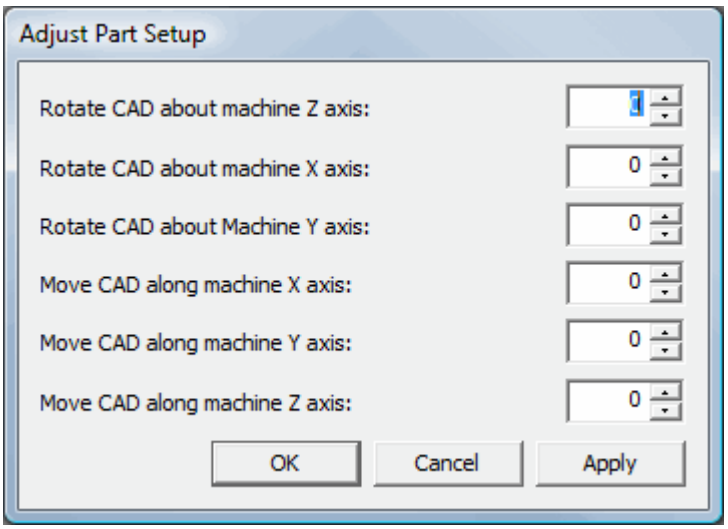
X offset box, Y offset box, Z offset box

These boxes allow you to enter the distance that PC-DMIS offsets the CAD drawing along the X, Y, or Z axis. PC-DMIS shifts the CAD drawing along the X, Y, or Z axis the specified distance. For example, if you enter in .5 in the X field, the entire CAD display in the Graphic Display window shifts the distance by .5 in the X direction.

All features created in the measurement routine *do not* shift along the axis with the CAD drawing.

Adjust button

The **Adjust** button opens the **Adjust Part Setup** dialog box.



Adjust Part Setup Dialog Box

You can use this dialog box to *rotate* or *move* the CAD in increments about and along the machine's XYZ axes.

- *If you're rotating the CAD,* then the values are in angle degrees. A value of 360 has the same effect as 0.
- *If you're moving the CAD,* then the values are in the units of measurement that the measurement routine is in. For example, a value of 2 would mean 2 inches or 2 millimeters, depending on the units of measurement used by your measurement routine.

To adjust the CAD along or about an axis:

1. Click on the appropriate box.
2. Type a new value. PC-DMIS dynamically shows the adjustment in the Graphic Display window.
3. Click **OK** to accept the values and close the dialog box.

PC-DMIS maintains this adjustment unless you re-import the part's CAD model.

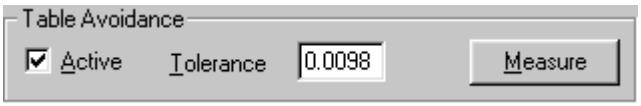
Auto Position button

The **Auto Position** button positions the part onto the graphical representation of the machine's table. Auto position best guesses where to position the part on the graphical representation. You can either let PC-DMIS determine where to put the part in relation to the CMM by using this function, or you can type your own positioning using the XYZ offset fields. (See "Defining Machines" in the "Defining Hardware" chapter for more information on setting up the graphical representation of the CMM.)

Apply button

When you click the **Apply** button, PC-DMIS immediately applies any changes made in the X, Y, or Z Offset fields. It also shifts the drawing along the appropriate axis (axes) while keeping the dialog box open.

Table Avoidance area



The **Table Avoidance** area of the of the **Part/Machine** tab allows PC-DMIS to ascertain if the probe comes in contact with the table (or set plane) while in DCC Mode.

Click the **Measure** button and PC-DMIS asks you to take a hit where the table surface is to be defined. This location defines the threshold for the Z axis. The tolerance field defines a location in the positive Z direction for positive values and in the negative Z direction for negative values, relative to the set plane.

- If a move goes beyond the indicated tolerance, PC-DMIS will display an error message indicating the potential danger.
- If a wrist rotation is requested that will pass through the defined zone, PC-DMIS will display a message alerting you to the error.

Select either **Cancel** or **Continue** to terminate or finish the operation.

A tolerance field of .25 will alert PC-DMIS to avoid the indicated threshold plus the tolerance value. If the threshold is on the table surface, PC-DMIS will alert you if the probe tip comes within one quarter inch (or millimeter depending on the set unit type) of the table.

The **Table Avoidance** option is available with certain interface types only while in DCC Mode.

CMM Limits area

The values in the **CMM Limits** area of the **Part/Machine** tab in the **Setup Options** dialog box enables PC-DMIS to avoid collisions with the legs on Bridge-type CMMs during the calibration of tactile probes.

When you calibrate a tactile probe with long extensions, collisions may occur when the probe rotates in the different tip positions. To avoid collisions, you can enable the Leg Collision check. PC-DMIS runs the check online and just before the probe calibration routine. The Leg Collision check can automatically add safety movements.

When PC-DMIS connects to a supported Hexagon CMM (common controllers and FDC controllers), it automatically gets the CMM limits. You can manually edit the CMM limits. This can be useful if you do not have a Hexagon CMM. In addition, you might want to

reduce the limits to avoid collisions with objects located within the machine volume (tool changers, fixtures, and so on).

To run the Leg Collision check, do the following:

1. If you need to modify or add the limits of the machine, enter the values in the **X Min**, **Y Min**, **Z Min**, **X Max**, **Y Max**, and **Z Max** boxes in the **CMM Limits** area.

2. Calibrate the probe tips. For details, refer to the "Calibrating Probe Tips" topic in the "Setting Up and Using Probes" chapter in the PC-DMIS CMM documentation.

To reset any modified values and obtain the CMM limits from your Hexagon CMM again, do the following:

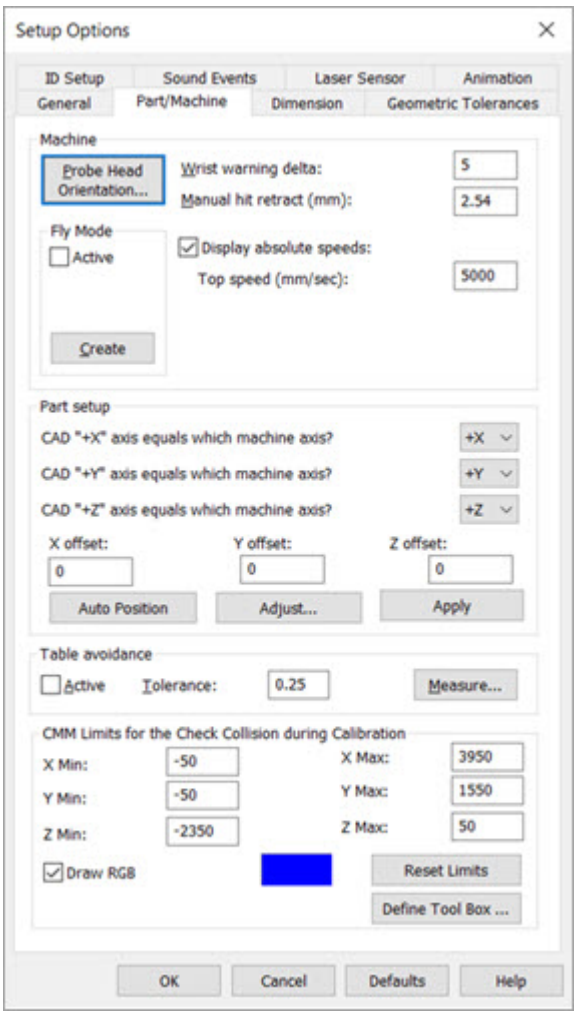
1. Type 0 into the **X Min**, **Y Min**, **Z Min**, **X Max**, **Y Max**, and **Z Max** boxes.

2. Click **OK** to close the **Setup Options** dialog box.

3. Restart the measurement routine, or restart your machine.

Horizontal/Dual Arms

When you define the probe head orientation for a horizontal arm in the **Part/Machine** tab of the **Setup Options** dialog box, the **CMM Limits** area shows additional options:



Setup Options Dialog Box

This example is for Arm1, but you can press F5 to obtain the same for Arm2 in a dual arm system with the Arm2 active. This allows PC-DMIS to read the CMM limits from the Arm2 controller and populate the dialog box with the proper limits.

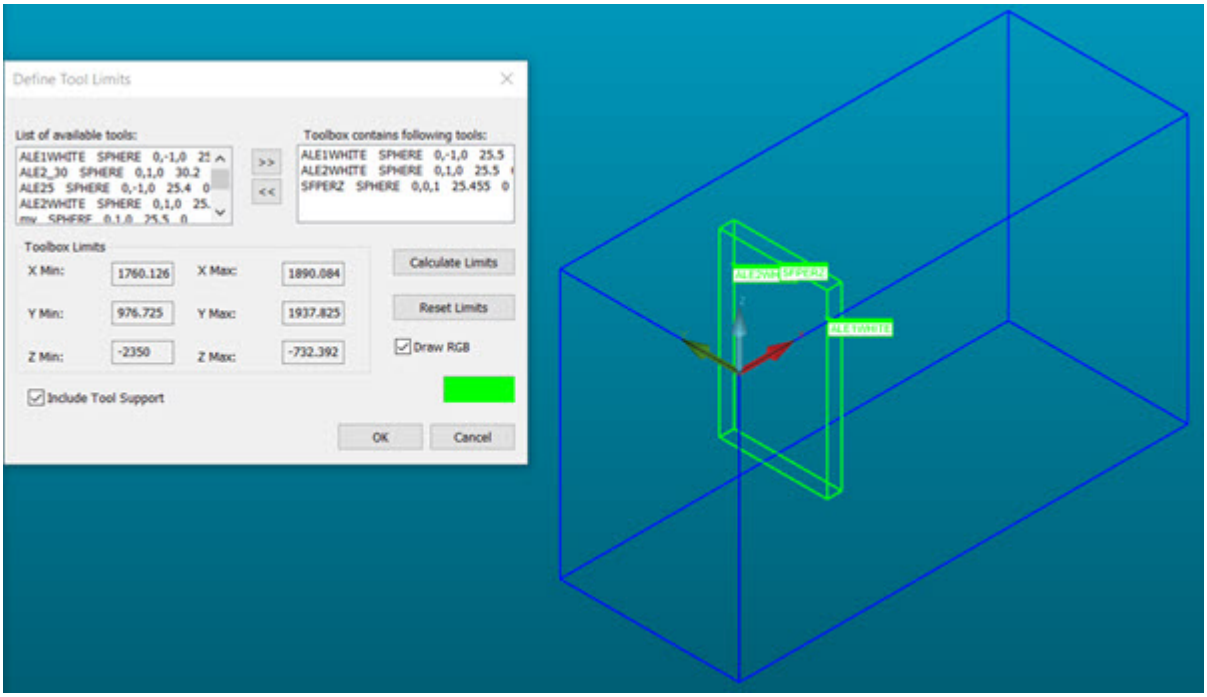
You can reduce the number of CMM limits read in from the computer, for example, to exclude the area where a probe changer is mounted (typically in the -X direction). Press the Reset Limits button to reset the CMM limit values back to the original values from the controller.

PC-DMIS can draw the CMM limits in the Graphic Display window so you can get a visual idea of the setup.

The **Define Tool Box** button allows you to define an additional area that is taken into account by the legs collision engine during the calibration. This is seen in the case of horizontal/dual arm machines where the software uses multiple gauges oriented in Y and Z. In that case, the risk of collisions with the gauges and their support is different compared to Bridge machines, where typically there's only one gauge oriented in Z+.

You can define that additional area by adding the gauges to a list. PC-DMIS then calculates the limits for the tool box to include them all. The defined tool box may or may

not include the tool supports, in which case PC-DMIS extends the calculated tool box using the positions of the selected gauges to the lower limit of the CMM (-Z).



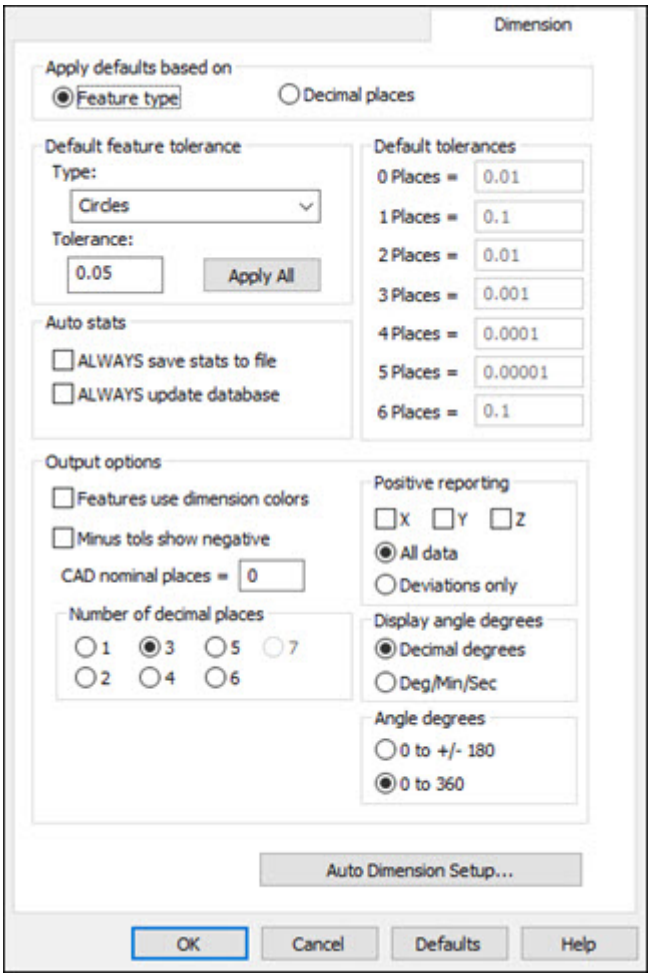
Example showing the defined tool box for a Horizontal or Dual Arm system.

Default button

The **Default** button allows you to update the default settings to several of the **Part/ Machine** tab's options on the **Setup Options** dialog box (**Edit | Preferences | Setup**). When you create a new measurement routine, it reflects any changes made to the accessible parameters, *only* if you click the **Default** button. If you click the **OK** button (without clicking the **Default** button) the defined parameters will only apply to the active measurement routine and will not affect PC-DMIS's entries. The default values are stored in a JSON file. You can update these parameters in the appropriate dialog box or you can use the PC-DMIS Settings Editor application. See the "Modifying Setting Entries" chapter.

If you change any of the parameters and you click the **Default** button, PC-DMIS updates the JSON file. This defines the current values as the default values.

Setup Options: Dimension tab



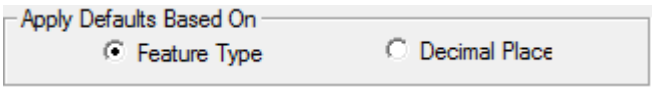
Setup Options Dialog Box - Dimension Tab

The **Dimension** tab lets you access the dimensional printout parameters.

To access the **Dimension** tab:

1. Access the **Setup Options** dialog box (**Edit | Preferences | Setup**).
2. Click the **Dimension** tab.

Apply Defaults Based On



Apply Defaults Based On Area

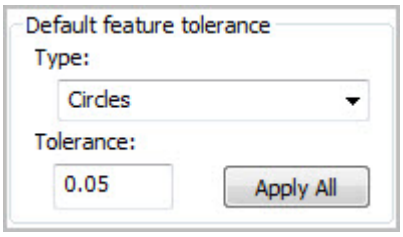
The **Apply Defaults Based On** area lets you apply default dimension tolerances either based on feature type or on the number of decimal places displayed.

- Selecting the **Feature Type** option enables the **Default Feature Tolerance** area, allowing you to define dimension tolerances based on individual feature types. Whenever PC-DMIS creates a dimension automatically, either because the **Auto**

option is selected in the **Location** dialog box (**Insert | Dimension | Location**) or because you used the **Auto Dimension Setup** button, the default dimension tolerance associated with that feature type is used. See the "Default Feature Tolerance" topic.

- Selecting the **Decimal Place** option enables the **Default Tolerances** area, allowing you to define dimension tolerances based on the number of decimal places. This is the old way that PC-DMIS determined dimension tolerances. See "Default Tolerances" topic.

Default Feature Tolerance



Default Feature Tolerance Area

The **Default Feature Tolerance** area lets you define default dimension tolerances based on individual feature types. This area is enabled when you select the **Feature Type** option from the **Apply Defaults Based On** area.

This capability only applies for legacy dimensions.

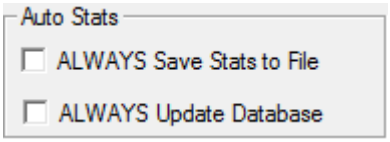
Whenever you manually create a location dimension or whenever PC-DMIS creates any dimension automatically (due to the **Auto Dimension Setup** button), the default dimension tolerance associated with that feature type is used, unless that same feature type already exists in the measurement routine. In that case, PC-DMIS instead uses the tolerance for the existing feature for any new automatic dimensions of that same feature type. This way you only need to modify the tolerance once for a feature type and PC-DMIS uses that same tolerance for other features of the same type throughout the rest of your measurement routine.

Type list
This list displays all the features for which you can set a default tolerance.

Tolerance box
This box defines the default tolerance used for the feature in the **Type** list.

Apply All button
This button lets you apply the current tolerance value in the **Tolerance** box *to all feature types*.

Auto Stats



Auto Stats Area

PC-DMIS can save statistical data to an output file and then update a database from that file. You define where to save stats in the `STATS/ON` command. For more information on the `STATS/ON` command, see the "Tracking Statistical Data" chapter.

The check boxes in the **Auto Stats** area control whether PC-DMIS shows certain prompts when it executes `STATS/ON` commands.

ALWAYS Save Stats to File

- If you clear this check box, PC-DMIS asks if it's okay to save the statistics. This occurs when execution starts and your measurement routine has a `STATS/ON` command in it.
- If you mark this check box, PC-DMIS saves the statistical data without asking you.

ALWAYS Update Database

- If you clear this check box, PC-DMIS asks if you want to update the database. This occurs after PC-DMIS saves the statistical data to the file and is about to update a database.
- If you mark this check box, PC-DMIS updates the database whenever it collects and saves statistical data without asking you.

For details on the locations of PC-DMIS files, see "Understanding File Locations".

Features Use Dimension Colors

The **Features Use Dimension Colors** check box tells PC-DMIS to color features that have an associated dimension. Features are drawn in the Graphic Display window with the same colors that the dimension uses to indicate deviation from the theoretical values.

By default, this only functions with location dimensions. You can use this with non-location dimensions as well by using the `NonLocationDimsSetFeatColor` entry in the **Dimensions** section of the PC-DMIS Settings Editor.

CAD Nominal Places =

The **CAD Nominal Places =** box allows you to enter a numerical value that defines how many decimal places PC-DMIS will use before rounding when it uses CAD data. For example, if a CAD circle has a diameter of 3.9995, and the value is set to 3, PC-DMIS will round its value to 4.000. This option only affects the way PC-DMIS interprets CAD data in the SHEET METAL MEASUREMENT mode. If the value is set to 0, PC-DMIS will not round off any values.

Minus Tols Show Negative

The **Minus Tols Show Negative** check box controls whether or not PC-DMIS displays the minus tolerances of the dimensions with a minus sign. For example, if the dimension is specified as 5.0000 +0.3 (upper tolerance), -0.2 (lower tolerance) and you mark this check box, PC-DMIS displays the dimension line as:

AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
Y	5.0000	0.3000	-0.2000	5.0000	0.0000	0.0000	0.0000	0.0000

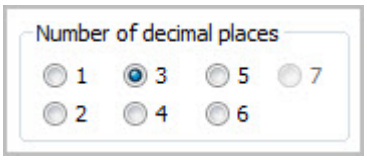
If you do not select this check box, PC-DMIS displays the same dimension line as:

AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
Y	5.0000	0.3000	0.2000	5.0000	0.0000	0.0000	0.0000	0.0000

This check box does not affect how PC-DMIS stores the values or how PC-DMIS uses the values in calculations. It only controls how PC-DMIS displays the values according to your preference. This check box is not selected by default.

If you do not select this check box, you can still have a tolerance with a minus sign in front of it. Under usual circumstances, your lower and upper limits are on opposite sides of the nominal. When you do not select this check box, PC-DMIS displays all values as positive values. However, if the upper limit and lower limit are both greater than the nominal - for example, your values actually read +TOL 0.03 and –TOL –0.02 before using this check box - then your minus tol value shows a positive value when you select this check box.

Number of Decimal Places



Number of decimal places Area

The **Number of decimal places** area controls the number of decimal places displayed in the Edit window and the inspection report.

Choose the desired option to determine the number of decimal places displayed.

Each time you change this option in a measurement routine, PC-DMIS places a command: `DISPLAYPRECISION/ #` into the measurement routine. This specifies the precision PC-DMIS displays at this section of the measurement routine. If you do not use this command, then PC-DMIS automatically uses the default value. If you do use this command, the precision stays as specified unless changed by another instance of the command.

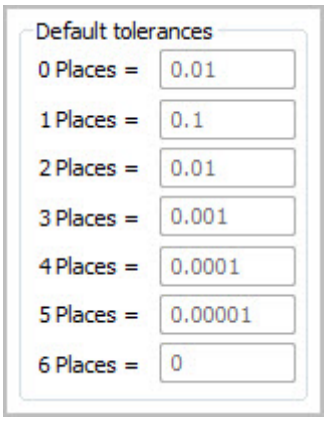
- Millimeter measurement routines allow up to six decimal places.
- Inch measurement routines allow up to seven decimal places.

For example, if you choose **6** for an inch measurement routine and you click **OK**, PC-DMIS inserts this command into the Edit window: `DISPLAYPRECISION/6`

This causes PC-DMIS to display any dimensions listed below this command with six decimal places, as illustrated in this Location dimension:

```
DISPLAYPRECISION/6
DIM LOC2= LOCATION OF POINT PNT1 UNITS=IN ,$
GRAPH=OFF TEXT=OFF MULT=10.00 OUTPUT=BOTH HALF ANGLE=NO
AX      NOMINAL        +TOL        -TOL         MEAS
           DEV          OUTTOL
X     2436.427000    0.001970    0.001970   2436.427000
      0.000000      0.000000 ----#----
Y      229.658000    0.001970    0.001970    229.658000
      0.000000      0.000000 ----#----
Z      849.992000    0.001970    0.001970    849.992000
      0.000000      0.000000 ----#----
T        0.000000    0.001970    0.001970      0.000000
      0.000000      0.000000 ----#----
END OF DIMENSION LOC2
```

Default Tolerances



Default Tolerances Area

The **Default Tolerances** area, enabled when you select the **Decimal Places** option from the **Apply Defaults Based On** area, lets you define the default tolerances PC-DMIS uses when you modify a dimension's nominal value in the Edit window. The default tolerance used is based on the number of decimal places in the nominal value.

For example, if you modify a nominal value to read 6.250, PC-DMIS sets the + and - tolerance to the **3 Places =** default tolerance value, because three decimal places were used. If you instead entered 6.25, PC-DMIS would set the + and - tolerance to the **2 Places =** value, because two decimal places were used.

0-6 Places = boxes
These boxes allow you to set different default tolerances that PC-DMIS applies when you define a nominal value with 0 to 6 decimal places.

Positive Reporting

The check boxes related to the **Positive Reporting** area control the reporting of features to the negative side of the origin. With positive reporting, features that would normally have negative values are always printed with positive values.

- The **X**, **Y**, and **Z** check boxes determine on which axis (or axes) PC-DMIS displays positive numbers.
- The **All Data** option tells PC-DMIS to flip the measured and nominal values of the selected axis (or axes) and to display any negative numbers for nominal axes as positive numbers.
- The **Deviations Only** option tells PC-DMIS to flip only the deviations of the selected axis (or axes) when the nominal values of axes are negative numbers.

When you select these check boxes, PC-DMIS inserts a `POSITIVEREPORTING` command into the measurement routine at the current cursor position. This command has the following format in the Edit window:

```
POSITIVEREPORTING/ a, b, c, TOG1
```

Where:

a = X when you select the X check box, or blank if you clear the X check box.

b = Y when you select the Y check box, or blank if you clear the Y check box.

c = Z when you select the Z check box, or blank if you clear the Z check box.

TOG1 = ALLDATA or DEVONLY depending on whether you selected the **All Data** or **Deviations Only** option.

The X, Y, and Z direction may each have positive reporting turned on in any combination of the three. You can use multiple `POSITIVEREPORTING` commands within the same measurement routine, and PC-DMIS displays any dimensions that are in the measurement routine using the `POSITIVEREPORTING` command that precedes the dimensions. If no `POSITIVEREPORTING` command exists in the measurement routine, PC-DMIS reports all dimensions with the options turned OFF in the X, Y, and Z directions.

This is an example of reporting Points E and D with the +0.3/-0.1 tolerance and deviation of 0.2, with Positive Reporting turned off:

	MM	LOC1 - POINT_E					
AX		NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
X		-1.000	0.100	0.300	-1.200	-0.200	0.000

	MM	LOC2 - POINT_D					
AX		NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
X		1.000	0.300	0.100	1.200	0.200	0.000

Example showing a report with Positive Reporting turned off.

You can see POINT E has a negative nominal value because it is X-. Often, you don't want to see the negative values because on a print it would not show a negative value. Also, as in this case if the tolerances are not the same, you also need to flip the tolerances so Point E is +0.1/-0.3 and point D is +0.3/-0.1 which again can be confusing because the drawing would not show this.

If you turn Positive Reporting on, the same report looks like this:

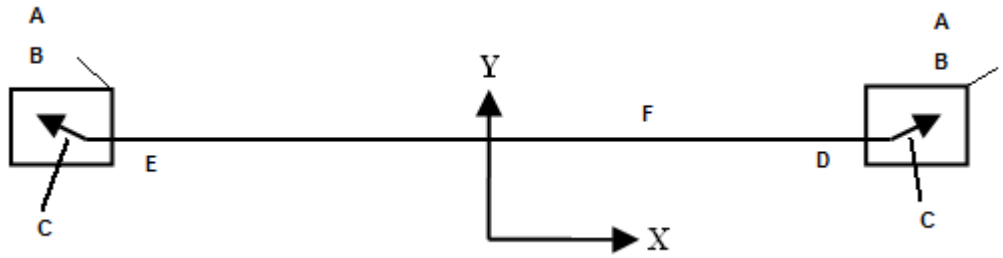
	MM	LOC1 - POINT_E					
AX		NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
X		1.000	0.300	0.100	1.200	0.200	0.000

	MM	LOC2 - POINT_D					
AX		NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
X		1.000	0.300	0.100	1.200	0.200	0.000

Example showing a report with Positive Reporting turned on.

You can see from this second example that POINT D is unaffected (it was already positive) but POINT E has changed. The nominal is now a positive number and the tolerances have switched.

You can see below how this occurs in the actual coordinate system:



Example showing the effect of Positive Reporting on tolerances.

A = 0.3 +tol in X

B = 0.1 -tol in X

C = 0.2 deviation in X

D = Point 1

E = Point 2

F = 1.0 nominal

Purpose of Positive Reporting

Positive reporting allows you to report features in a symmetrical manner, so that, regardless of which side of the origin the feature exists, deviations *away* from the origin are considered positive, and deviations *toward* the origin are considered negative.

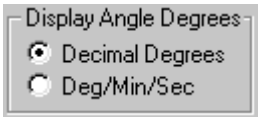
Thus, in the diagram above, both Point1 and Point2 display positive deviations when positive reporting in the X axis. This also means, however, that:

- plus tolerances are applied *away* from the origin.
- minus tolerances are applied *toward* the origin.

Migrating Older Measurement Routines

When migrating measurement routines from an older version of PC-DMIS (such as 3.7) to version 4.x or higher, you may have a problem with the tolerance band being flipped when you use Positive Reporting in your dimensions and you use variables to insert the tolerance values into the PLUS and MINUS tol fields. The `UseLegacyPositiveReporting` entry, located in the **Option** section of the PC-DMIS Settings Editor, lets you use the legacy positive reporting in these cases. This makes it so that PC-DMIS does not flip the tolerance values.

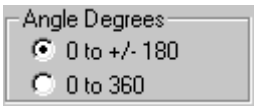
Display Angle Degrees



Display Angle Degrees Area

The **Display Angle Degrees** area allows you to display angle dimensions using decimal degrees or by degree/minute/second. When you select the desired option, PC-DMIS changes any PA (Polar Angle) Location axes and Angle dimensions to display the selected option.

Angle Degrees

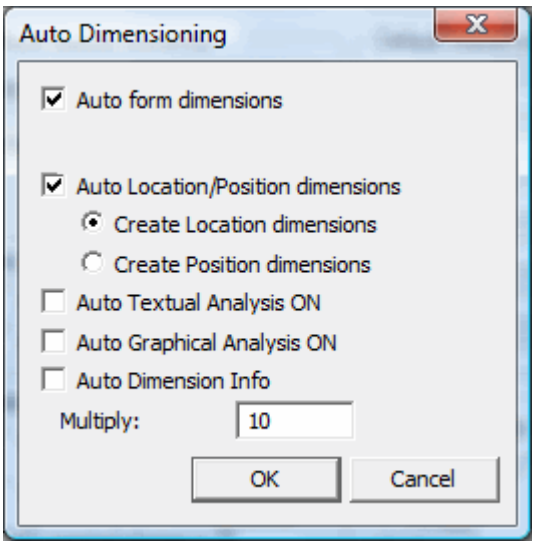


Angle Degrees Area

The **Angle Degrees** area also allows you to display the angle dimension from 0° to +/- 180° or 0° to 360° for the current measurement routine. PC-DMIS changes any PA (Polar Angle) Location axes and Angle dimensions to lie within the selected angle degree range. If you want to change the default value for all future measurement routines, use the `AngleRange0To360` entry in the **Option** section of the PC-DMIS Settings Editor.

Auto Dimension Setup

The **Auto Dimension Setup** button from the **Dimension** tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**) opens the **Auto Dimensioning** dialog box.



Auto Dimensioning Dialog Box

This dialog box provides you with several options that allow you to determine whether or not PC-DMIS automatically dimensions features immediately after creating them and how it should create those dimensions.

To enable or disable automatic dimension creation, clear or mark the following check boxes:

Auto Form Dimensions
This check box determines whether or not PC-DMIS automatically creates form dimensions for feature types that have a form dimension.

Feature	Associated Form Dimension
Circle	Roundness
Cylinder	Roundness
Cone	Roundness
Sphere	Roundness
Plane	Flatness
Line	Straightness

Auto Location/Position Dimensions
This check box determines whether or not PC-DMIS automatically creates location or position dimensions for feature types that have a location or position dimension.

Create Location Dimensions
If you select **Auto Location/Position** dimensions, this option button tells PC-DMIS to create those dimensions as Location dimensions.

Create Position Dimensions
If you select **Auto Location/Position** dimensions, this option button tells PC-DMIS to create those dimensions as Position dimensions.

Auto Textual Analysis ON
This check box controls whether or not PC-DMIS automatically creates textual analysis of the dimension. It is considered ON if the box is marked. See "Analysis Settings" in the "Using Legacy Dimensions" chapter and "Analysis" in the "Inserting Report Commands" chapter.

Auto Graphical Analysis ON
This check box controls whether or not PC-DMIS automatically creates a graphical analysis of any dimension that is created with **Auto Create Dimensions** or **Auto Roundness**. See "Analysis Settings" in the "Using Legacy Dimensions" section and "Analysis" in the "Inserting Report Commands" chapter.

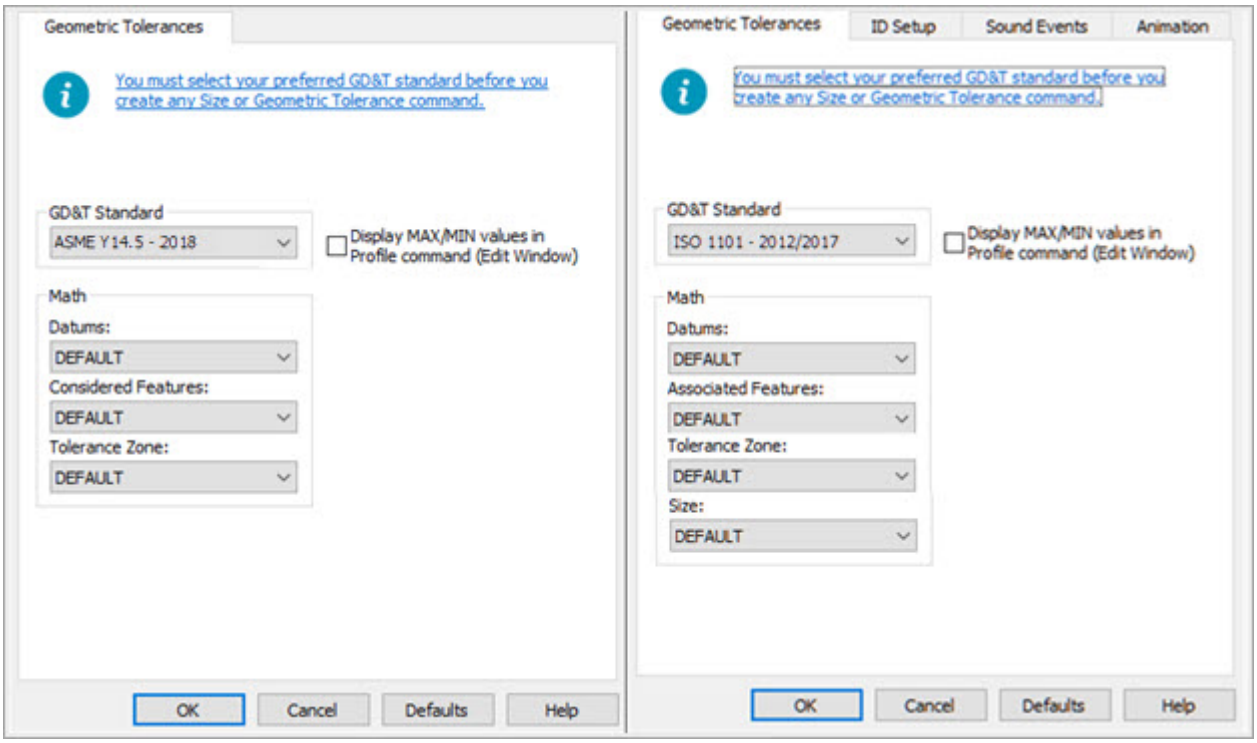
Auto Dimension Info
This check box controls whether or not PC-DMIS automatically creates a **Dimension Information** check box for any dimension created with the **Auto Create Dimensions** check box or the **Auto Roundness** check box. See "Inserting Dimension Info Boxes" in the "Inserting Report Commands" chapter for information on how to set the default formats for this Dimension Info boxes.

Multiply
The **Multiply** value is a scaling factor that magnifies the arrow and tolerance zone for the graphical analysis mode. If a value of 2.0 is entered, PC-DMIS scales the arrow two times the graphical image.

The **Multiply** box is used for viewing purposes only, and is not reflected in the text printout.

PC-DMIS creates dimensions as either legacy dimensions or Geometric Tolerance dimensions. Mark or clear the **Use Legacy Dimension** check box from the **Insert | Dimensions** submenu to set the appropriate dimension type.

Setup Options: Geometric Tolerances tab



Setup Options dialog box Geometric Tolerances tab for ASME (left) and ISO (right)

The **Geometric Tolerances** tab controls several defaults for the creation of new geometric tolerance commands. For more information on geometric tolerance commands, see the "Using Geometric Tolerances" chapter.

Dialog Box Options

GD&T Standard - This area shows the available standards that you can set as the default standard that you want new geometric tolerance commands to use. When you create a new geometric tolerance command, or access the **Geometric Tolerance** dialog box, PC-DMIS automatically selects the standard that you set here (**ASME Y14.5** or **ISO 1101**).

Starting with PC-DMIS 2023.2, you are no longer able to toggle the selected GD&T standard from within Geometric Tolerance commands. For details, see "Comparison to Past Practices - Referencing the GD&T Standard" section of the "Structuring your Measurement Routine for Geometric Tolerances" topic.

This tab is the only place where you can change the GD&T standard. Starting with 2023.2, PC-DMIS no longer attempts to convert between ASME and ISO standards. In the past, this was somewhat possible due to the limited level of support of ISO functionality in PC-DMIS. With the expanded development of ISO capabilities in PC-DMIS, divergence from the ASME standard has become increasingly significant. In many cases, no equivalency exists between the standards, causing conversion to be impossible.

The GD&T standard affects Size or Geometric Tolerance commands in your measurement routine. The standard you select does not affect legacy dimensions. You can change the selected GD&T standard at any time from the **Geometric Tolerances** tab of the **Setup Options** dialog box. However, because the setting applies to the entire measurement routine, depending on the measurement routine's content at the time of change, it may behave differently.

- If there are no Geometric Tolerance or Size commands in the measurement routine, you can change the GD&T standard from the **Geometric Tolerances** tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**), and it becomes the default standard going forward. PC-DMIS updates the program header to reflect the GD&T standard that is now referenced and uses the standard for all new Geometric Tolerance and Size commands that you create.
- If the measurement routine contains existing Geometric Tolerance or Size commands and you attempt to change the GD&T standard from the **Geometric Tolerances** tab of the **Setup Options** dialog, the following rules apply:
    - Changing between ASME Y14.5 publication years:
        - Changing from ASME Y14.5 - 1994 to ASME Y14.5 - 2009: PC-DMIS converts profile tolerances to use the ASME Y14.5.1 - 2019 single value definition. PC-DMIS displays a warning message.
        - Changing from ASME Y14.5 - 2009 to ASME Y14.5 - 1994: PC-DMIS converts profile tolerances to use the ASME Y14.5.1 - 1994 two value definition. Any Geometric Tolerance command that includes a customized datum reference frame, a translation modifier, or a specified material boundary size is rendered invalid. PC-DMIS displays a warning message.
        - Changing from ASME Y14.5 - 1994 to ASME Y14.5 - 2018: PC-DMIS converts profile tolerances to use the ASME Y14.5.1 - 2019 single value definition. Any Concentricity or Symmetry Geometric Tolerance commands are rendered invalid. PC-DMIS displays a warning message.

- Changing from ASME Y14.5 - 2018 to ASME Y14.5 - 1994: PC-DMIS converts profile tolerances to use the ASME Y14.5.1 - 1994 two value definition. Any Geometric Tolerance command that includes a customized datum reference frame, a dynamic profile modifier, a translation modifier, or a specified material boundary size is rendered invalid. PC-DMIS displays a warning message.
- Changing from ASME Y14.5 - 2009 to ASME Y14.5 - 2018: Any Concentricity or Symmetry Geometric Tolerance commands are rendered invalid. PC-DMIS displays a warning message.
- Changing from ASME Y14.5 - 2018 to ASME Y14.5 - 2009: Any Geometric Tolerance commands containing a dynamic profile modifier are rendered invalid. PC-DMIS displays a warning message.

◦ Changing between ISO and ASME is not allowed. All existing Size and Geometric Tolerance commands are rendered invalid. PC-DMIS shows this warning message:

PC-DMIS

All Geometric Tolerances and Size commands within a measurement routine must reference the same GD&T standard. Once you click OK, PC-DMIS disables any pre-existing Geometric Tolerance and Size commands in the measurement routine. After the conversion finishes, you must then recreate these commands. Click OK to continue or click Cancel to abort this operation.

For all the cases above where PC-DMIS displays a warning message:

- If you click **Cancel**, the GD&T standard does not change and your measurement routine remains in its current state.
- If you click **OK** to continue, the GD&T standard for the measurement routine changes to the one you selected. It becomes the default standard for all new Geometric Tolerance and Size commands and the program header updates in the Edit window to reflect this change. PC-DMIS renders invalid all existing Geometric Tolerance and Size commands that could not be converted.

PC-DMIS shows invalid commands in red in the Edit window. You cannot edit or execute these commands. Any command dependent on invalid commands will no longer function.

The main purpose in preserving these commands is to allow you to re-create them and reference them using the newly selected GD&T standard. Once completed, you can then delete the invalid commands and update the dependent commands to reference the new commands.

As discussed in the "Using Geometric Tolerances" chapter, the following geometric tolerance math types are available:

ASME Math Types

- **Datum** math options
- **Considered Feature** math options
- **Tolerance Zone** math options

ISO Math Types

- **Datum** math options
- **Associated Feature** math options
- **Tolerance Zone** math options
- **Size** math options

This **Math** area lets you define what math options you want PC-DMIS to use for new geometric tolerance commands. You can change the math options in individual geometric tolerance commands, and it does not affect future geometric tolerances that you create, nor does it affect what you set here.

For information on how to choose the math options for your application, see the "Using Geometric Tolerances" chapter.

Profiles display MAX/MIN values in Profile command (Edit Window) - This check box defines whether PC-DMIS displays the minimum and maximum deviation values in profile tolerance commands inside the Edit window.

For ISO 1101 2012/2017, ASME Y14.5 – 2009 & ASME Y14.5 - 2018

- If you clear this check box, geometric tolerance commands that represent profile tolerances display a single measured value. This value is based on the single actual value defined by the GD&T standard you selected.
- If you select this check box, profile tolerances show the minimum and maximum deviation values instead of the single measured value.

For ASME Y14.5 - 1994

- This control is greyed out. The check box is always selected and cannot be cleared. Profile tolerances show the minimum and maximum deviation values (see note below).

ASME Y14.5-2009 and ASME Y14.5-2018 use the ASME Y14.5.1-2019 math standard which defines how to calculate an "actual value" of a profile tolerance. Section 8.3.1 (Uniform Tolerance Zones) of the Y14.5.1-2019 standard states, “This concept applies in the same way to equally disposed, unequally disposed and unilateral profile specifications" (see Figures 8-5 thru 8-7). "The actual value of a profile tolerance for a single feature is the value of t_0+2g for the enveloping zone to which the actual surface will conform." This results in the single measured value, equivalent to twice the farthest deviation from the centre of the tolerance zone that PC-DMIS reports.

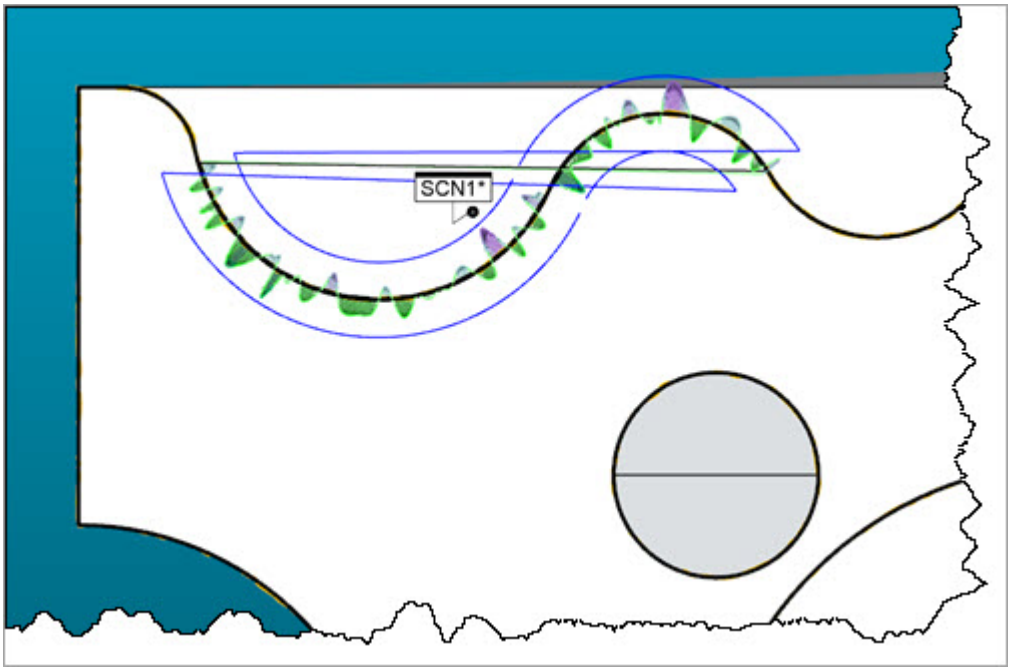
ASME Y14.5 1994 uses the ASME Y14.5.1M-1994 math standard, which states, "For both unilateral and bilateral profile tolerances two actual values are necessarily calculated: one for surface variations in the positive direction and one for the negative direction. For each direction, the actual value of profile is the smallest intermediate tolerance to which the surface conforms. Note that no single actual value may be calculated for comparison to the tolerance value in the feature control frame, except in the case of unilateral profile tolerances." This means that when you select ASME Y14.5 1994 as your GD&T standard, you no longer get a single measured value, you get the minimum and maximum values instead. The only real difference is the way in which the information is presented, tolerance boundaries and conformance are unaffected. For more information, download the "ProfileReporting_Handout_V2" document from the PC-DMIS Knowledgebase repository.

For example, if you select this option and create a Profile, PC-DMIS shows the **MAX** and **MIN** values as part of the MEASURED component of the associated code snippet as seen here:

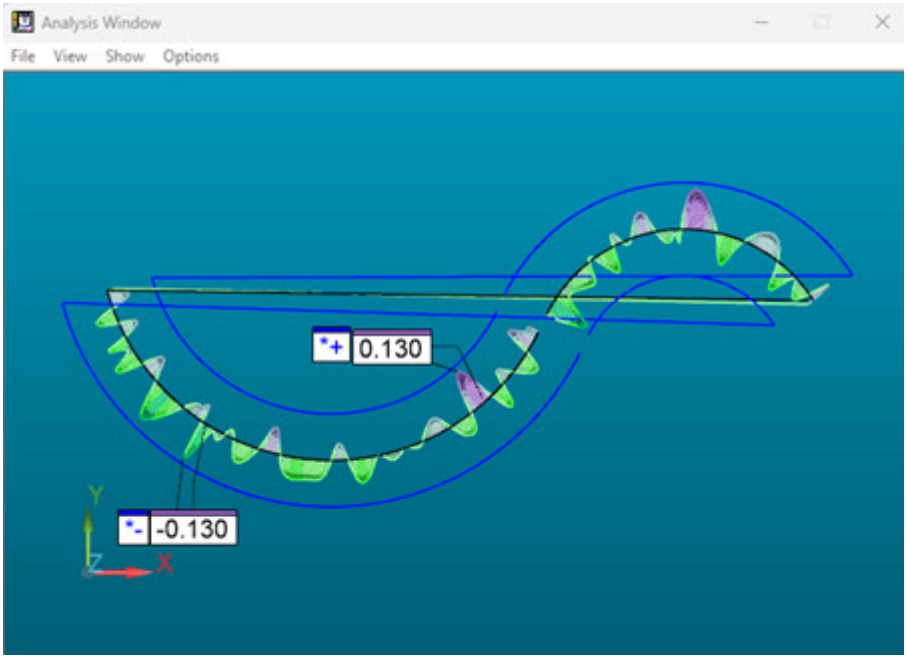
```
FCFPROF1    =GEOMETRIC_TOLERANCE/STANDARD=ASME Y14.5 - 2018,SHOWEXPANDED=YES,
             DESCRIPTION=ON,,
             DISPLAY_COORDS=DRF,
             UNITS=MM,OUTPUT=BOTH,ARROWDENSITY=10,ITERATEANDREPIERCECAD=YES,
             SEGMENT_1,PROFILE_SURFACE,0.3,__,<dat>,<dat>,<dat>,TOL_ZONE_MATH=DEFAULT,
             TEXT=OFF,CADGRAPH=OFF,REPORTGRAPH=OFF,MULT=1,
               MEASURED:
                 SCN1:0.130,-0.130,
             ADD
             FEATURES/SCN1,,
```

The first value (0.130) is the **MAX** value, the second value (-0.130) is the **MIN** value.

You should view these values in conjunction with the CAD graphics or a graphical analysis command in order to better understand the deviation direction with respect to the CAD surface.



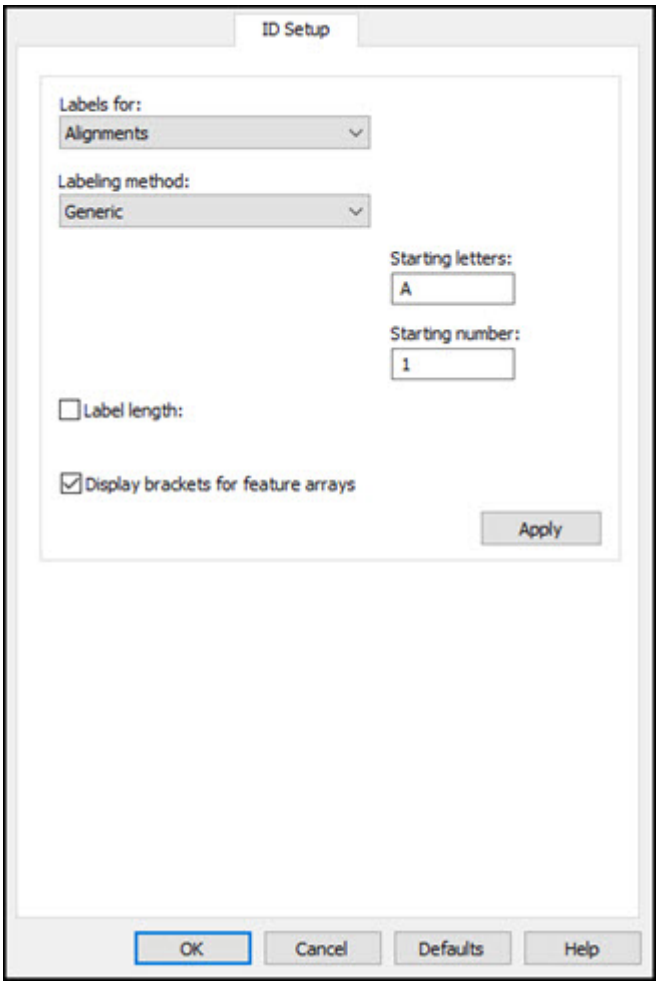
CAD model in the Graphic Display window showing the Profile for the above code snippet



CAD model in the Analysis Window showing the Profile for the above code snippet

This setting does not affect the report. Geometric Tolerance report labels for Profile of a Surface and Profile of a Line always report the single measured value, regardless of the **Profiles display MAX/MIN values in Profile command** setting.

Setup Options: ID Setup tab



Setup Options Dialog Box - ID Setup Tab

Be sure to keep track of IDs already set when changing an identification. It is possible to have ID duplication through multiple changes to this option.

The **ID Setup** tab allows you to alter the format used to identify alignments, dimensions, features, comments, labels, variables, and other items.

To access this option:

1. Access the **Setup Options** dialog box (**Edit | Preferences | Setup**).
2. Select the **ID Setup** tab.

The default **Labeling method** is **Generic**. As you create each feature, PC-DMIS assigns it an ID beginning with the letter **F**, followed by a number (incrementally set from the starting number of one). Type a new value in the appropriate box on this tab to override this setting.

ID Rules

When you create or modify an ID for any command (feature, alignment, dimension, comment, label, variable, and so on), follow these rules:

- Use only letters, numbers, and the underscore character (_). Do not use any other character, such as @ # $ % & * ( ) + - = / \ [ ] { }
- Start the ID with a letter.
- Do not use spaces. Use an underscore instead.
- Do not use the same ID for two different commands, even when the commands are of different types. For example, an alignment should not have the same ID as a feature or a label.
- Do not use names that are identical to PC-DMIS keywords or commands (ALIGN, PROBE, OFFSET, and many more).

While PC-DMIS does not prevent you from breaking most of these rules, doing so may cause problems with expressions, reporting, or how that ID functions with routines that use other products (like DataPage+, Microsoft Excel, and so on).

Apply these same ID rules when you name a probe file. PC-DMIS does not allow a period or any of these characters in a probe file name: < > : " / \ |

For more information, see "Probe File Name" in the "Defining Hardware" chapter.

Options in the ID Setup Tab

Labels for - The **Labels for** drop-down list is used to select the identification used for these items: (See "Labeling Method" below.)

Alignments
Generic is the only method available for identifying alignments.

Comments
Generic is the only method available for identifying comments.

Dimensions
You can identify Dimensions with either the **Generic** or **By Type** method. If you use the **By Type** method, identifications can be similar to each dimension type, or different based on individual need.

Features
You can identify Features with either the **Generic** or **By Type** method.

If you select the **By Type** method, you can also change the color used to display the feature ID.

If you select the **Show All ID** check box and you click **Apply**, PC-DMIS displays all feature ID labels in the Graphic Display window for all features from the current cursor location to the end of the measurement routine. Newly created features also show their ID. If this check box is deselected and you click **Apply**, all features IDs from current cursor location to the end of the measurement routine are hidden. Newly created features still get created in the Edit window, but the ID label doesn't appear in the Graphic Display window.

If the **Color** option is selected (marked), all features created after the **Apply** button is pressed will be affected. (Features created prior to the color change will not be replaced.)

Labels
Generic is the only method available for identifying labels.

Variables
Generic is the only method available for identifying variables.

Call Subs
Generic is the only method available for identifying Called Subroutines.

Spc Queries
You can identify Spc queries with either the **Generic** or **By Type** method.

Geometric Tolerances
You can identify Geometric Tolerances with either the **Generic** or **By Type** method.

Pointcloud Operators
You can identify Pointcloud Operators with either the **By Type** or **Generic** method. If you use the **By Type** method, identifications can be similar to each operator type, or different based on individual need.

Labeling Method - You can use this drop-down window to select between **By Type** and **Generic** identification methods.

By Type
This lets you set the identification for each element type (for example: circle, cone, cylinder, line, plane, point, and sphere).

Generic
This applies the same identification system regardless of feature (dimension) type.

PC-DMIS has no inherent limit on the number of letters used for identifications. However, the Graphic Display area and Edit window have limits on the ID length. Even if the Edit window does not show the complete ID, PC-DMIS internally keeps track of the complete identification.

Starting Letters - This box determines the first letter or letters used in the identification process. PC-DMIS always displays the ID using capital letters.

In various dialog boxes where the ID is displayed, if you modify the ID there, PC-DMIS displays a prompt to ask you if you would like to change the default ID for that item type.

Starting Number - The Starting Number box determines the first number used in the identification process. Any number between 1 and 9999 can be entered.

In various dialog boxes where the ID is displayed, if you modify only the number portion of an ID, the counter may be reset to a desired count.

Label length - The **Label length** check box determines the length of the identification. Selecting it displays a small edit box, into which you can type a number value. The check box must be selected in order for this option to be active. If this length is set, PC-DMIS appends zeros to the ID letters to make up the necessary length.

ID Length = 10, ID Letters = CIRCLE.

PC-DMIS generates an ID = CIRCLE0001, etc. This is done only if the Length is set.

Display brackets for feature arrays - The **Display brackets for feature arrays** check box determines whether array brackets are displayed with IDs for commands executed more than once. When selected, the inspection report displays which instance of the command's execution is being referenced.

F1[3]=POINT MEASURED FROM 1 HIT

Shows that the feature, F1, is measured here for the third (designated by the number three in brackets) time.

You can control the format of the bracketed expression with the array_indices object. See "Array Indices Object" in the "Using Expressions and Variables" chapter.

Apply - The **Apply** button applies the changes described in "Labeling Method" to any feature identifications. These changes apply only to feature IDs. If the **Apply** button is not

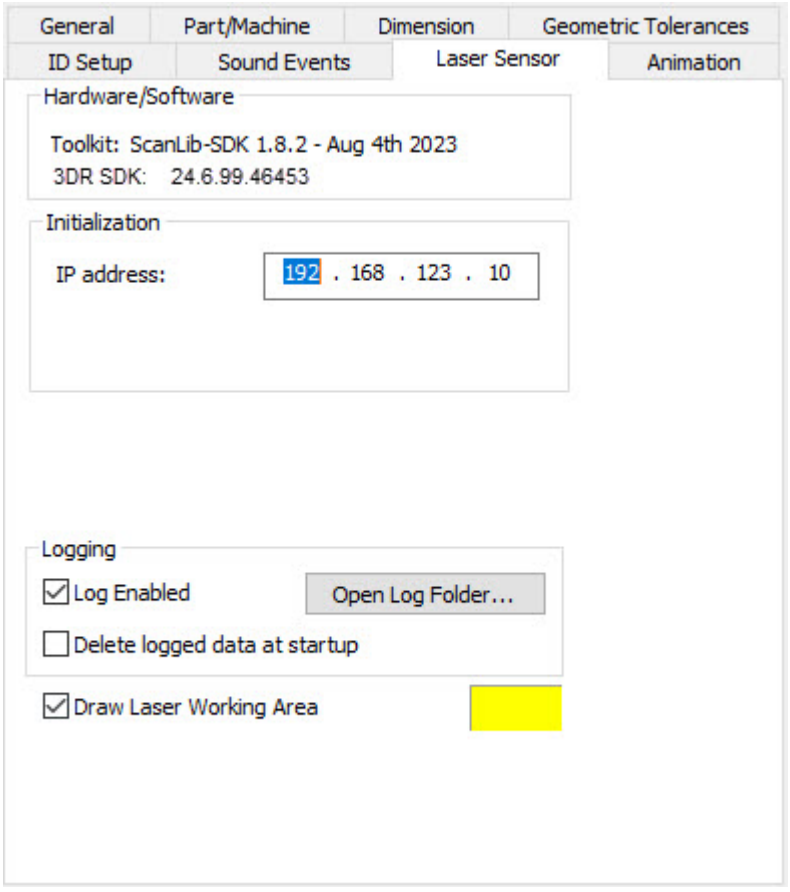
pressed, PC-DMIS will continue to assign feature identifications using the previous method listed.

Each feature, dimension, and other command should have a unique ID.

Default - The **Default** button allows you to update the default settings to all of the ID Setup parameters. When a new measurement routine is created, it will reflect any changes made to the parameters, *only* if the **Default** button is clicked. For additional information on **Default** buttons, see the "Default" topic in the "Navigating the User Interface" chapter

Always press the **Apply** button after you make a change (before you press the **OK** or **Default** buttons).

Setup Options: Laser Sensor tab



Setup Options Dialog Box - Laser Sensor Tab

The **Laser Sensor** tab (**Edit | Preferences | Setup**) contains information and controls to define the defaults settings for your laser sensor.

Hardware/Software - This area provides you with the current versions of the listed hardware and software.

Initialization - This shows the IP address for your laser sensor.

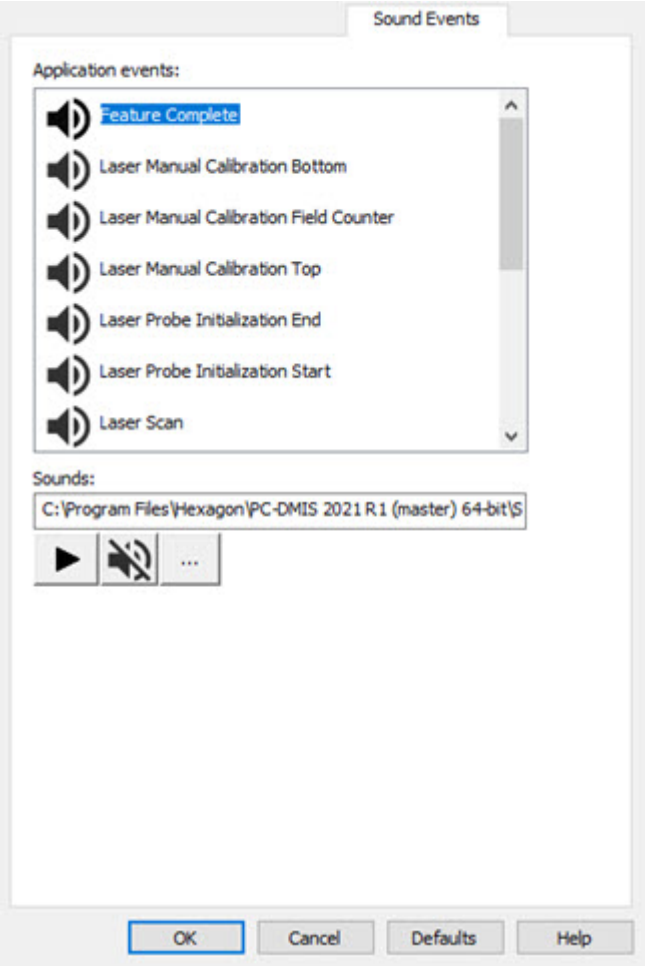
Logging - This area provides you with the following options to perform data logging.

> **Log Enabled** check box - Select this check box to enable data logging. You can click the **Open Log Folder** button to view the location of the generated log file.
>
> **Delete logged data at startup** check box - This option is only available when you select the **Log Enabled** check box. When you select this option, PC-DMIS deletes the log data at startup.

Draw Laser Working Area check box- Select this check box and then use the color patch to select a color. The next time you scan a CAD model, PC-DMIS colors the scan working areas with the selected color.

The **Laser Sensor** tab is available only when you are licensed with the laser option and when using a laser probe. For additional information on this tab, see the "Step 3: Define Setup Options for the Laser Sensor" in the PC-DMIS Laser documentation.

Setup Options: Sound Events tab



Setup Options Dialog Box - Sound Events Tab

The **Sound Events** tab (**Edit | Preferences | Setup**) contains a list of application events that you can associate with a sound file of your choice. When the event occurs, PC-DMIS automatically plays the associated sound.

Application Events list
This list shows the application events to which you can associate sound files.

Sounds box
This box lists the path to the sound file for the selected application event.

Play Sound button

This button tests the specified sound file. It is disabled if no sound is associated with the event.

Turn Sound Off button

This button turns off the specified sound file.

Browse button

This button is used for navigating to and selecting a sound file for the selected application event.

Associating a Sound

To associate a custom sound file with an event:

1. Select the event from the **Applications Events** list.
2. Click the **Browse** button ( ).
3. Navigate to the directory containing your sound file. PC-DMIS only supports the playing of .wav files.
4. Select the .wav file and click **Open**. The **Sounds** list box displays the path to the selected sound file.
5. Test the file by pressing the **Play** button ( ).
6. Click **OK** to save your changes.

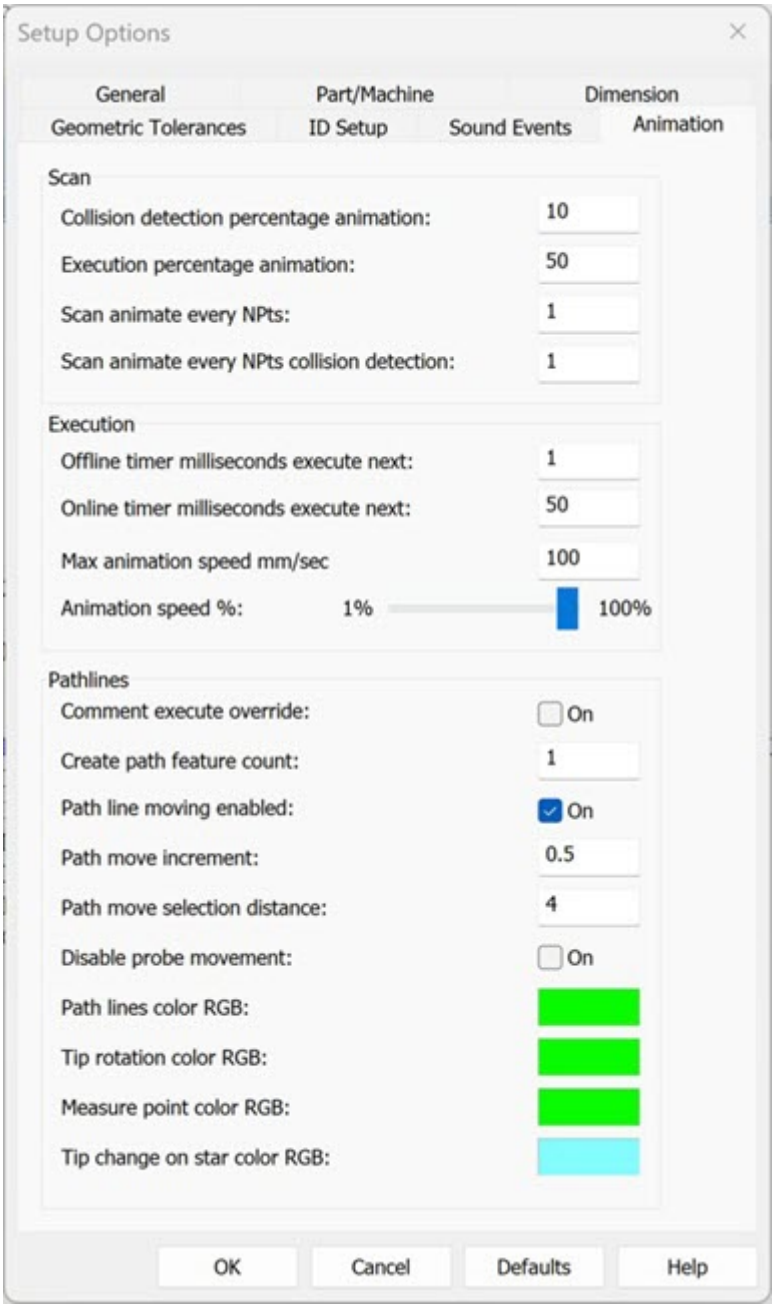
Turning Off a Sound

You can turn off an associated sound from an event. To turn off a sound:

1. Select the event from the **Applications Events** list.
2. Click the **Sound Off** button ( ).

   The speaker icon ( ) to the left of the event changes to show a circle with a line through it ( ), indicating that the event is turned off.
3. Click **OK** to save your changes. The sound is removed from the event.

Setup Options: Animation tab



Setup Options Dialog Box - Animation Tab

The **Animation** tab (**Edit | Preferences | Setup**) contains offline animation and path line settings.

Scan area

Collision detection percentage animation: - This defines the percentage of probe animation that occurs during a collision detection operation.

- A value of 100 indicates that the display is redrawn at its maximum rate.
- A value of 0 indicates that the display is not redrawn at all.
- The default value is 50.

Execution percentage animation: - This defines the percentage of probe animation that occurs during normal measurement routine execution.

- A value of 100 indicates that the display is redrawn at its maximum rate.
- A value of 0 indicates that the display is not redrawn at all.
- The default value is 50.

Scan animate every NPts: - This limits the number of points that PC-DMIS uses for the animation. For example, if you set this value to 10, PC-DMIS only takes every 10th point, plus the first and last points. PC-DMIS uses this value for probe animation during execution. The default value is 50.

Scan animate every NPts collision detection: - This limits the number of points that PC-DMIS uses for the collision detection animation. For example, if you set this value to 10, PC-DMIS only takes every 10th point, plus the first and last points. PC-DMIS uses this value for probe animation during collision detection.

Execution area

Offline timer milliseconds execute next: - This sets the frequency of how often PC-DMIS processes commands during execution in Offline mode. This is a number of milliseconds. The default is 50.

Online timer milliseconds execute next: - This sets the frequency of how often PC-DMIS processes commands during online execution. This is a number of milliseconds. The default is 50.

For example if these are set to 1 then PC-DMIS would try to process a command during execution every millisecond.

Max animation speed (mm/sec): - This lets you define the maximum animation speed that the animated probe uses in the Graphic Display window during measurement routine execution. The speed is in mm per second. You may find it useful to alter this value for complex measurement routines that cause the animation to render too slowly. To increase the duration between redrawn views of the animation, increase this value. This causes PC-DMIS to draw fewer animation steps.

Animation speed %: - The slider allows you to quickly and easily adjust the actual percentage used of the **Max animation speed** value.

The **Animation speed %** slider is directly linked to the **Offline Animation Speed** slider on the **Execution** dialog box. The value you set this slider to, for example, is the same value set for the slider on the **Execution** dialog box. When you close and then reopen the measurement routine, the slider value in both locations is set back to the default value of 100%.

For details on the **Execution** dialog box, see the "Using the Execution Dialog Box" topic in the "Using Advanced File Options" chapter of the PC-DMIS Core documentation.

Changing Animation Speeds: If you want to further fine-tune your offline animation speeds, see the "Executing and Debugging Measurement Routines Offline" topic in the "Working in Offline Mode" chapter.

Pathlines area

Comment execute override: - This check box determines whether or not PC-DMIS executes `COMMENT` commands when you generate path lines. If you mark this check box then they are executed. This check box is cleared by default.

Create path feature count: - This box is used when you select **View | Path Lines from Cursor**. It defines how many features above and below the cursor location are used. For example, if you set this to 3, PC-DMIS would use three features above and three features below the cursor location. The default value is 1, which means that PC-DMIS draws path lines for one feature that precedes the current feature and one feature that follows the current feature. See "Showing, Animating, and Moving Path Lines" in the "Editing the CAD Display" chapter.

Path lines color RGB: - This box defines the color for generated path lines in the Graphic Display window. Clicking on the color opens up the standard **Color** dialog box, from which you can choose a new color.

Path line moving enabled: - This check box determines whether or not path-line moving is enabled. If marked, you can click on a path line to insert a `MOVE/POINT` command at that location. See "Moving Path Lines" in the "Editing the CAD Display" chapter.

Path move increment - This defines the increment distance for moving path lines in the **Move Path Line** dialog box. See "Moving Path Lines" in the "Editing the CAD Display" chapter.

Path move selection distance - This determines the selection distance from a start and end point of a path line. If the **Path line moving enabled** check box is marked, and you click on a path line within the specified distance inside the Graphic Display window, PC-

DMIS searches for an existing `MOVE/POINT` command to modify instead of inserting a new `MOVE/POINT` command that splits the selected path line.

Disable probe movement - This check box is cleared by default, which causes the probe to move during path line creation. If this box is checked, the probe no longer moves during path line creation.

Path lines color RGB - This defines the main path line color as a probe moves between features.

Tip rotation color RGB - This defines the color for a probe's path lines as it rotates its tip to a new angle.

Measure point color RGB - This defines the color for a probe's path lines as it contacts with the part to measure points that define the feature.

TIP change on star color RGB - This defines the color of the path lines that PC-DMIS displays when you change the TIP in star configuration. The machine or wrist does not move. The path line indicates the change in the hot spot from one TIP to another.

Modifying Report and Motion Parameters

The **Edit | Preferences | Parameters** menu option allows you to modify the content, form, and method of calculation used in any report. Additionally, it allows you to modify the machine motion parameters of a DCC CMM. This menu option opens the **Parameter Settings** dialog box.

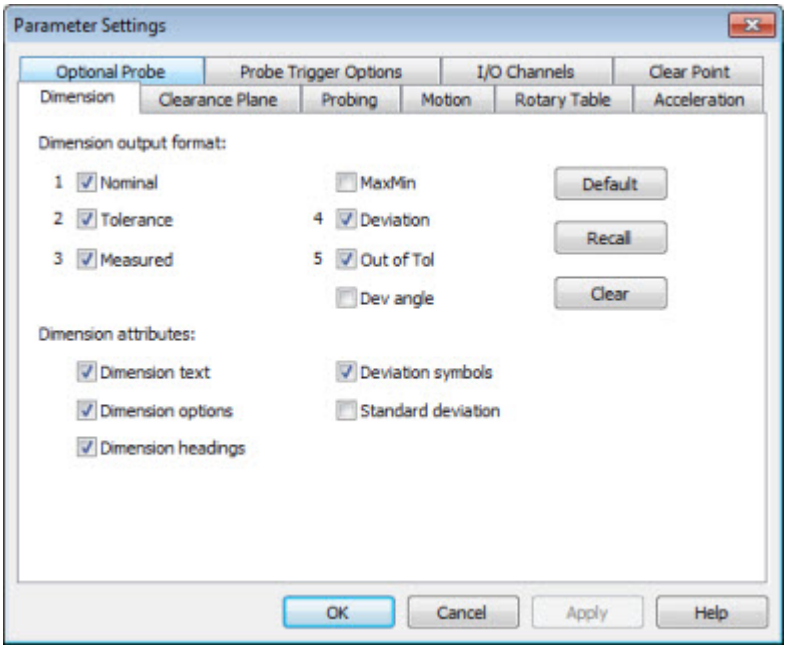
In addition to accessing the **Parameter Settings** dialog box, you can insert the commands from this dialog box directly into the measurement routine by selecting them from the **Insert | Parameter Change** submenu.

The following tabs are available on the **Parameter Settings** dialog box.

- Parameter Settings: Dimension Tab
- Parameter Settings: Clearance Plane Tab
- Parameter Settings: Probing Tab
- Parameter Settings: Motion Tab
- Parameter Settings: Rotary Table Tab
- Parameter Settings: Acceleration Tab
- Parameter Settings: Probe Options Tab
- Parameter Settings: Probe Trigger Options Tab

- Parameter Settings: I/O Channels Tab
- Parameter Settings: Clear Point Tab

Parameter Settings: Dimension Tab



Parameter Settings Dialog Box - Dimension Tab

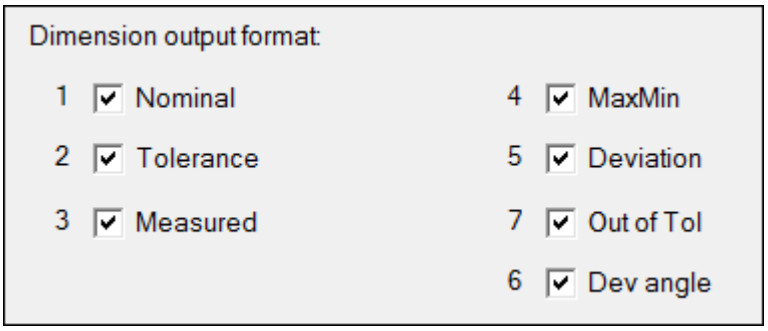
Use the **Dimension** tab to vary the format of the dimension output and alter the printed report. The settings on this tab apply only to labels in dimension templates.

The reports from DEFAULT.RPT and TEXTONLY.RPT reflect any changes made to these settings.

To access the **Dimension** tab:

1. Access the **Parameter Settings** dialog box (**Edit | Preferences | Parameters**).
2. Click the **Dimension** tab.

Dimension Output Format



The `FORMAT/TEXT` command controls the PC-DMIS dimension output format. To change the format, select the desired check boxes.

Available Formats	Description
Nominal	Displays the nominal values for all dimensions.
Tolerance	Displays the tolerance values for all dimensions.
Measured	Displays the measured values for all dimensions.
MaxMin	Displays the maximum and minimum deviation values from the points that make up Line Profile and Surface Profile dimensions.  *Example of the Report window showing MaxMin values on four different profile dimensions.*
Deviation	Displays the deviation values for all dimensions.
Out of Tol	Displays the out of tolerance values for all dimensions.
Dev Angle	Displays the deviation angles on the Position dimensions.

When switching from box tolerancing to position (and back), it is important to check the format for correctness.

PC-DMIS offers the same print formats for box tolerancing and positioning tolerancing, although their columns look slightly different due to additional columns for position dimensions.

PC-DMIS displays a number to the left of the check box to indicate the order of the output selection. This enables you to alter the order of the format to meet your needs.

The Edit window command line for this option reads:

```
FORMAT/TEXT,OPTIONS,HEADINGS,SYMBOLS, SD; "DIMENSION OUTPUT"
```

DIMENSION OUTPUT = The format of the output is based on the order of selection. The default output displays the entire selection, in the order indicated.

Dimension Text

The **Dimension Text** check box controls whether or not the dimension text will be displayed in the Edit window for any dimensions that follow the command.

The Edit window command line for this option reads:

```
FORMAT/TEXT, , , , ;NOM,TOL,MEAS,MAXMIN,DEV,OUTTOL,DEVANG
```

For a description the options on this command, see "Dimension Output Format".

Dimension Options

The **Dimension Options** check box controls whether or not the dimension options will be displayed in the Edit window for any dimensions that follow the command.

These options include:

- Units (see "Units" in the "Using Legacy Dimensions" chapter)
- Graphical analysis (see "Analysis Settings" in the "Using Legacy Dimensions" chapter)
- Textual analysis (see "Analysis Settings" in the "Using Legacy Dimensions" chapter)
- Arrow multiplier (see "Analysis Settings" in the "Using Legacy Dimensions" chapter)
- Output options (see "Analysis Settings" in the "Using Legacy Dimensions" chapter)

The Edit window command line for this check box reads:

```
FORMAT/OPTIONS, , , , ;NOM,TOL,MEAS,MAXMIN,DEV,OUTTOL
```

Dimension Headings

The **Dimension Headings** check box controls the column headings on the inspection report. If this check box is not selected, then PC-DMIS does not print any column headings.

Deviation Symbols

The **Deviation Symbols** check box shows the deviation within the set range. If the out of tolerance range is high, PC-DMIS indicates the deviation using the "greater than" symbol (>) on the right side of the line. If the out of tolerance range is low, PC-DMIS indicates the deviation using the "less than" symbol (<).

For example:

Nominal = 0.00

Measured = 0.02

Positive Tolerance = 0.10

Negative Tolerance = 0.20

Total Tolerance Range = (.10 - (-.20)) = .30

Percentage = 100*(.02 - (-.20))/.3 = 73.3 %

- - - - - - # - - looks at the % and shifts based on the %.

DIM D1= LOCATION OF CIR F5 GRAPH=OFF TEXT=OFF MULT=1.00

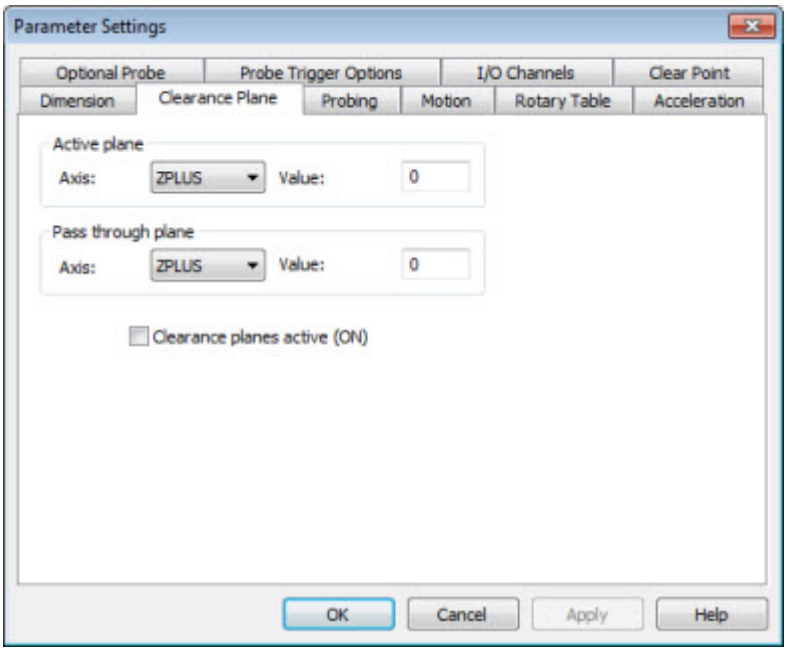
END OF DIMENSION D1

Standard Deviation

The **Standard Deviation** check box displays the standard deviation of features.

Parameter Settings: Clearance Plane Tab

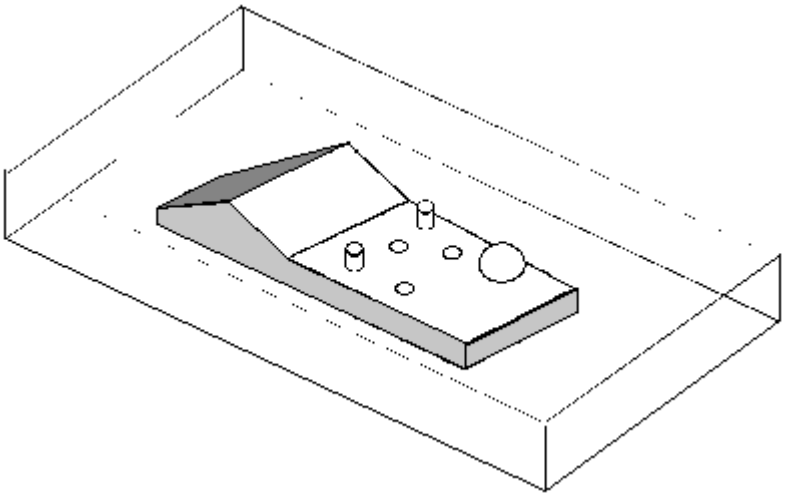


Parameter Settings Dialog Box - Clearance Plane Tab

The **Clearance Plane** tab provides the means to define and add clearance planes. Clearance planes, in essence, create an envelope around a part. The probe stays on this envelope when it moves from one feature to another.

PC-DMIS moves the probe out from the part at a predetermined distance, relative to the coordinate system in which it was defined.

After the last hit on the feature is measured, the probe stays at probe depth until called to the next feature. This can help reduce routine creation time because you don't have to define as many intermediate moves. In addition, properly-defined clearance planes can help protect your probe from accidental collisions with the part.



Example showing a part with an imaginary envelope from clearance planes.

To use clearance planes:

1. Open the **Parameter Settings** dialog box (**Edit | Preferences | Parameters**) and then select the **Clearance Plane** tab.
2. Select the clearance plane through the **Active plane** and **Pass through plane** areas, and use the respective **Value** boxes to specify the clearance distances.
3. Click **OK** to finish defining the clearance plane. PC-DMIS inserts a `CLEARP` command that contains the clearance plane information into the Edit window. The finished command looks something like this:

```
CLEARP/ACTIVE_PLANE, n, PASS_THROUGH_PLANE, n,TOG1
```

   - `ACTIVE_PLANE` and `PASS_THROUGH_PLANE` refer to the axes selected.
   - `n` refers to the offset distances specified.
   - `TOG1` is an ON/OFF toggle field that determines whether the clearance plane is active and automatically used for newly-created Measured and Auto features.

4. You can then insert `MOVE/CLEARPLANE` commands into your measurement routine. A `MOVE/CLEARPLANE` command does not in itself create motion to move the probe to the clearance plane. Rather, when PC-DMIS encounters a `MOVE/CLEARPLANE` command during execution, that command essentially gives permission to move to the predefined clearance plane on the next move, measure, tip selection, or Auto feature command. When PC-DMIS is about to execute one of those motion commands, the probe moves to the specified distance away from the selected active plane.
5. If you define another `CLEARP` command, the very next `MOVE/CLEARPLANE` command moves first to the old clearance plane, then to the Pass Through plane, and then to the new clearance plane.

To display the current clearance plane as a translucent image in the Graphic Display window, from the **Graphic Items** toolbar, select the **Show Clearance Plane** icon ( ). For more information, see "Viewing Clearance Planes" in the "Editing the CAD Display" chapter.

Active Plane Area

The **Active Plane** area defines the plane (or axis) that PC-DMIS locates and measures features. The **Value** box defines the clearance plane as an offset distance in the current units of measurement away from the specified plane. To define a clearance plane, select the plane from the **Axis** list and then enter a new value in the **Value** box.

Pass Through Plane Area

The **Pass Through Plane** defines a clearance plane that the probe moves to and then passes through to get to the next active clearance plane after a probe's `TIP` command. The new `CLEARP` definition command must immediately follow the `TIP` command to properly define the pass through plane. When PC-DMIS encounters the next `MOVE/CLEARPLANE` command, it moves to the pass through plane and remains at that offset distance until it reaches the next active clearance plane.

If you add additional moves or a loadprobe command before a tip change command, PC-DMIS deactivates the pass through plane.

When you make adjustments to commands in your measurement routine, be sure to review the path lines. This allows you to see the effect your changes make without having to run the measurement routine.

Clearance Plane Active (ON) Check Box

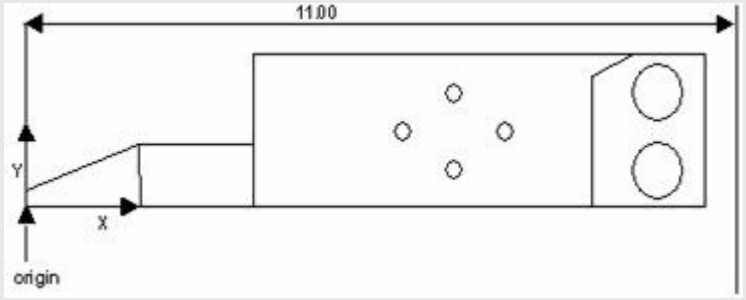
If you select the **Clearance planes active (ON)** check box, PC-DMIS automatically inserts a `MOVE/CLEARPLANE` command before any Measured or Auto features you insert into the Edit window from that point on.

Notes on Clearance Planes

Be aware of the sign of a clearance plane when you enter its distance value. The sign must correspond to the positive or negative end of the normal axis that defines the plane. For example, to define a top clearance plane, enter a positive value, and to define a bottom clearance plane, enter a negative value.

Movement from one clearance plane to another affects the position of the probe. Make sure that the set clearance plane is sufficient to clear the part.

PC-DMIS defines a clearance plane relative to the current coordinate system and part origin. Therefore, you must be careful when you define a clearance plane to ensure adequate clearance around the part.



Clearance Plane example

Using the above drawing, suppose your part is ten inches long, and it is lined up close to the machine axes with the X origin at the bottom left-hand corner. To define a one-inch clearance from the right side of the part, set the XPLUS clearance plane to 11 inches.

Always define clearance planes relative to the current coordinate system. When you create a new coordinate system, the clearance planes still relate to the first alignment. If you wish to associate the clearance planes with the new coordinate system, you must redefine them.

PC-DMIS does not use clearance planes when taking sample hits. It is therefore important, when you measure pins, to set the spacer value to a distance that will allow the probe to move around the pin.

For a clearance plane example, see "Clearance Plane Example".

Clearance Plane Example

This example provides a complete measurement routine with comments in the routine that provide explanation. Below the code sample, there are screen captures of the clearance planes.

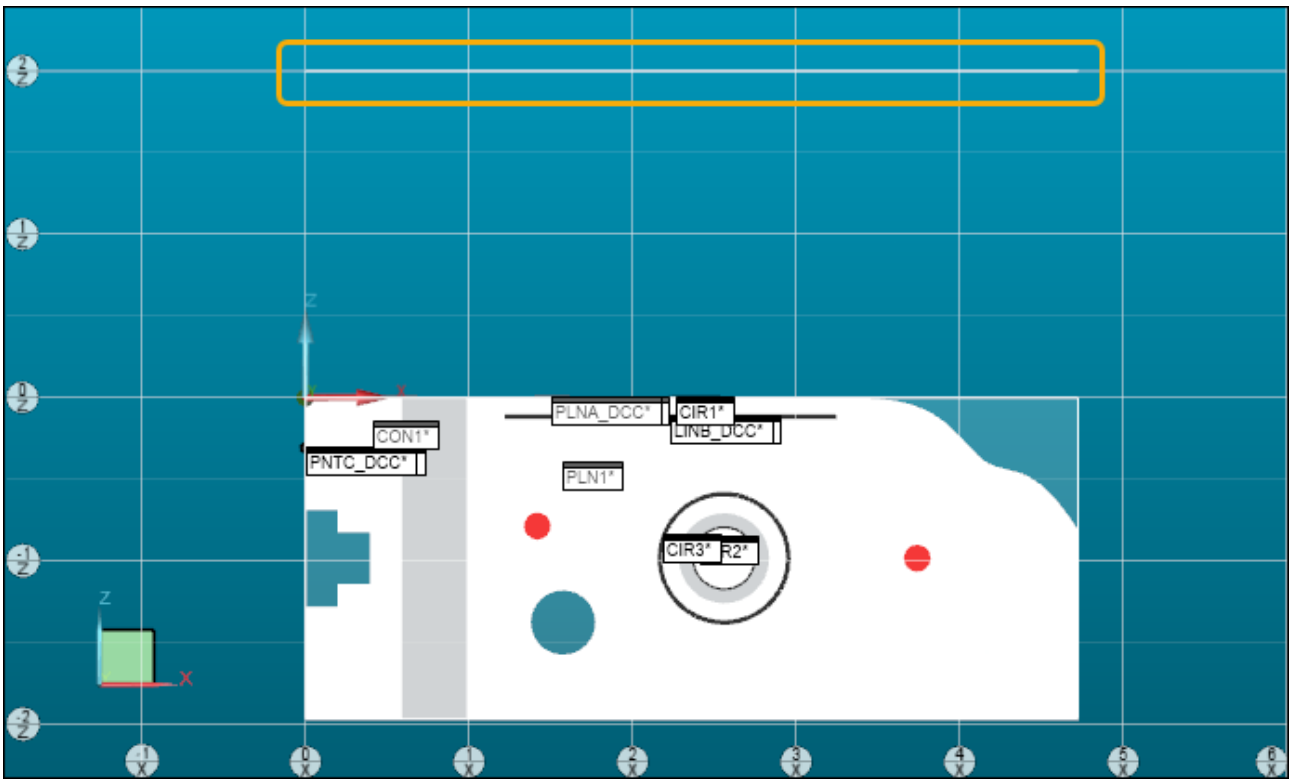
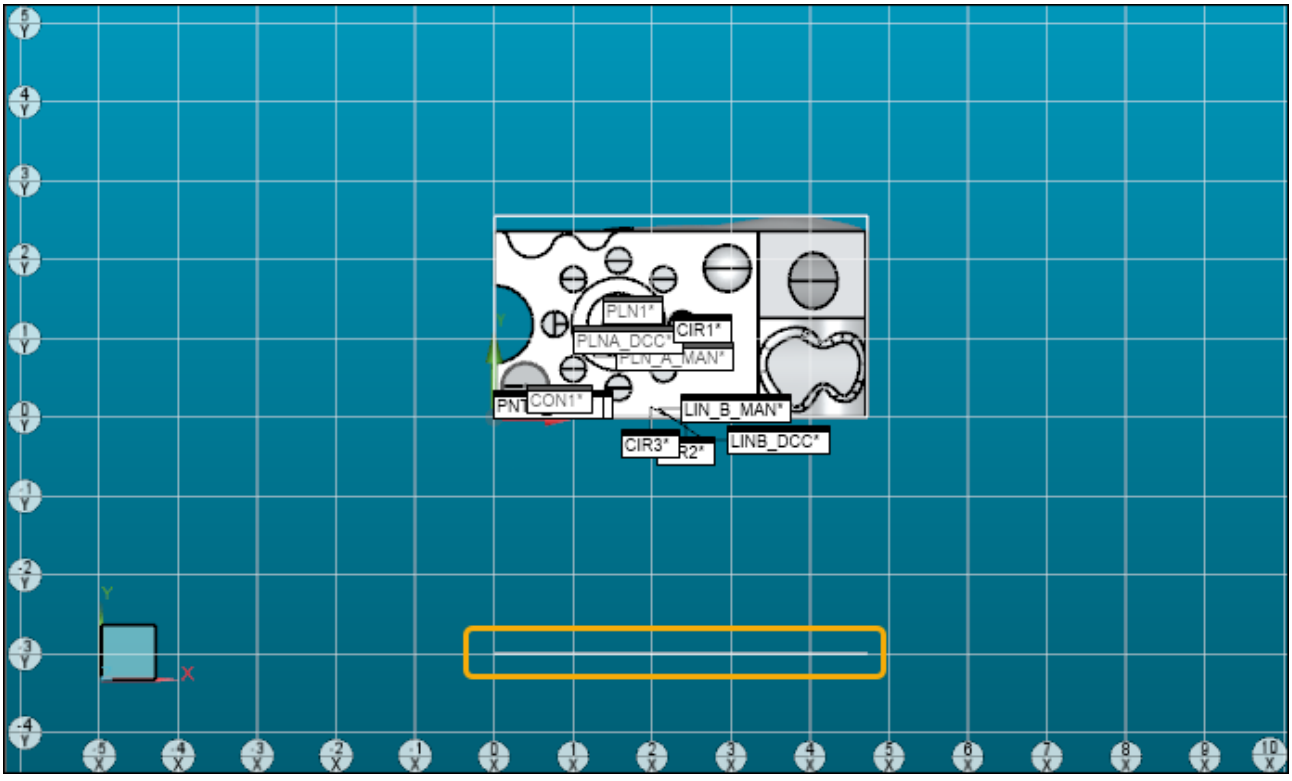
If you add additional moves or a loadprobe command before a tip change command, PC-DMIS deactivates the pass through plane.

When you make adjustments to commands in your measurement routine, be sure to review the path lines. This allows you to see the effect your changes make without having to run the measurement routine.

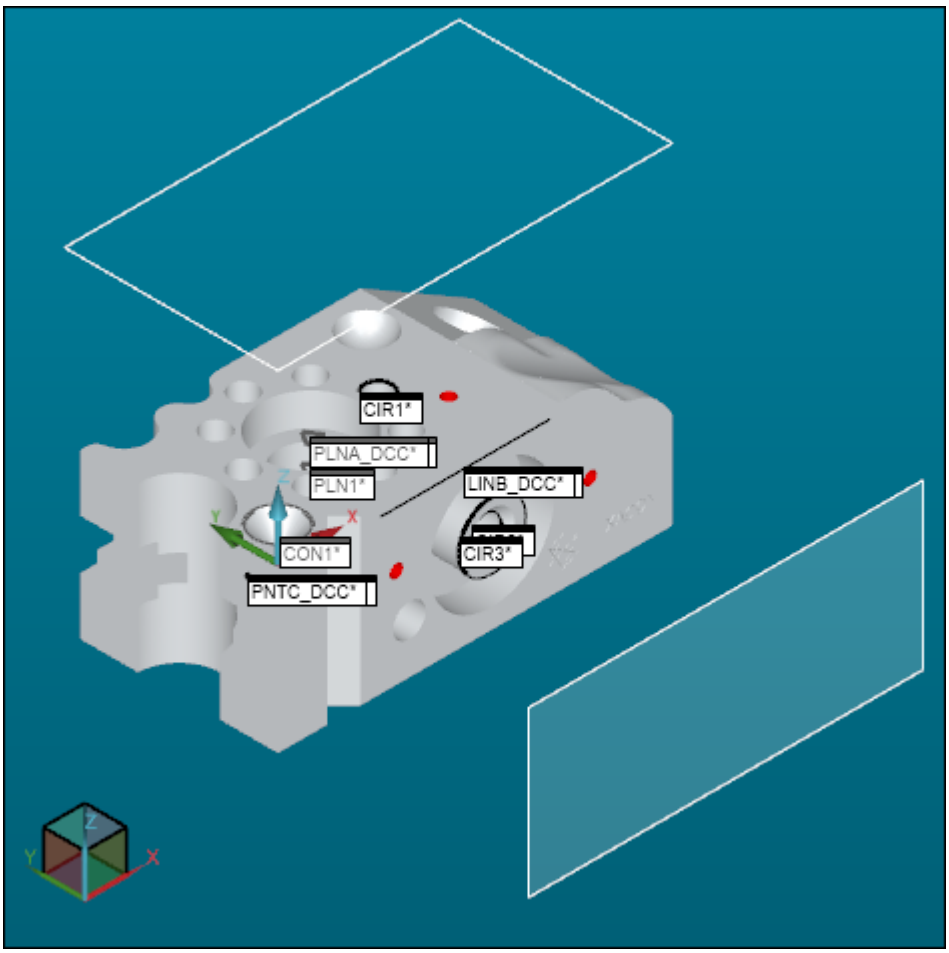
First Clearance Plane - YMINUS View



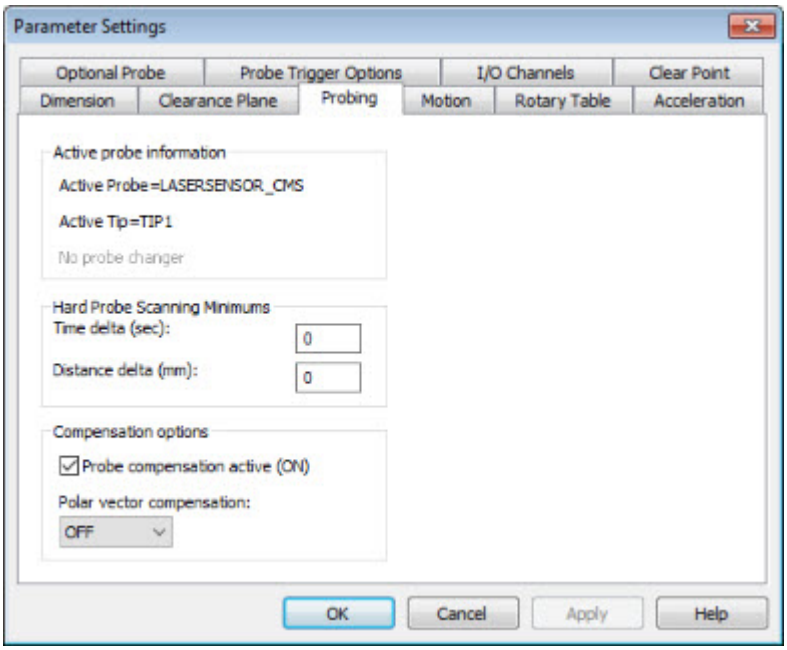
Second Clearance Plane - ZPLUS View



Both Clearance Planes - Isometric View



Parameter Settings: Probing Tab



Parameter Settings Dialog Box - Probing Tab

The **Probing** tab displays the current probe file, active tip, and probe port (if being used). It also allows you to set the **Hard Probe Scanning Minimums** for time delta and distance

delta, select the **Probe compensation active (ON)** check box, and select the **Polar vector compensation**.

The **Hard Probe Scanning Minimums** area is disabled for trackers that do not support this functionality.

To access the **Probing** tab:

1. Open the **Parameter Settings** dialog box (**Edit | Preferences | Parameters**).
2. Select the **Probing** tab.

Active Probe Information area

Active Probe

Active Probe=PH9

This line on the **Probing** tab displays the current probe file. For more information on selecting a different probe file or creating a new probe file name, see "Probe File Name" in the "Defining Hardware" chapter.

Active Tip

Active Tip=T1A0B0

This line on the **Probing** tab displays the current and active tip. For more information on the values and selecting, creating, and deleting tips, see "Active Tip List" in the "Defining Hardware" chapter.

The Edit window command line for this option reads:

```
TIP/active_tip_name
```

Probe in Port

This line on the **Probing** tab indicates the port number on the probe changer of the probe or stylus that you are currently using. This option is only available if you set up a probe changer.

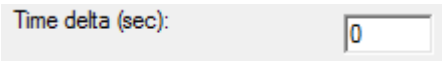
If you aren't using a probe changer, or if your current probe isn't in a probe changer, then PC-DMIS displays text informing you that your current probe or stylus isn't in the probe changer or that a probe changer isn't being used.

For information on adding probes or styli to a probe changer, see "Ports Tab" in the "Setting Up Probe Changer Options" topic.

Hard Probe Scanning Minimums Area

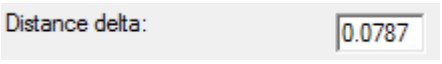
The **Hard Probe Scanning Minimums** area is disabled for trackers that do not support this functionality.

Time Delta (sec) box



This value allows PC-DMIS to reduce the amount of points that are scanned by deleting hits that are read in faster than the specified time delay in milliseconds.

Distance Delta box



This value allows you to reduce the measured data by deleting hits that are closer than the distance specified in millimeters. The reduction of hits happens as data comes from the machine. PC-DMIS only keeps the points that are set apart by more than the specified increments.

Notes

If Both are Greater than Zero

If both the time delta and distance delta values are greater than zero, PC-DMIS checks the amount of time elapsed and the distance and the probe moves. Whenever both the time AND the distance exceed the values specified, PC-DMIS accepts a hit.

If Both Are Zero

If both the time delta and distance delta values are set to zero, PC-DMIS uses the maximum-allowed sampling rate of the measurement device to accept hits.

Compensation Options area

Probe Compensation Active (On)

The **Probe Compensation Active (On)** check box allows PC-DMIS to compensate for the probe radius. If marked, and you click **OK**, this check box inserts a `PROBECOM/ON` command into the Edit window. PC-DMIS will compensate for the probe radius on each feature it measures. If cleared, then the command is set to `PROBECOM/OFF` in the Edit window. If you're using a Portable device, you can use **Insert | Parameter Change | Probe | Probe Compensation** to toggle this on or off as well.

Polar Vector Compensation

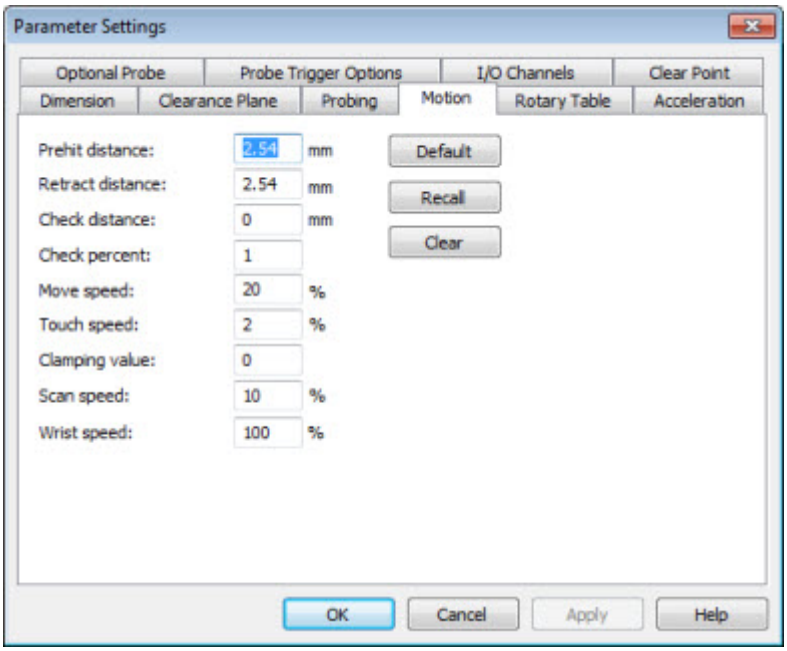
The **Polar Vector Compensation** drop-down list allows the measurement of Vector and Surface points to always be compensated along a Polar vector. The following options are available:

- **OFF** - Vector and Surface points behave normally.
- **XYPL** - Vector compensations for each Vector and Surface point will be 2D in the XY plane along a vector from the point to the current origin.
- **YZPL** - Vector compensations for each Vector and Surface point will be 2D in the YZ plane along a vector from the point to the current origin.
- **ZXPL** - Vector compensations for each Vector and Surface point will be 2D in the ZX plane along a vector from the point to the current origin.
- **3D** - Causes a polar vector compensation along a 3D vector from the point to the current origin.

The Edit window command lines for these options read:

```
POLARVECTORCOMP/ OFF
POLARVECTORCOMP/ XYPL
POLARVECTORCOMP/ YZPL
POLARVECTORCOMP/ ZXPL
POLARVECTORCOMP/ 3D
```

Parameter Settings: Motion Tab



Parameter Settings Dialog Box - Motion Tab

The **Motion** tab allows you to change the distances that the probe is allowed to travel when taking a hit. It also allows you to set the speed that PC-DMIS uses to take a hit and move from point to point.

To determine whether the speed boxes (**Move Speed**, **Touch Speed**, and **Scan Speed**) list the values as either **mm/sec** or as a percentage of the total allowed speed, select or clear the **Display Absolute Speeds** check box on the **Part/Machine** tab in the **Setup Options** dialog box.

To edit information in the **Motion** tab:

1. Access the **Parameter Settings** dialog box (**Edit | Preferences | Parameters**).
2. Click on the **Motion** tab. You'll see a variety of boxes.
3. Highlight the value you want to change.
4. Type a new value.
5. Click **Apply** or **OK**. PC-DMIS inserts any changed command into your measurement routine.

To reset the motion values to the original factory setting, click the **Recall** button. The **Recall** button returns the displayed motion values to the values stored in the PC-DMIS Settings Editor. If you click the **Defaults** button, the displayed values are saved to the

Settings Editor. For information on the PC-DMIS Settings Editor, view the "Modifying Setting Entries" section.

Changing Animation Speeds: If you want to modify your offline animation speeds, see the **Execution** area on the **Animation** tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**). In addition, see the "Executing and Debugging Measurement Routines Offline" topic in the "Working in Offline Mode" chapter.

Prehit Distance

The **Prehit Distance** box lets you enter the value for the machine prehit distance. This value determines the distance away from the theoretical hit location on the surface where PC-DMIS starts searching for the part. The machine travels at touch speed while traversing this distance to search for the part.

If necessary, PC-DMIS can automatically change this when the software takes hits within an arc or circle.

The Edit window command line for this option reads:

```
PREHIT/nnn.nnnn
```

Where `nnn.nnnn` is a number value for the distance.

For an example of how **Prehit Distance** and **Check Distance** work together, see the example in the "Check Distance" topic.

The Probe Readout window shows the probe location based on the probe's center. However, the machine uses the outer diameter of the probe to drive to the surface. This means the values in the Probe Readout always show a probe radius less than what you might expect when it moves to this distance.

Retract Distance

The **Retract Distance** box lets you enter the distance the probe retracts from the surface after taking a hit. If necessary, PC-DMIS can automatically change this value when it takes hits on an arc or circle.

The Edit window command line for this option reads:

```
RETRACT/nnn.nnnn
```

Where `nnn.nnnn` is a number value for the distance.

How the probe retracts depends on the CMM controller:

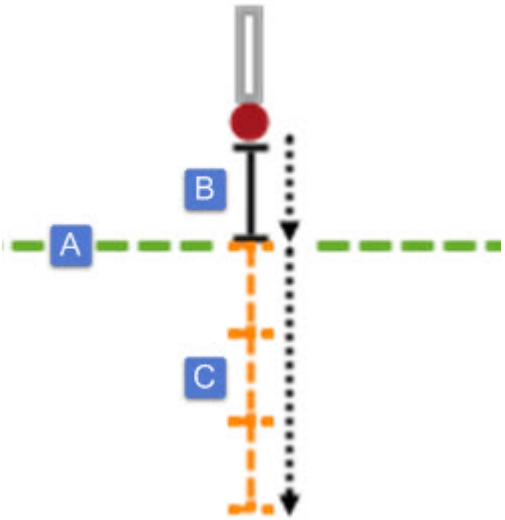
- **Some controllers handle the retract internally.** After a hit, the controller automatically retracts the probe, but it may only know the prehit distance, not the retract distance. In these cases, the controller retracts the probe to the prehit standoff, and PC-DMIS then issues an additional move to reposition the probe at the retract distance. If the retract distance is less than or equal to the prehit distance, the probe remains at the prehit standoff; PC-DMIS does not move the probe back toward the part after the controller's retract. *The retract value takes effect only when it is greater than the prehit.*
- **Some controllers do not retract on their own.** In these cases, PC-DMIS issues the move to perform the retract, and the distance is based on the probe tip's ball surface to the part's theoretical hit location.

When the controller does perform its own retract, the distance may be calculated from either the ball surface or the ball center to either the theoretical or measured hit location, depending on the particular controller.

Check Distance

The **Check Distance** box defines the distance past the theoretical hit location that the machine continues to search or check for the surface of the part. This distance is after it traverses the **Prehit Distance** value. The default value is zero.

- If this is zero, after the prehit distance, the machine searches to a maximum distance of three times the **Prehit Distance** value. For example:

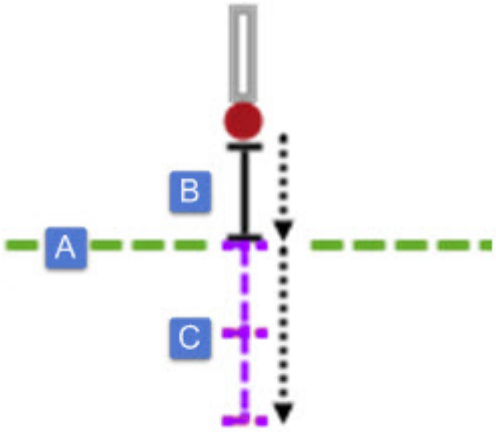


A. *Theoretical surface location.*

B. *Prehit distance.*

C. *Check distance (three times the prehit)*

- If this is a positive, non-zero number, after the prehit distance, the machine searches up to the maximum distance specified by the **Check Distance** value. For example, if the **Check Distance** is set to 2, the probe moves by two units:



A. *Theoretical surface location.*

B. *Prehit distance.*

C. *Check distance (moves the specified Check Distance value; in this example, two units)*

The Probe Readout window shows the probe location based on the probe's center. However, the machine uses the outer diameter of the probe to drive to the surface. This means the values in the Probe Readout always show a probe radius less than what you might expect when it moves to this distance.

The measurement units for the distance depend on the measurement system used for the part

The Edit window command line for this option reads:

```
CHECK/distance,percentage
```

Percentage Movement During Find Hole Operations

When defining the check distance for a Find Hole operation, you can tell PC-DMIS to move by a percentage of the check distance.

To do this:

1. Access the Edit window and place it in Command Mode.
2. Click on the `CHECK` command in the Edit window.
3. Press the Tab key to move to the second number.
4. Type a new percentage value. The default value is 1 which means 100% of the check distance. Thus .1=10%, .2=20%, .3=30% and so on.

For example, in the following code, the .3 value represents 30% of the total check distance of twenty units:

```
CHECK/20,.3
```

For information on the Edit window command see "Check Distance" in the "Using the Edit Window" chapter.

For additional information on Find Hole, see the "Working with Contact Find Hole Properties" topic in the "PC-DMIS CMM" documentation.

Check Percent

The **Check Percent** value determines the percent of the total distance moved when performing a Find Hole operation. Be aware that if you type **1**, the value is equal to 100 percent. Thus, 100% would be entered as **1**, 25% would be entered as **.25**, and 10% would be **.10**.

Move Speed %

The **Move Speed** box lets you change the point to point positioning speed of the CMM. Depending on the state of the **Display absolute speeds** check box in the **Part/Machine** tab of the **Setup Options** dialog box, this will either be an absolute speed (mm/sec) or a percentage of the machine's defined top speed.

(See the "Measure" topic under "Defining Probes" in the "Defining Hardware" chapter for information regarding the move speed option and probe calibration.)

The Edit window command line for this option reads:

```
MOVESPEED/ nnn.nnnn
```

Where `nnn.nnnn` is a number value for the speed.

Touch Speed %

The **Touch Speed** box lets you change the speed at which the CMM takes hits. Depending on the state of the **Display absolute speeds** check box in the **Part/Machine** tab of the **Setup Options** dialog box, this is either be an absolute speed (mm/sec) or a percentage of the machine's defined top speed. This cannot exceed twenty percent.

The Edit window command line for this option reads:

```
TOUCHSPEED/nnn.nnnn
```

Where `nnn.nnnn` is a number value for the speed.

> To understand the effects of changing either PREHIT or RETRACT distances and MOVE or TOUCH SPEED, it's important to understand how the options interact during DCC feature measurement. The order of events is that the machine moves toward the feature at MOVE SPEED. When it reaches PREHIT distance, it approaches the feature at TOUCH SPEED to take the hit. After it takes the hit, it backs away at TOUCH SPEED until it reaches the RETRACT DISTANCE. At this point, it proceeds to the next location at MOVE SPEED.

Clamping Value

The **Clamping Value** only works with the Leitz controller and the Leitz brand TTP. This value tells the controller how firmly to hold the probe on a Leitz CMM.

Depending on the weight of the probe tips, you may need to increase or decrease the clamping value.

- For a large tip weight, you may need to increase the clamping value.
- For a small tip weight, you may need to decrease the clamping value.

Scan Speed %

The **Scan Speed** box lets you change the speed at which the CMM scans the part. Depending on the state of the **Display absolute speeds** check box in the **Part/Machine** tab of the **Setup Options** dialog box, this is either an absolute speed (mm/sec) or a percentage of the machine's defined top speed.

The Edit window command line for this option reads:

```
SCANSPEED/nnn.nnnn
```

Where `nnn.nnnn` is a number value for the speed.

When scanning using the **DEFINED** mode of execution (see "Defined" discussed in the "Exec Controls area" topic in the "Scanning your Part" chapter), **Scan Speed** plays an important role in getting back data at increments specified by you. When you specify a very high **Scan Speed**, the CMM may execute the scan at the speed you requested, but the data from the CMM may not be spaced at the increments you specify.

> Assume the CMM gathers data at the rate of one Hit per 20 milliseconds in the **DEFINED** mode. If you specify an increment (minimum distance between hits) of 0.5 mm and a **Scan Speed** of 75 mm/sec, the CMM would give back points at every 1.5 mm. To avoid this you could reduce the **Scan Speed** to 15 mm/sec or 20 mm/sec which, at the rate of 1hit/20ms, would satisfy your requirements.

PC-DMIS will warn you about this case by displaying a message informing you that the supplied increment couldn't be measured at the specified scan speed. You will then be required to reduce your **Scan Speed** or increase the increment.

You can then select the **Scan Speed** setting and change to a suitable scan speed.

Wrist Speed %

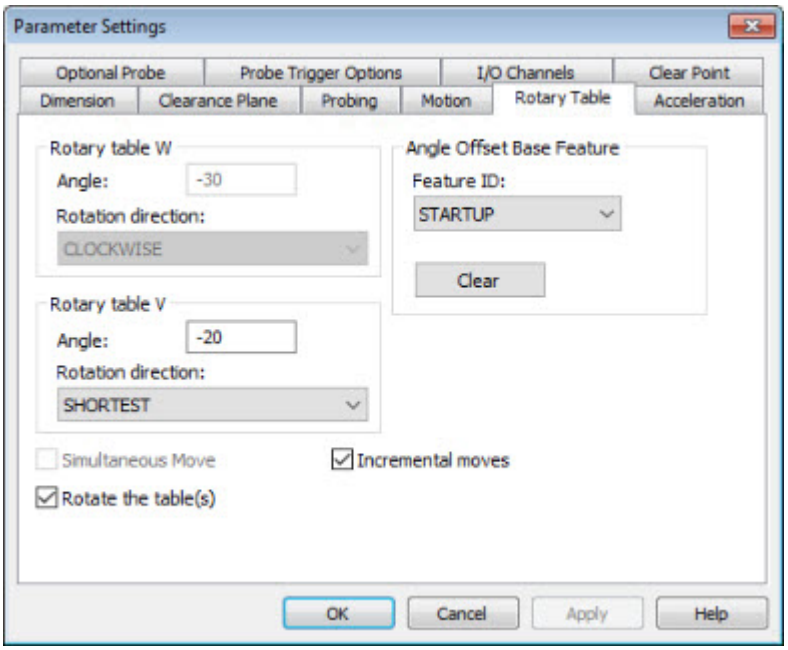
The **Wrist Speed** box lets you change the speed your measuring machine will use when rotating a probe's wrist (such as a CW43L). Depending on the state of the **Display absolute speeds** check box in the **Part/Machine** tab of the **Setup Options** dialog box,

this will either be an absolute speed (mm/sec) or a percentage of the machine's defined top speed.

The Edit window command line for this option reads:

```
WRISTSPEED/ nnn.nnnn
```

Parameter Settings: Rotary Table Tab



Parameter Settings Dialog Box - Rotary Table Tab

The **Rotary Table** tab allows you to rotate the current active rotary table by a defined angle and direction. You can also use it to automatically set the rotation based on a specified feature or alignment; or, you can combine the two and rotate to a specific feature or alignment and then rotate a relative angle on an offset based on the feature or alignment.

The **Rotary Table** tab becomes available when you select **Single Rotary Table**, **Dual Rotary Tables**, or **Stacked Rotary Tables** from the **Rotary Table Setup** dialog box. See "Defining the Rotary Table".

To insert a `MOVE/ROTAB` command that rotates the table, follow this procedure:

1. Access the **Parameter Settings** dialog box (**Edit | Preferences | Parameters**).
2. Select the **Rotary Table** tab.
3. Choose to rotate by a specific angle or to rotate to a feature (or both).
    - If you want to rotate by a specific angle, complete the **Rotary Table W** or **Rotary Table V** areas, and define the **Angle** and the **Rotation Direction**.

- If you want to rotate to a specific feature or alignment, complete the **Angle Offset Base Feature** area.

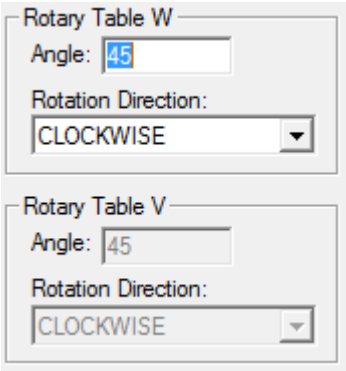
4. If you want to combine the individual movements of the W (rotary axis) and V (swivel axis) axes of a stacked rotary table into a single joint movement, select the **Simultaneous Move** check box.
5. If you want to rotate the table immediately, select the **Rotate the Table(s)** check box.
6. Click the **Apply** button. PC-DMIS inserts a `MOVE/ROTAB` command into the Edit window.

The Edit window command line for this option reads:
`MOVE/ROTAB, angle, DIRECTION,feature`

If you have a stacked configuration, the Edit window command line for this option reads:
`MOVE/ROTAB, angle, DIRECTION, angle2, DIRECTION2,feature`

Additionally, the **Rotary Table Setup** menu option is only available if your PC-DMIS license is programmed for rotary tables.

Rotary Table W / Rotary Table V



Parameter Settings Dialog Box - Rotary Table W and Rotary Table V Area

The **Rotary Table W** area and the **Rotary Table V** area let you control up to two rotary tables, table W and table V. PC-DMIS activates the area associated with the currently active rotary table. If you have a stacked rotary configuration, PC-DMIS activates both areas allowing you to type the angle and define the rotation direction for both tables at the same time. See "Defining the Rotary Table".

These areas contain the same options:

Angle box
This defines the angle of the table's rotation.

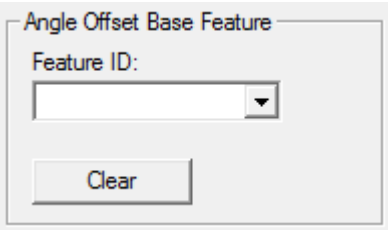
Rotation Direction list
In the **Rotation Direction** drop down list you can select the direction you want the table to rotate. Available options are:

Clock Wise: Rotates the table in a clockwise direction until it reaches the angle entered in the Rotate Table Angle box.

Counterclockwise: Rotates the table in a counterclockwise direction until it reaches the angle entered in the Rotate Table Angle box.

Shortest: Rotates taking the shortest route (either Clockwise or Counterclockwise) until it reaches the angle entered in the Rotate Table Angle box.

Angle Offset Base Feature



Parameter Settings Dialog Box - Angle Offset Base Feature Area

The **Angle Offset Base Feature** area lets you select a feature or alignment from the **Feature ID** list. The angle where the feature normal matches the machine Z (or where it matches as closely as possible for the hardware configuration) will become the 0 angle on the rotary table. This allows you to rotate to the desired feature or alignment without defining an initial angle. You simply specify the desired feature or alignment. The selected feature or alignment becomes the base feature (or the 0 angle) from which PC-DMIS rotates the table by a relative angle. Relative measurements like these are especially useful in camera-based vision environments where initial starting angles may not be known.

This works for both single and stacked rotary tables.

Feature ID
This list contains all the features and alignments in the measurement routine. It allows you to choose a feature or alignment to which the table will rotate.

Clear
This button clears the selected feature or alignment.

You can use the `MOVE/ROTAB` command to rotate the table to the feature or alignment during measurement routine execution. See "Inserting a Move Rotary Table Command" in the "Inserting Move Commands" chapter.

Simultaneous Move

Parameter Settings Dialog Box - Simultaneous Move Option

The **Simultaneous Move** option allows you to combine the individual movements of the W (rotary axis) and V (swivel axis) axes of a stacked rotary table into a single joint movement.

The result is a faster positioning and thus an overall faster processing of the measurement routine.

This option is only available if you have an FDC and an activated stacked rotary table.

If you select the **Simultaneous Move** check box, the individual paths of the W and V axes must both have either the SHORTEST direction selected or not selected for the simultaneous movement of the tables. That is, if the **Simultaneous Move** check box is selected, but one of the axis has the SHORTEST direction selected and the other axis has CLOCKWISE or COUNTERCLOCKWISE direction selected, PC-DMIS executes the rotary table moves one at a time.

If you do not select the **Simultaneous Move** check box, the software executes the rotary table moves individually.

The V axis (swivel axis) cannot rotate 360° due to the software limitations in the FDC configuration. This restriction does not always allow clockwise or counterclockwise movement.

Rotate the Table(s)

Parameter Settings Dialog Box - Rotate the table(s) Option

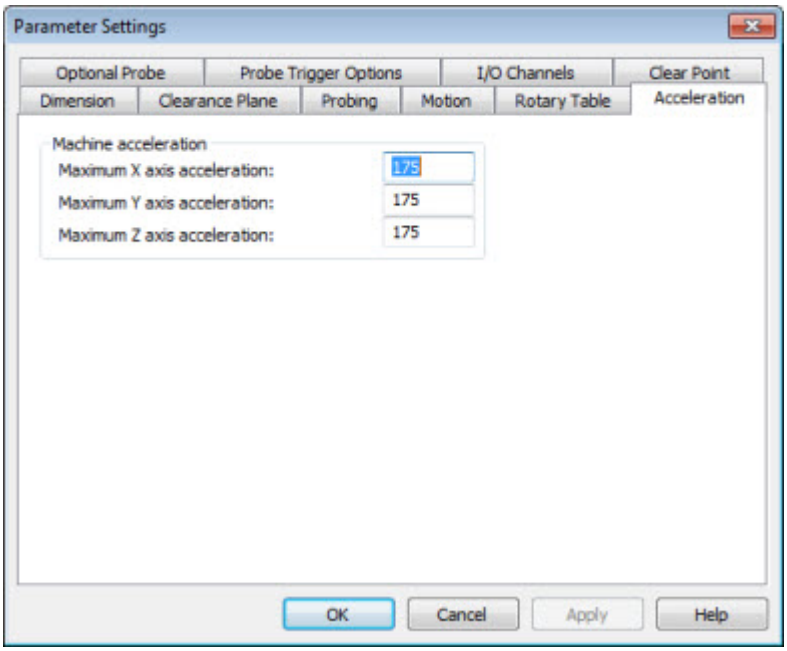
The **Rotate the Table(s)** check box enables you to activate the current table's rotation by the specified **Angle** value once you select the **Apply** or **OK** button.

Incremental Moves

Parameter Settings Dialog Box - Incremental moves Check Box

The **Incremental moves** option applies to the `MOVE/ROTAB` command. When you select this option, instead of using the NORMAL parameter for absolute values, you can use incremental values for the angle.

Parameter Settings: Acceleration Tab



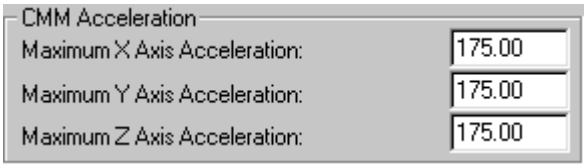
Parameter Settings Dialog Box - Acceleration Tab

The **Acceleration** tab displays additional editing capabilities for both CMM and Table motion.

To access the **Acceleration** tab:

1. Access the **Parameter Settings** dialog box from the main menu (**Edit | Preferences | Parameters**).
2. Select the **Acceleration** tab.

CMM Acceleration



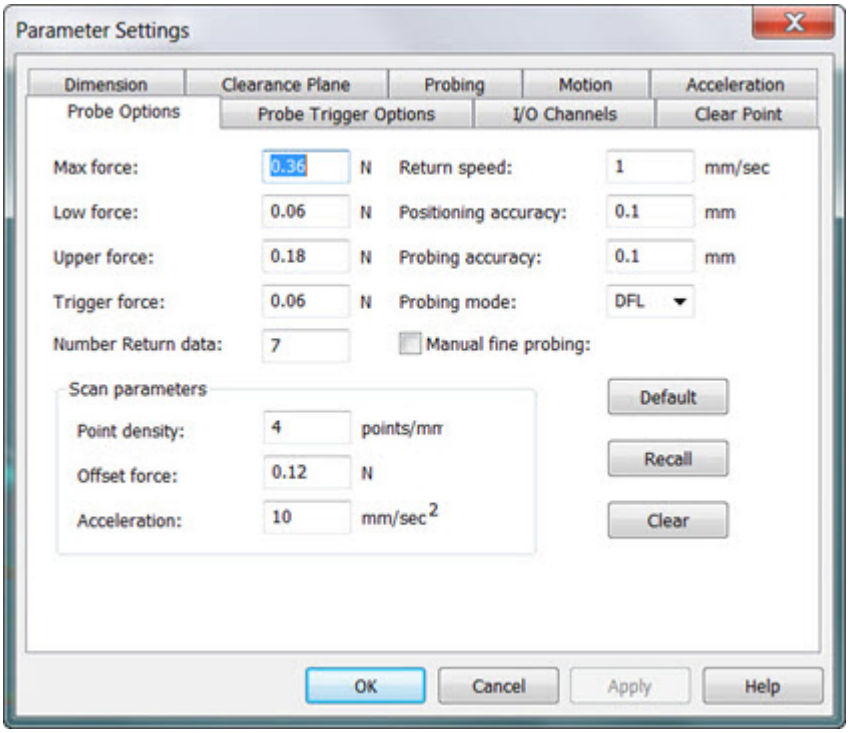
The **CMM Acceleration** area of the **Acceleration** tab allows you to change the maximum acceleration (at mm/sec2) along the X, Y, or Z axis of the CMM. Available options are:

Maximum X Axis Acceleration
The number in this box represents the maximum acceleration that the CMM will take when traveling along the X axis.

Maximum Y Axis Acceleration
The number in this box represents the maximum acceleration that the CMM will take when traveling along the Y axis.

Maximum Z Axis Acceleration
The number in this box represents the maximum acceleration that the CMM will take when traveling along the Z axis.

Parameter Settings: Probe Options Tab



Parameter Settings Dialog Box - Probe Options Tab

The **Probe Options** tab gives you additional capabilities for controlling analog probes. These capabilities include the following probing-related values:

- Max force
- Low force
- Upper force
- Trigger force
- Number Return data
- Return speed
- Positioning accuracy
- Probing accuracy
- Probing mode
- Manual fine probing

It also includes the following scan-related values and general purpose buttons:

- Point density
- Offset force
- Acceleration
- **Default** button
- **Recall** button
- **Clear** button

Each of these is described below in greater detail.

To access the **Probe Options** tab:

1. Access the **Parameter Settings** dialog box from the main menu (**Edit | Preferences | Parameters**).
2. Select the **Probe Options** tab.

The values on the **Probe Options** tab are machine-specific. With the exception of the **Manual fine probing** check box and the **Point density** box, *they generally shouldn't be changed*. Check with your machine's manufacturer before you make changes.

Click **Apply** or **OK** to insert an `OPTIONPROBE` command into the Edit window.

Max Force

The **Max Force** box allows you to enter the maximum force that a probe takes before an error occurs, thus stopping measurement.

A "newton" is a unit of force. One newton is the force needed to accelerate a mass of 1 kilogram to a speed of 1 meter per second per second.

During an analog probing cycle, when the probe first touches the part it continues to move into the part until it reaches this Max Force value. It then reverses direction and moves away from the part. This movement into the part, after touching the part, is sometimes referred to as the *contact force*. The value is specified in newtons. In a normal deflection mode (DFL) probing cycle, the controller collects data as the probe moves away from the part.

Low Force

The **Low Force** box allows you to enter the minimum force required to determine when the machine is in contact with the object being measured.

For a normal deflection mode (DFL) probing cycle, this is the force at which the controller stops collecting data. The value is specified in newtons.

Upper Force

The **Upper Force** box is the upper limit for a measurement. When this force is reached the machine moves back, away from the object being measured.

For a normal deflection mode (DFL) probing cycle, this is the force at which the controller starts collecting data. The value is specified in newtons.

Trigger Force

The **Trigger Force** box allows you to enter the force at which a measurement reading is taken.

For a normal deflection mode (DFL) probing cycle, this is the force at which the Actual Point (APT) will be calculated and returned to PC-DMIS. The value is specified in newtons. Not all analog probes/controllers use this input.

Return Data

The **Number Return data** box allows you to enter the number of readings taken when the machine is moving away from the object being measured.

This value defines the minimum number of data to be collected within the **Probe Options** tab defined by the **Upper Force** and **Lower Force** values.

Return Speed

The **Return Speed** box allows you to set the value, which determines the speed at which the probe comes off the object being measured. This is specified in mm/sec.

Positioning Accuracy

The **Positioning Accuracy** box is a parameter specific to the Leitz interface. The value submitted tells the CMM how carefully it should remain on the approach vector as the probe is moved into the part for a measurement.

With smaller values the difficulty for the machine to acquire the desired location increases. However, using a smaller value provides a more accurate measurement. This value is always in millimeters.

This should normally be left at the default value.

Probing Accuracy

The **Probing Accuracy** box allows you to determine the accuracy required to take a measurement. If this value is not met, then no measurement is taken, and an error is given. It is specified in mm and should normally be left at the default value.

Probing Mode

This box specifies the type of probing cycle used. The most common cycle is deflection mode (DFL). Other cycles, such as soft probing (SFT), may also be supported by some analog probes/controllers. In some cases, the probe /controller may not have multiple modes, and this value is ignored.

Type or select the probing cycle that you want to use.

Manual Fine Probing

If the **Manual Fine Probing** check box is selected, then when a manual probing point is taken, the controller automatically switches to DCC Mode while moving away from the part in order to use the normal deflection probing cycle. This may result in slower manual probing but improves accuracy.

While recent machines with analog probing systems may support **Manual Fine Probing**, not all analog probes/controllers support this mode of manual probing. In those cases, PC-DMIS ignores this check mark. Your CMM controller's manufacturer will know if your controller supports this option.

Point Density

The **Point Density** box allows you to set the number of readings to take per millimeter of measurement during a scan.

If you give a scan increment smaller than the **Point Density** defined in the entry in the Settings Editor, PC-DMIS displays a warning explaining that the minimum increment is smaller than Point Density for scans. You are then asked to verify increment settings in the dialog box.

You can then change the scan's **Point Density** value to a suitable number.

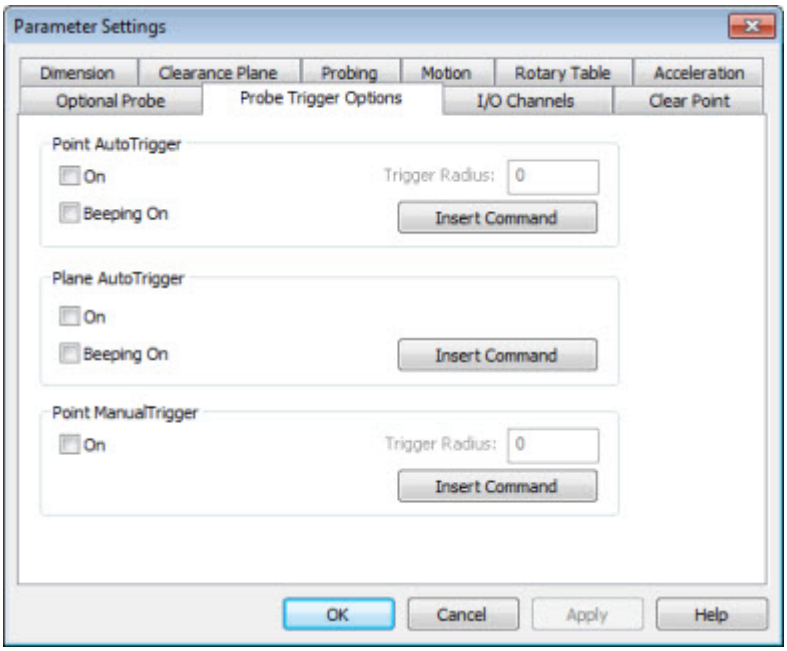
Offset Force

This allows you to specify what level of force to maintain during a scan. The value is specified in newtons.

Acceleration

This allows you to specify what acceleration to use during a scan. The value is specified in mm/sec/sec.

Parameter Settings: Probe Trigger Options Tab



Parameter Settings Dialog Box - Probe Trigger Options Tab

The **Probe Trigger Options** tab allows you to determine tolerance zones and then insert `POINT AUTOTRIGGER`, `PLANE AUTOTRIGGER`, and `POINT MANUAL TRIGGER` commands into the Edit window. These commands trigger a hit when certain conditions are met.

Only manual CMMs with certain interfaces support these probe trigger options. These interfaces include Faro, Romer, Garda, Leica, and Polar.

To access this tab:

1. Select **Edit | Preferences | Parameters** to display the **Parameter Settings** dialog box.
2. Select the **Probe Trigger Options** tab.

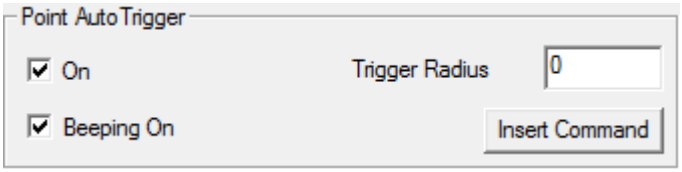
Supported Features

These trigger commands function with these supported features:

- Auto Features: Circle, Ellipse, Edge Point, Round Slot, Square Slot, Notch Slot, and Polygon
- Measured Features: Circle, Line, and Round Slot

In addition, the `POINT AUTOTRIGGER` command supports the Auto Vector Point and Measured Point features.

Point AutoTrigger area



With the **Point AutoTrigger** area, you can insert `POINT AUTOTRIGGER/` commands into the Edit window with a tolerance zone.

The `POINT AUTOTRIGGER/` command tells PC-DMIS to automatically take a hit when the probe enters a tolerance zone at a specified distance from the original hit location. For example, if the tolerance zone, the **Radius** value, is set to 2 mm, a hit is taken when the probe is within 2 mm of the hit location.

You can use this option with manual machines; instead of pressing a button to take a hit, you can place `POINT AUTOTRIGGER/` commands at any standard location in the Edit window.

On

Selecting the **On** check box activates the point auto trigger command. Commands in the Edit window that follow the inserted `POINT AUTOTRIGGER/` command and require you to take a hit will then have the hit automatically taken when the probe enters the defined tolerance zone. The **Trigger Radius** capability is disabled until you turn the option back on.

If you do *not* select this check box and you click the **Insert Command** button, PC-DMIS inserts the command line into the Edit window, but it doesn't activate the command.

Beeping On

Selecting the **Beeping On** check box activates a beeping sound associated with your `POINT AUTOTRIGGER/` command. The closer you get to the target, the more frequently your computer emits beeps.

Trigger Radius

The **Trigger Radius** box allows you to type a tolerance zone value. When the probe moves into this tolerance zone, it automatically and immediately takes a hit.

Insert Command

Clicking the **Insert Command** button inserts the `POINT AUTOTRIGGER/` command into the Edit window for the current measurement routine. This command line reads:

```
POINT AUTOTRIGGER/ TOG1, TOG2, RAD
```

TOG1: This toggle field corresponds to the **On** check box. It displays either ON or OFF.

TOG2: This toggle field corresponds to the **Beeping On** check box. It displays either ON or OFF.

RAD: The radius field contains the value for the tolerance zone, and it corresponds to the **Trigger Radius** box. This value is the distance from the actual point that PC-DMIS takes the hit.

Plane AutoTrigger area

With the **Plane AutoTrigger** area, you can insert a `PLANE AUTOTRIGGER/` command into the Edit window. The `PLANE AUTOTRIGGER/` command tells PC-DMIS to automatically take a hit when the probe passes the plane defined by the surface normal of a supported feature at the level of the defined depth. For Auto features, this defined location is adjusted based on options such as sample hits or RMEAS features. As the probe center passes from one side of the plane to the other, the probe triggers and the hit is taken.

You can use this command with manual machines; instead of pressing a button to take a hit, you can place `PLANE AUTOTRIGGER/` commands at any standard location within the Edit window.

This command only works in Online mode. If you use the `POINT AUTOTRIGGER/` command, it takes precedence over the `PLANE AUTOTRIGGER/` command.

As defined above, PC-DMIS automatically takes a hit when the probe passes the plane. However, if you are using a Faro or a Romer machine, the probe does not trigger again until you press the **Accept** or **Release** button. You must press this button after each registered hit to continue.

On

Selecting the **On** check box activates the `PLANE AUTOTRIGGER/` command. Commands in the Edit window that follow the inserted `PLANE AUTOTRIGGER/` command and require you to take a hit then have the hit automatically taken when the probe center passes the plane defined by the surface normal and depth of the feature.

If you do *not* select this check box and you click the **Insert Command** button, PC-DMIS inserts the command line into the Edit window but doesn't activate the command. The `PLANE AUTOTRIGGER/` command does not function until the option is turned on.

Beeping On

Selecting the **Beeping On** check box activates a beeping sound associated with your `PLANE AUTOTRIGGER/` command. The closer the probe gets to the target, the computer emits the beeping sound more frequently.

Insert Command

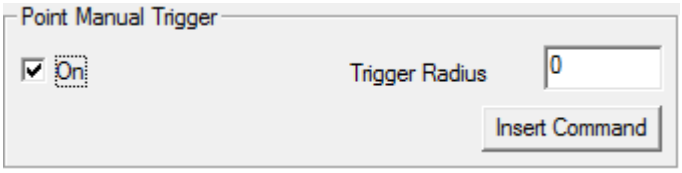
Clicking the **Insert Command** button inserts the `PLANE AUTOTRIGGER/` command into the Edit window for the current measurement routine.

```
PLANE AUTOTRIGGER/ TOG1,TOG2
```

TOG1: This toggle field corresponds to the **On** check box. It displays either ON or OFF.

TOG2: This toggle field corresponds to the **Beeping On** check box. It displays either ON or OFF.

Point Manual Trigger area



With the **Point Manual Trigger** area, you can insert a `POINT MANUAL TRIGGER/` command into the Edit window.

The `POINT MANUAL TRIGGER/` command tells PC-DMIS to only accept a manual hit when it is within the specified tolerance zone.

You can use this option with manual machines; when PC-DMIS prompts you to take a hit, trigger the probe as you wish. Each trigger will be evaluated to see if it is within the cylindrical trigger tolerance zone. If it is *not,* you will receive an error in the **Machine Errors** list of the **Execution** dialog box. PC-DMIS will then ask you to take the hit again. You can place `POINT MANUAL TRIGGER/` commands at any standard location within the Edit window.

This option works only in Online mode.

On

Selecting the **On** check box activates the `POINT MANUAL TRIGGER/` command. Commands in the Edit window that follow the inserted `POINT MANUAL TRIGGER/` command and require you to take a hit will then only accept the hit when the probe enters

the defined tolerance zone. The **Trigger Radius** capability is disabled until the option is turned on.

If you do *not* select this check box and you click the **Insert Command** button, PC-DMIS inserts the command line into the Edit window but doesn't activate the command. **Insert Command**

Clicking the **Insert Command** button inserts the `POINT MANUAL TRIGGER/` command into the Edit window for the current measurement routine with the following options.

```
POINT MANUAL TRIGGER/ TOG1, RAD
```

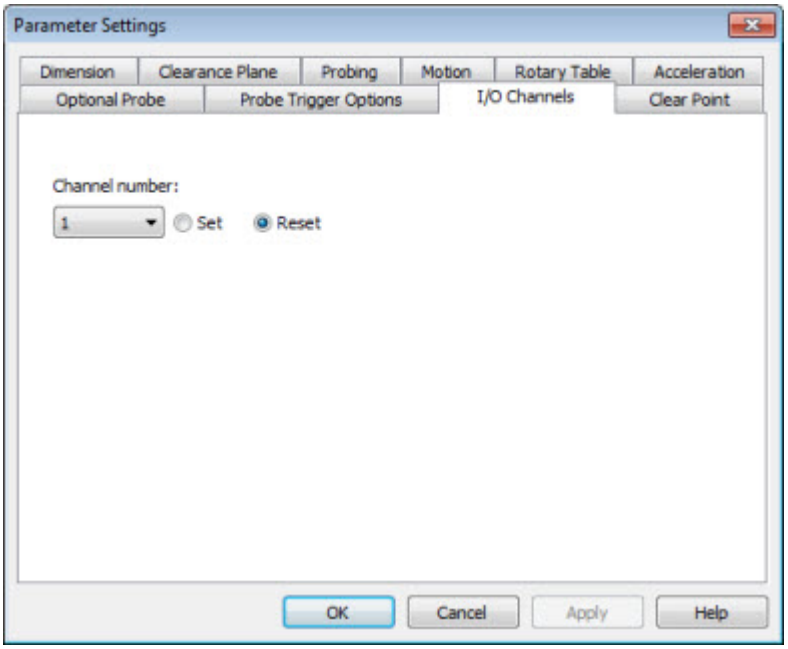
TOG1: This toggle field corresponds to the **Use Trigger Tolerance** check box. It displays either ON or OFF.

RAD: The radius field contains the value for the tolerance zone. This corresponds to the **Trigger Radius** box. This value is the distance from the actual point that PC-DMIS accepts the hit.

Trigger Radius

The **Trigger Radius** box allows you to type a tolerance radius value. When the probe is triggered, PC-DMIS will check to see if the probe is within this tolerance zone. If it is, the hit will be accepted. It is it *not*, you will be asked to take another hit.

Parameter Settings: I/O Channels Tab



Parameter Settings Dialog Box - I/O Channels Tab

*Currently, the options on the **I/O Channels** tab only function on DEA machines. Other machine types may be added in the future.*

With the **I/O Channels** tab, you can select options related to the use of controller I/O channels and place an `IOCHANNEL/` command into the Edit window that define the state of the controller.

Some machine controllers are equipped with I/O channels that can be `SET` to an ON state (a value of 1) or `RESET` to an OFF state (a value of 0). The `IOCHANNEL/` command tells PC-DMIS to set the state as specified.

To edit information in the **I/O Channels** tab:

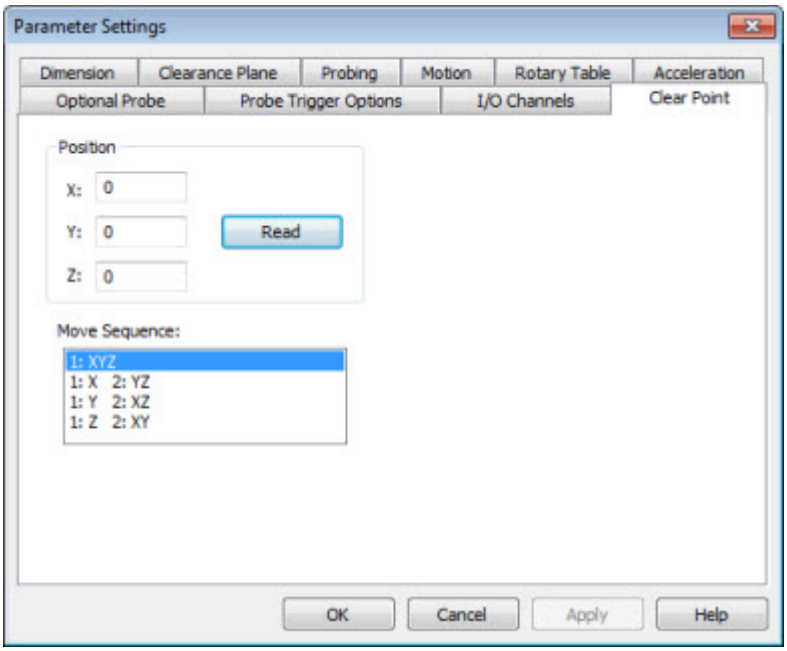
1. Access the **Parameter Settings** dialog box (**Edit | Preferences | Parameters**).
2. Click on the **I/O Channels** tab.
3. Make any changes.
4. Click **Apply** or **OK**.

Channel - Specifies the channel number that you will **Set** or **Reset**.

Set - Inserts an `IOCHANNEL/SET` command into the measurement routine. When PC-DMIS executes this command, the state of the specified channel number is set to 1.

Reset - This option inserts an `IOCHANNEL/RESET` command into the measurement routine. When PC-DMIS executes this command, the state of the specified channel number is set to 0.

Parameter Settings: Clear Point Tab



Parameter Settings Dialog Box - Clear Point Tab

The **Clear Point** tab lets you define a single move point position in machine coordinates, called a clear point, for your machine. This causes your machine to move the end of the arm to the defined position. This is intended to be a safety position the arm moves to when using a probe changer. This differs from standard MOVE/POINT command in that it uses **Move Sequence** list to specify the form of the move and the move position is absolute to the machine.

Position area - The **XYZ** boxes define the location of the move point. When you click the **Read** button, PC-DMIS reads the machine's current position and enters the coordinates into the **XYZ** fields.

Move Sequence list - This list lets you choose the form of the move to take to arrive at the clear point. It contains these options:

1: XYZ - The machine moves in a straight line to the clear point position.

1: X 2: YZ - The machine first moves the X axis and then the YZ axis.

1: Y 2: XZ - The machine first moves the Y axis and then the XZ axis.

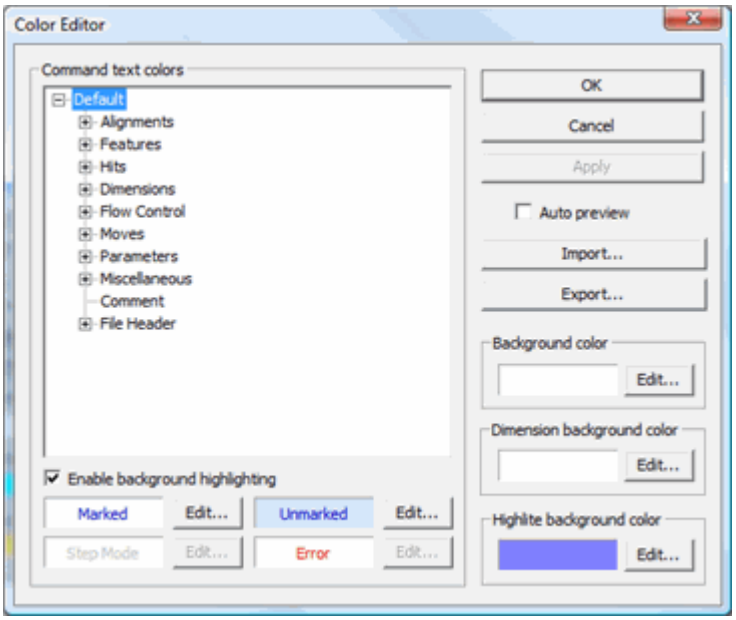
1: Z 2: XY - The machine first moves the Z axis and then the XY axis.

To insert this command, select the **Insert | Move | Clear Point** menu item. PC-DMIS inserts a `MOVE/CLEARPOINT` command in the Edit window. When you execute this command, PC-DMIS uses the selected move sequence to move to the defined clear point.

Setting Up the Edit Window

PC-DMIS lets you determine the Edit window's appearance as well as what information to display within some of the Edit window's modes.

Defining Edit Window Colors



Color Editor Dialog Box

The **Edit | Preferences | Edit Window Colors** menu option displays the **Color Editor** dialog box. You must be in Command Mode or DMIS Mode to select this menu item.

The **Color Editor** dialog box allows you to define the colors used for the Edit window text and background when you have the Edit window in Command and DMIS Modes. You can also export your color scheme to use on different computer systems or import external color schemes.

The **Color Editor** dialog box only specifies the colors in textual modes of the Edit window such as the Command and DMIS.

There are four principal colors that you can configure for all commands or for individual commands. To determine whether to show these colors as a highlighted background color or as text color, select or clear the **Enable Background Highlighting** check box. These are listed in the four boxes in the **Command Text Colors** area.

- Marked
- Unmarked
- Step Mode

- Error

By default, PC-DMIS selects the **Enable Background Highlighting** check box which makes the boxes appear with these colors:

If you clear this check box to enable text coloring instead, PC-DMIS shows the boxes as follows:

Color Editor dialog box showing the principal colors.

Marked - PC-DMIS uses this color on features that you mark for execution. PC-DMIS always executes some features such as alignments are always executed and are always displayed in the Marked color.

Unmarked - PC-DMIS uses this color for unmarked features. This color is the default color. If no other condition is present, then PC-DMIS uses the default color.

Step Mode - PC-DMIS uses this color to highlight the next execution line of code that occurs when executing a measurement routine that contains breakpoints.

Error - PC-DMIS uses this color for commands that are in error or measurements that are outside of their tolerance limits. For example, if the measurement routine calls for a tip that is not defined in the probe database, PC-DMIS colors this tip text with the Error color.

You can also change background colors for the Edit window, dimensions, and the highlight color.

Background Color - This sets the Edit window's background color.

Dimension Background Color - This sets the dimension's reporting boxes' background color.

Highlight Background Color - This sets the background color when dragging the mouse to select a command or group of commands.

You might be interested in color schemes created by other users. You can search for those on the PC-DMIS Community Group. For example, to get an unsupported dark theme created by one of our writers, go to this post.

Understanding the Default Edit Window Colors and Formatting

To change the command text colors used

1. Select **Edit | Preferences | Edit Window Colors** from the menu bar. The **Color Editor** dialog box opens.
2. Click the **Auto Preview** check box. This allows you to preview your changes inside the Edit window as you make them.
3. Select a specific command or a parent command from the list of commands in the **Command Text Colors** area. Click on the plus signs to expand the list to view additional sub commands. This allows you to set the principal colors (**Marked**, **Unmarked**, **Step Mode**, and **Error**) for specific commands or parent commands. To set the changes for *all* command text, select **Default** from the top of the list.
4. Simply click the **Edit** button for the text or background color in the **Command Text Colors** area. A **Color** selection box appears.
5. Select the new color, or customize a color by selecting the **Define Custom Colors** button.
6. Click the **OK** button. The **Color** selection box closes. If you selected a parent command, PC-DMIS presents you with an option to set all child commands under the parent command to use the same color as well. At this prompt, select either **Yes** or **No**.
7. When you finish defining your colors, click the **Apply** button to see the changes without closing the **Colors** dialog box.
8. Click the **OK** button to apply the changes and close the **Color Editor** dialog box.

PC-DMIS applies the color changes immediately.

To change the background colors used

1. Select **Edit | Preferences | Edit Window Colors** from the menu bar. The **Color Editor** dialog box opens.
2. Click the **Auto Preview** check box. This allows you to preview your changes inside the Edit window as you make them.
3. Simply click the **Edit** button for the background or highlight color from the **Background Color** area. A **Color** selection box appears.
4. Select the new color, or customize a color by selecting the **Define Custom Colors** button.

5. Click the **OK** button. The **Color** selection box closes.
6. When finished defining your colors, click the **Apply** button to see the changes without closing the **Colors** dialog box.
7. Click the **OK** button to apply the changes and close the **Color Editor** dialog box.

The color changes are immediately made.

To export a color scheme

1. Select **Edit | Preferences | Edit Window Colors** from the menu bar to open the **Color Editor** dialog box.
2. Make changes to your color scheme as needed.
3. Click the **Export** button. A **Save As** dialog box appears. This dialog box allows you to store your Edit window color scheme as a color file (a file with a *.clr* extension).

Save As Dialog Box

4. Navigate to where you want to store this file.
5. Type a name for the stored color file in the **File name** box.
6. Click **Save**.

To import and use a color scheme

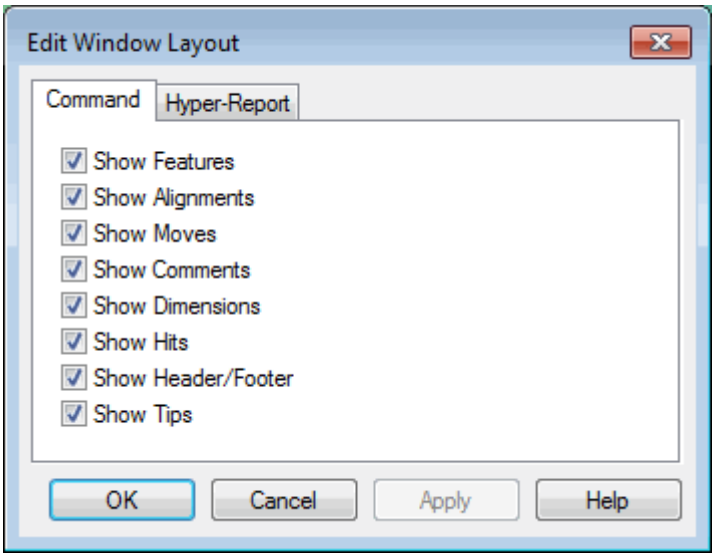
1. Select **Edit | Preferences | Edit Window Colors** from the menu bar. The **Color Editor** dialog box opens. Click the **Auto Preview** check box. This allows you to preview your changes inside the Edit window once you select the color scheme.
2. Click the **Import** button. An **Open** dialog box appears.
3. Navigate to the color scheme file (a file with a *.clr* extension).
4. Select the file and click **Open**. The **Open** dialog box closes.
5. Click **Apply** and then **OK** to use the color scheme you just imported.

Defining the Edit Window Layout

The **Edit | Preferences | Edit Window Layout** menu option displays the **Edit Window Layout** dialog box. The dialog box contains these tabs:

- **Command** tab - This tab lets you hide or show certain commands in the Edit window. For more information, see "Command Mode Display Options".
- **HyperReport** tab - This tab usually does not appear, but it might for some older measurement routines. It determines if PC-DMIS automatically loads a legacy HyperView report once a measurement routine finishes execution. For more information, see "Hyper-Report Configuration Options".

Command Mode Display Options



Edit Window Layout Dialog Box - Command Tab

The **Command** tab of the **Edit Window Layout** dialog box (**Edit | Preferences | Edit Window Layout**) allows you to choose which of the following display options are available for Command Mode.

Show Features
This option displays the features measured by the measurement routine.

Show Alignments
This option shows alignment changes as they occur during the measurement routine. It displays all alignment changes that occur in the dimension or feature lists.

Show Moves
This option shows any moves that have been added to the measurement routine.

Show Comments
This option shows any comments that have been added to the measurement routine.

(See "Inserting Programmer Comments" in the "Inserting Report Commands" chapter for additional information.)

Show Dimensions
This option displays the specified dimension for the features inspected by PC-DMIS. It is displayed in the selected format using the `FORMAT` command described in the "Dimension Format" topic in the "Using the Edit Window" chapter.

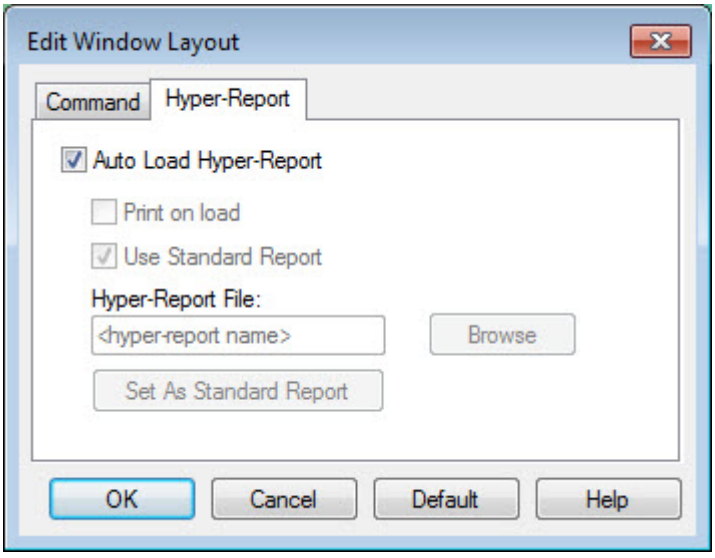
Show Hits
This option displays each hit.

Show Header / Footer
This option displays the header or footer from the LOGO.DAT, HEADER.DAT, and ELOGO.DAT files. (See "Modifying the Edit Window's Headers and Footers" in the "Using the Edit Window" chapter for information on altering these files.)

Show Tips
This option displays the tip file names used to inspect the part.

For information on working with Command Mode, see the "Working in Command Mode" topic in the "Using the Edit Window" chapter.

Hyper-Report Configuration Options



Edit Window Layout Dialog Box — Hyper-Report Tab

> This older tab remains to support legacy HyperView reports. It only appears if the **Auto Load Hyper-Report** check box is marked. Once you clear that check box, the tab never reappears for the current measurement routine.

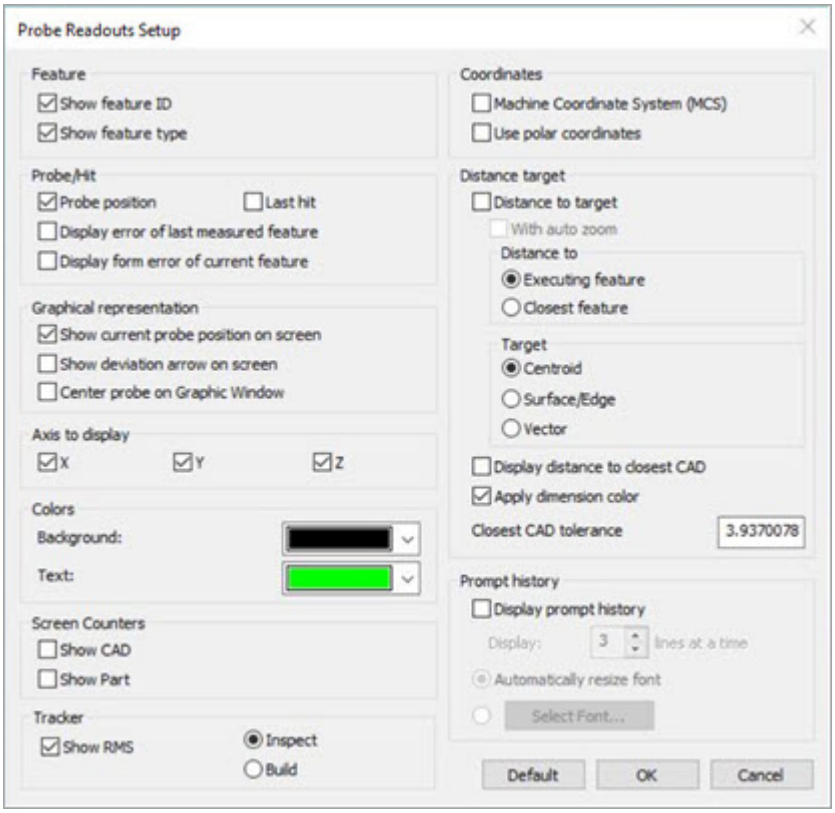
The **Auto Load Hyper-Report** check box tells PC-DMIS to load a specific legacy HyperView report (.rpt) as soon as execution finishes.

The current purpose of this tab is to let you clear the **Auto Load Hyper-Report** check box so that the legacy HyperView report no longer opens for the measurement routine.

If you need information on the other options on this tab or on HyperView reports, see "Working with Legacy (HyperView) Reports" in the "Reporting Measurement Results" chapter.

For information on current reporting practices, see the "Reporting Measurement Results" chapter.

Setting Up the Probe Readouts Window



Probe Readouts Setup Dialog Box

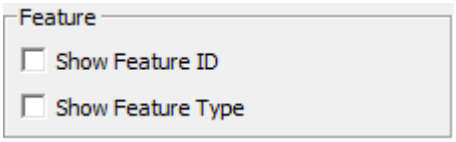
The **Probe Readouts Setup** dialog box (**Edit | Preferences | Probe Readouts Setup**) allows you to select the desired format of the Probe Readouts window. Select the check boxes that meet your probe readout needs. When you next access the Probe Readouts window, it will reflect the chosen format.

Example of a Probe Readouts window.

You can also right-click on the Probe Readouts window and click **Setup** to access the **Probe Readouts Setup** dialog box.

For information on how to use the Probe Readouts window, see "Using the Probe Readouts Window" in the "Using Other Windows, Editors, and Tools" chapter.

Feature Area



Feature Area

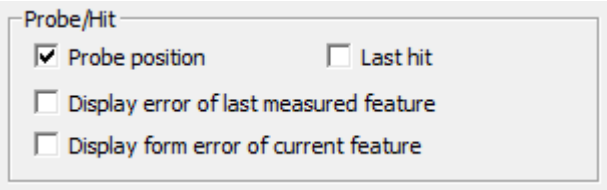
Show Feature ID check box
If in Learn Mode and there are CAD elements, this shows the text label of the nearest CAD element.

If in Execute Mode and PC-DMIS is executing sequentially through the measurement routine, this shows the ID of feature being executed. If PC-DMIS is executing in any order,

and the **Closest Feature** option is selected from the **Distance Target** area, it will show the ID of the closest feature.

Show Feature Type check box
If in Execute Mode and PC-DMIS is executing sequentially through the measurement routine, this displays the executing feature type. If PC-DMIS is executing in any order this displays the feature type of the closest feature.

Probe/Hit Area



Probe/Hit Area

Probe Position check box

When you select the **Probe Position** check box, PC-DMIS displays the current position of the probe. The Probe Readouts window displays the probe's position in the active coordinate system.

Last Hit check box

When you select the **Last Hit** check box, PC-DMIS displays the location of the last hit taken with the probe. If this option is not selected, PC-DMIS displays the current position of the probe.

Display error of last measured feature check box

When you select the **Display error of last measured feature** check box, PC-DMIS displays any deviations along the XYZ coordinates (and D for circular features) for the last measured feature in the Probe Readouts window. Even if the deviation is 0 then only 0 is displayed.

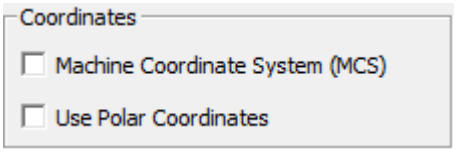
Display form error of current feature check box

When you select the **Display Form error of current feature check box**, PC-DMIS displays the form error for the feature being learned or executed.

If the feature has a valid form dimension (circularity, straightness, flatness, or cylindricity), then PC-DMIS displays the appropriate GD&T symbol near the value. Otherwise, PC-DMIS displays the Greek letter Sigma indicating standard deviation.

If there are not enough hits to calculate a form value, PC-DMIS displays a line of dashes for the value until sufficient hits are processed.

Coordinates Area



Coordinates Area

Machine Coordinate System (MCS) check box
When you select the **Machine Coordinate System (MCS)** check box, PC-DMIS displays the information in the machine's coordinate system, not the part coordinate system. This check box switches between these coordinate systems. Deselecting it will once again display the information in the part's coordinate system.

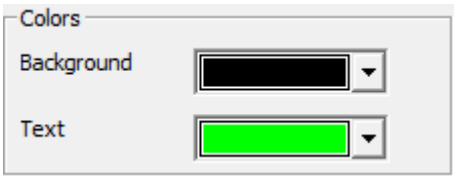
Use Polar Coordinates check box
When you select the **Use Polar Coordinates** check box, PC-DMIS switches between rectangular and polar coordinates. When polar coordinates are used, the normal direction of the workplane is also displayed.

Axis to Display Area

Axis to display Area

Check Box	Description
X	This hides or displays the X axis in the Probe Readouts window.
Y	This hides or displays the Y axis in the Probe Readouts window.
Z	This hides or displays the Z axis in the Probe Readouts window.

Colors Area

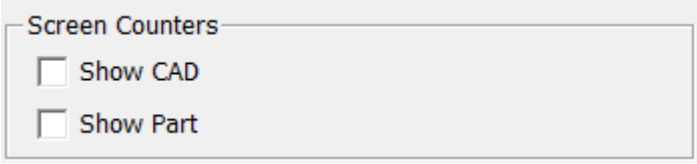


Colors Area

Background list - This sets the background color of the Probe Readouts window.

Text list - This sets the text color of the Probe Readouts window.

Screen Counters Area



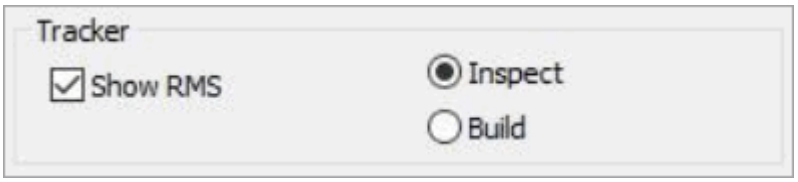
Screen Counters Area

Show CAD check box
This check box hides or displays the CAD X, Y, Z, I, J, K information for the CAD element at the mouse pointer's location in the Probe Readouts window. The origin is based off of the CAD model.

Show Part check box
This check box hides or displays the Part X, Y, Z, I, J, K information for the CAD element at the mouse pointer's location in the Probe Readouts window. The origin is based off of the current part alignment.

See "Displaying Mouse Coordinates in Screen Counter Text" in the "Editing the CAD Display" chapter.

Tracker Area



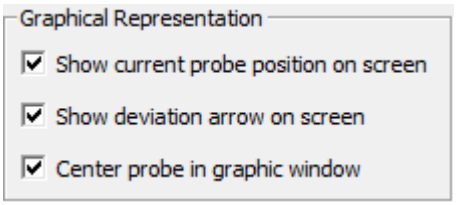
Tracker Area

Show RMS check box
This check box shows the **RMS** value in the Probe Readouts window if the measure machine is a portable tracker device.

Inspect or **Build** option
These options determine whether or not the information in the tracker is reported according to the **Inspect** mode or **Build** mode.

See the PC-DMIS Portable documentation for more information.

Graphical Representation Area



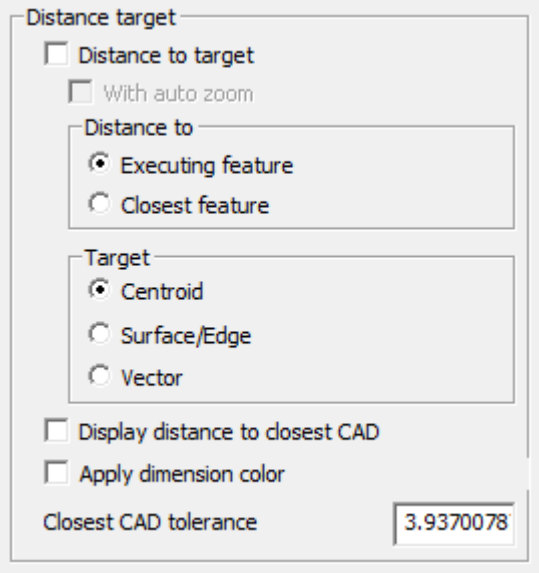
Graphical Representation Area

Show current probe position on screen - This check box shows a graphical representation of the probe on screen, relative to the machine when you move the probe's position using the jog box. This is helpful when you work in Online mode. When you use the jog box to move the probe, a graphical representation of the probe also moves on the PC-DMIS Graphic Display window. This only functions when you run PC-DMIS in Online mode connected to a physical machine and the measurement routine has an alignment.

Show deviation arrow on screen - This check box shows a 3D arrow in the Graphic Display window, which indicates the direction of deviation during execution. The **With Auto Zoom** check box in the **Distance Target** area must be marked.

Center probe in graphic window - This check box shifts the display in the Graphic Display window so that the animated probe always appears centered in the window whenever PC-DMIS executes motion commands or takes hits on the part. This is useful when you want to keep your view zoomed in close to your part model during execution yet visually follow the probe's progress. This functions only if PC-DMIS is not in Program Mode.

Distance Target Area

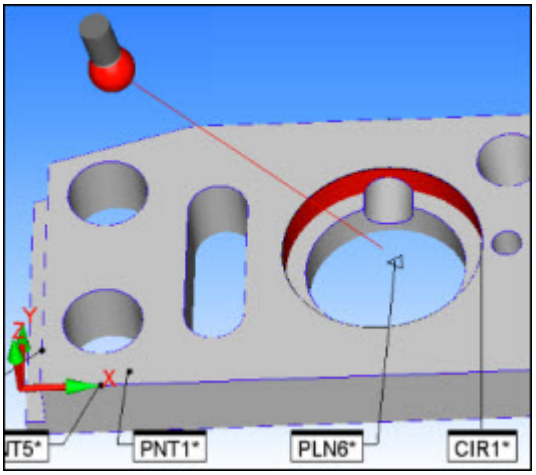


Distance Target Area

Distance to target check box
When you select the **Distance to target** check box, and the **Display distance to closest CAD** check box is not checked, PC-DMIS displays the distance of the probe to the target point depending on the **Distance to** setting. Otherwise, PC-DMIS always displays the distance to the closest CAD.

The probe's position is displayed in the active coordinate system. Manually drive the probe to the keyed in location. When the target point is reached, the Probe Readouts window will display 0,0,0.

A red line also appears on the Graphic Display window from the probe tip to the target, indicating the next feature to measure.



Example showing the red line pointing to the center of the PLN6 feature.

The target is based on the combination of options specified in the **Distance to** and **Target** areas of the dialog box. See a description of these options below and in the "Description of Target for T Value" topic.

With Auto Zoom check box
When you select both the **Distance to Target** check box and **With Auto Zoom** check box, PC-DMIS also displays the distance of the probe to the target point. The probe's position is displayed in the active coordinate system. As the probe is manually driven to the keyed in location, PC-DMIS makes the target point the center of the screen and zooms in on the point in the Graphic Display window.

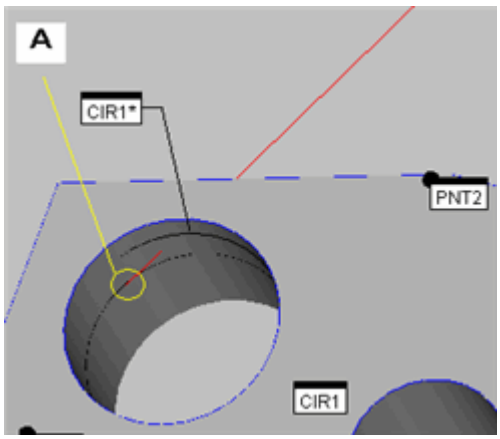
Distance area
This area contains these two option buttons to further define the target:

- **Executing feature** defines the target as the next executing feature.
- **Closest feature** defines the target as the feature closest to the probe.

You can determine the exact location on the target feature (either the centroid or the closest surface/edge point) by selecting the desired option from the **Target** area.

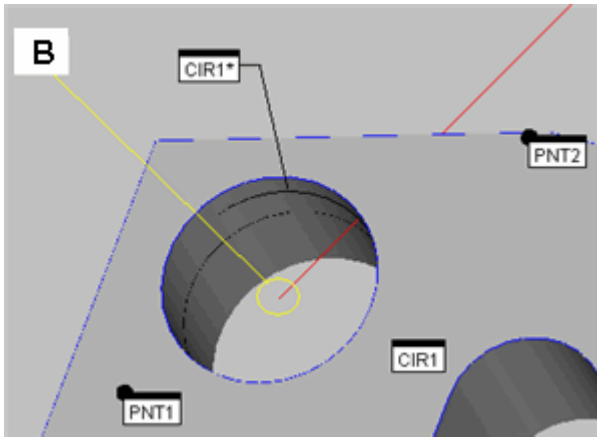
Target area
This area contains two option buttons to determine the exact target location to use:

- **Surface/Edge** defines the target as either the closest point on the feature or the next expected point based on what you selected from the **Distance** area:
  - If you selected **Closest feature**, the target is the closest point on the feature.
  - If you selected **Executing feature**, the target is the next expected point to take on the feature.



As shown in the above image, for example, while measuring the circle (CIR1), the **Surface/Edge** option causes the Probe Readouts window to show the distance to the actual target point at location A.

- **Centroid** calculates the distance to the feature's centroid.



As shown in the above image, for example, while measuring the circle (CIR1), the **Centroid** option causes the Probe Readouts window to show the distance to the feature's centroid at location B, instead of the actual target point.

- **Vector** calculates the distance from the probe's center to the nearest point on the feature's vector.

Display distance to closest CAD check box
Marking this check box has several effects. When marked, the target becomes the closest point on the nearest CAD surface. The red line connects the probe tip to this target.

Also, PC-DMIS displays a ‘T’ (CAD) value, or total deviation value, in the Probe Readouts window. See the "Description of Target for T Value" topic for information on exactly how the distance is used for each feature's T value.

This setting overrules the **Distance to Target** setting during execution.

Apply dimension color check box
This check box changes the colors of the deviation values (Distance to Target values) to match the out of tolerance dimension colors.

Closest CAD tolerance field
This is the field to enter the tolerance (in current units), which is used to determine the maximum distance the software tries to locate the surface to compare the current probe position to. Beyond this distance, no distance to CAD will be returned.

Description of Target for T Value

The T Value is always the magnitude (or length) of the vector from the probe tip to a target point. The target point is determined by the **Centroid**, **Surface/Edge**, or **Vector** option buttons located in the **Target** area of the **Probe Readout Setup** dialog box (**Edit | Preferences | Probe Readout Setup**).

- If you selected **Centroid** or **Vector**, PC-DMIS uses the distance from the probe's center point.
- If you selected **Surface Edge**, PC-DMIS uses the probe-compensated distance.

During Execution with "Closest Feature" and "Centroid" Selected and Closest Distance to CAD Not Selected

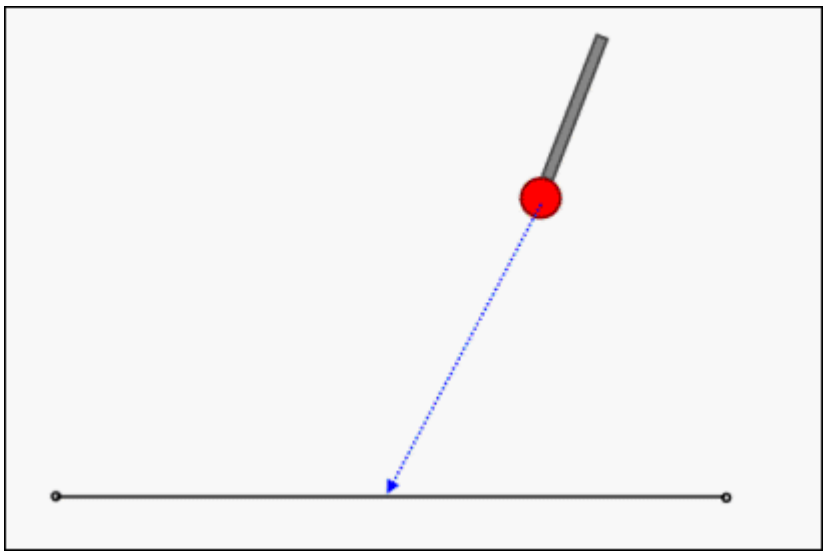
The Centroid is the feature's center. While this makes more sense for some features than others, all features have a center. For the nine basic feature types, the center for each is defined below with illustrations where necessary.

- Point

  The T value is the distance to the point itself.

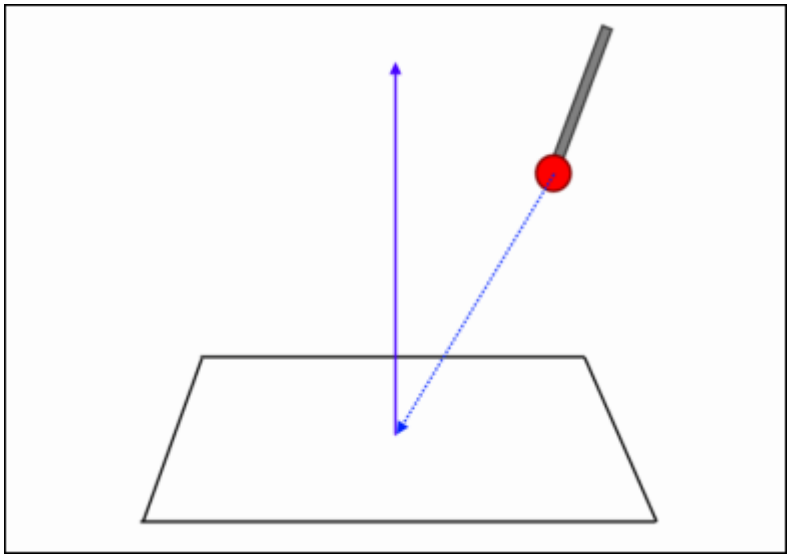
- Line

  The T value is the distance to the midpoint between the two outermost hits on the line segment.



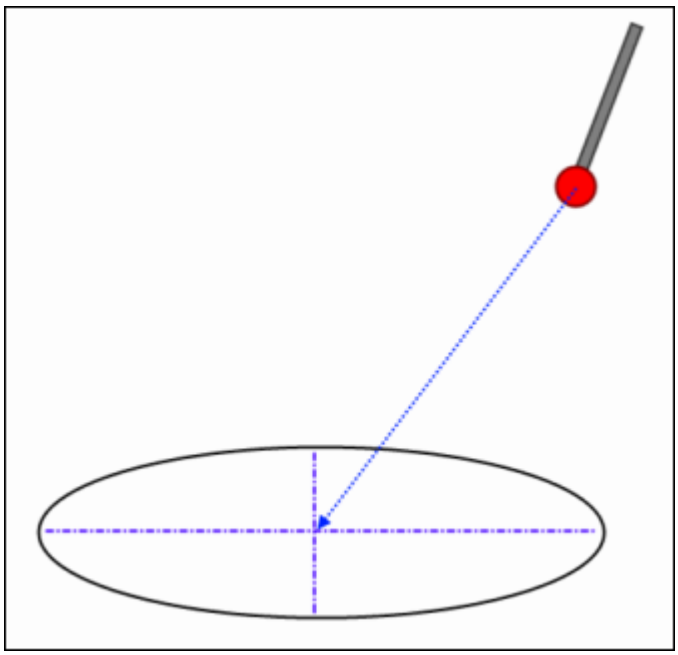
- Plane

  The T value is the distance to the center of the plane. The center is the midpoint of the polygon defined by the bounding hit points defining the plane.



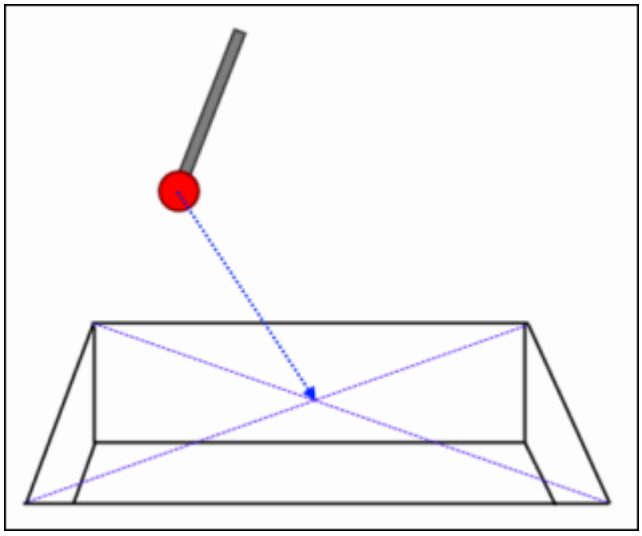
- Circle

  The T value is the distance to the circle's centroid.



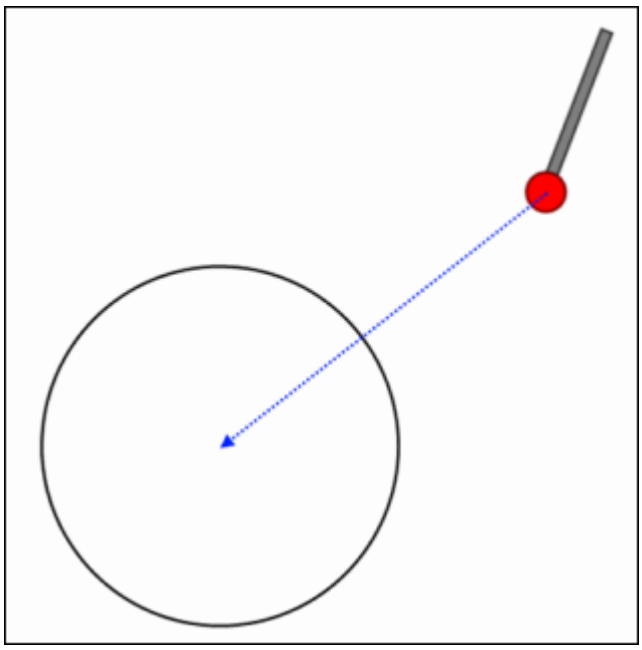
- Round and Square Slots

  The T value is the distance to the midpoint of the slot's plane.



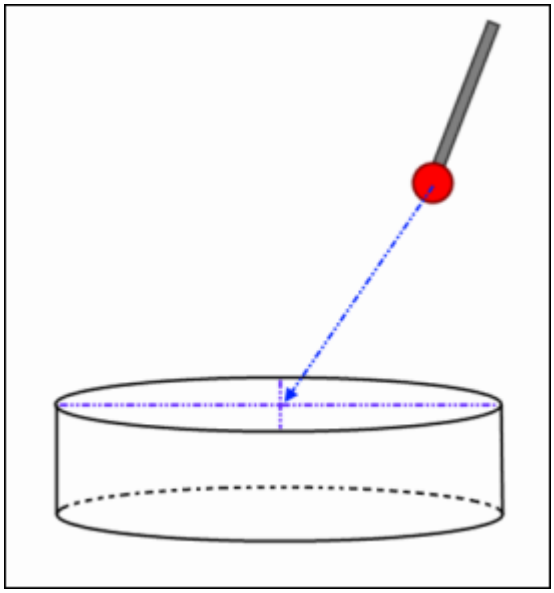
- Sphere

  The T value is the distance to the center of the sphere.



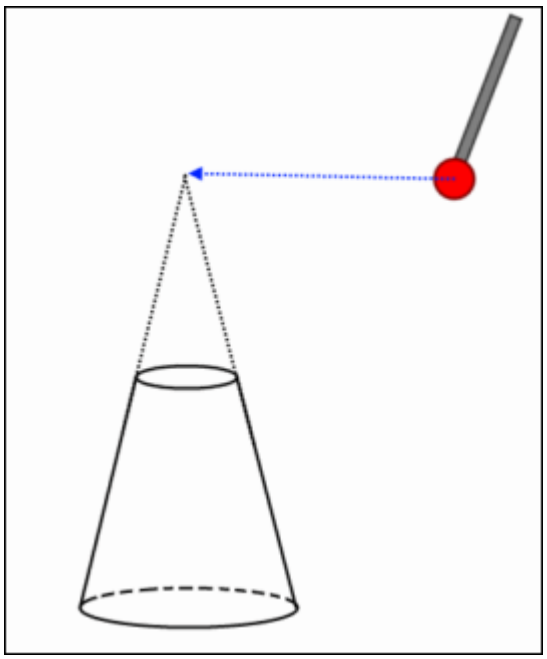
- Cylinder

  The T value is the distance to the center of the top of the cylinder:



- Cone

  The T value is the distance to the cone's vertex.



During Execution with "Closest Feature" and "Surface/Edge" Selected and Closest Distance to CAD Not Selected

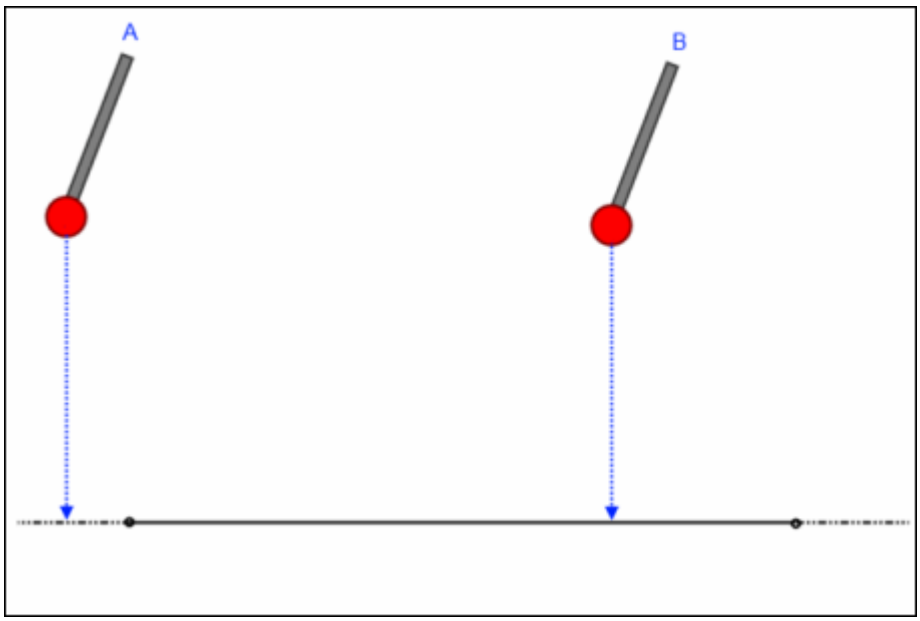
When locating the surface/edge, the target for the T value is the point on the feature that is closest to the probe. For 3D features, the closest point is on the surface of the feature; for 2D features, it is on the edge. For the nine basic feature types, the center for each is defined below with illustrations where necessary.

- Point

  The T value is the distance to the point itself.

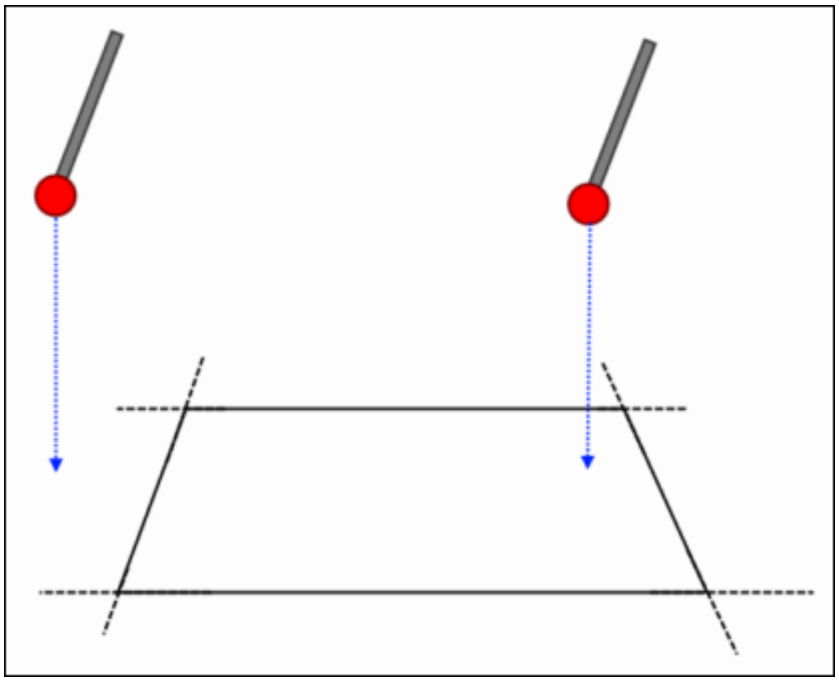
- Line

  The T value is the distance to the closest point on the line defined by two or more hits. This is not a line segment but a true geometric line. The example below shows two different cases.



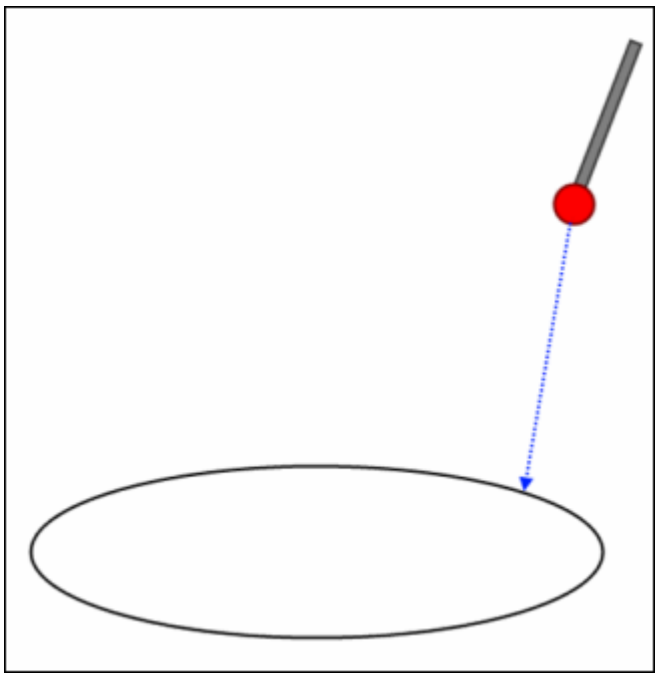
- Plane

  The T value is the distance to the closest point on the geometric plane defined by the three or more hits.



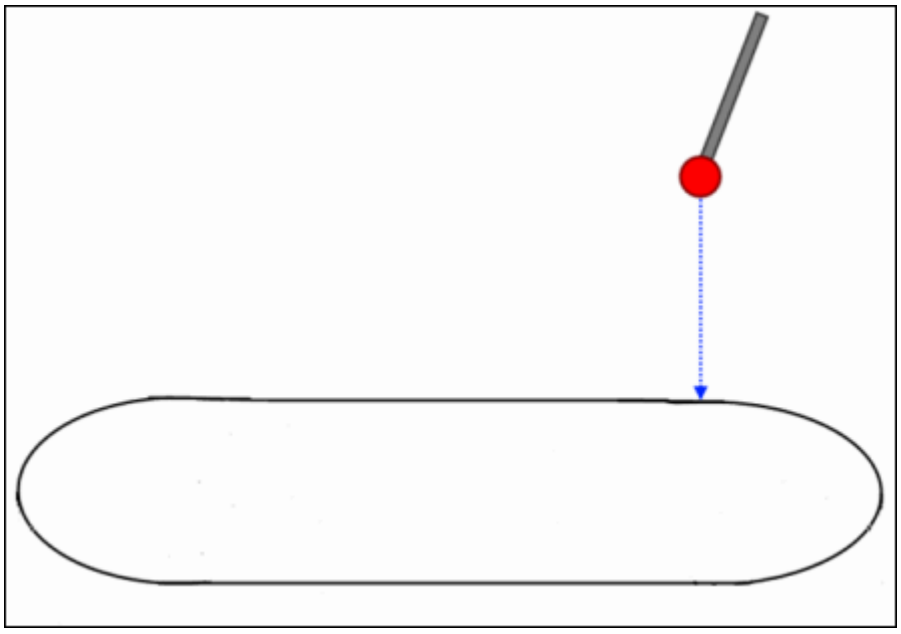
- Circle

  The T value is the distance to the closest point on the circle's edge.



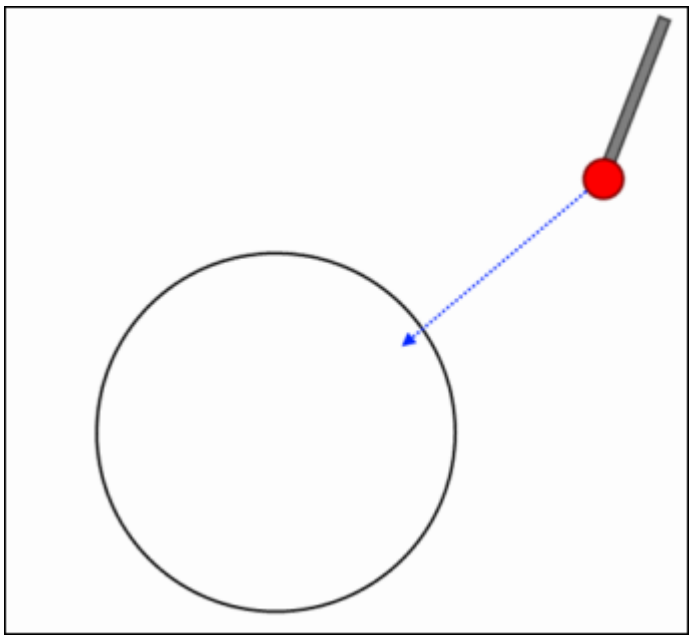
- Round and Square Slots

  The T value is the distance to the closest point on the slot's edge.



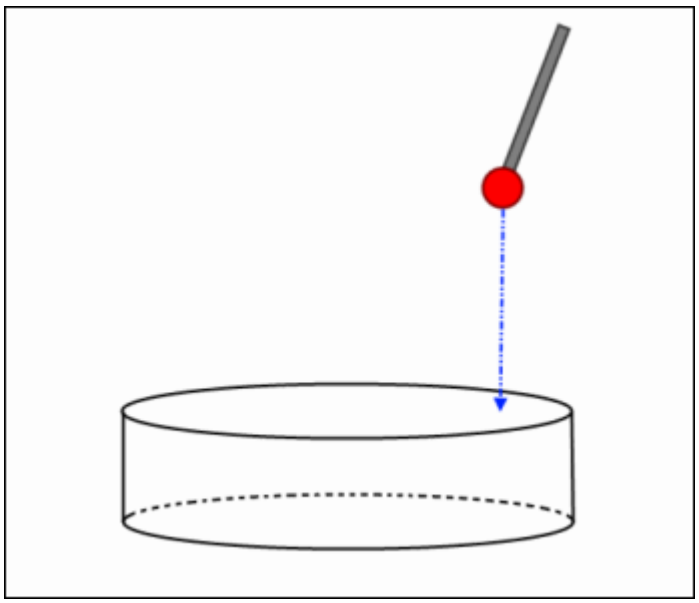
- Sphere

  The T value is the distance to the closest point on the sphere's surface. The illustration below shows the point on the surface of an outer feature, but an inner feature works the same and uses an inner surface.



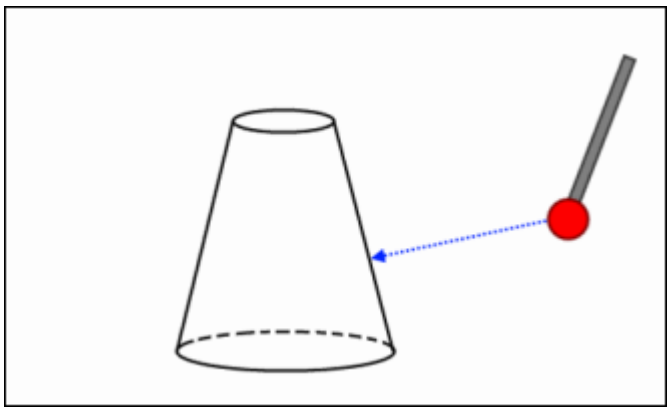
- Cylinder

  The T value is the distance to the closest point on the surface of the cylinder. The illustration below shows the point on the surface of an outer feature, but an inner feature works the same and uses an inner surface.



- Cone

  The T value is the distance to the closest point on the surface of the cone (not the geometric cone). The illustration below shows the point on the surface of an outer feature, but an inner feature works the same and uses an inner surface.



During Execution with "Closest Feature" and "Vector" Selected and Closest Distance to CAD Not Selected

When locating the vector, the target for the T value is the point on the feature vector closest to the probe. For the nine basic feature types, the center for each is defined below with illustrations where necessary.

- Point

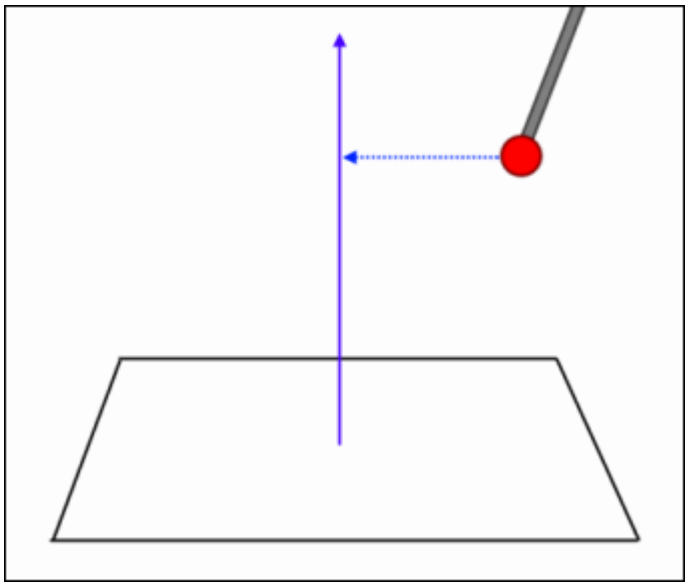
  The T value is the distance to the closest point on the point's hit vector.

- Line

  The T value is the distance to the closest point along the line's vector.

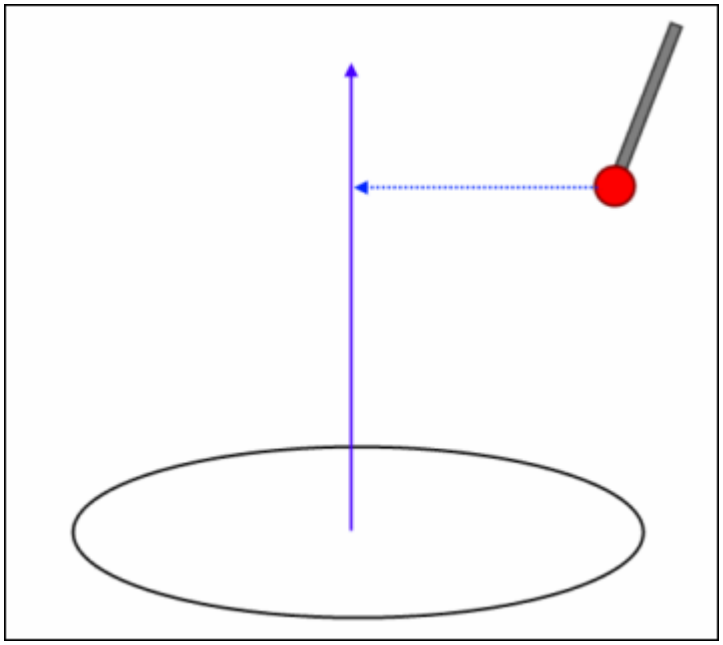
- Plane

  The T value is the distance to the closest point on the plane's normal vector that is anchored to the plane's center (see the Plane Centroid example above for a description of the plane's center).



- Circle

The T value is the distance to the closest point on the circle's normal vector that is anchored to the circle's center point.

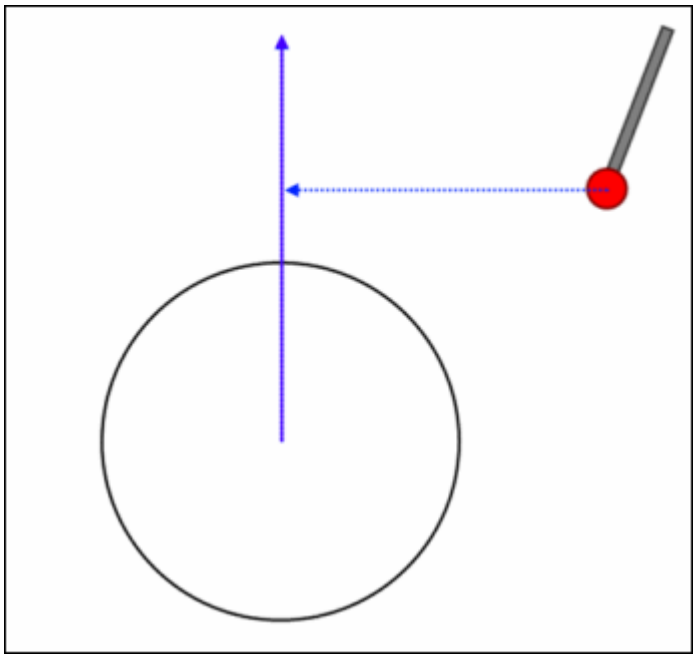


- Round and Square Slots

  The T value is the distance to the closest point on the normal vector of the slot's plane. The plane is defined by the slot's hit points. See the Plane Vector example above. As with that example, the normal vector is anchored to the center point of the slot's plane.

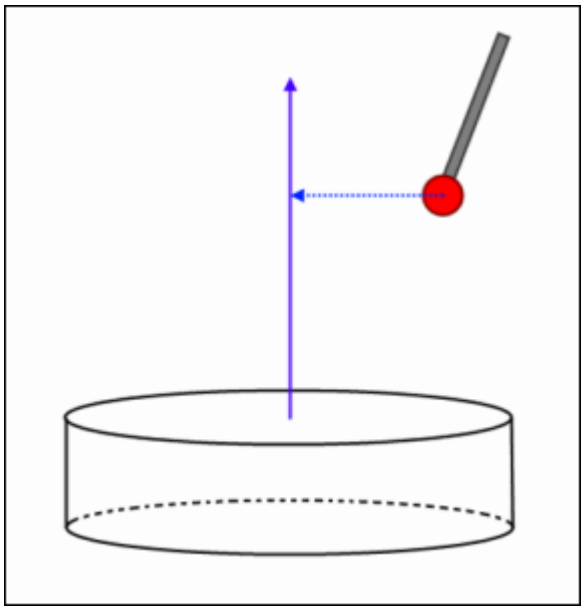
- Sphere

  The T value is the distance to the closest point on the sphere's normal vector. The vector is the same as the defined workplane or reference plane.



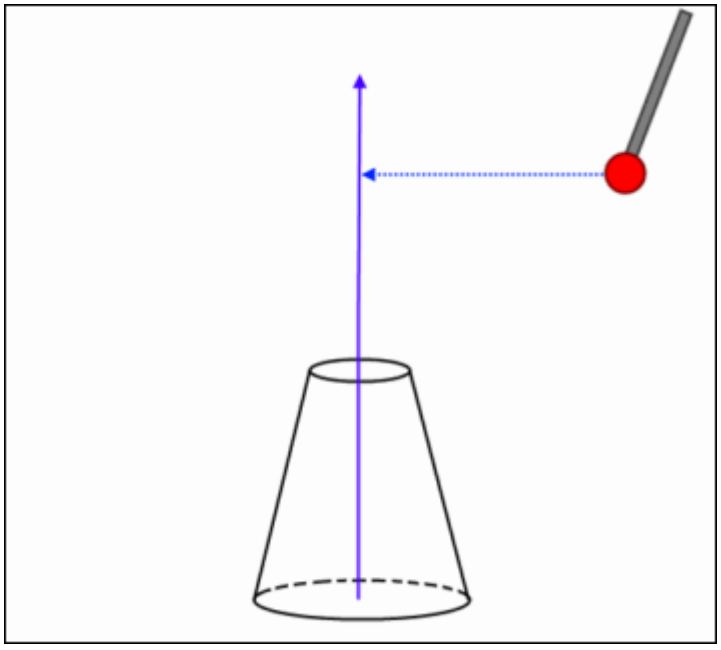
- Cylinder

  The T value is the distance to the closest point on the cylinder's central axis vector:



- Cone

  The T value is the distance to the closest point on the cone's central axis vector:



No Execution or Execution with "Closest CAD" Selected and a CAD File Loaded

The T value appears as T (CAD) and refers to the closest point on the CAD. The DX, DY, and DZ are the vector components of the T (CAD) value. There must be surface CAD data, and you must set your view to Surface Mode for this to work. If no CAD is loaded, the T,

DX, DY and DZ values refer to the **Distance to Target** setting, which is only active during execution.

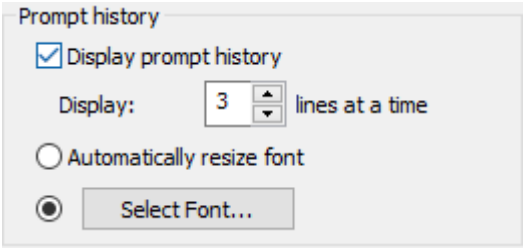
During Execution with "Executing Feature" and "Surface/Edge" Selected

This mode is for backwards compatibility and is the original functionality. In this state, the target point is the distance to the next hit on the feature.

During Execution with "Executing Feature" and "Centroid" or "Vector" Selected

If you selected **Centroid** or **Vector**, these options behave as the "Closest Feature" examples above, but they show distances to the next executing feature.

Prompt History Area



When you select the **Display prompt history** check box, PC-DMIS displays the new Probe Readouts comment type inside the Probe Readouts window.

- Using the **Display lines at a time** box, you can specify how many lines PC-DMIS should set apart for these comments on the Probe Readouts window.
- When the **Automatically resize font** button is marked, PC-DMIS automatically resizes the font size for the Operators Comments in Report Commands based on the value for the `ReadoutDisplayFont_AutoHistoryFontSizeRatio` entry in the PC-DMIS Settings Editor. For details, see "ReadoutDisplayFont_AutoHistoryFontSizeRatio" in the PC-DMIS Settings Editor documentation.
- Using the **Select Font** button, you can also specify the font type and size for these comments on the Probe Readouts window.

For information on inserting comments, see "Inserting Programmer Comments" in the "Inserting Report Commands" chapter.

For information on displaying the Probe Readouts window, see "Using the Probe Readouts window" in the "Using Other Windows, Editors, and Tools" chapter.

Always Track FOV Center

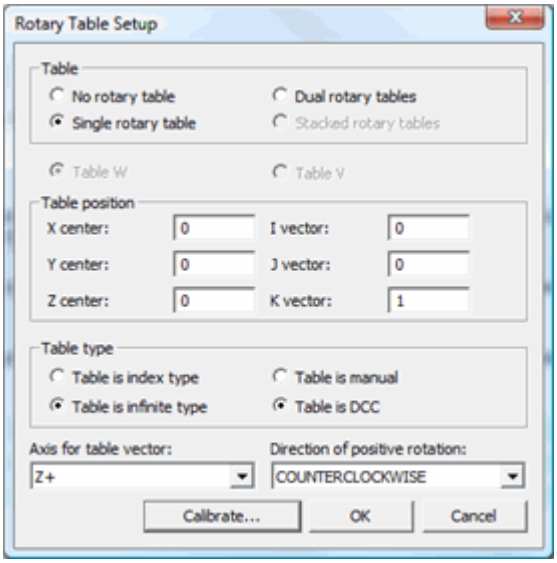
If this item is selected, PC-DMIS displays the FOV center of a non-contact video probe. This item only appears if you have a non-contact video probe defined.

Setting Up Multiple Arms

See the "Using Multiple Arm Mode" chapter for information regarding setup procedures for multiple arms.

Defining the Rotary Table

Select the **Edit | Preferences | Rotary Table Setup** menu option to open the **Rotary Table Setup** dialog box.



Rotary Table Setup Dialog Box

PC-DMIS disables rotary table motion when ClearanceCube motion is active.

This dialog box allows you to define the rotary table. You can only accept one option per category.

1. Select the type of table being used. If you select **Dual Rotary Table** or **Stacked Rotary Tables**, indicate the active table (Table W or Table V). If you select **Dual Rotary Tables** or **Stacked Rotary Tables**, PC-DMIS also displays the **Active Rotary Table** toolbar once you click the **OK** button. This toolbar contains two icons that allow you to select which rotary table is active.

2. Select either **Table is Index Type** or **Table is Infinite Type** option to define if the table is an indexable or infinite type.

> Index type rotary tables have a finite number of specific angles to which they can be positioned. Generally, they have a fixed increment (in degrees of rotation) from a given position to the next available position. The incremental amount varies based on your specific table. Please consult your rotary table documentation if necessary. Infinite type rotary tables accept any position (in degrees).

3. Select either the **Table is Manual** or **Table is DCC** option to define if the table is a manual or DCC table type.
4. From the **Axis for Table** list, select the machine axis closest to the axis of rotation for the table.
5. From the **Direction of Positive** list, select whether or not the table has a positive rotation about the chosen axis in either the CLOCKWISE direction or the COUNTERCLOCKWISE direction. The reference point of view for the direction is the perspective of looking down the axis for the table towards the origin.
6. If known, type the XYZ and IJK values. For PC-DMIS NC, the approximate location of the table center (within the probe's prehit distance) must be included because the entire calibration is done under DCC control.
7. Click **Calibrate** to begin the calibration process.

> **WARNING:** When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

> The **Rotary Table Setup** menu option is available only if your PC-DMIS license is configured to accept rotary tables.

ROTABSPEED Command

When you define a `Move/Rotab` command, the command uses the speed value set in the **Rotary Table** tab of the **Parameter Settings** dialog box (**Edit | Preferences | Parameters**). You can override this value to slow down or speed up the rotary table with the `ROTABSPEED` command.

For example:

```
STARTUP=ALIGNMENT/START,RECALIBRATE:USE_PART_SETUP,LIST=YES

  ALIGNMENT/END

  MODE/DCC

  MOVESPEED/ 96

  FLY/ON

  FORMAT/
TEXT,OPTIONS,,HEADINGS,SYMBOLS,;NOM,TOL,MEAS,DEV,OUTTOL,,

  LOADPROBE/X5HD

  TIP/X5HD, SHANKIJK=0,0,1, ANGLE=90

  MOVE/ROTAB,30,SHORTEST,

  .

  .

  .

  ROTABSPEED/ 72

  .

  .

  .

  MOVE/ROTAB,60,SHORTEST,

  .

  .

  .

  ROTABSPEED/ 20

  .

  .

  .

  MOVE/ROTAB,77,SHORTEST,
```

```
.
.
.
```

In this example, the last five lines show the insertion of the `ROTABSPEED` command. The first instance speeds up the rotary table to 72 degrees per second, possibly to speed up the measurement process for a small part. The second `ROTABSPEED` command slows the rotary table down to 20 degrees per second, possibly for a larger part.

If you use the default value of 0 (zero) for the `ROTABSPEED` command, the rotary table's speed is proportional to the value set for the `MOVESPEED` command. This is necessary for backward compatibility prior to the implementation of the `ROTABSPEED` command.

For systems with stacked rotary tables, you need to account for both tables in the ROTABSPEED command, `ROTABSPEED <wspeed>[,<vspeed>]` where `<wspeed>` is table one and the optional `<vspeed>` is table two.

```
ROTABSPEED/ 50,40
```

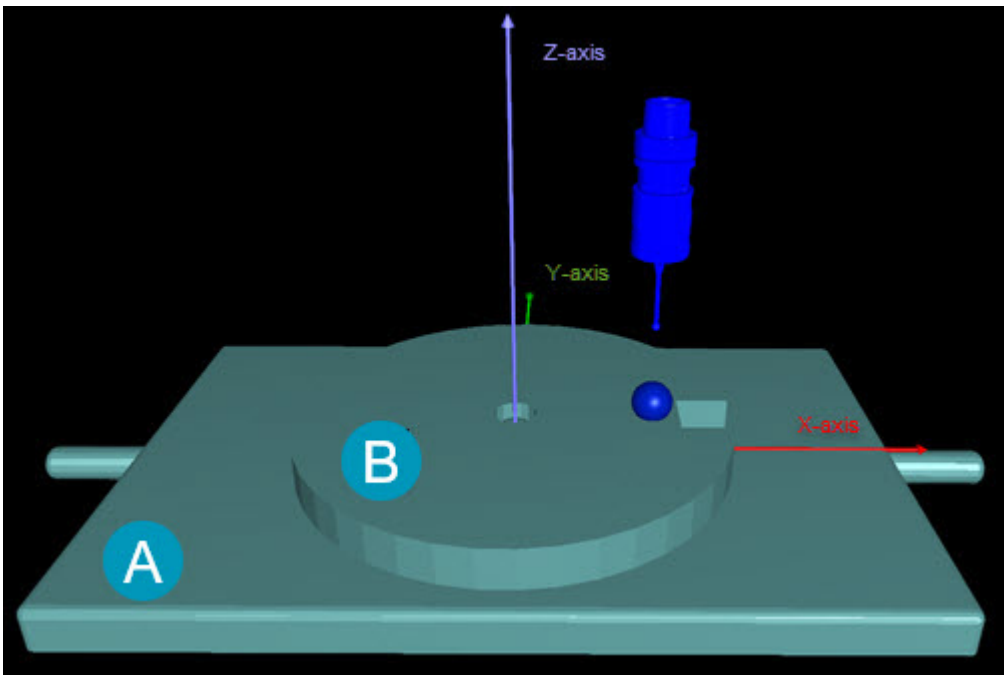
An example of a system with a stacked rotary table is the Optive CMM for vision systems.

Difference between a Stacked and Dual Rotary Table

Stacked Rotary Table

Stacked rotary tables provide the ability of rotating a part or calibration artifact beyond the standard XYZ axes.

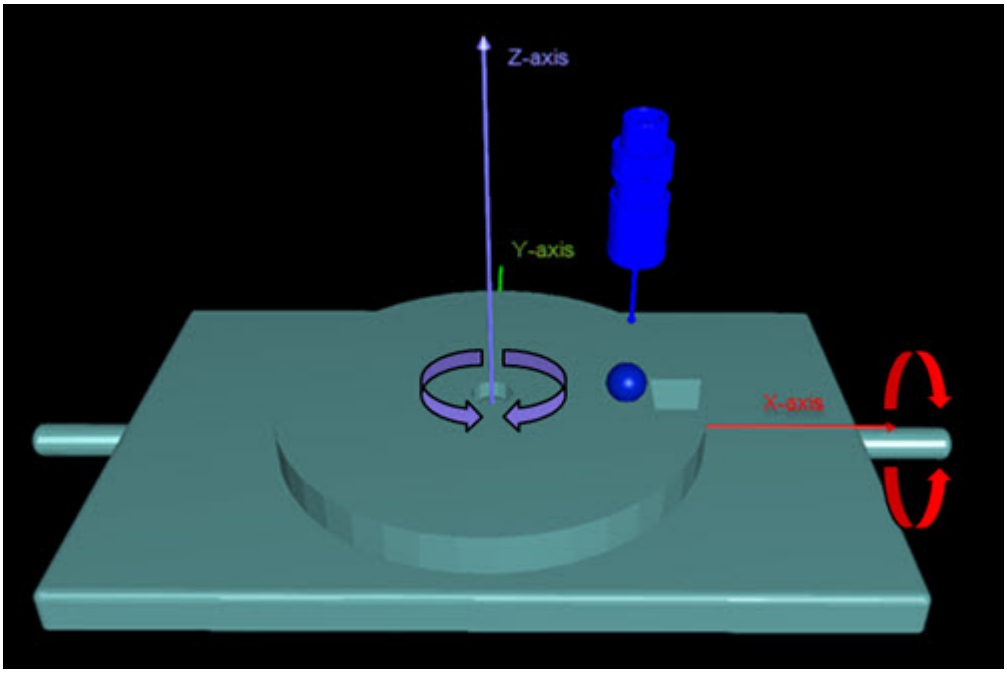
A stacked table system has two tables stacked on top of each other.



A. *Bottom table*

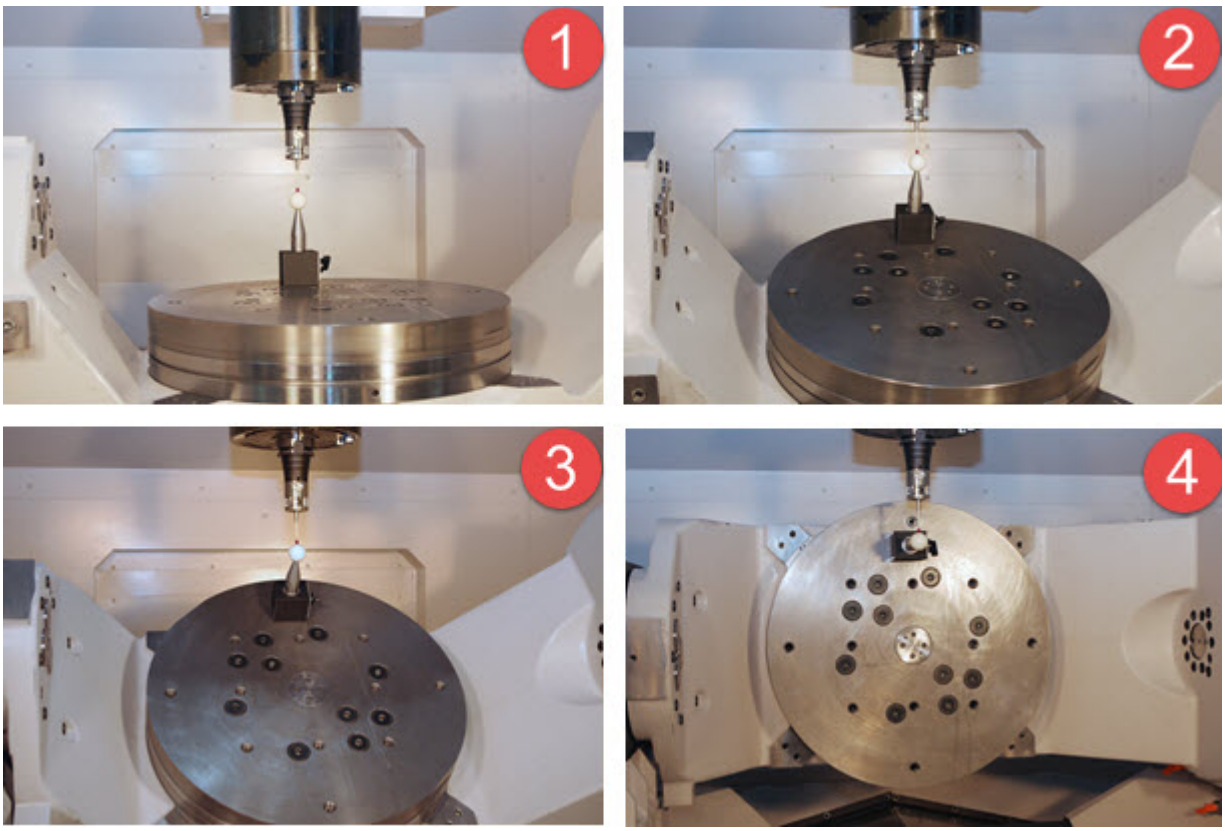
B. *Top table*

The top table rotates about the Z axis and the bottom table rotates about the X axis.



Example showing the table rotation directions.

The following four images show a real-world example of the A table on a stacked rotary table as it rotates 90 degrees.

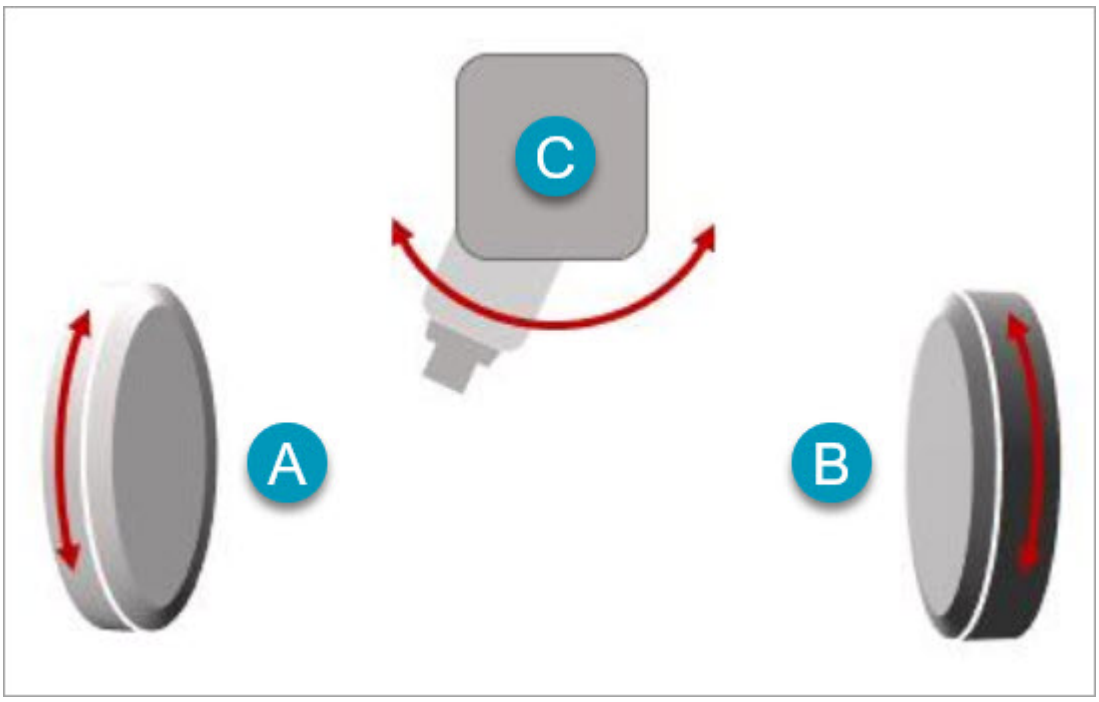


Example showing a stacked rotary table rotating 90 degrees.

Dual Rotary Table

The configuration of a Dual Rotary Table system has these properties:

- It is comprised of two independent rotary tables as typically seen on multitasking machines.
- Each table represents a lathe spindle. You define one spindle as the main spindle, and the other as the secondary spindle.
- The tables within the machine must be far enough apart from each other to provide the necessary operating space.



Example of a typical multitasking machine setup with two independent rotary tables (A and B) and a single-axis rotary head (C).

On a multitasking machine, both rotary tables (A and B) are lathe spindles and are powered separately. The single axis rotary head (C) is a positional milling spindle. The spindles turn at very high speeds and are used to cut (or mill) stationary parts. With two lathe spindles and a positional milling spindle, this is what makes a multitasking machine special. You can use it to completely manufacture all sides of a part, which allows you to have two parts in various stages of completion on the machine. You can cut on both lathe spindles independently and at the same time. In most cases you can also transfer a part clamped in one lathe spindle to the other automatically. For example, you can drive the B table to the A table until the jaws on the B table can grab the part from the A table.

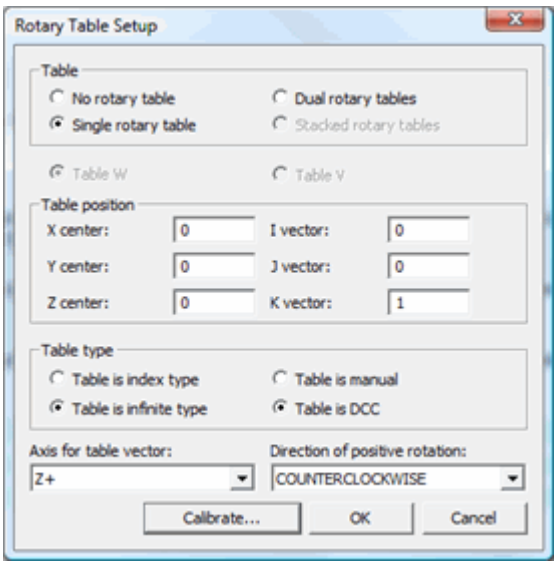
> **!** If you want to control two independent rotary tables, you should use two separate measurement routines, one for each table.

On non-multitasking machines, you can only have one table active at a time. You can select the active table from the Active Rotary Table toolbar. Once you activate a table, it remains active for the entire length of the measurement program. The other table stays inactive.

You can calibrate and use the active table just as you would a single table system.

Calibrate Rotary Table

The **Edit | Preferences | Rotary Table Setup** menu item accesses the **Rotary Table Setup** dialog box.

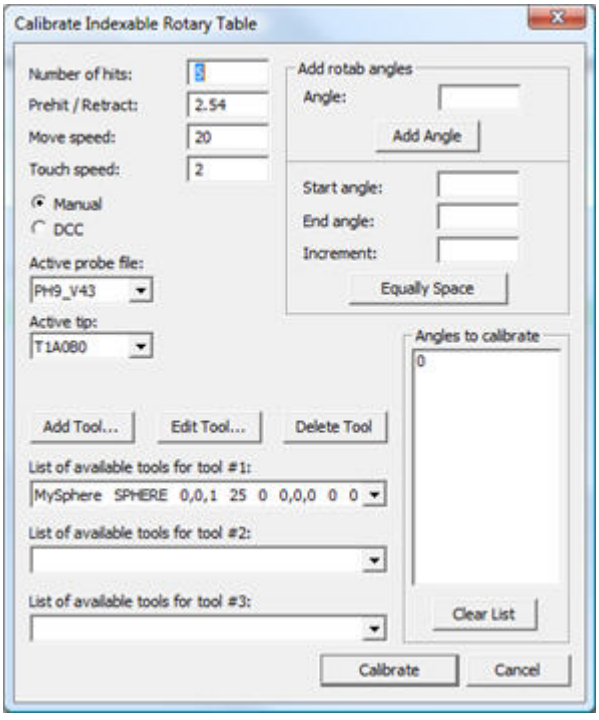


Rotary Table Setup Dialog Box

Depending on the options selected **Table Type** area of the **Rotary Table Setup** dialog box (see "Defining the Rotary Table"), one of two dialog boxes opens when you click the **Calibrate** button.

- Selecting the **Table is Infinite Type** option and clicking the **Calibrate** button opens the **Calibrate Infinite Rotary Table** dialog box.
- Selecting the **Table is Index Type** option and clicking the **Calibrate** button opens the **Calibrate Indexable Rotary Table** dialog box.

Calibrate Indexable Rotary Table



Calibrate Indexable Rotary Table Dialog Box

Using the **Calibrate Indexable Rotary Table** dialog box, you can select the options PC-DMIS uses to calibrate the selected table. Once the options within the dialog box are satisfactory, click the **Calibrate** button to start the rotary table calibration process.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

Usage Requirements: The indexable rotary table calibration must include the 0 position. Additionally, all the angles used in a measurement routine must also be calibrated. This calibration procedure calculates and stores a transformation for all other angles relative to the 0 position.

Calibration Requirements: The indexable rotary table calibration procedure requires a valid XYZ, IJK for the table in order to run properly. This can be accomplished in two ways:

1) If the values are known, they can be manually typed into the **Rotary Table Setup** dialog box. This is usually *not* the case.

2) Initially select the **Table is Infinite Type** option and complete an infinite rotary table calibration, which calculates and saves the XYZ, IJK. Then select the **Table is Indexable Type** and perform the indexable rotary table calibration. This is normally only an issue during the initial software installation/setup or if the rotary table has been moved or if something has happened to significantly alter the origin of the machine coordinate system. Once the XYZ, IJK is determined closely enough that the indexable rotary table calibration procedure can run successfully it is not necessary to go back and re-run the infinite rotary table calibration in order to re-run the indexable rotary table calibration.

Add Rotab Angles

The **Add Rotab Angles** area allows you to define the list of table angles that are included in the calibration. You can define one angle at a time, or you can define an incremented range of angles. Defined angles are then placed in the **Angles to Calibrate** list. When you click **Calibrate**, PC-DMIS then calibrate the rotary table using the defined angles.

If you want to calibrate all the angles between 5 and 95 degrees with a 10 degree increment between each angle, you would fill in the **Start Angle**, **End Angle**, and **Increment** boxes with 5, 95, and 10 respectively, and then click the **Equally Space** button.

Angles to Calibrate List

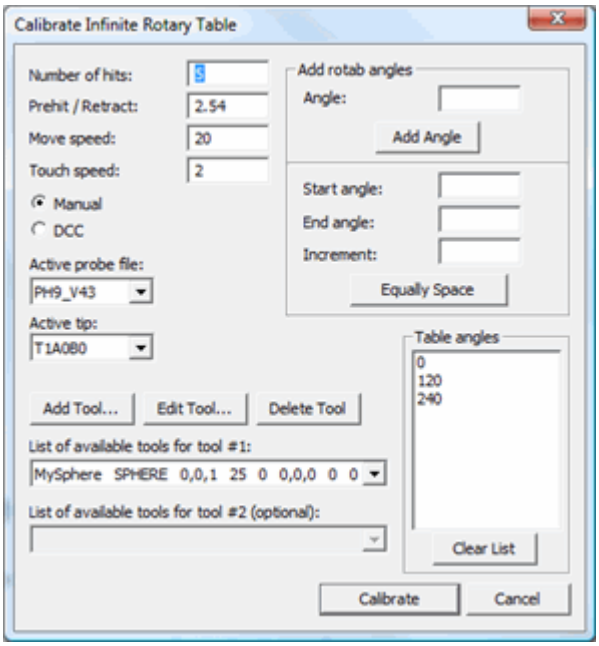
This list contains all the table angles for the calibration. You can add angles to this list from the **Add Rotab Angles** area. The **Angles to Calibrate** list must use the zero angle.

Other Dialog Box Parameters

This dialog box also contains many of the same options described in the "Defining Hardware" chapter.

- For information on **Number of Hits**, **Prehit / Retract**, **Move Speed**, **Touch Speed**, **Manual / DCC**, **List of Available Tools**, **Add Tool**, and **Delete Tool**, see the "Measure" topic in the "Defining Hardware" chapter.
- For information on **Active Probe File** and **Active Tip**, see the "Defining Probes" topic in the "Defining Hardware" chapter.

Calibrate Infinite Rotary Table



Calibrate Infinite Rotary Table Dialog Box

For information on many of the options on this dialog box, see the "Calibrate Indexable Rotary Table" topic in the PC-DMIS Core documentation.

The **Calibrate Infinite Rotary Table** dialog box differs from the **Calibrate Indexable Rotary Table** dialog box in these areas:

- Instead of the **Angles to Calibrate** list, the dialog displays the **Table Angles** list.
- You don’t have to use the 0.0 angle in the **Table Angles** list.
- Instead of three calibration tools, the dialog box only displays one calibration tool.

Once the options within the dialog box are satisfactory, click the **Calibrate** button to start the rotary table calibration process.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

Setting Up Probe Changer Options

Use the **Probe Changer** dialog box to set up various options that you can use on a probe changer. To display the dialog box, select **Edit | Preferences | Probe Changer**.

For complete information, see "Defining Probe Changers" in the "Defining Hardware" chapter.

Managing Multiple Probe Changers

The topics below discuss the more popular probing systems used today (the TP2, ACR1, TP20 and TP200, and the SP600). The "Configuring Multiple Racks" and "SP25 Probe/Stylus Change system" topics then provide detailed examples of how to work with multiple probe changers.

Background on TP2

When Renishaw developed the small touch trigger probe (TP2), it attached to the CMM ram via a probe head with a threaded M8 connection in line with the probe body itself. However, this design required a probe recalibration whenever it was removed or reattached.

To alleviate this need to recalibrate, Renishaw developed a quick-connect adapter (termed QuickConnect) which used a ¼ turn of a key to lock and unlock the adapter from the CMM. The TP2 screwed into this adapter. This adapter could be detached and re-attached very quickly and repeatedly without the necessity of always recalibrating.

Background on ACR1

The ACR1 was the first probe changer introduced by Renishaw. It held up to eight of the quick-connect extensions, each with a separate TP2 probe body. Once the probes were qualified and placed into the rack, they could be automatically dropped off and picked up by the CMM with simple move commands and coordinated with the locking/unlocking mechanisms of the rack. A software module was eventually developed which controlled the rack operations.

Background on TP20 and TP200

Over time, design evolution and electronic developments paved the way for alternatives to the TP2 probe body. In addition, for some customers, purchasing up to eight probe bodies proved prohibitive. New probe body designs were developed, which allowed for removal and attachment of new stylus adapters. These took the place of the quick-connect joints. Individual stylus assemblies could then be removed and re-attached repeatedly and inexpensively.

Two of the better-known probe bodies of this design from Renishaw include the TP20 and the TP200. The TP20 uses a magnetic coupling, which allows the exchange of multiple probe modules. You can store the individual modules in the TP20 probe rack, which is actually called the MCR20 (where "MCR" is Module Change Rack).

Each probe body is roughly equivalent to the TP2 in size and shape, but there are two main differences:

- Due to their enhanced electronics, they can hold more weight and still produce more accurate and repeatable results.
- They are designed with a magnetic "split" between the upper probe body and the lower stylus holder. This allows them to be used with their own stylus change rack systems: the MCR20 and the SCR200, respectively.

Background on the SP600 Analog Probe

Another improvement is the popular SP600 analog probe. This probe can perform analog scans as well as touch trigger measurements. While its body design is much larger than the TP series of probes, a magnetic stylus holder can separate from the body. Accordingly, it also has its own rack system, the SCR600 tip changer.

Configuring Multiple Racks

While there are other probing systems on the market, the four most popular probing systems, as discussed, are the TP2, TP20, TP200, and SP600 systems. Each has its own rack system which can function on its own as a single rack. Alternately, you can use more than one rack with a CMM. The PC-DMIS software has the ability to move between the racks to drop off and pick up probes and stylus holders as needed.

Important Notes:

- Each rack has its own calibration method in PC-DMIS. While they share a lot of commonality, for calibration purposes, they are completely independent of each other.

- The clearance move point for each rack is only related to that rack, except that some consideration must be given to where to will travel next. For this reason, the clearance move should be at such a location to allow free travel to any other rack which may be involved. Even when using a single rack, this clearance move must be sufficient to travel from and return to the part inspection operations.
- Defining the ports' contents for multiple racks is the most critical part of configuring multiple racks for simultaneous use. Since each port may contain multiple probe references (the contents of the port can be used with multiple probes) each port must identify all of the probes it will potentially use.

Example of Multiple Probe References

Suppose you have these three probe configurations:

PROBE_01	PROBE_02	PROBE_03
QuickConnect AutoJoint	QuickConnect AutoJoint	QuickConnect AutoJoint
TP2	TP20	TP20
3 mm x 10 mm stylus	2 mm x 10 mm stylus	4 mm x 20 mm stylus

The ACR1 will switch between the TP2 and the TP20 probes. The MCR20 will switch between the styli associated with the TP20 probe system(s).

A typical port definition might look like this:

ACR1	MCR20
Port 1	Port 2
Probe_01	Probe_02
	Probe_03

In operation, suppose the system is using PROBE_01 and it needs to switch to PROBE_02. The system would:

- Pause the measurement routine.
- Travel to the clearance location for the ACR1.
- Return the currently loaded probe to port #1 of the ACR1.
- Move to port #2 of the ACR1 and pick up the TP20 body for PROBE_02.
- Use the respective Safety/Clearance points and move to the MCR20.
- Move into port #1 of the MCR20 to attach the stylus adapter with the desired stylus.
- Return to the MCR20’s Clearance point.
- Continue with the measurement routine.

Suppose after measuring some features, the system then needs to use PROBE_03. The system would:

- Pause the measurement process.
- Travel to the clearance location for the MCR20.
- Move into port #1 to drop off PROBE_02’s stylus.
- Travel out, over, and into port #3 to pick up the stylus required for PROBE_03.
- Travel to the clearance location.
- Continue with the measurement routine.

Now, suppose the system needs to switch from PROBE_03 (the TP20 with the 4 mm x 20 mm stylus) back to Probe_01 (the TP2 with the 3 mm x 10 mm stylus). The system would:

- Pause the measurement routine.
- Move to the clearance point for the MCR20.
- Go into port #2 and drop off the stylus assembly.
- Return to the MCR20’s clearance location
- Move to the ACR1’s clearance location.
- Go into port #2 to drop off the TP20 assembly.
- Move out and return to port #1 to pick up the TP2 assembly (the TP2 probe already has the stylus attached).
- Move to the clearance point for the ACR1.
- Continue the measurement routine.

Note that in this example, you only need one TP20 probe body. You use the MCR20 to switch between two different probe stylus assemblies for varied measurement requirements.

SP25 Probe/Stylus Change system

The SP25 rack is an extension of the same procedures used in other racks. This discussion covers the ARC1 and TP20 racks and then branches out to describe the SP25 rack system.

Understanding the ACR1 Rack

When using the ACR1, the system uses the Quickened joint between the probe head and the probe body. All of the ports in the ACR1 are identical, so if you had an SP600 in port 1, it would connect directly to the probe head. If you wanted to put a TP2 into port 2, you would need to mount an adapter to the TP2 (as with TP20 and TP200 probing systems).

With this configuration in mind, you only need to define one probe name for each port. Technically, the ACR1 is a probe changer, and each probe would have a stylus already attached to it when it sits in the rack.

Suppose you want to assign these probes to the ACR1 rack: "SP600", "TP2", "TP20", and "TP200". The port definitions in the ACR1 rack would be:

PORT 1	PORT 2	PORT 3	PORT
SP600	TP2	TP20	TP200

Understanding the ACR1 with a TP20 Stylus Changer

Now, if you want to combine the ACR1 with a TP20 rack (a stylus changer), things get slightly more complicated. The ACR1 will switch between the SP600 and the TP20 probe bodies. Once the system picks up the TP20, it will go to the MCR20 rack to pick up an appropriate stylus for it.

Suppose you have 3 separate styli that you wanted to use with the TP20 and that the SP600 is used as a single probe (no stylus changing).

When you define the ports, you might call the SP600 probe "SP600_1", and the TP20 probes with the varied styli attached, you might call "TP20_1", "TP20_2", and "TP20_3".

The ports in the ACR1 probe changer would be defined as:

PORT 1	PORT 2	PORT 3	PORT 4
SP600	TP2	TP20_1	TP200
		TP20_2	
		TP20_3	

The ports in the TP20 stylus changer would be defined as:

PORT 1	PORT	PORT 3	PORT 4
TP20_1	TP20_2	TP20_3	empty

Understanding the SP25 Rack System

You can extend the logic from the above topics to the SP25 rack system. This rack can hold two different types of probe components. For one type the port is calibrated empty, and for the other type a port is calibrated with an insert.

This discussion will abandon the previous references to SP600, TP2, TP20, and TP200 since the SP25 rack system uses these components instead:

- SP25M
- SM25-x
- SH25-x

The SP25M system can adapt to any of five different SM25 modules for varied styli lengths and weights, and a sixth module for use with the TP20. They all use the same SP25M probe body.

- SM25-1 module - This module accepts only the SH25-1 stylus holder. It is used for styli lengths between 20 mm and 50 mm.
- SM25-2 module - This module accepts only the SH25-2 stylus holder. It is used for styli lengths between 50 mm and 105 mm.
- SM25-3 module - This module accepts only the SH25-3 stylus holder. It is used for styli lengths between 120 mm and 200 mm.

- SM25-4 module - This module accepts only the SH25-4 stylus holder. It is used for styli lengths between 220 mm and 400 mm.
- SM25-5 module - This module accepts only the SH25-5 stylus holder. It supports straight styli lengths of approximately the same range as the SM25-2. However, it is specially designed for improved handling of perpendicularly attached styli (that is, crank styli configurations). The maximum length of a crank stylus depends on how far down from the stylus holder it is attached. The maximum crank stylus length forms an approximately conical shape varying from 105 mm at 15 mm down to 20 mm at 80 mm down.
- TM25-20 module - This module can only accept TP20 touch trigger probes and therefore does not support scanning.

Any of the SM25-x modules above are capable of individual touch probing as well as scanning.

Example of SP25 with Multiple Probes

Suppose your SP25 rack has these six probe assemblies that are always attached to the probe head:

P1	P2	P3	P4	P5	P6
SP25M	SP25M	SP25M	SP25M	SP25M	SP25M
SM25-1	SM25-1	SM25-2	SM25-3	TM25-20	TM25-20
SH25-1	SH25-1	SH25-2	SH25-3	TP20	TP20
2 mm x 20 mm stylus	4 mm x 30 mm stylus	6 mm x 80 mm stylus	8 mm x 100 mm stylus	2 mm x 20 mm stylus	4 mm x 20 mm stylus

You would define the ports in the FCR25 rack to hold components making up the various probe configurations. This first table shows the ports that hold components for the above probe configurations.

PORT 1	PORT 2	PORT 3	PORT4	PORT5	PORT6
P1	P1	P2	P3	P4	P5*
P2					

In detail, the ports would hold these components:

PORT 1	PORT 2	PORT 3	PORT4	PORT5	PORT6
SM25-1	SH25-1	SH25-1	SH25-2	SM35-3	TM25-20
	2 mm x 20 mm stylus	4 mm x 20 mm stylus	6 mm x 80 mm stylus	SH25-3	TP20*
				8 mm x 100 mm stylus	2 mm x 20 mm stylus*

- Slot 1 contains the SM25-1 module only. It uses no insert for this. This component attaches directly to the SP25 and requires the addition of the SH25-1 with the 2 mm stylus found in Slot 2 or the SH25-1 with the 4 mm stylus found in port 3.
- Slot 2 contains the SH25-1 stylus holder with an attached 2 mm x 20 mm stylus. This component requires an insert in the port to adapt the physical characteristics of the port for this component. This component requires an SM25-1 module (found in port 1). Once it picks up the SM25-1, the probe assembly is complete.
- Slot 3 contains the SH25-1 stylus holder with an attached 4 mm x 30 mm stylus. This component requires an insert in the port to adapt the physical characteristics of the port for this component. This component requires an SM25-1 module (found in port 1). Once it picks up the SM25-1, the probe assembly is complete.
- Slot 4 contains the SH25-2 stylus holder and an attached 6 mm x 80 mm stylus. It uses no insert for this. Once this is picked up, the probe assembly is complete.

- Slot 5 contains the SM25-3 with the SH25-3 stylus holder and an attached 8 mm x 100 mm stylus. It uses no insert for this. Once this is picked up, the probe assembly is complete.
- Slot 6 contains the TM25-20 module only. It uses no insert for this. This component attaches directly to the SP25M.

  * When used with a single stylus, the TP20 probe module and stylus can be attached to the TM25-20 module while in the port, and requires no additional rack system. However, when used with multiple styli (as in this example), the TM25-20 module has no other components attached while it sits in the port, but requires the use of additional FCR25 ports with adapters specifically for the purpose of holding the TP20 module/stylus combinations. For this example, the added three ports would look like this:

PORT 7	PORT 8	PORT 9
P5	P6	empty

PORT 7	PORT 8	PORT 9
TP20	TP20	empty
2 mm x 20 mm stylus	4 mm x 20 mm stylus	

- **When using P1**, the CMM would drop off any existing components. Then it would pick up the SM25-1 found in port 1 of the FCR25 and proceed to pick up the SH25-1 found in port 2 of the same rack.
- **When using P2**, the CMM would drop off any existing components. Then it would pick up the SM25-1 found in port 1 of the FCR25 and proceed to pick up the SH25-1 found in port 3 of the same rack.
- **When using P3**, the CMM would drop off any existing components. Then it would pick up the SM25-2 and SH25-2 combination found in port 4. With this, the probe assembly is complete.
- **When using P4**, the CMM would drop off any existing components. Then it would pick up the SM25-3 and SH25-3 combination found in port 5. With this, the probe assembly is complete.

- **When using P5**, the CMM would drop off any existing components. It would then pick up the TM25-20 body in port 6 of the FCR25 and proceed to pick up the TP20 module/stylus combination in port 7 of the FCR25.
- **When using P6**, the CMM would drop off any existing components. It would then pick up the TM25-20 body in port 6 of the FCR25 and proceed to pick up the TP20 module/stylus combination in port 8 of the FCR25.

As with other tool changers and probe assemblies, components are dropped off in reverse order from how they are picked up.

Loading the Active Probe

The **Operation | Load Active Probe** menu option loads the active probe required by the measurement routine. While in Learn mode, use the **Probe Utilities** dialog box (**Insert | Hardware Definition | Probe**) to change the loaded probe file or files.

Use the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**) to define the appropriate probe configurations for each port that is used. You can then use the **Load Active Probe** option to tell the machine to exchange the necessary probe configuration or configurations.

Examples of Working with Single and Multiple Probe Changers

A probe changer is a mechanical rack system that changes components at the kinematic joint. This topic shows examples of working with single and multiple probe changers in the same measurement routine after calibration.

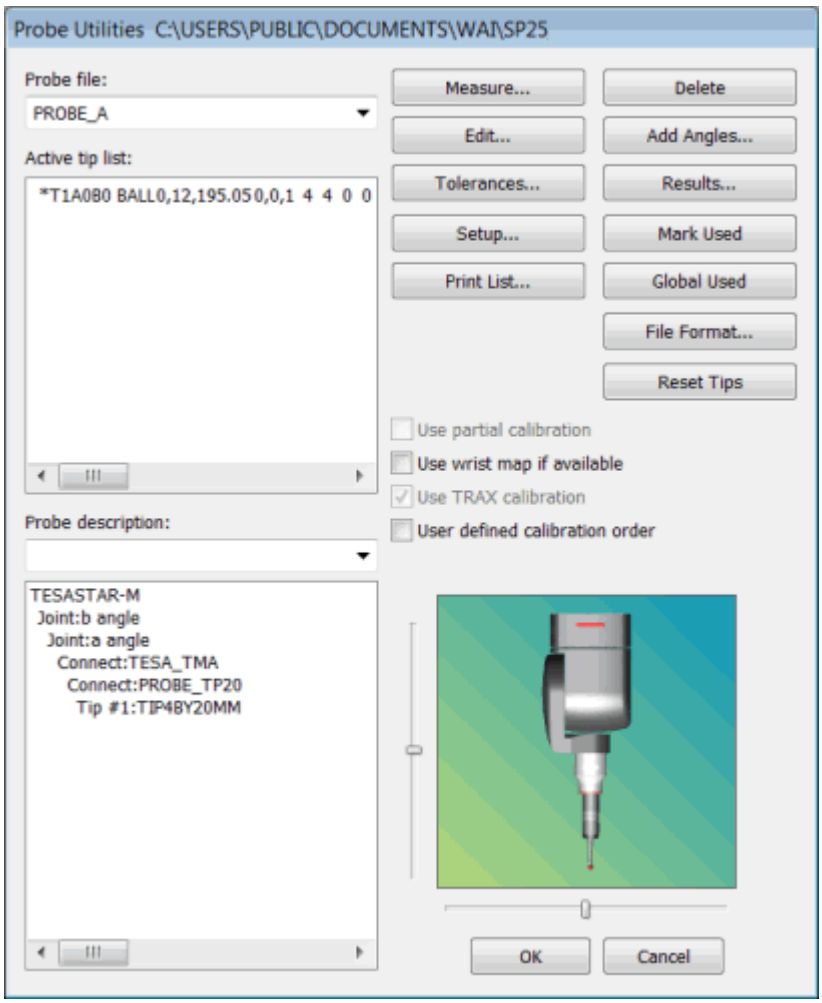
The "Defining Probe Changers" topic in the "Defining Hardware" chapter provides you with a step-by-step description of how to set up and calibrate a probe changer. It also describes how to display an existing probe changer inside the Graphic Display window.

The examples use the TP20, which is a single probe, and the LSPX1. Also, in these examples, the kinematic joint is the Autojoint. The Autojoint is the connection where a key is used to engage the male and female halves of this coupling. For systems with no probe racks, the operator manually uses a key to engage and disengage the autojoint. For rack systems, this is done with a rack and pinion style device to turn the key.

Example - Working with a TP20 Probe

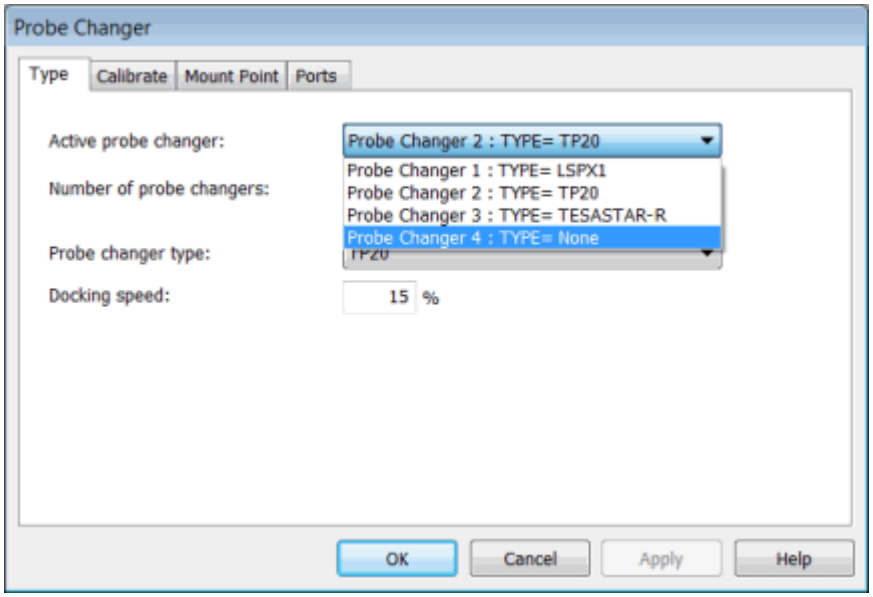
In this example, you would do the following:

1. Set up the TP20 in the **Probe Utilities** dialog box. For example:



TP20 setup in Probe Utilities Dialog Box

2. Select **Edit | Preferences | Probe Changer**. The **Type** tab in the **Probe Changer** dialog box appears:

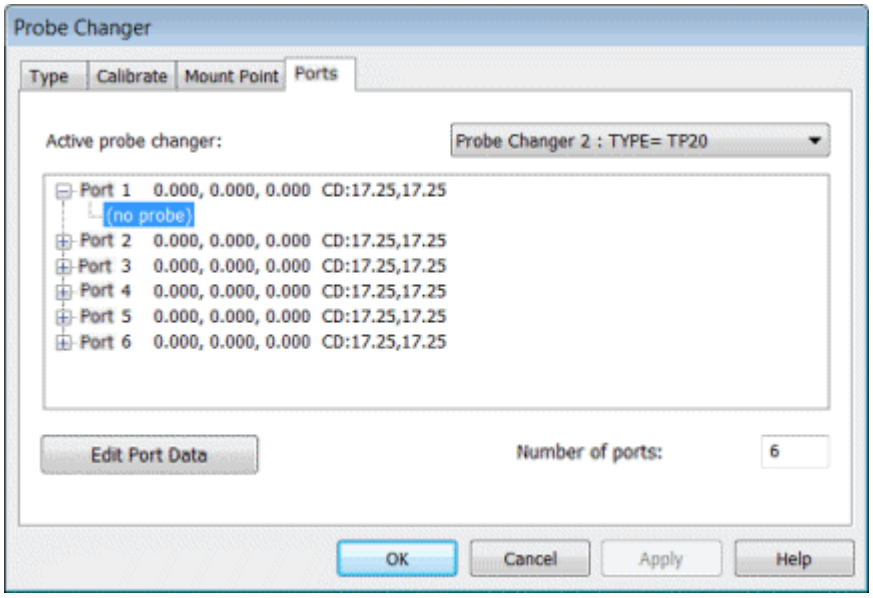


Probe Changer Dialog Box - Type Tab

To use different modules for the TP20 probe and load them automatically, you would use a probe changer. In this case, it is referred to as the "TP20" probe changer in the **Active probe changer** list. The example above shows that the TP20 probe changer (and others) has already been configured.

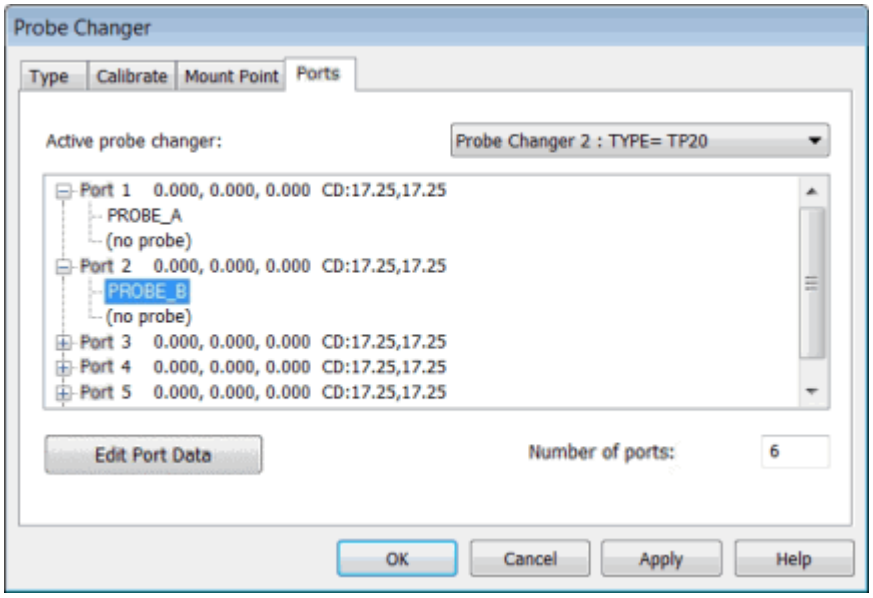
3. Select **TYPE= TP20**.

4. Select the **Ports** tab:



Ports Tab

5. To define the port contents for the TP20 probe changer, click the plus sign (+) to the left of the port number and then assign a probe file to each port from the list that appears. (For help with assigning probe files, see "To Define the Probe Configuration for Each Port".) Repeat this procedure for each port, until you have defined all of the ports that you need to use. For example:



Example showing assigned probe files for the TP20 probe.

You should assign each probe file to only one port. If you are using a single probe changer, and the name of one of the probe files appears in multiple ports, PC-DMIS may not perform as you would expect.

6. Click **Apply**, and then click **OK** to close the dialog box.

7. Use the probes in your measurement routine. To do this, you only need to include the `LOADPROBE` command in your measurement routine where you want to use that probe. When PC-DMIS encounters this command, it moves the machine.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

The machine does the following:

- It drives from the current position on the table to the probe changer's mount point.
- It proceeds to drop off the current probe and then to pick up the new one.
- It returns to the mount point for that probe changer.

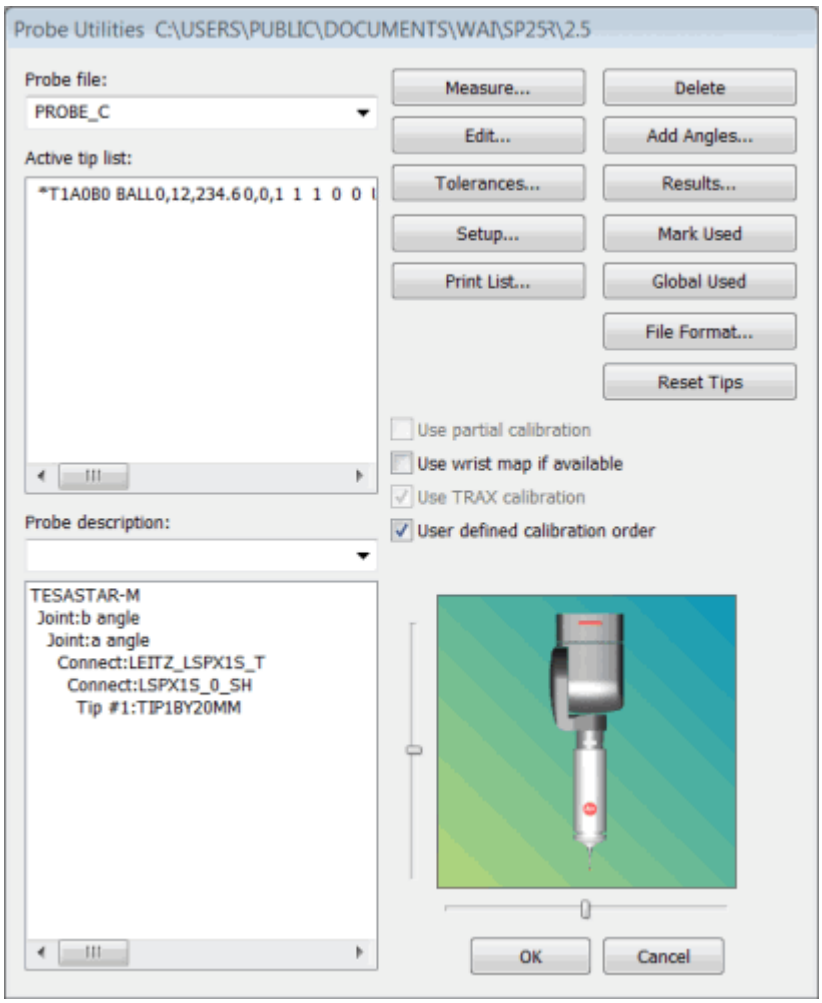
Your measurement routine must contain the necessary Move Point and Clearance Plane commands to ensure safe travel between the last position, the mount point, and the next position in the measurement routine. For more information about these commands, see "Inserting Move Commands".

Example - Working with Two Different Probes

Suppose you have two different probes, and you want to use them in the same measurement routine. This example uses the TP20 and LSPX1. The LSPX1 also has its own probe changer.

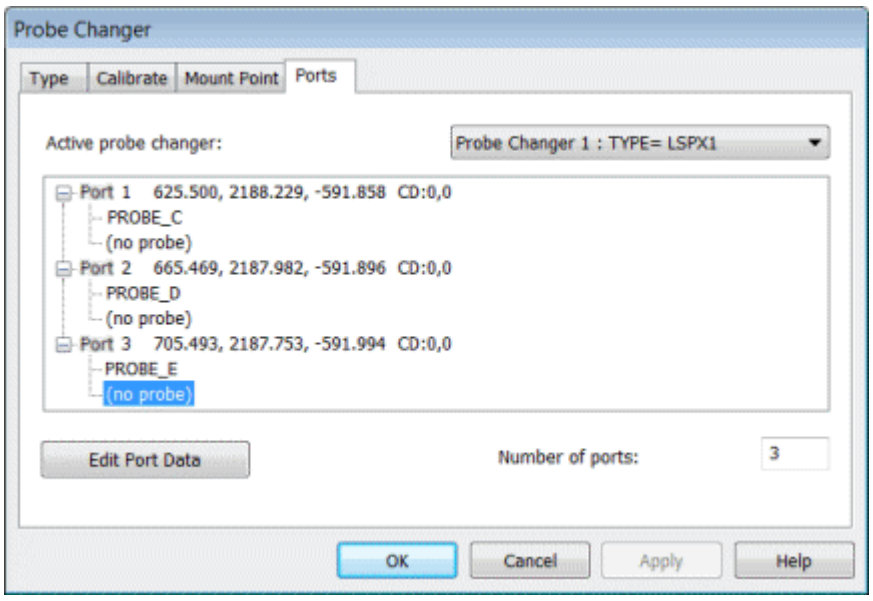
In this example, you would do the following:

1. Set up the LSPX1 in the **Probe Utilities** dialog box. For example:



Example of a LSPX1 probe setup in Probe Utilities dialog box.

2. Select **Edit | Preferences | Probe Changer**. The **Type** tab in the **Probe Changer** dialog box appears.
3. Select **TYPE= LSPX1**.
4. Select the **Ports** tab to define the port contents for the LSPX1 probe changer. For example:



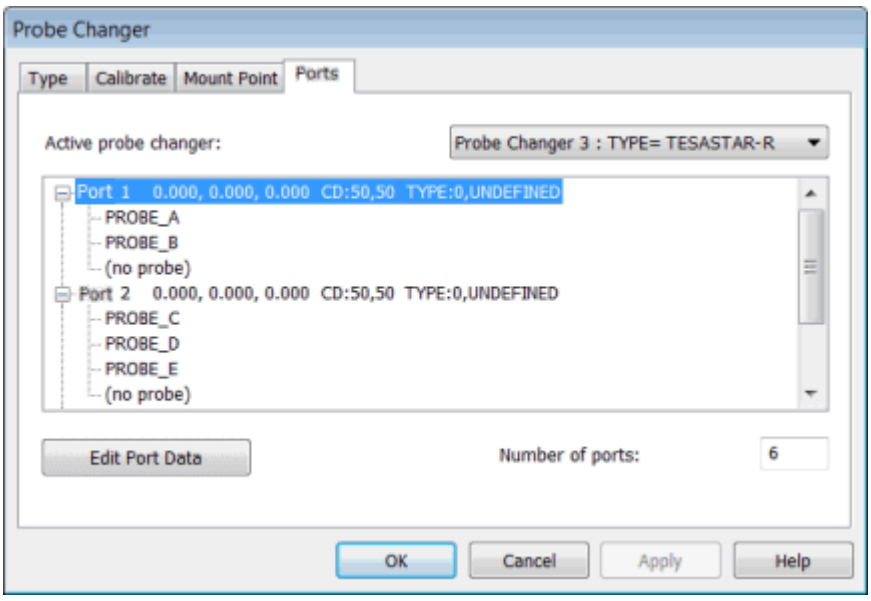
Example showing assigned probe files for the LSPX1 probe.

At this point, you could have a measurement routine that uses each probe from the LSPX1 rack and picks them up automatically. However, suppose that you want a measurement routine that uses a combination of the TP20 and LSPX1 probes. When the changeover occurred, the measurement routine would stop and prompt you to remove one probe and attach the other one. It would then continue to drop off and pick up modules specific to that probe.

To automate this process, you could use a third, intermediate rack. In this example, the third rack is the TESASTAR-R / HR-R. The challenging task is to define the port contents for the TESASTAR-R / HR-R probe changer. In the previous example, the TP20 probe changer has two defined probes: PROBE_A and PROBE_B. In this example, the LSPX1 probe changer has three defined probes: PROBE_C, PROBE_D, and PROBE_E.

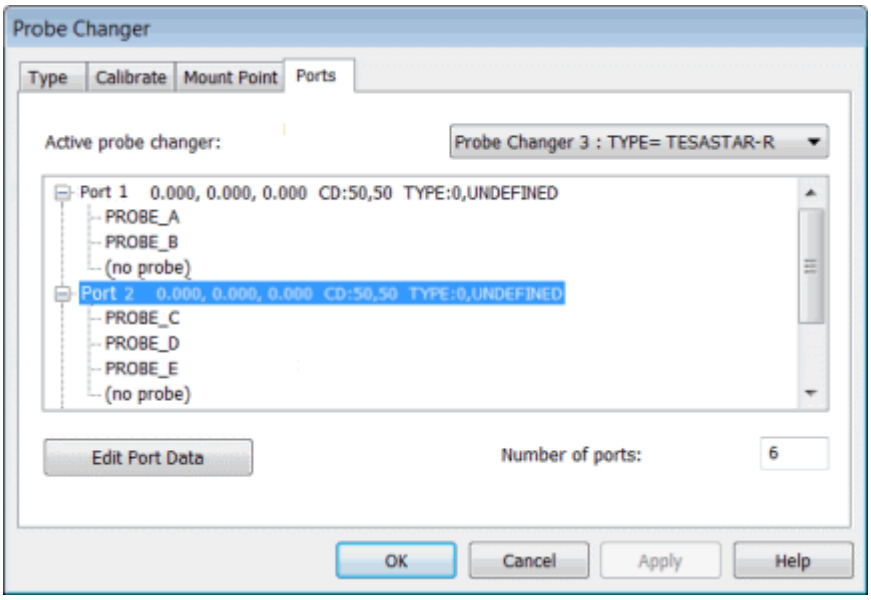
The TESASTAR-R / HR-R does not hold any of the individual modules for the other two probes; it holds only the probe bodies. The body is the upper part of the probe from the kinematic joint down to the magnetic probe coupling. The probe body for the TP20 is associated with two different modules (PROBE_A and PROBE_B). The probe body for the LSPX1 is associated with three other modules (PROBE_C, PROBE_D, and PROBE_E) for that probe.

Therefore, you would define two of the probes in one port and the remaining three probes in the other port, as shown in the example below:



Example showing the Port 1 assigned for the TP20 probe body.

In this case, you have selected the first port of the TESASTAR-R / HR-R probe changer to hold the probe body for the TP20. You have selected the second port to hold the probe body for the LSPX1:



Example showing the Port 2 assigned for the LSPX1 probe body.

Physically, there is only one part in the port. Logically, that one part is associated with multiple probe assemblies. In this example, the TP20 body is used with two other modules and the LSPX1 probe body is used with three other probes. You can have more entries in the port than this example shows; the example is just a guide to explain how the multiple racks interact with each other.

One way to think about this is the following: If any piece of the probe assembly is in that port, you must select the probe file name (of the entire probe assembly) for that port. It is feasible to find the same probe file name in two or more ports because a piece of the probe assembly can be found in that port.

If you had PROBE_B loaded (TP20) and you want to use PROBE_D (LSPX1) when you execute the measurement routine, and PC-DMIS encounters the LOADPROBE command, this is what would happen next:

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

1. The CMM moves to the mount point for the TP20 rack, drops off the PROBE_B module, and then returns to the mount point for this same rack.
2. The CMM then moves to the mount point for the TESASTAR-R / HR-R rack and drops off the TP20 body.
3. From there, the CMM picks up the LSPX1 probe body and returns to the mount point for this rack.
4. The CMM moves to the mount point for the LSPX1 rack, picks up the PROBE_D assembly, and then returns to the mount point for this rack.
5. The CMM continues with the part inspection from there.

If the probes and ports have been properly set up, PC-DMIS drops off the current probe, loads the new probe, and continues executing the measurement routine. This process does not require any operator intervention.

Configuration Error

If PC-DMIS stops DCC execution with a prompt to either unload the current probe or load the probe that you expected to be loaded automatically, a configuration error may have occurred. Possible causes are:

- The same probe is defined in too many ports, and PC-DMIS may not know how to deal with it.
- The probe in question has not been assigned to any port.
- You are using a probe that is incompatible with the probe rack where it is defined.

How to Protect Probes from Probe Changer Collisions

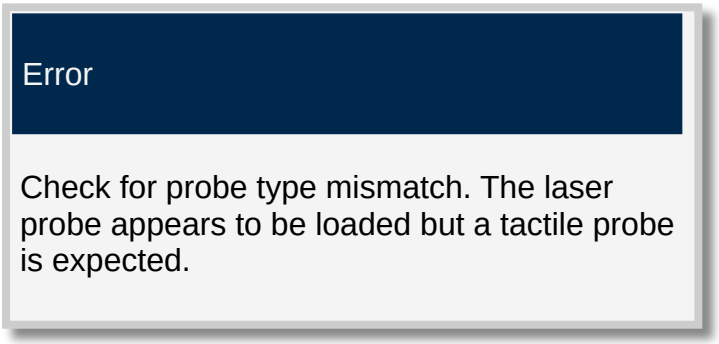
Depending on a variety of circumstances, including user errors, there’s the possibility that a physical crash happens during a probe change cycle. PC-DMIS provides multiple levels of protection against that event.

To avoid this type of situation, a safety mechanism that you can enable is the probe changer collision safety check. For details, see the topic "Protecting Probes from Probe Changer Collisions" in the PC-DMIS Core documentation.

Check to Verify the Location of the Laser Sensor in the Probe Changer

If you mistakenly inform PC-DMIS that you have a tactile probe mounted on the probe assembly head when you actually have a laser sensor mounted, when you attempt a probe change, PC-DMIS performs a proximity check on the laser slot to ensure it doesn't try to drop off the laser sensor in the slot that has the tactile probe.

If this is the case, PC-DMIS shows a warning message similar to this:



You must enable the Settings Editor entry "`CW43LTTest3AxisSlotAlwaysTC`" to use this feature. For details, see the "CW43LTTest3AxisSlotAlwaysTC" topic in the PC-DMIS Settings Editor documentation.

Setting Up the Machine Interface

The **Edit | Preferences | Machine Interface Setup** menu option opens the **Machine Options** dialog box for your machine interface. The **Machine Interface Setup** option is only available when you work in Online mode.

In most cases, *you should not change any of the values* in the **Machine Options** dialog box. Some items in this dialog box, such as the items in the **Mechanical Offsets** area, permanently overwrite values stored for your machine on the controller's hard drive. For questions on how and when to use the **Machine Options** dialog box, please contact your local service representative.

For information on this dialog box, please refer to the "Machine Options Dialog Box" topic in the Machine Interface Installation Manual (MIIM). The MIIM is typically used only by Hexagon service engineers.

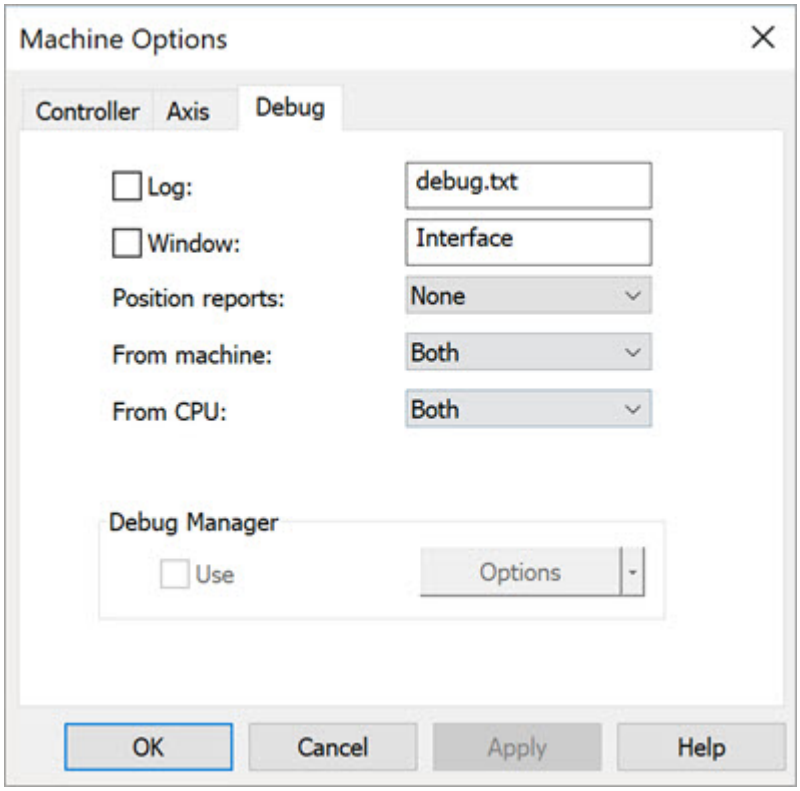
Generating a Debug File

You can tell PC-DMIS to generate a debug file. This special text file contains all of the communication data between PC-DMIS and the CMM during measurement routine execution. A debug file can help Hexagon Technical Support resolve certain problems that involve your CMM.

The debug file lists all of the commands that PC-DMIS sends to the CMM, the responses it receives, and the error messages that the controller generates. If you encounter repeatable problems that involve the movement of your CMM in Online mode, you may want to submit that to Hexagon Technical Support.

To generate a debug file, follow this procedure:

1. From the **Machine Options** dialog box (**Edit | Preferences | Machine Interface Setup**), select the **Debug** tab.



Machine Options Dialog Box - Debug tab when connected to non-vision machines

> Be sure to modify only the **Debug** tab. The other tabs on the **Machine Options** dialog box are used by service personnel to set up your machine.

2. Select the **Log** check box.

3. Type a name for the debug file in the box next to the **Log** check box. The default file name is debug.txt. You can also precede the file name with a full path to specify the drive and directory where PC-DMIS should send the debug file.

4. Click **Apply** and then **OK** to close the dialog box.
5. Execute your measurement routine. When you encounter the error, immediately exit PC-DMIS.
6. Navigate to the directory that contains your debug file.
7. Rename the debug file. If you don't rename the debug file, the next time you start PC-DMIS, it automatically overwrites all existing data in the debug file. This results in a loss of data that may be necessary for debugging purposes.
8. Send the debug file, measurement routine file (.prg), probe file (.prb), and any other necessary files to Hexagon Technical Support.

By default, PC-DMIS sends the debug file to the ProgramData directory. This is typically "C:\ProgramData\Hexagon\PC-DMIS\<version>", where <version> is the version of PC-DMIS you're running.

For details on the default locations for PC-DMIS files, see "Understanding File Locations".

Starting a Fresh Debug File

You can use the `DebugLogReset` entry in the Settings Editor application to specify whether to overwrite all existing data in the debug file or append new data to the file each time you execute a measurement routine. For details, refer to "DebugLogReset" in the "Option" section in the Settings Editor documentation.

Setting Additional Debug Options

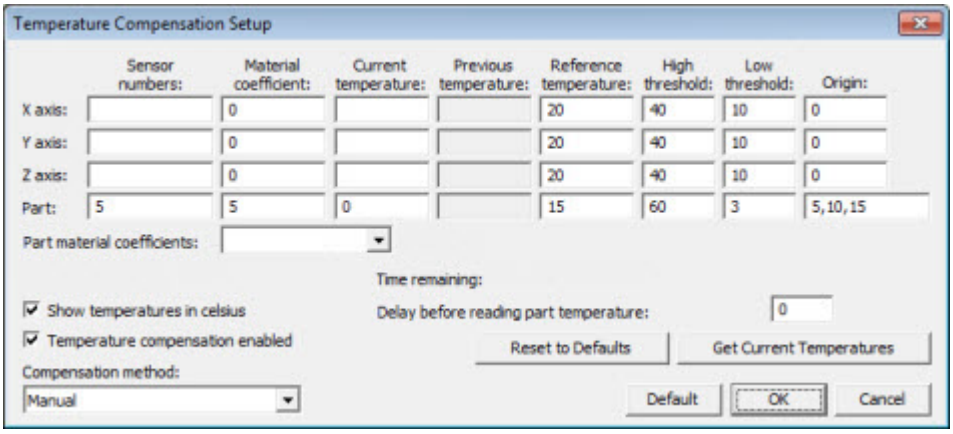
You can control the type of debug information that PC-DMIS logs and where it is sent.

- **Window** check box: To display debug information in a window for review, select this check box and enter a name for the window in the box.
- **Position reports** list: To log position reports from PC-DMIS, select **None**, **Both**, **Log**, or **Window**.
- **From machine** list: To log debug information that your machine sends to your computer, select **None**, **Both**, **Log**, or **Window**. Some machine interfaces do not support this option.
- **From CPU** list: To log debug information that your computer sends to your machine, select **None**, **Both**, **Log**, or **Window**. Some machine interfaces do not support this option.

Vision Machine Focus Debug Option

When connected to a vision machine, the **Focus** mode option is available. For details, see "Machine Options: Debug Tab" in the PC-DMIS Vision documentation.

Compensating for Temperature



Temperature Compensation Setup Dialog Box

To open the **Temperature Compensation Setup** dialog box, select **Edit | Preferences | Temperature Compensation Setup**.

> To set up temperature compensation for your system as shown in this legacy section, you need to start PC-DMIS as an administrator. In addition, the value for the `UseTemperatureCompensationV2` entry must be False.

This dialog box enables you to compensate for room and part temperature, which increases the accuracy of the inspection process.

To compensate for temperature during multiple arm calibration, see "Using Temperature Compensation with Multiple Arm Calibration" in the "Using Multiple Arm Mode" chapter.

To use advanced options for temperature compensation, see "Using Advanced Temperature Compensation" in the Toolkit Modules documentation. Advanced options enable you to use the continuous temperature compensation ability of the Firmware Distributed Controller (FDC) and Hexagon B3C controller.

Using STP Files

Each CMM uses machine-specific parameters for temperature compensation for each axis, such as thermal coefficients and sensor assignments. These parameters, along with embedded code that tells PC-DMIS if the file is a structural or linear compensation file, are stored inside special STP files (named for the .stp extension) created by your CMM vendor.

PC-DMIS requires these STP files to compensate for temperature.

Prior to compensating for temperature, ensure that these STP files reside in the appropriate locations on your hard drive:

- The DEA Structural Thermal Compensation method expects to find the Serv1.stp file in the *C:\Thermal_OCX* directory.
- The DEA Linear Thermal Compensation method expects to find the Serv1.stp file in the *C:\Program Files\Thermal_OCX* directory.

Linear and Structural Temperature Compensation

Linear compensation = (Thermal Coefficient of Expansion) X (Displacement + Change in Temperature of Each Axis and the Part). If multiple temperature sensors exist on an axis, PC-DMIS averages the readouts to find the temperature change.

Structural compensation recognizes that a CMM's various material components may have different temperatures (a single axis of the machine, for example, may have several different temperatures, which cause bending, bowing or skewing of the machine in some way). Structural compensation, then, applies the temperature corrections for specific areas of the CMM. When you select **Edit | Preferences | Temperature Compensation Setup**, the Structural Thermal_OCX gets called, and PC-DMIS calculates a new temporary volumetric compensation map.

Available Input Parameters

The following parameters are in the **Temperature Compensation Setup** dialog box (**Edit | Preferences | Temperature Compensation Setup**):
Temperature Compensation Setup Dialog Box

Sensor numbers boxes

The **Sensor numbers** boxes contain a list of one or more sensor numbers to be used for the given axis or part. These values are very important when reading temperatures from the controller because they *must* correspond to how the sensors are actually configured.

- Each sensor is a number in the range of 1 to 32.
- Items in the list can be either a single number or a range from first to last.
- Items are separated by commas or left blank.
- The input allows up to 32 values for any axis or the part.

For "manual" mode, these numbers are relatively meaningless, but at least one sensor number must be assigned for each axis and the part.

Material coefficient boxes

The **Material coefficient** boxes contain numbers that reflect the material property. They are the fractional change in length per unit change in temperature.

- The values vary depending on what type of material was used to make the scales on the machine axes and on the part's material.
- The units are meter per degree C.

A scale with a coefficient of 11.5 microns is written as 0.0000115 Meters/Degree/C.

Acceptable Part Values on Leitz Machines

If you are using a Leitz machine, PC-DMIS forces you to use an acceptable material coefficient value in the **Part** box. An acceptable value lies within the range of -0.001 through 0.001 Meters/Degrees/Celsius.

- If you enter a value outside of this acceptable range in the **Temperature Compensation Setup** dialog box, a warning message appears, and the value in the **Part** box is reset to 0.0.
- If you open a measurement routine created from an older version of PC-DMIS that permitted unacceptable values, a message box now informs you of the unexpected material coefficient value, and PC-DMIS resets the value to 0.0.
- If you attempt to manually edit the `TEMPCOMP/ORIGIN` command to use an unacceptable value, PC-DMIS displays an error message in the **Execution** dialog box during execution. The message informs you that the part material coefficient value is out of range. The only option is to click **Cancel**, and modify the command to contain an acceptable value.

Part material coefficients list

The **Part material coefficients** list contains a list of standard material types. Selecting one of these materials automatically puts its associated coefficient in the **Material coefficient** box.

Part materials and coefficients are stored in the MaterialCoefficients.xml file. You can use a text editor or the Material Coefficients Editor to modify this file. For information, see "Editing Part Materials and Coefficients".

Current temperature boxes

The **Current temperature** boxes contain the current temperatures in the appropriate units. You can either type them or read them in from the controller, depending on the type of machine available and the selected options.

Previous temperature boxes

The **Previous temperature** boxes always contain the previously-read temperatures. If no temperatures were previously read in, these values are either zero or left blank.

Reference temperature boxes

The **Reference temperature** boxes contain the reference temperature from which temperature compensation adjustments need to be applied.

- The amount of correction to be applied is based on multiplying the material coefficient by the difference between the current and reference temperatures.

  Amount of Correction = Material coefficient x (Current temperature – Reference temperature)

- If the current temperature is the same as the reference temperature, the net effect is that no thermal compensation adjustment is applied.
- The value in these boxes is almost always 20 degrees C, or the Fahrenheit equivalent.

High threshold boxes

The **High threshold** boxes contain an upper limit (in the appropriate units) on the current temperature above which no further thermal compensation will be applied. PC-DMIS doesn't display any warning or error message.

With a reference temperature of 20 degrees C, a current temperature of 35 degrees C, and a high threshold of 30 degrees C, the amount of correction actually applied would be based on a difference of (30 – 20) instead of (35 – 20) because the current temperature exceeded the upper limit.

Low threshold boxes

The **Low threshold** boxes is conceptually like the high threshold except it provides a lower limit on the current temperature below which no further thermal compensation will be applied.

Origin boxes

The **Origin** boxes in the **Temperature Compensation Setup** dialog box (**Edit | Preferences | Temperature Compensation Setup**) determine the length of the item to which thermal compensation is being applied.

Length Value = Current Position Value – Origin Value

The X, Y, and Z values in the **Origin** boxes are zero most of the time. However, some types of machines do not use zero for the origin of their scales.

Typically, the **Part** value is also zero unless there is some special type of fixture constraint. The part origin coordinates can be inserted into the coordinate system for a machine or an active alignment. The type of coordinate system depends on where the temperature compensation command (`TEMPCOMP`) is inserted into the measurement routine:

- If you insert a `TEMPCOMP` command before an alignment, the part origin coordinates are expressed in the machine's coordinate system. For example:

```
          TEMPCOMP/ORIGIN=376.627,293.461,-489.749 Material Coeff=0.0000113,Reference Temp=20
            ,Hi Threshold=40,Lo Threshold=10,Sensor num=8
            ,X Axis Temp=,Y Axis Temp=,Z Axis Temp=,Part Temp=26.797
          MOVE/POINT,NORMAL,<292.876,360.313,-394.495>
A1        =ALIGNMENT/START,RECALL:STARTUP,LIST=YES
            ALIGNMENT/LEVEL,ZPLUS,
            ALIGNMENT/ROTATE,XPLUS,TO,,ABOUT,ZPLUS
            ALIGNMENT/TRANS,ZAXIS,
            ALIGNMENT/TRANS_OFFSET,ZAXIS,-9
            ALIGNMENT/TRANS,YAXIS,
            ALIGNMENT/TRANS,XAXIS,
          ALIGNMENT/END
```

- If you insert a `TEMPCOMP` command after an alignment, the part origin coordinates are expressed in the alignment's coordinate system. For example:

```
A1        =ALIGNMENT/START,RECALL:STARTUP,LIST=YES
            ALIGNMENT/LEVEL,ZPLUS,PLN1
            ALIGNMENT/ROTATE,XPLUS,TO,LIN1,ABOUT,ZPLUS
            ALIGNMENT/TRANS,ZAXIS,PLN1
            ALIGNMENT/TRANS_OFFSET,ZAXIS,-9
            ALIGNMENT/TRANS,YAXIS,LIN1
            ALIGNMENT/TRANS,XAXIS,PNT1
          ALIGNMENT/END
          MODE/DCC
          MOVE/POINT,NORMAL,<0,0,50>
          TEMPCOMP/ORIGIN=100.008,17.576,4.502 Material Coeff=0.0000113,Reference Temp=20
            ,Hi Threshold=40,Lo Threshold=10,Sensor num=9
            ,X Axis Temp=,Y Axis Temp=,Z Axis Temp=,Part Temp=26.784
```

Show temperatures in celsius check box

The **Show temperatures in celsius** check box affects both the temperatures and the material coefficient.

- If you select this check box, PC-DMIS uses degrees Celsius.
- If you clear this check box, PC-DMIS uses degrees Fahrenheit.

Temperature compensation enabled check box

The **Temperature compensation enabled** check box tells PC-DMIS to use temperature compensation.

- If cleared, PC-DMIS does not perform any temperature compensation, and the `TEMPCOMP` command (if present in the measurement routine) has no effect.
- If marked, PC-DMIS behaves according to the input parameters.

If you mark this check box and choose one of the compensation methods where PC-DMIS does the part compensation rather than the machine controller, the diameter for probes on non-portable machines in the **Edit Probe Data** dialog box may vary with the current part temperature. See "Edit Probe Data" in the "Defining Hardware" chapter.

Compensation method list

Following are the compensation methods and their respective processes in PC-DMIS.

For Sheffield controllers, you *must* define the **Material coefficient** and **Reference temperature** boxes and then click **Default**, regardless of the compensation method you are using.

Manual

- Compensation is manual (controlled by your input) with no involvement from the machine controller.
- PC-DMIS performs all compensation calculations.
- During measurement routine execution, the **Temperature Compensation Setup** dialog box opens. You can edit the current settings before you proceed with the rest of the measurement routine.

Read Temperatures from Controller

- When you use a machine that supports this option, PC-DMIS reads the current temperatures from the controller automatically rather than you supplying the data.
- PC-DMIS performs all compensation calculations. The controller only provides the current temperatures.
- During measurement routine execution, the **Temperature Compensation Setup** dialog box does not open.
- The measurement routine does not pause for your confirmation.

To retrieve the CTE (Coefficient of Thermal Expansion) values for the axes for Sheffield controllers, click the **Get Current Temperatures** button.

Controller Compensates Axes Only

- The controller performs compensation of the machine axes itself.
- The inputs for the axes are not used.
- Part input parameters apply since PC-DMIS still performs compensation for the part.
- During measurement routine execution, the **Temperature Compensation Setup** dialog box does not open.
- The measurement routine does not pause for your confirmation.

Controller Comps Axes and Part

- The controller performs compensation of both the machine axes and the part.
- The inputs for the axes are not used.
- PC-DMIS does not perform any compensation calculations.
- The input for the part for the material coefficient, reference temperature, and origin must still be supplied because PC-DMIS must pass that information down to the controller.
- The input for the part channel is optional. If it is provided, PC-DMIS sends the temperature reading of this channel (or the average in case of multiple sensors) to the controller instead of the temperature reading associated with the part sensor defined in the controller configuration.
- During measurement routine execution, the **Temperature Compensation Setup** dialog box does not open.
- The measurement routine does not pause for your confirmation.

For Sheffield controllers, you do not need to enter the CTE values for the axes.

Time remaining display

The **Time remaining** display shows the time remaining before the temperature reading takes place. This only displays if you set up a delay period for execution. See "Delay Before Reading Part".

Delay before reading part temperature box

The **Delay before reading part temperature** box enables you to specify a period that PC-DMIS will wait during measurement routine execution before reading the sensors to obtain the current temperatures. If you enter zero, then there is no pause.

Reset to Defaults button

The **Resets to Defaults** button updates any previously modified values with the previously saved values. If this is on a DEA machine and a serv1.stp is available, then PC-DMIS reads that file.

Get Current Temperatures button

If you select the **Read Temperatures from Controller** method in the **Compensation method** list, and if you use a machine that supports this option, the **Get Current Temperatures** button causes PC-DMIS to read the current temperatures from the controller and display them in the **Temperature Compensation Setup** dialog box.

TEMPCOMP/ORIGIN Command in the Edit Window

When you click the **OK** button to accept the inputs in the **Temperature Compensation Setup**, PC-DMIS inserts a `TEMPCOMP/ORIGIN` command into the measurement routine.

```
TEMPCOMP/ORIGIN=0,0,0,CTE=0.000012778,Reference Temp=73
  ,Hi Threshold=32,Lo Threshold=32
  ,PART SENSOR NUM=4
  ,X AXIS TEMP=68,Y AXIS TEMP=68,Z AXIS TEMP=68,PART TEMP=68
```

Command Mode

Normally, a measurement routine only uses one `TEMPCOMP` command. The `TEMPCOMP` command should be placed near the top of the measurement routine prior to any measurements. When you execute the measurement routine, it executes according to the various input parameters.

Controller Support

Not all compensation methods are supported by all controllers. The following are the supported controllers for the different compensation methods. For detailed information about compensation methods, see "Compensation method list".

Compensation Method	Supported Controllers
Manual	All since there is no controller involvement with this method.
Read Temperatures from Controller	DEA (only with DEAC family controllers), and Sharpe32z with the Leitz protocol.
Controller Compensates Axes Only	Sharpe32z with the Leitz protocol, and dual-arm configurations with an FDC interface.
Controller Comps Axes and Part	Sharpe32z using the Leitz protocol, Sheffield, stand-alone configurations with an FDC interface, and single-arm configurations with an FDC interface.

Local Temperature Settings

When it opens a measurement routine containing a TEMPCOMP command, PC-DMIS verifies the part sensor number with the local settings.

- If the values differ, PC-DMIS automatically updates the command to reflect the current settings, and a comment is inserted into the measurement routine reflecting the old and new values.
- If no local setting is available for the part sensor, PC-DMIS marks the TEMPCOMP command RED in the Edit window.

Using Simplified Temperature Compensation

Simplified temperature compensation is available for machines that are connected to Hexagon controllers. Currently, only stationary products, Leica Trackers and Romer Portable Arms are supported.

You can access Simplified Temperature Compensation through the menu (**Edit | Preferences | Temperature Compensation Setup**).

The following product lines and machine types are not supported. They must use the original temperature compensation command.

- PC-DMIS NC
- Non-Hexagon controllers and equipment
- Controllers that do not support temperature sensors
- Controllers with the Sheffield interface
- DEA controllers

> ⚠ If you use a controller with the Sheffield interface, you must set the `UseTemperatureCompensationV2` entry in the **Option** section of the PC-DMIS Settings Editor application to **FALSE**. If you set it to **TRUE**, that entry may affect your measurement routine's move points in unexpected ways.

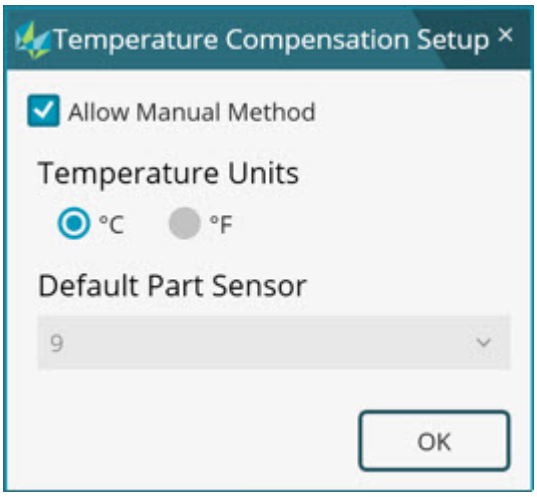
Temperature Compensation Setup

To set up your system, select **Edit | Preferences | Temperature Compensation Setup**.

> ❗ To set up temperature compensation for your system as shown in this topic, you need to start PC-DMIS as an administrator. In addition, the value for the `UseTemperatureCompensationV2` entry must be True.

Hexagon Systems

For a machine that is connected to a Hexagon controller, the following options appear in the **Temperature Compensation Setup** dialog box:



Hexagon system

Allow Manual Method check box:

- In special cases, if you would like to manually enter the part temperature, select this check box. Both the automatic and manual methods of temperature compensation become available.
- If you clear this check box, only the automatic method of temperature compensation becomes available in the **Temperature Compensation** dialog box. By default, the check box is cleared. Hexagon recommends use of only the automatic method where available.

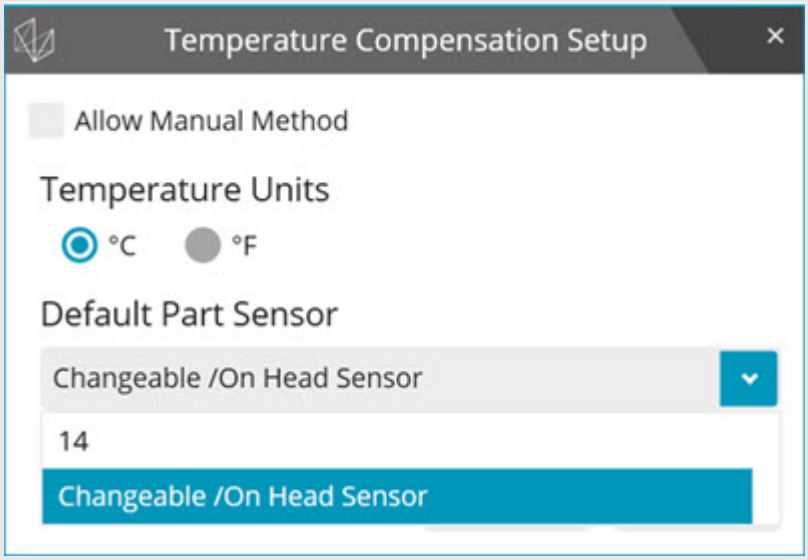
Temperature Units - Select degrees Celsius or degrees Fahrenheit.

Default Part Sensor list - Most machines are supplied with one part temperature sensor. This list displays the sensor number with which it is connected to the controller when the machine is online.

Some machines have multiple part temperature sensors. If your system is configured with multiple sensors, multiple sensor numbers appear in this list.

In PC-DMIS version 2023.1 and earlier, when the software detected the "Changeable Part Sensor" setup in the CMM configuration, PC-DMIS did not consider any of the standard sensors. This made it so the "Changeable Part Sensor" was always set as the default sensor.

Starting with PC-DMIS version 2023.2, for Leitz CMM's (Bx family of controllers), you can now configure the setup to default to "Changeable /On Head Sensors" or a "Standard" sensor.



This is only for V2 Temperature Compensation and only if the sensors are present in the CMM configuration.

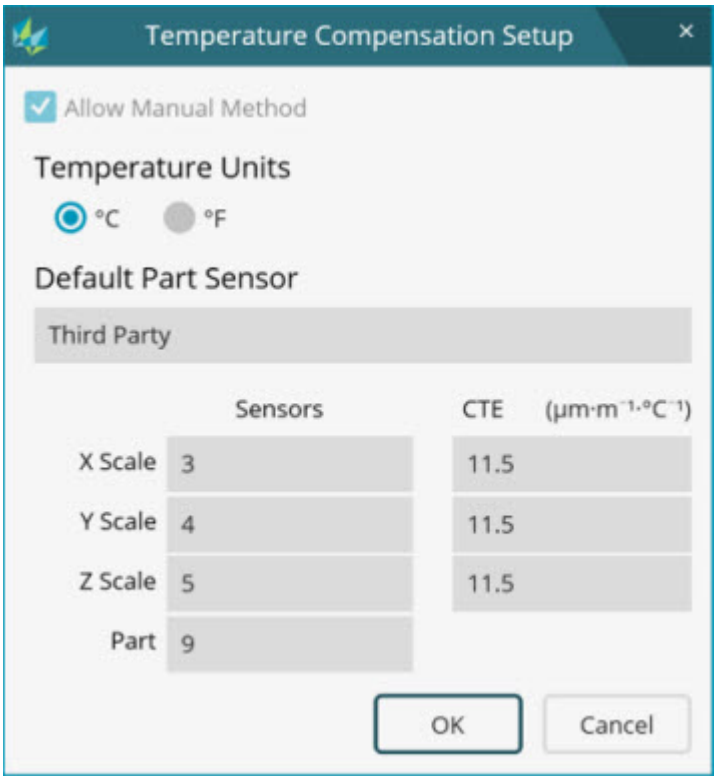
Select a sensor number that you want to designate as the default number. The advantage of using a default sensor number is portability of the measurement routine to another system with a different default sensor number.

If PC-DMIS is connected to a Leica Tracker device, the default part sensor displays as **Tracker**.

OK button - To save your settings, click **OK**.

Non-Hexagon Systems

For a machine that is connected to a non-Hexagon controller, the following options appear in the **Temperature Compensation Setup** dialog box:



Non-Hexagon system

Allow Manual Method check box - It may or may not be possible for PC-DMIS to get the temperature of axes and parts from the controller. When PC-DMIS cannot automatically read the temperatures, the only temperature compensation option is the manual entry of temperatures. This check box is selected by default. You must enter the CTE values for the scale of each axis to compensate for temperature of scales.

You need to enter the temperature of the X scale, Y scale, Z scale, and part at the time of measurement routine execution.

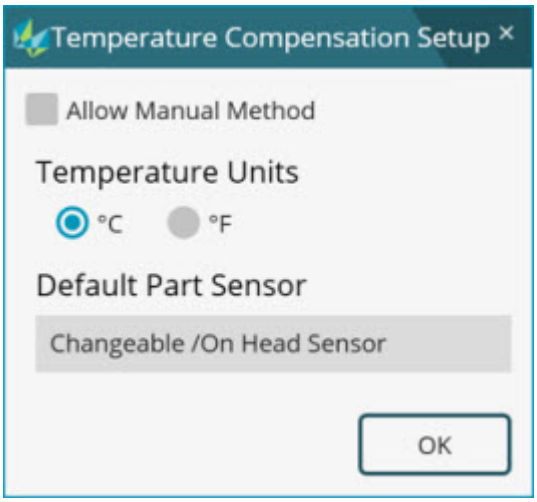
In some cases, it may be possible for PC-DMIS to read the temperature from the controller. In these cases, enter the sensor numbers and CTE values for the scale of each axis and part.

Default Part Sensor list - This list, and the **Part Sensor** area in the **Temperature Compensation** dialog box, display **Third Party**.

OK button - To save your settings, click **OK**.

Changeable or On-Head Part Temperature Sensor

If PC-DMIS determines that a changeable or on-head temperature sensor is mounted on the probe head, it displays that information in the **Default Part Sensor** area of the dialog box:



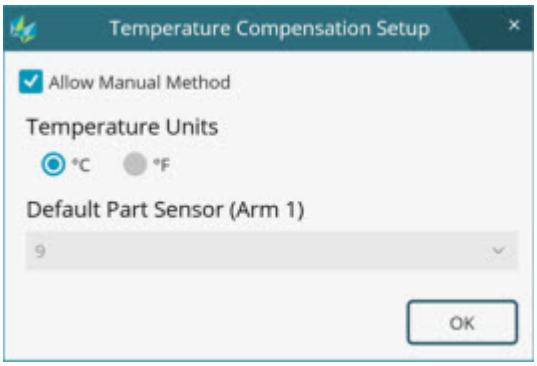
Changeable or on-head sensor

For more information on changeable or on-head sensors, see "Temperature Compensation".

> PC-DMIS does not support a changeable or on-head part temperature sensor and a magnetic sensor on the same machine.

Temperature Compensation with a Multiple Arm CMM

If PC-DMIS is connected to a multiple arm CMM, the default part sensor is one of the part sensors attached to Arm 1. Multiple Arm Mode allows the use of part sensors attached to Arm 1 only.



Multiple arm

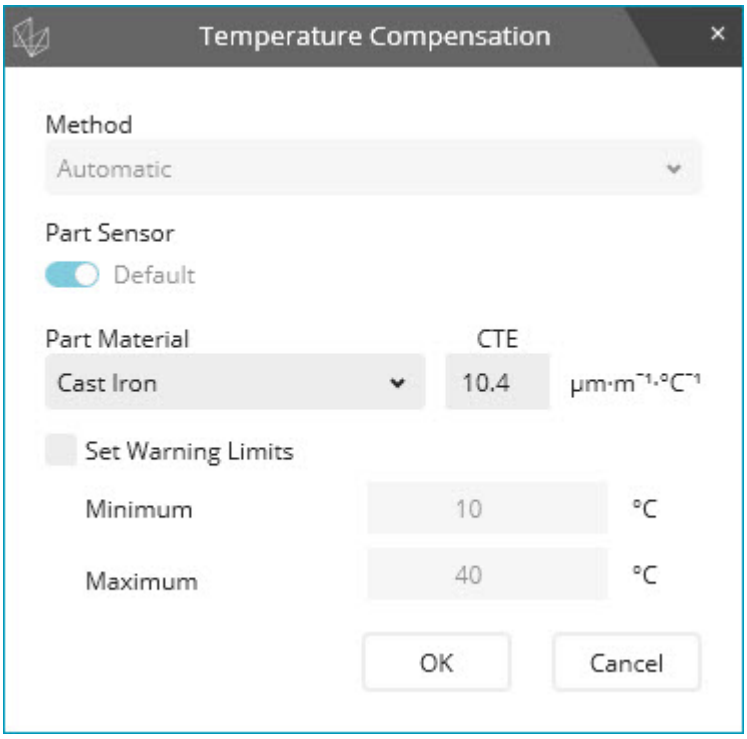
For a multiple arm CMM, note the following:

- Part sensors attached to Arm 1 can only be used to measure the temperature of the part.
- Each arm compensates for its own axis. PC-DMIS compensates for the part.
- You must ensure that the arms are synchronized before and after temperature compensation. To synchronize the arms, insert `MOVE/SYNC` commands before and after the `TEMPCOMP` command.

For more information about multiple arms, see the "Using Multiple Arm Mode" chapter.

Temperature Compensation

To compensate the measurement for a temperature other than 20 °C as required by ISO-1, select **Insert | Parameter Change | Temperature Compensation**. The following dialog box appears:



Temperature Compensation Dialog Box

Method list - From the list, select the temperature compensation method:

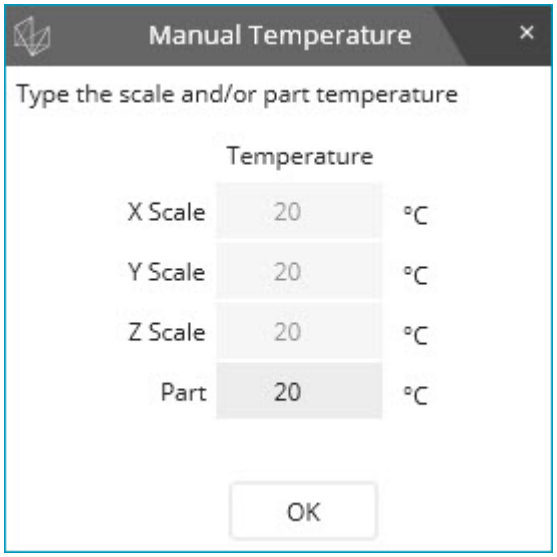
- **Automatic** - The automatic method is the default method. It is available for most machines that are connected to a Hexagon controller. These controllers can measure the temperature using a sensor that is mounted on scales and has one or more sensors that can be attached to a part.

  If you select this method, PC-DMIS reads the temperatures from the controller. You do not need to enter any temperatures.

- **Manual** - Third-party equipment (non-Hexagon controllers) may not support the automatic method of temperature measurement. For these controllers, only the manual method is available. For this method, you measure and enter the temperature at the time of measurement routine execution.

  The manual method is available if the **Allow Manual method** check box is selected in the **Temperature compensation setup** dialog box.

  If you select this method, the **Manual Temperature** dialog box appears during measurement routine execution:



Manual Temperature Dialog Box

  - For a Hexagon CMM, PC-DMIS reads and enters the X scale, Y scale, and Z scale temperatures from the controller. You cannot change the temperatures.
  - You must use a custom sensor to measure the part temperature. Enter the temperature in the **Part** box.
  - If the controller does not support a temperature sensor, you must enter the X scale, Y scale, Z scale, and part temperatures.

  To continue with measurement routine execution, click **OK**.

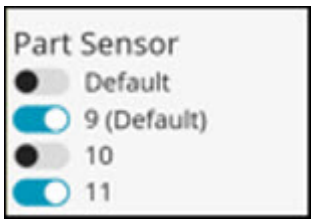
If you are using a Leica Tracker device, select the appropriate temperature compensation method:

- If your Tracker device is equipped with a part temperature sensor that can read the part temperature, you can select either the automatic or manual compensation method. If you select the automatic method, PC-DMIS reads the temperature as measured by the Tracker's part temperature sensor. Ensure that the part temperature sensor is connected to your Tracker and is in contact with the part during measurement.

- If your Tracker device is not equipped with a part temperature sensor, only the manual compensation method is possible. During measurement routine execution, you will need to enter the current part temperature in the **Part** box in the **Manual Temperature** dialog box. You can use any external device to measure the part temperature.

Part Sensor - The option that appears in this area depends on the type of part sensor:

- One part temperature sensor - Usually, a controller is equipped with only one part sensor. This sensor appears in the dialog box as **Default**. You cannot cancel the selection of this sensor.
- Multiple part temperature sensors - Some controllers support multiple part sensors. If your controller is equipped with multiple part sensors, each part sensor number appears in this area. For example:



Part Sensor area showing multiple part sensors.

Select the sensor or sensors that are connected to the part being measured. Ensure that you select the correct sensor number. If you select multiple sensors, PC-DMIS uses the average temperature for thermal compensation.

- External temperature sensor - You may need to use an external sensor to measure the part temperature. In this case, you can use a variable to determine the temperature of a part. This sensor appears in this area as follows:

For more information, see "Variable for Part Temperature in Temperature Compensation Command".

- Changeable or on-head part temperature sensor - The Hexagon FDC and Leitz controllers on fixed-head CMMs can be equipped with a changeable or on-head part sensor that is mounted on the probe head. The controller can also be equipped with a probe-like sensor that can measure the part temperature by probing a point on the part. These sensors appear in this area as follows:

Part Sensor area showing the Changeable / On Head Sensor option.

PC-DMIS can determine whether the part sensor on the Leitz controller is a changeable or an on-head part sensor. For the FDC controller, the `UseChangeableTemperatureProbes` entry in the PC-DMIS Settings Editor must be set to True.

For information about creating and using a changeable temperature probe file, see "Working with Temperature Sensors" in the PC-DMIS CMM documentation.

- For a machine that is connected to a non-Hexagon controller, the sensor appears as **Third Party**. For more information, see "Temperature Compensation Setup".

Part Material list - From the list, select the material of the part. The material's coefficient of thermal expansion (CTE) appears in the **CTE** box.

Part materials and coefficients are stored in the MaterialCoefficients.xml file. You can use a text editor or the Material Coefficients Editor to modify this file. For complete information, see "Editing Part Materials and Coefficients".

CTE (Coefficient of Thermal Expansion) - This is a unique value. When you select a part material, the coefficient value appears in the **CTE** box. You cannot modify this value in the dialog box, but you can change it in the Edit window. When you modify the CTE value in the Edit window and press Tab, PC-DMIS attempts to find a matching material. It searches through the available materials in the MaterialCoefficients.xml file. It then displays the material that corresponds to the typed value. If it cannot find a corresponding material, PC-DMIS sets the MATERIAL field in the Edit window to "Custom Material". When you next open the **Temperature Compensation** dialog box, you will see "Custom Material" in the **Part Material** list. You can select any other material from the list.

The CTE field in the Edit window also supports variables. If you use a variable in this field, PC-DMIS uses the current variable value during execution. If you type a variable name for the CTE field in the Edit window, the material appears as "Variable". If you press F9 to edit this command, the material appears as "Variable", and the CTE is the current value of the variable. You cannot select another material in the **Part Material** list. To change the material, you need to remove the variable name from the CTE field in the Edit window.

The CTE value's units are in micron per meter per degree C (or µm·m-1·°C-1). Before version 2017 R2, this was in meter per degree C. This means, for example, that a previous value of 0.0000115 now appears as 11.5.

The CTE value must be a unique value. If you have two or more materials that have the same CTE value, you must enter them on the same row in the Material Coefficients Editor separated by a forward slash.

For example, if Material1 has the same CTE value as Material2, you must enter "Material1/Material2" in the **Materials** column. In the corresponding **Coefficients** column, you would enter the CTE value.

For information on how to use the Material Coefficients Editor, see the "Editing Part Materials and Coefficients" topic.

Based on the CTE value, PC-DMIS will search for the corresponding material in the MaterialCoefficients.xml file.

Set Warning Limits check box - The `TEMPCOMP` command displays a warning if the temperature of the X scale, Y scale, Z scale, or part is outside of the limit.

The `TEMPCOMP` command also supports the "Temperature Outside Limits" error type.

You can use the options in the **On Error** dialog box to control the measurement only if the specified temperature conditions are met. For detailed information about setting up the options in the dialog box, see "Branching on an Error".

Minimum and **Maximum** boxes - These boxes display temperatures as follows:

- If you select the **Set Warning Limits** check box, PC-DMIS sets the suggested minimum temperature to 18 °C and the maximum temperature to 22 °C. You can modify the values.
- If you clear the **Set Warning Limits** check box, the minimum temperature is set to 10 °C and the maximum temperature is set to 40 °C. You cannot modify the values.

You can input temperature values between 50°F (10°C) and 104°F (40°C). You can also use variables in the Edit window for the MINIMUM and MAXIMUM fields. Ensure that the **Minimum** value is less than the **Maximum** value.

TEMPCOMP/METHOD Command in the Edit Window

When you click **OK**, PC-DMIS inserts a `TEMPCOMP/METHOD` command into the measurement routine.

```
TEMPCOMP/METHOD = AUTOMATIC,MATERIAL = Aluminium,CTE=23
  ,SET WARNING LIMIT = TRUE,MINIMUM = 18,MAXIMUM = 22
  ,PART SENSOR NUM=PORTABLE ,X SCALE= 20,Y SCALE= 20,Z SCALE= 20,PART TEMP=20
```

Command Mode

Normally, a measurement routine only uses one `TEMPCOMP` command. The `TEMPCOMP` command should be placed near the top of the measurement routine prior to any measurements. When you execute the measurement routine, it executes according to the various input parameters.

Variable for Part Temperature in Temperature Compensation Command

You can use a variable to determine the temperature of a part.

You cannot use variables for scale temperatures.

If it is not feasible to attach a sensor to the part, you may want to use an external sensor to measure the part temperature. You can update the variable with a measured part temperature value and use the variable to execute the temperature compensation command. For example, this is useful when you place a part on the CMM, and the temperature of the part is measured through an external method.

To use a variable for the temperature of the part:

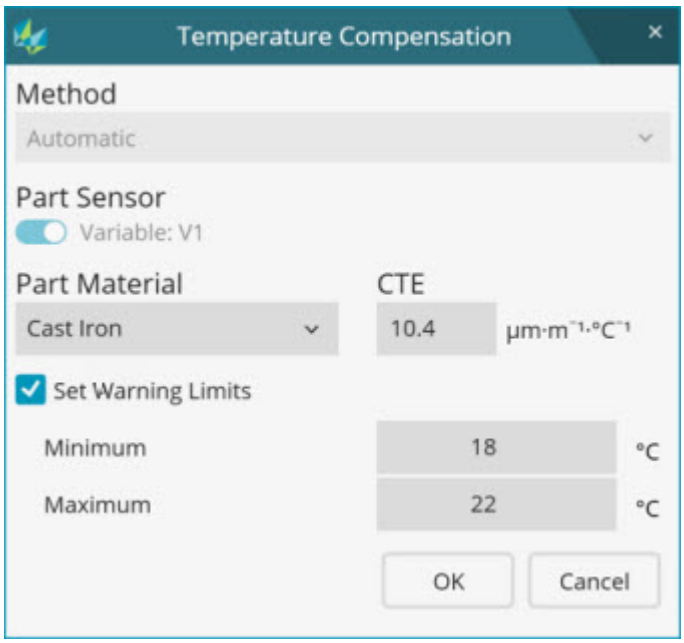
1. Create the variable in the measurement routine.
2. Update the `Part Temp` parameter in the Edit window with the name of the variable.

   In this code, V1 contains the temperature and is assigned to `Part Temp` :

   ```
   TEMPCOMP/CTE=10.4,Lo Threshold=18,Hi Threshold=22,PART SENSOR
   NUM=V1,X Axis Temp=,Y Axis Temp=,Z Axis Temp=,Part Temp=V1
   ```

3. Press F9 on the `TEMPCOMP` command.

   The sensor appears as a variable in the **Part Sensor** area in the **Temperature Compensation** dialog box. For example:



Temperature Compensation Dialog Box

Automatic Insertion of Temperature Compensation Command

For many types of machines, PC-DMIS automatically inserts the `TEMPCOMP` temperature compensation command when you create a measurement routine. This provides you with the opportunity to set up a measurement routine for temperature compensation. The **Temperature Compensation** dialog box appears, and you need to select the material of the part.

If you want PC-DMIS to automatically insert the temperature compensation command into a new measurement routine, select the **Auto Insert Temperature Compensation in New Routine** check box on the **General** tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**).

If you do not want PC-DMIS to automatically insert the temperature compensation command into a new measurement routine, clear this check box.

PC-DMIS does not automatically insert the temperature compensation command into a new measurement routine for the following items:

- PC-DMIS NC software application
- Dual-arm CMMs
- Portable equipment
- Non-Hexagon controllers
- Machines with controllers that do not support temperature sensors

Temperature Compensation Dimensioning

The Temperature Compensation command can report the temperature of the scale and part that you are using for compensation. The Temperature Gage command dimensions the Temperature Compensation command when you place the Temperature Gage command immediately after the Temperature Compensation command. There should be no other command between the Temperature Compensation command and the Temperature Gage command.

For more information about the Temperature Gage command, see "Temperature Gage".

Thermal Expansion Origin Command

The default setting for the origin of the thermal expansion is the machine zero point. In some cases, you may want to set the origin at the location on the part. For example, you may want to set the origin when the part is clamped down on the center location and the part will not expand at that point.

To set the origin of the thermal expansion:

1. Select **Insert | Parameter Change | Thermal Expansion Origin**. The **Thermal Expansion Origin** dialog box appears.
2. Enter the **X**, **Y**, and **Z** values in the current coordinate system.
3. To insert the `THERMALEXPANSIONORIGIN` command into the Edit window, click **OK**. To cancel your changes and close the dialog box, click **Cancel**.

If you want to set the thermal expansion origin at a location other than the machine origin, then you must insert the thermal expansion origin command above the temperature compensation command or above the advanced temperature compensation command.

- For more information about the temperature compensation command, see "Temperature Compensation".
- For more information about the advanced temperature compensation command, see "Creating an Advanced Temperature Compensation Command".

Temperature Gage

You can create a Temperature Gage command that reads the temperature of the X scale, Y scale, Z scale, and part without starting temperature compensation.

Temperature Gage Command

The Temperature Gage command reads the temperature of the X scale, Y scale, Z scale, and part.

To create a Temperature Gage command:

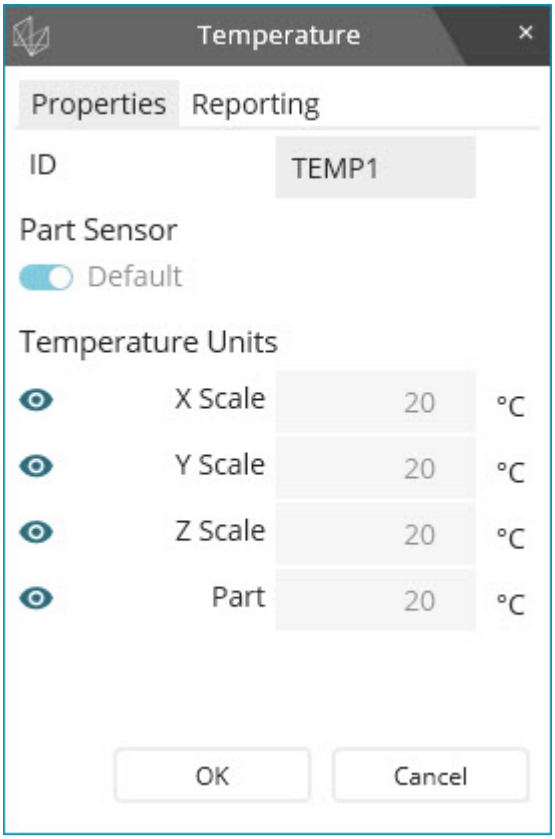
1. Select **Insert | Gage | Temperature** to open the **Temperature** dialog box.

> You can also access the **Temperature** dialog box from the **QuickMeasure** toolbar. Click the **Gage** drop-down arrow, and then click the **Temperature** button.

2. Complete the **Properties** tab and **Reporting** tab.

Properties Tab

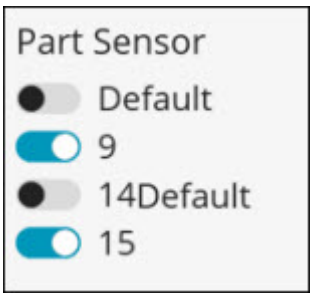
Use the **Properties** tab to set the ID, sensor numbers, and other parameters.



Temperature Dialog Box - Properties Tab

ID box - Type the ID of the Temperature Gage command.

Part Sensor option - Usually, a machine is equipped with only one part temperature sensor. This sensor appears as **Default**. You cannot cancel the selection of this sensor. If your machine is equipped with multiple part sensors, they appear in this area. For example:



Part Sensor Area

Select the sensor or sensors that are connected to the part being measured. Ensure that you select the correct sensor number. If you select multiple sensors, PC-DMIS uses the average of the measured values.

Temperature Units area - The **X Scale**, **Y Scale**, **Z Scale**, and **Part** boxes display the current temperatures as measured. You cannot change the values. The temperature units and the default sensor number are as defined in the **Edit | Preferences | Temperature Compensation Setup** menu option.

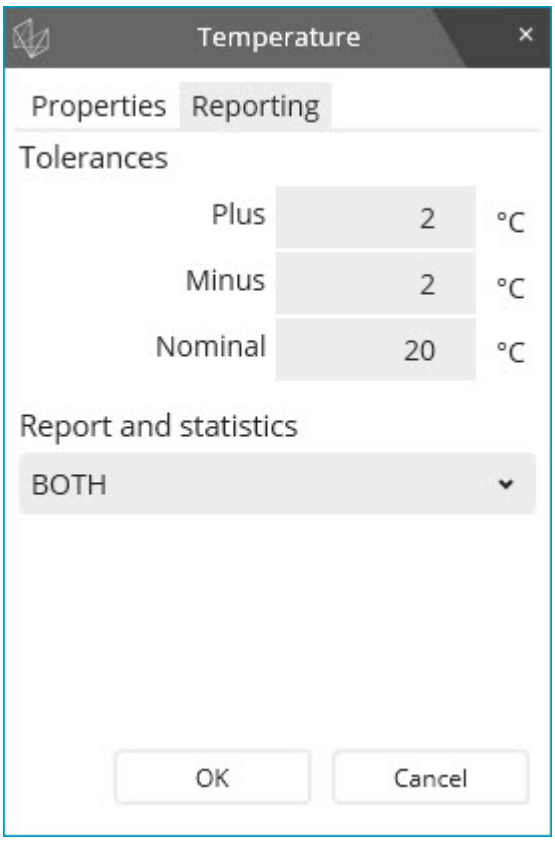
> **Show in Dimension/Hide in Dimension** - This button shows ( ) or hides ( ) the temperature units in the command. You need to show at least one temperature unit or axis.

OK button - Click this button to save your settings and insert the Temperature Gage command into the Edit window.

Cancel button - Click this button to close the dialog box without applying any changes.

Reporting Tab

Use the **Reporting** tab to set tolerances and the type of report output.



Temperature Dialog Box - Reporting Tab

Tolerances area:

- **Plus** box - Type the plus tolerance. You can change the plus tolerance for each axis and/or part.
- **Minus** box - Type the minus tolerance.
- **Nominal** box - Type the nominal value. The default nominal temperature is 20°C.

The same nominal and tolerance values apply to scale and part temperatures.

If necessary, you can change the nominal temperature and tolerances for each axes and/or part in the Edit window.

Report and Statistics area - In the list, choose how to send the output of the command when it is executed:

- **STATS** - Sends the output to a statistical file.
- **REPORT** - Sends the output to an inspection report.
- **BOTH** - Sends the output to both an inspection report and statistical files.
- **NONE** - Does not send the output anywhere.

Edit Window

The Edit window displays the command as a dimension.

It appears in Summary Mode as shown below:

Summary Mode

It appears in Command Mode as shown below:

```
DIM TEMP1= TEMPERATURE  OUTPUT=STATS,PART SENSOR NUM=DEFAULT,UNITS=C
AX       MEAS        DEV     NOMINAL       +TOL       -TOL     OUTTOL
X       19.890     -0.110      20.000      2.000      2.000      0.000 ----#----
Y       20.460      0.460      20.000      2.000      2.000      0.000 -----#---
Z       20.995      0.995      20.000      2.000      2.000      0.000 ------#--
M       21.870      1.870      20.000      2.000      2.000      0.000 --------#
END OF DIMENSION TEMP1
```

Command Mode

The command appears according to the format statement in your measurement routine.

If the controller is equipped with only one part temperature sensor, the `PART SENSOR NUM` field appears in the Edit window. If your controller is equipped with multiple part sensors, and you selected a part sensor number in the **Part Sensor** area in the **Temperature** dialog box, the number appears in the Edit window.

Expressions

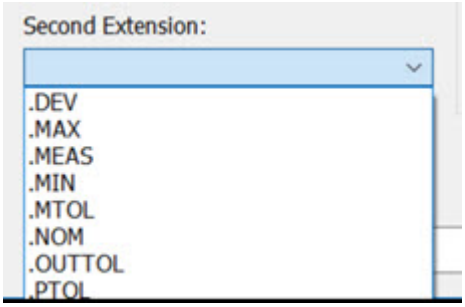
The Temperature Gage command supports expressions, such as:

```
ASSIGN/V1=READTEMP1.M.Meas
```

To create an expression:

1. Press F2 on the `ASSIGN` statement in the Edit window to open the **Expression Builder** dialog box.
2. From the **Expression Element Type** list, select "Temperature". All of the Temperature Gage commands that are in the measurement routine appear in the **ID** list.
3. From the **Extension** list, select the temperature of the X, Y, Z, or M (part). Select them as required to build an appropriate expression.

4. From the **Second Extension** list, select the type of value you want to store, such as deviation, maximum, measured, and so forth.



For details about expressions, see "Using Expressions and Variables". For details about the **Expression Builder** dialog box, see "Creating Expressions with the Expression Builder".

Temperature Compensation Dimensioning

The Temperature Compensation command can report the temperature of the scale and part that you are using for compensation. For details, see "Temperature Compensation Dimensioning".

Offline Mode and Non-Hexagon CMM

Temperatures cannot be read in Offline Mode. Therefore, in Offline mode, the measured value shows as 20 °C.

Similarly, the temperature shows as 20 °C if the controller of the connected machine does not support the ability to define and read temperature sensors.

Editing Part Materials and Coefficients

A material coefficient (also called a coefficient of thermal expansion, or CTE) is a number that describes how much a material expands or contracts as its temperature changes. Different materials — such as steel, aluminum, or titanium — expand at different rates. PC-DMIS uses these values during temperature compensation to adjust measurements and account for the fact that a part may be a different size at shop floor temperature than it would be at the standard reference temperature of 20 °C (68 °F).

PC-DMIS ships with coefficients for common materials, but you can use the editor discussed below to add materials or refine values for specific grades.

About the XML Files

Part materials and coefficients for temperature compensation are stored in a MaterialCoefficients.xml file. You can find this file in your system's hidden data path (where your computer stores program data files). When you modify materials or coefficients, PC-DMIS saves your changes to a separate file named usrMaterialCoefficients.xml in the same location. If this user file is present, PC-DMIS loads it instead of the default

MaterialCoefficients.xml. For more information about file locations, see "Understanding File Locations" in the "Setting Your Preferences" chapter.

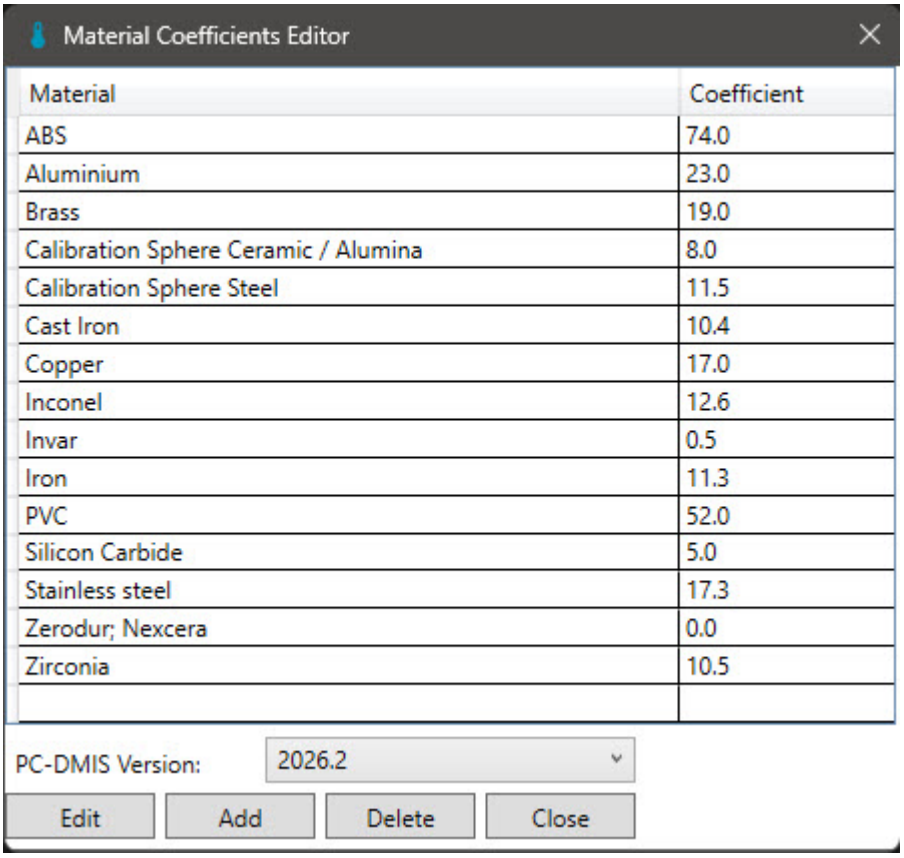
Starting with PC-DMIS 2026.2, your custom material coefficients (usrMaterialCoefficients.xml) are automatically migrated when you install a new version of PC-DMIS. You no longer need to manually redefine your custom materials after an upgrade.

About the Material Coefficients Editor

You can use the Material Coefficients Editor to add or modify coefficient values. When you do, PC-DMIS modifies the usrMaterialCoefficients.xml file. After you make any changes, you must reopen the **Temperature Compensation Setup** dialog box or **Advanced Temperature Compensation** dialog box to see any changes that you made to the file.

All coefficient values must include a decimal point. The Material Coefficients Editor displays a message about a wrong input if you don't include a decimal.

To use the Material Coefficients Editor, run the **MaterialCoefficientsEditor.exe** utility. This utility is located in the folder where you installed PC-DMIS.



Material Coefficients Editor

This editor lists the materials and their corresponding coefficients. It also provides buttons for you to edit the materials and values.

For the **Material Coefficients Editor** dialog box, the entered values are evaluated to **n X 10^{-6}**.

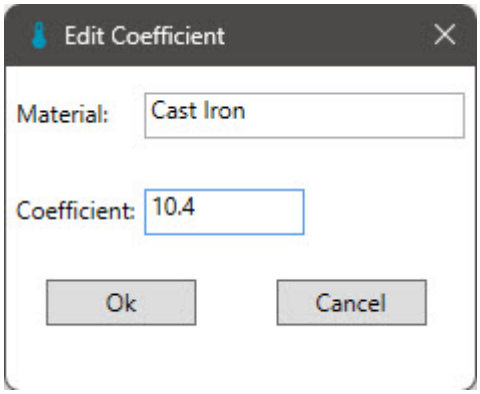
For example, iron has a coefficient of 11.3 in the example above. The software would evaluate this to 0.0000113.

For the **NewCoefficient** dialog box (see the **Edit** option below), you must enter temperature values in Celsius units.

This is very important when you edit an existing material coefficient value or add a new one.

PC-DMIS Version - This list defines the PC-DMIS version that is affected by the changes you make; it lists the versions of PC-DMIS that you have installed. Select a version from this list to pull in that version's materials and coefficients.

Edit - This button enables you to edit a selected material. It displays the **NewCoefficient** dialog box, where you can edit the material name or its coefficient value.

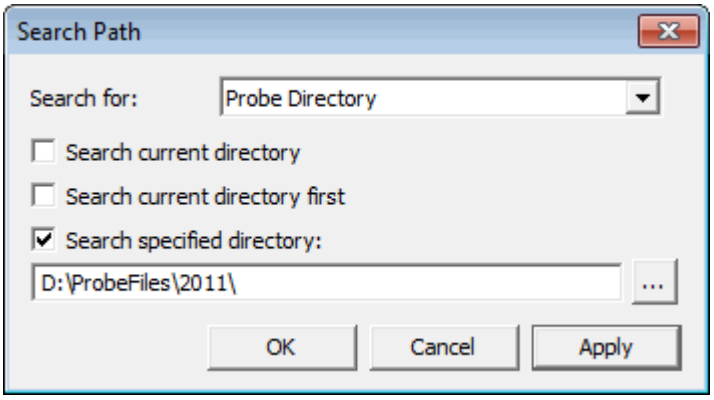


Add - This button enables you to add a new material and coefficient to the list. It displays the **Add Coefficient** dialog box, which is similar to the **NewCoefficient** dialog box discussed for the **Edit** button.

Delete - This button removes the selected row from the list of materials.

Close - This button closes the editor and displays a message that asks if you want to save your changes. To make the change to the usrMaterialCoefficients.xml file, click **Yes**. To close it without saving any changes, click **No**, or select the red X at the top right of the editor to close the editor.

Specifying Search Paths



Search Path Dialog Box

The **Edit | Preferences | Set Search Path** menu option displays the **Search Path** dialog box. You can use this dialog box to define the directories PC-DMIS uses when:

- Exporting CAD data or measurement routine data
- Importing CAD data or measurement routine data
- Loading and saving measurement routine files (.prg)
- Loading probe files (.prb)
- Recalling alignments (.aln)
- Calling subroutines

See the "Understanding File Locations" topic for information on where PC-DMIS stores specific settings and files.

Available Dialog Box Options

Search for - This list contains all the different items that you can associate directories with. The rest of the dialog box changes based on your selection. When PC-DMIS needs to find one of these file types or perform an action, it uses the directory associated with the selected item. These are the items in this list:

Default Export Directory - PC-DMIS exports CAD data or measurement routine data into the directory defined here.

Default Import Directory - PC-DMIS imports external CAD or measurement routine data into PC-DMIS from the directory defined here.

Default Measurement Routine Directory - PC-DMIS stores and loads measurement routine files from the directory defined here.

Probe Directory - PC-DMIS locates and stores probe files from the directory defined here.

Recall Directory - PC-DMIS recalls saved alignment files from the directory defined here.

Subroutine Directory - PC-DMIS loads measurement routine files and the subroutines stored within them from the directory tied to this item.

These check boxes may become available for selection based on what you choose above:

Search current directory - When marked, the software searches within the same directory where your current measurement routine resides.

Search current directory first - When marked and if both the **Search current directory** and the **Search specified directory** check boxes are selected, the software searches in both the current measurement routine's directory and the user specified directory. The order of the search depends on whether or not this check box is selected:

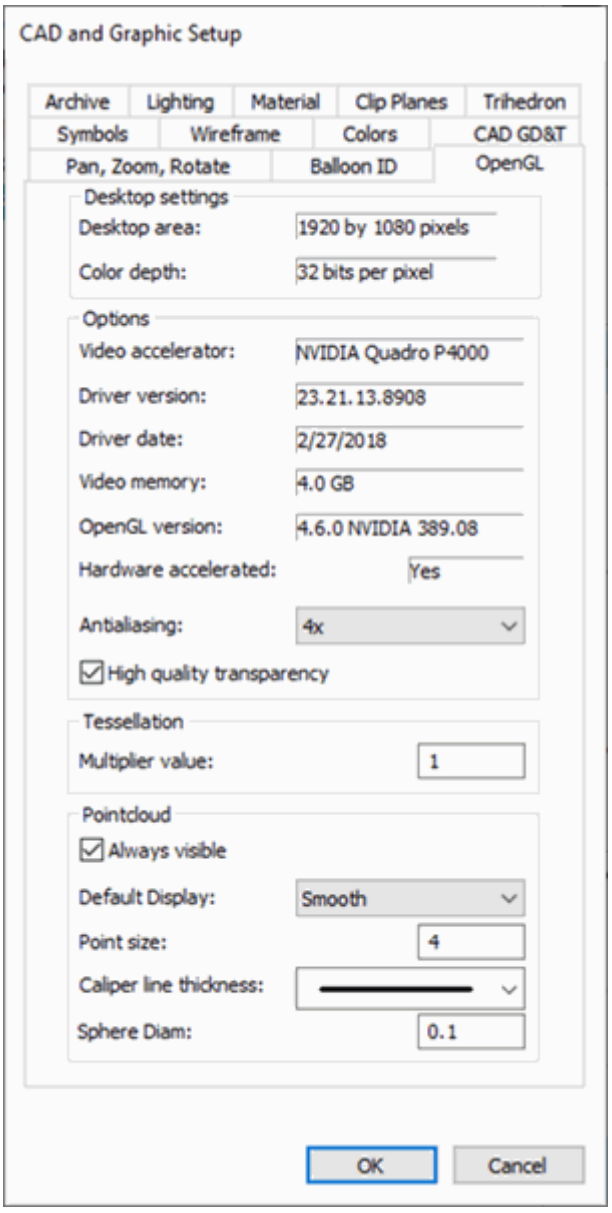
- If marked, PC-DMIS first accesses the same directory where your current measurement routine resides and then it accesses the user specified directory.
- If cleared, the search order is reversed, accessing first the user specified directory and then second the directory where your current measurement routine resides.

Search specified directory - When marked, this check box searches in a directory you specify. The pathway for the directory you specify appears in the box just below the check box. If no pathway is defined, you can type a full system pathway, or you can use the **...** button to choose a directory from your system's directory structure

To specify a new default directory to use:

1. Choose **Edit | Preferences | Set Search Path** to access the **Search Path** dialog box.
2. From the **Search for** list choose an item for which you want to define a pathway.
3. Mark any check boxes as needed.
4. Type the directory pathway in the box (or use the **...** button to browse to and select a directory).
5. Click **Apply**.
6. As needed, repeat the above steps to set additional search paths for other items.
7. Click **OK**.

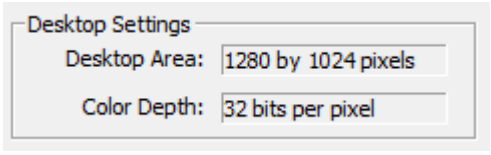
Changing OpenGL Options



CAD and Graphic Setup Dialog Box - OpenGL Tab

The **Edit | Graphic Display Window | OpenGL** menu option displays the **OpenGL** tab of the **CAD and Graphic Setup** dialog box. This allows you to change the OpenGL options that affect the display of the model in solid view mode. To change the part to solid view, see "Setting Up the Screen View" in the "Editing the CAD Display" chapter.

Desktop Settings area

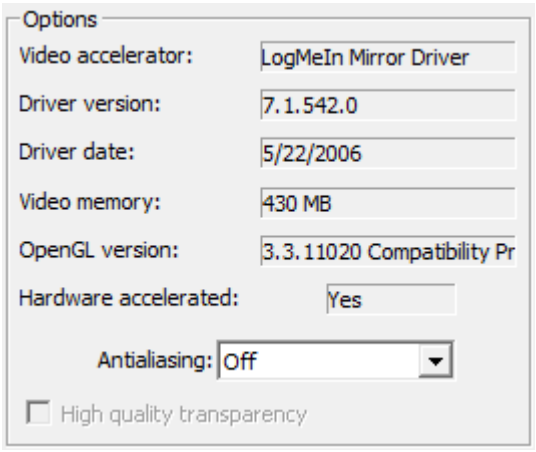


There can be different OpenGL options for each desktop display setting. The **Desktop Settings** area shows what the current desktop settings are.

Resolution Ratios of Different Monitor Sizes

Wide screen monitors need a 1.6 ratio instead of a 1.3333 ratio used by normal monitors. For example, a resolution of 1200x1600 has a 1.3333 ratio (1600/1200) and works well for a normal-size monitor, while a resolution of 1680x1050 has a 1.6 ratio, good for a wide screen monitor. If you use a wide screen monitor and your screen appears stretched (perhaps your circle features appear as ellipses in the Graphic Display window), use a 1.6 resolution ratio to resolve this problem.

Options area



The **Options** area displays information about the system's video card:

- **Video Accelerator** - Video card description
- **Driver version** - Video driver version
- **Driver date** - Video driver date of release
- **Video memory** - Amount of video card RAM
- **OpenGL version** - Version of OpenGL supported by the video driver
- **Hardware accelerated** - Displays Yes or No depending on whether graphics rendering is hardware accelerated. Hardware acceleration is much faster than software acceleration.

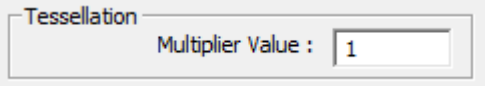
Antialiasing - The **Antialiasing** list allows the level of antialiasing by specifying the number of multisamples. 2x antialiasing samples each pixel twice. 4x antialiasing samples each pixel four times, and so on. When antialiasing is enabled, each pixel is sampled multiple times at slightly different locations within the pixel. An average color is computed from these samples to determine the final pixel color. This effectively reduces the model's jagged edges in the Graphic Display window. Higher antialiasing settings produce better visual results at the expense of slower system performance.

The capabilities of your video card determine the antialiasing options. Some graphics accelerators may support 64x antialiasing while others may only support up to 16x, or they may not support antialiasing at all. If your graphics accelerator supports antialiasing, the

amount of RAM it possesses and the resolution of your screen determine the default value (with a maximum default value of 4x). If your video card does not support antialiasing, PC-DMIS sets the default to **Off**.

The **High quality transparency** check box controls the `HighQualityTransparency` entry. By default, PC-DMIS clears this check box. It only functions if your graphics driver supports OpenGL 4.2 and your video adapter has at least 1 GB of memory.

Tessellation area



The **Tessellation** area controls the drawn image by setting a tessellation multiplier in the **Multiplier Value** box. PC-DMIS multiplies the **Multiplier Value** by the tessellation value for the given CAD system. These values are then used in the generation of the shaded image.

The tessellation value is the default value used to break up surfaces into patches for shading.

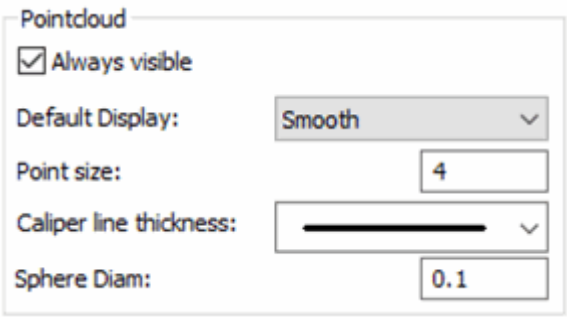
The tessellation multiplier updates the Graphic Display window immediately once you click outside of the **Multiplier Value** box or press Tab to move to a different item on the dialog box.

Modifying this tessellation value affects perimeter scans because PC-DMIS computes the distance around a curved surface edge by adding the segment lengths of a polyline that represents that edge. The tessellation multiplier changes the length of each polyline segment (lower tolerances result in smaller segments). While the actual perimeter points lie exactly on the edge curve, different tessellation tolerances result in small differences in where each point is located along the edge curve.

The size of the CAD data file and the tessellation multiplier value used affects the amount of memory needed. These both affect the number of tessellated facets needed to display the model. The smaller the tessellation multiplier value used, the more memory needed for the facets. For large CAD models, this could cause an "Out Of Memory" error. If this occurs, the current PC-DMIS session is left in an unstable state and should be terminated.

The default tessellation multiplier value is 1.0. Setting a tessellation multiplier of 0.1 results in a 10 to 20 percent increase in the memory required over the default value of 1.0. Decreasing the tessellation multiplier further to 0.01 results in an additional 50 to 65 percent increase of memory required.

Pointcloud area



The **Pointcloud** section determines how PC-DMIS draws a pointcloud (COP) in the Graphic Display window. A COP typically is generated from laser probes that can quickly collect large numbers of points. For more information on pointclouds, see the "PC-DMIS Laser" documentation.

Always visible - This setting applies to Pointcloud Point Colormaps when the Dots, Needles, and/or Text options are enabled.

- When you enable this option, the Dots, Needles, and/or Text for the Point Colormap are visible even if they are lower than the CAD model (negative relative to the CAD face).
- When this option is not enabled, PC-DMIS only displays the Point Colormap points and text if they appear in the current view.

Default Display - Sets the default graphical representation of the pointcloud in the Graphic Display window.

The valid options are:

- Smooth (default)
- Flat
- Two sided

- Normals

The software uses the display setting each time you create a pointcloud feature. For details, see "Pointcloud Graphical Representation" in the PC-DMIS Laser documentation.

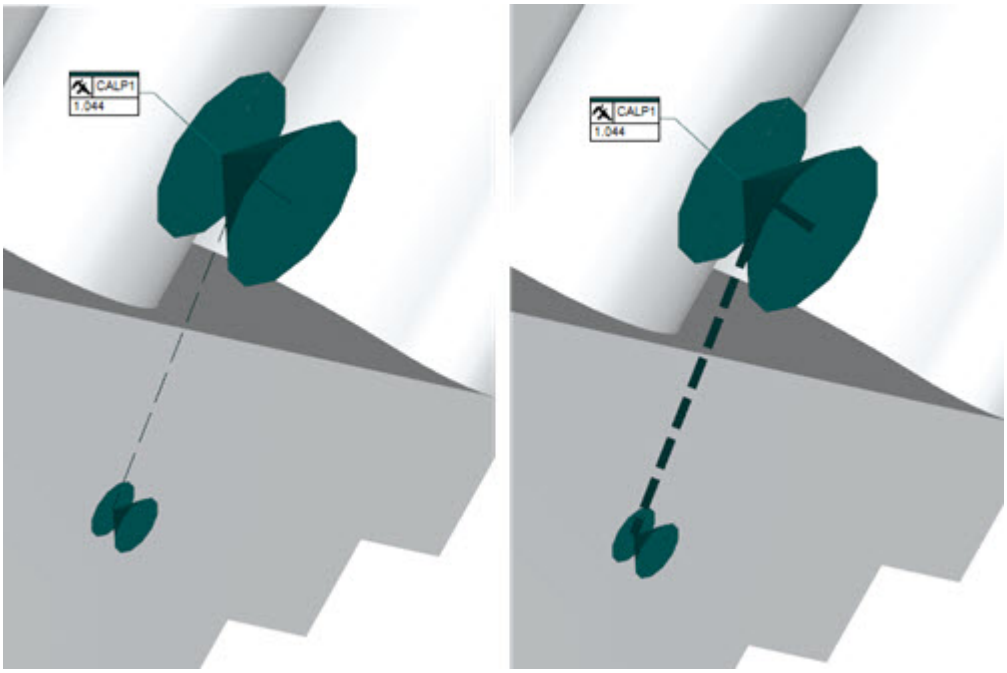
Point size - Specifies the pixel size of the points in a pointcloud.

Caliper line thickness - Specifies the thickness of the Caliper gage line, and the connecting line for thickness colormap annotations when the opposing sides are shown. The line thickness options are shown below with the default option selected:

Caliper line thickness options

The line thickness options correspond to (from thinnest to thickest) 1, 3, 5, and 7 pixels.

For details on the Caliper feature, see the "Caliper Overview" topic in the PC-DMIS Laser documentation.

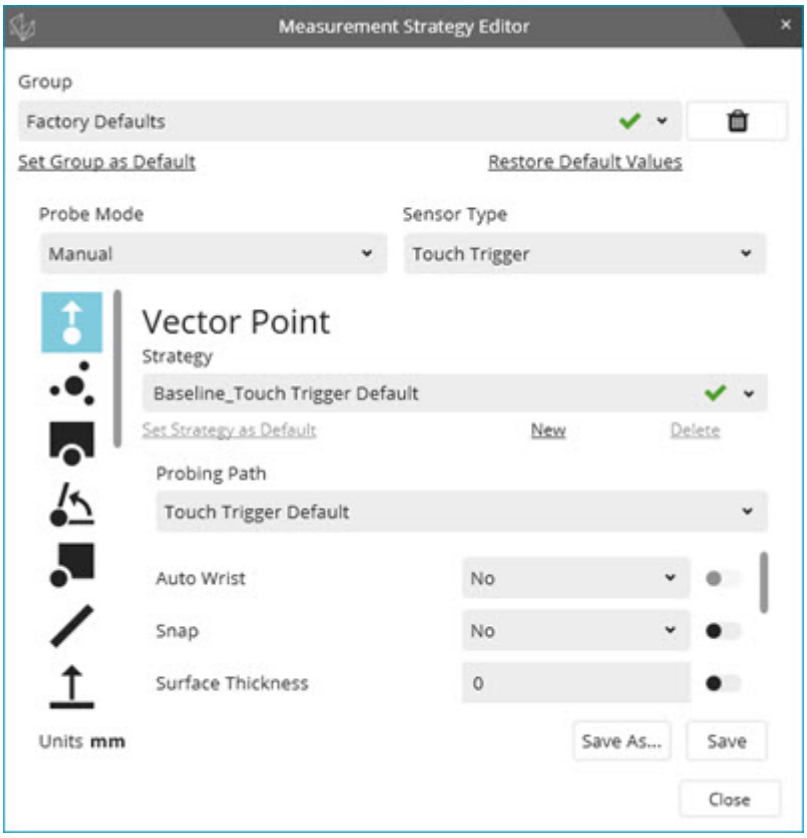


Examples that show the Caliper line thickness option set to minimum (left) and maximum (right).

Sphere Diam - Specifies the size of the thickness annotation points when you select the **Show opposing annotation points** check box on the **Pointcloud Operator** or **Mesh Operator** dialog box when you select the Pointcloud or Mesh Thickness Colormap operator. For details, see "Mesh Thickness Colormap" in the PC-DMIS Laser documentation.

Using the Measurement Strategy Editor (MSE)

You can use the Measurement Strategy Editor (MSE) to modify the settings for all the Auto features. You can store the modified settings as strategies and as custom groups.



Measurement Strategy Editor Dialog Box

To access the MSE, select **Edit | Preferences | Measurement Strategy Editor**. By default, PC-DMIS shows the MSE for CMM configurations. For portable configurations, it hides the MSE.

If the MSE is not available, you can enable it with the **Use Measurement Strategy Editor** check box from the **Setup Options** dialog box, **General** tab. For more information, see "Use Measurement Strategy Editor" in this chapter.

Related Topics

For information on the different settings in the MSE, see "The Auto Feature Dialog Box" in the "Creating Auto Features" chapter and "Using the Probe Toolbox" in the "PC-DMIS CMM" documentation.

For information on the measurement strategy widget, see "Using the Measurement Strategy Widget" in the "Creating Auto Features" chapter.

For information on measurement strategies in general, see "Working with Measurement Strategies" in the "PC-DMIS CMM" documentation.

Description of the MSE

Group - This shows an alphabetized list of all your saved strategies along with the original settings. When you first use the Measurement Strategy Editor, this list only shows **Factory Defaults** because you haven't yet saved any new groups. This list grows as you use **Save As** to create more groups. Each group in the **Group** list stores its settings in a .msexml file of the same name. The software stores them in the C:\ProgramData\Hexagon\PC-DMIS\<version> folder, where <version> is your version of PC-DMIS.

Delete Group ( ) - This button deletes the selected group from the database and selects the top-most item in the **Group** list. This also deletes the associated .msexml file. You cannot delete the **Factory Defaults** group. A green check mark indicates when the operation finishes.

Set Group as Default - Sets the selected group as the default group when you next use the Measurement Strategy Editor. A green check mark appears in the **Group** list to indicate the default group. This also sets the default group in the **Measurement Strategy** toolbar. For more information see, "Measurement Strategy Toolbar" in the "Using Toolbars" chapter.

Restore Default Values - Restores the values for the selected group to their stored defaults. If you add a feature to the Edit window and press F9 on that feature and make changes to it, the software writes those changes to the JSON file. This means the software uses those changes as the new default for that feature type and not what's in the selected group. The **Restore Default Values** button restores your default settings on the feature to match the settings stored within the selected group.

Probe Mode - For a traditional CMM, this list shows **Manual** and **DCC** (Direct Computer Control). With this list, you can save settings according to machine type, either a manual CMM or a CMM capable of DCC motion.

Sensor Type - Determines the type of sensor. The application only shows settings that the selected sensor type can use. For a traditional CMM, this shows **Touch Trigger** and **Analog**. A touch-trigger sensor or probe records hits based on discrete hits. An analog sensor or probe remains in contact with the part and records hits based on time and distance as it scans.

Strategy - Sets the strategy to modify. This list initially shows a default strategy for the feature and sensor type. A green check mark appears in the **Strategy** list to indicate the default strategy. You can select a strategy to modify it, or you can click **New** to create a custom strategy. When you save the settings to a group, PC-DMIS also saves the current settings for the feature to the current selected strategy.

Strategy Type - This list does not appear at first. It only appears if, under **Sensor Type**, you choose **Analog** and then you select a supported feature (High Point, Circle, Plane, Line, Cylinder, or Cone). It allows you to choose an internal strategy. These strategies provide predefined ways to measure that feature, and they provide additional parameters that you can modify. You can select one of these internal strategies and use it as a base

for your own custom strategy. These internal strategies may also hide parameters that don't make sense in that context (such as **Number of Hits** for a continuous contact probe).

Features Toolbar - The toolbar down the left side contains all the Auto features. When you select an Auto feature, its settings appear in the window.

Settings - This topic does not cover the individual settings for each Auto feature. You can find those in the Auto Feature documentation. Many Auto feature settings have a switch to the right ( ). You can turn a switch on to have that setting appear in the Measurement Strategy Widget. You can turn a switch off to hide that setting from the widget.

Unit - If this shows **mm**, the application displays values in millimeters. If it shows **in**, the application displays values in inches. The server always stores its settings in millimeters.

Save - This button saves all the defaults settings for all the features in the current group to the PC-DMIS JSON files. This also saves the settings for each feature to each feature's current selected strategy. You cannot overwrite the original factory defaults. If **Group** shows **Factory Defaults**, a **Group Name** input box appears so you can save the modifications as a new group of settings.

Save As - A **Group Name** input box always appears so you can save the group as a new set.

Close - Closes the MSE application. If you haven't saved your changes, PC-DMIS asks if you want to save them.

How to Use the MSE

1. Select **Edit | Preferences | Measurement Strategy Editor** to access the Measurement Strategy Editor application. You can position the application and resize the window height as needed.
2. Choose the desired **Probe Mode** and the **Sensor Type**.
3. From the toolbar on the left, you can scroll up and down and then select an Auto feature to modify its settings.
4. Modify a feature's default settings for that group. (You can also define strategies. For information, see "Creating or Modifying Strategies" below.) By default, PC-DMIS decides what features to send to the Measurement Strategy Widget but you can override that with the switches to the right of each setting ( ).
5. Once you're done modifying one feature, if you like, click to another feature. The application temporarily stores your modifications as you click between the different features.
6. Continue to modify the settings as needed.

7. Save your changes. This also inserts your settings as defaults into PC-DMIS.
    - To save the current settings for the feature to the current selected group of settings, click **Save**. If you attempt to save the settings in **Factory Defaults**, the software opens the **Group Name** input box. You can type a name to save your group of settings under a different group name.
    - To save your changes to a new group of settings, click **Save As**. The software opens the **Group Name** input box. Type a name to save your group of settings under the new group name.
8. Save as many groups of settings as you want.
9. From the **Group** list, choose the group of settings you intend to use most frequently, and click **Set Group as Default**. This tells PC-DMIS to use those settings as the new default settings.
10. Click **Close** to close the MSE.
11. Create your Auto features.

The Unit option displays the units (inches or millimetres) that are being applied. This is the same as the measurement routine’s units setting.

How the MSE Works

You can use the MSE to modify the settings for all Auto feature and then store them as strategies and custom groups. Strategies are specific to each feature. Groups contain any modified settings for all the features.

The MSE saves the settings for each custom group in text files. These text files use the XML format. Each text file has the group name as its name with an .msexml filename extension. Whenever you delete a group, PC-DMIS deletes the corresponding .msexml file.

PC-DMIS stores these files in the C:\ProgramData\Hexagon\PC-DMIS\2026.2 folder.

When you set a group of settings as the default (and at other times discussed in "About Default Settings" below), the MSE writes those settings into the JSON file for PC-DMIS Auto features to use.

When you create Auto features, PC-DMIS takes into account the current probe mode (DCC or Manual) and the current sensor type (Touch-trigger or Analog). It then uses the appropriate settings for that mode or type. For example, a circle feature that you insert after a DCC Mode command can have a different number of hits than one that you insert after a Manual Mode command.

Touch-trigger and Analog probes only work in DCC Mode. Scan strategies only work in DCC Mode.

The MSE does not yet manage laser and vision settings.

About the Default Settings

You can use the MSE to modify the default settings (number of hits, depth, void detection, strategy types, and so on) for all Auto feature types. By default, PC-DMIS writes these changes to the JSON file whenever you modify and then save settings in the Measurement Strategy Editor.

If your default settings don't update, mark the **Use Measurement Strategy Widget** check box from the **General** tab of the **Setup Options** dialog box (F5). The measurement strategy widget applies modifications into the JSON file. If that check box is cleared, the MSE stores your changes only in the .msexml files. For information, see "Using the Measurement Strategy Widget" in the "Creating Auto Features" chapter.

PC-DMIS queries the JSON file and uses those settings when you create an Auto feature.

You can also update the JSON file for a specific setting if you modify that setting in the **Auto Feature** dialog box or in the Edit window command.

PC-DMIS updates the JSON file with the settings stored in the default MSE group whenever you do one of the following:

- Save a change to the default group of settings with the MSE.
- Change to a new probe mode (such as from Manual to DCC) in the Edit window.
- Change to a new probe type in the Edit window.

Creating or Modifying Strategies

Each feature in the MSE has one or more internal strategies that come with PC-DMIS. You can modify settings for these strategies or you can create a custom strategy.

1. Access the MSE.
2. From the MSE, under **Strategy**, choose the strategy to modify. If you want to create a new strategy for the feature, click **New**, and type the strategy name.
3. Make modifications as usual to the feature's settings.
4. When you click **Save** or **Save As** for the group, PC-DMIS also saves the current settings for the feature to the current selected strategy.

5. Create as many strategies as you want.
6. From the **Strategy** list, choose the strategy you intend to use most frequently, and click **Set Strategy as Default**.
7. Create your Auto features.

You can select the strategy to use when you create or edit features with the Measurement Strategy Widget.

How to Attach a Scan Adaptive Strategy to a Supported Feature

1. Access the MSE.
2. From the **Probe Mode** list, choose **DCC**.
3. From the **Sensor Type** list, choose **Analog**.
4. From the toolbar on the left, select the feature to modify (High Point, Circle, Plane, Line, Cylinder, or Cone).
5. From the **Strategy Type** list, select the desired internal measurement strategy.
6. Beneath the **Strategy Type** list, click **Set Strategy as Default**. Only the strategy that you set as default is assigned to that feature. If you don't set the strategy as the default, the software uses TTP_STRATEGY.
7. Click **Save** to update the .msexml file and to use the defined settings for that feature.

Working with Smart Parameters

Terminology Note: In this topic, the word "parameter" also means "setting".

Typically, in the MSE, you can only provide a single value for a setting. In some cases, however, you may need to provide more than a single value, based on different conditions. This is best explained with an example:

Suppose you need to measure circle features on a part that have different sizes, and you want the number of hits to adjust based on the size of the diameter. With smart parameters, you can do this.

By default, a circle feature has these smart parameters defined for its **Hits** setting:

Maximum Diameter	Number of Hits
6	4
15	6
25	10
50	18

If you create a circle feature with smart parameters enabled, PC-DMIS checks the diameter and uses the numbers of hits for the row up to the diameter's maximum value. So, with the above grid of values, if you create a circle feature with a diameter of 12 units, then PC-DMIS uses six hits to create that circle. With a diameter of 20 units, PC-DMIS gives the circle 10 hits.

Now, suppose you want to have a different number of hits (maybe 20 hits) for circles with a diameter within the range of 51 to 75. You can add a new row and then for that row, set the **Maximum Diameter** to 75 and **Number of Hits** to 20.

If the measured circle feature is larger than the highest diameter in the grid, PC-DMIS doesn't use any smart parameter for the number of hits; instead, it uses the default number of hits (usually seven) from the **Auto Feature** dialog box.

Available Smart Parameters

These are the available smart parameters where you can provide multiple values:

Feature	Strategy	Smart Parameters
Circle	Baseline_ Touch Trigger Default	Hits
Circle	Baseline_ Adaptive Circle Scan	Point Density Scan Speed Acceleration
Cylinder	Baseline_ Touch Trigger Default	Hits per Level Ending Offset
Cylinder	Baseline_ Adaptive Cylinder Line Scan	Ending Offset
Cylinder	Baseline_ Adaptive Cylinder Concentric Circle Scan	Point Density Scan Speed Acceleration Ending Offset

Plane	Baseline_Adaptive Free Form Plane Scan Baseline_Touch Trigger Free Form Plane	Inner Offset Outer Offset Perimeter Jump Hole You can access these Smart Parameter options from the **Measurement Strategy Editor** dialog box and the **Measurement Strategy Widget**. For details, see the "Using Smart Parameters from the Auto Feature dialog box, the Measurement Strategy Editor, and the Measurement Strategy Widget" section in the "Using Smart Parameters on the Measurement Strategy Widget" topic of the PC-DMIS Core documentation.

Enabling and Editing Smart Parameters

To enable smart parameters:

1. Locate the setting in the MSE. If the setting supports smart parameters, a grid button appears next to it. If smart parameters is disabled, it has a gray crossed out grid button next to it.

2. Click the gray, crossed-out grid button ( ) to the right of the parameter. The button turns to a green grid button ( ) to indicate it's enabled.

To edit smart parameters:

1. Click the **Edit Smart Parameter** button ( ) to the right of the setting. A smart parameters dialog box opens with a table of values.
2. Use **Add Row** ( ) and **Remove Row** ( ) buttons to define the number of rows in the grid. You can have up to seven rows.
3. Define the values in the grid.
4. Click **Apply** ( ) to accept your changes. You can also click the **Cancel** button ( ) to not save your changes.
5. When you enable smart parameters, during feature creation, PC-DMIS chooses the number of hits based on the diameter.
6. When you create the feature, if the diameter size is less than or equal to the set maximum diameter value, PC-DMIS uses those numbers of hits.

Using Smart Parameters on the Measurement Strategy Widget

You can also enable or disable smart parameters from the measurement strategy widget. For more information about the widget, see "Using the Measurement Strategy Widget".

When the measurement strategy widget appears, click the **Properties** button ( ) to see if that feature type uses smart parameters.

- If the button is gray, smart parameters are currently disabled. You can click this button to enable them.
- If the button is green, smart parameters are currently enabled. You can click this button to disable them.

The value of the setting to the left of the grid button shows the value PC-DMIS chooses for the feature. You can click the grid button to switch between the smart parameter value and the default value for the feature you're creating.

If you want to define a custom value, turn off smart parameters and type the value.

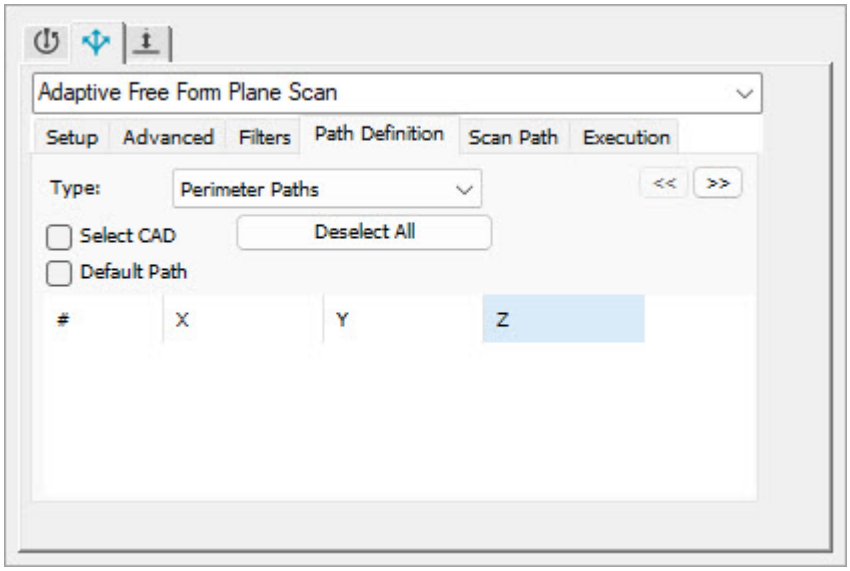
Using Smart Parameters from the Auto Feature dialog box, the Measurement Strategy Editor, and the Measurement Strategy Widget

Using Smart Parameters from the Auto Features Dialog Box

To use Smart Parameters on an Auto Feature Plane using the Free Form Plane Strategy, follow these steps:

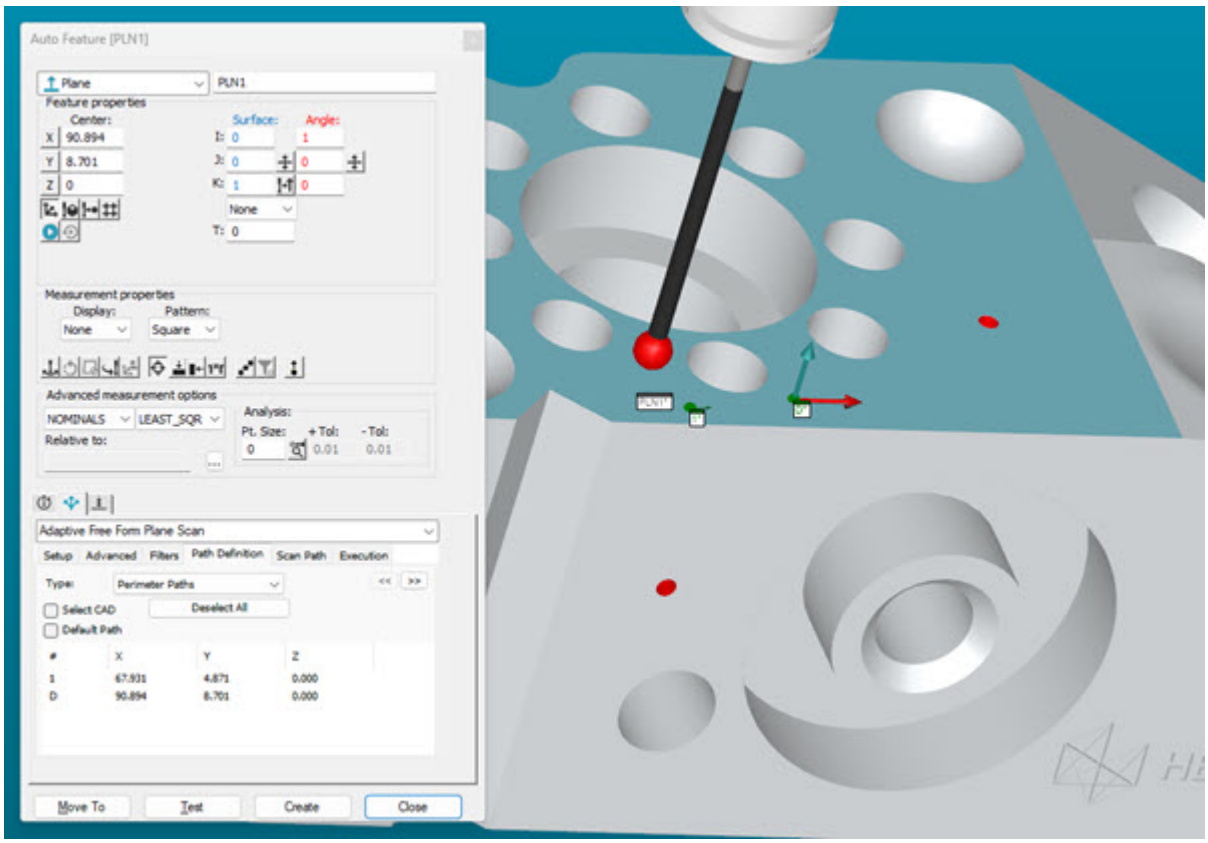
1. Select the Auto Feature Plane option (**Insert | Feature | Auto | Plane**) or click the **Auto Plane** button from the **Auto Feature** or **QuickFeature** toolbar (**View | Toolbars**).

2. From the **Measurement Strategy** tab at the bottom of the **Auto Feature** dialog box, select the **Path Definition** tab.



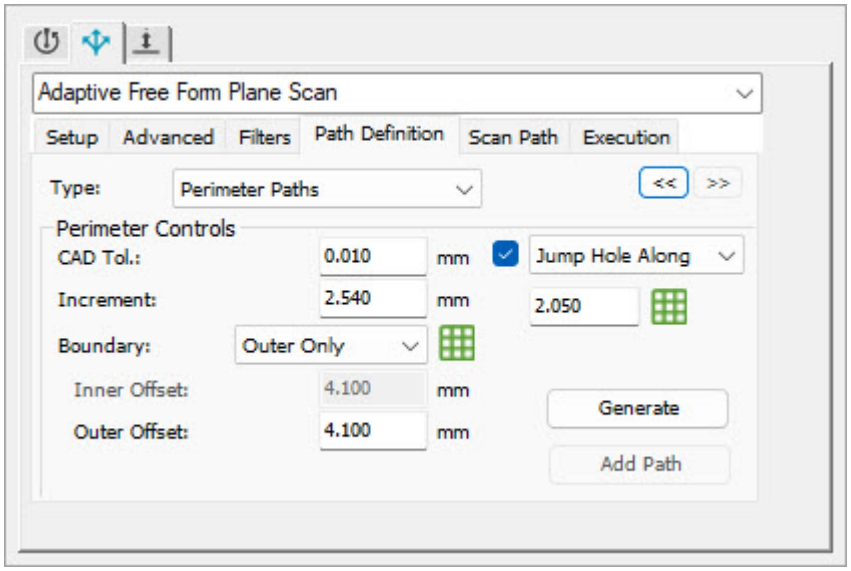
Probe Toolbox - Path Definition Tab

3. Select the **Adaptive Free Form Plane Scan** option from the **Measurement Strategy** list and then select the first point (**1**) and the direction point (**D**) on the CAD model in the Graphic Display window.



Example showing the Auto Feature dialog box for a Plane feature using the Adaptive Free Form Plane Scan strategy.

4. Click the double-arrow button **>>** to show the next set of **Path Definition** options.

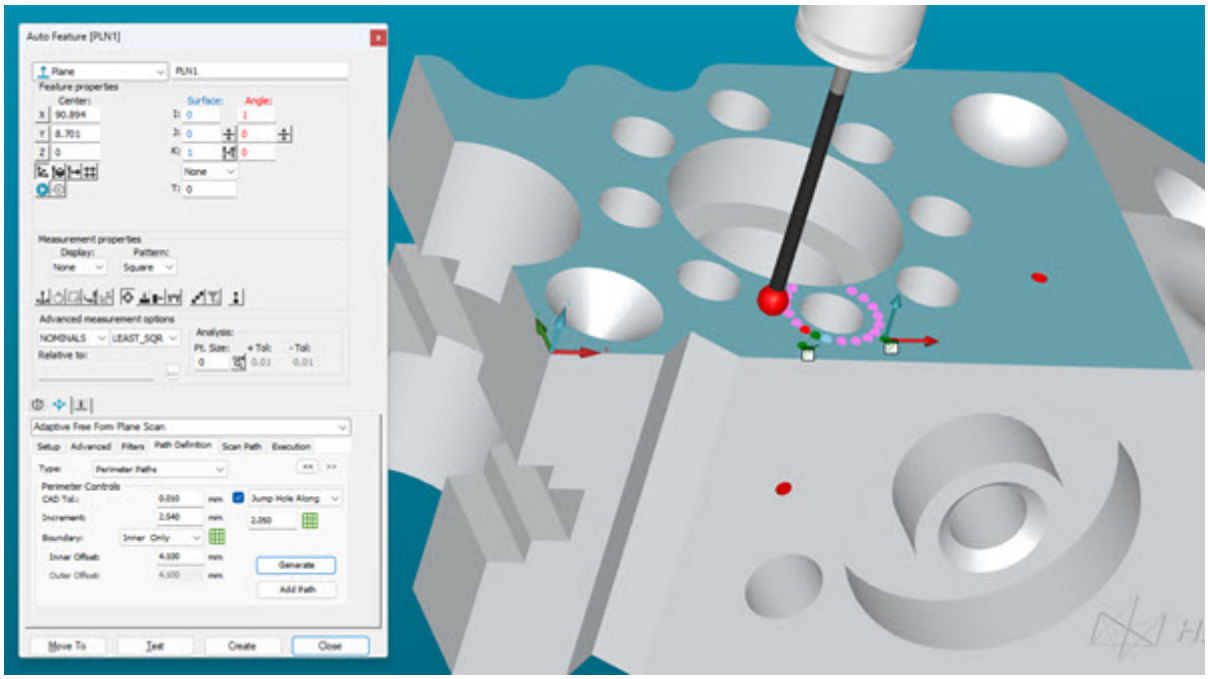


This example uses an 8 mm diameter probe tip. You can see in this example that, with the Smart Parameters turned on , the **Inner Offset** and **Outer Offset** values are set to one half of the probe tip's diameter plus 0.1 mm, or 4.100 mm. Also, the **Jump Hole Along** value is set to half the **Inner Offset** and **Outer Offset** values, or 2.050 mm in this example. You can set the values manually by typing a new value

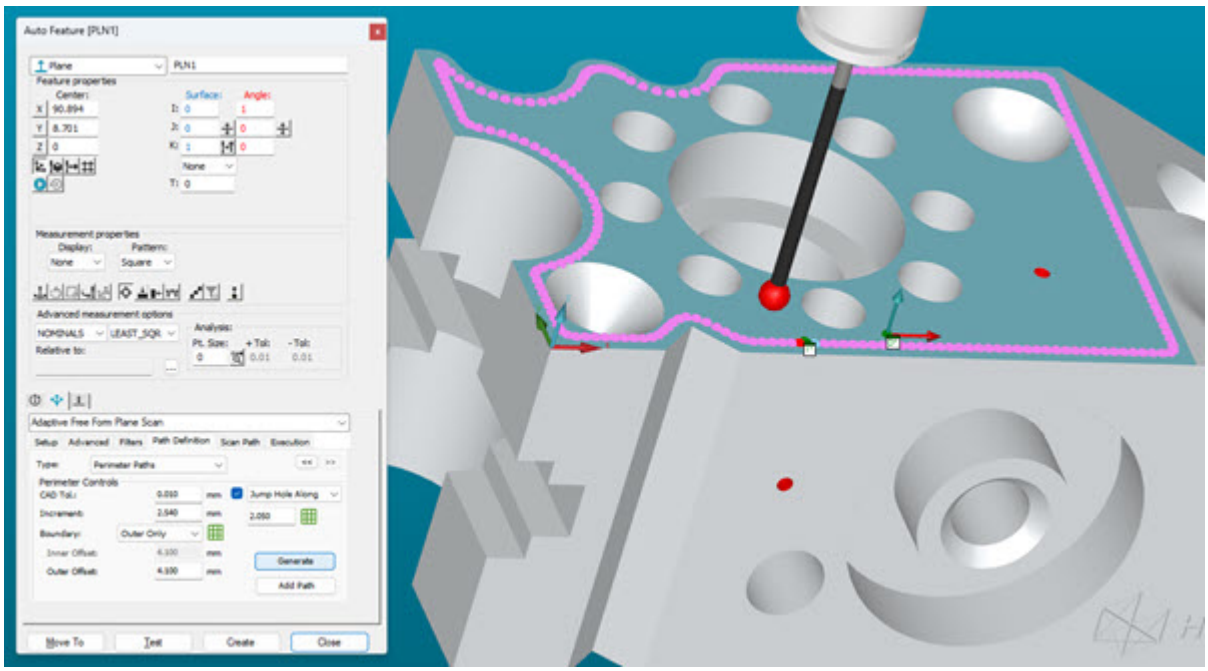
directly into any of the boxes. As soon as you start to type a new value into a box that has Smart Parameters turned on, the Smart Parameter option turns off .

The **Boundary** option can be set to **Inner Only**, **Outer Only**, or **Inner and Outer**. You can see examples of the resulting path after you click the **Generate** button for each of the **Boundary** options below.

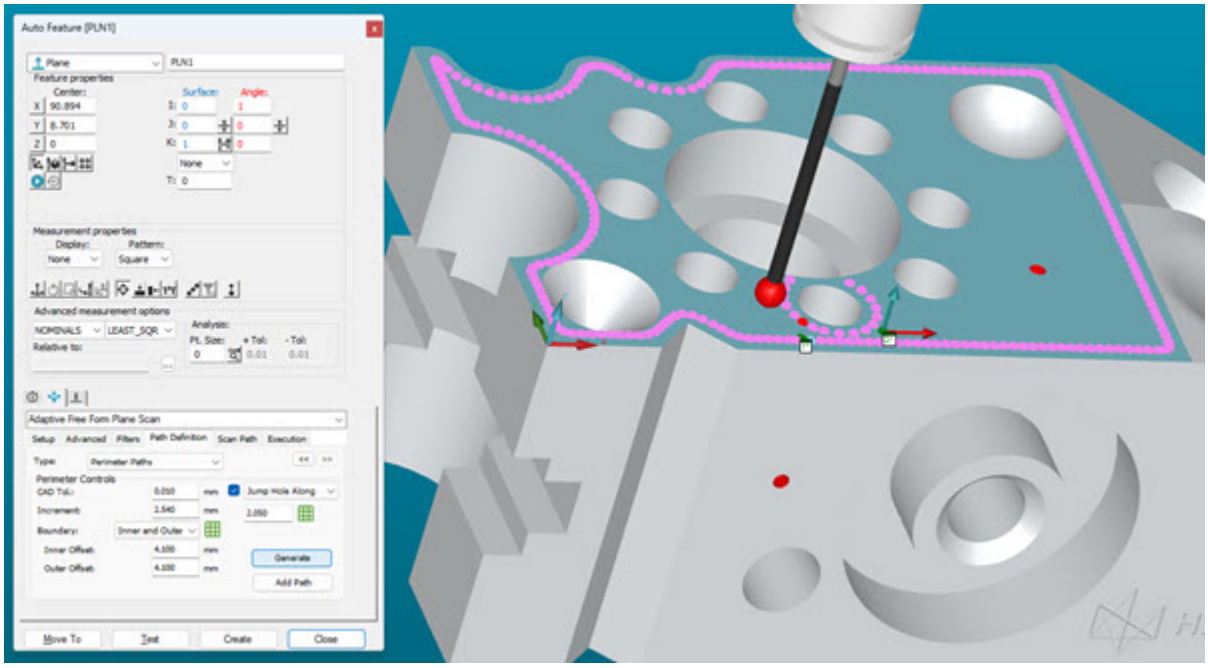
Smart Parameters functionality is initially off by default but retains the state it was in the last time your measurement routine was closed.



Example showing the Boundary option set to Inner Only.



Example showing the Boundary option set to Outer Only.



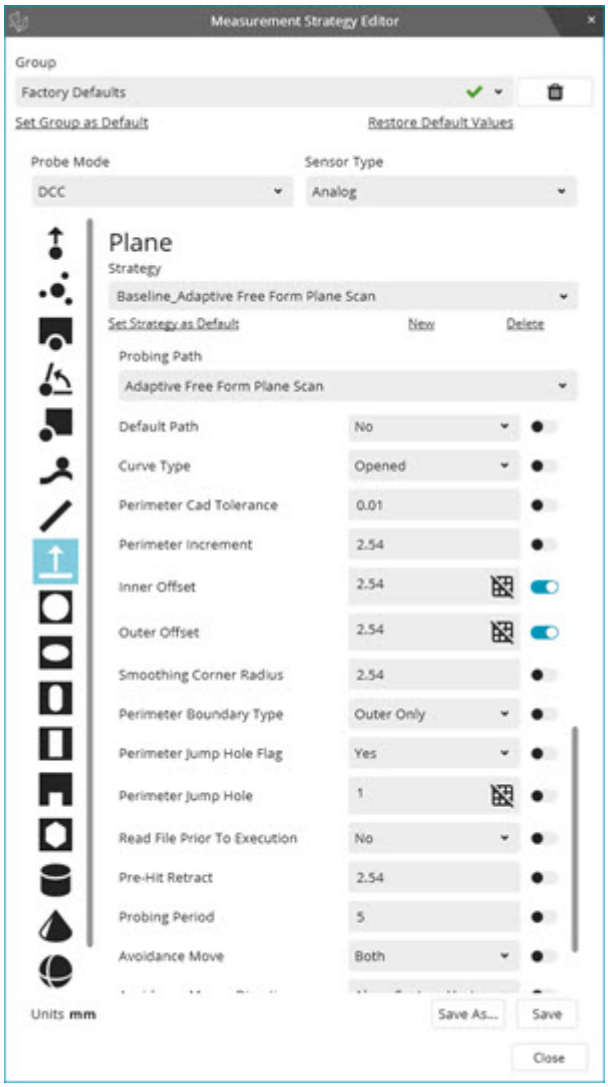
Example showing the Boundary option set to Inner and Outer.

Using Smart Parameters from the MSE dialog box and the Measurement Strategy Widget

The Smart Parameter functionality is identical to how it works from the **Auto Feature** dialog box described above.

To use Smart Parameters from the **Measurement Strategy Editor** dialog box, follow these steps:

1. From the **Measurement Strategy** toolbar (**View | Toolbars**), click the **Measurement Strategy Editor** button to open the **Measurement Strategy Editor** dialog box.
2. From the list of feature types on the left, click the **Plane** icon.
3. Click each toggle option to turn it on. Each option you turn on will show up in the **Measurement Strategy Widget** for the defined **Group**.
4. From the **Strategy** list, select the **Baseline_Adaptive Free Form Plane Scan** or the **Baseline_Touch Trigger Free Form Plane** strategy.



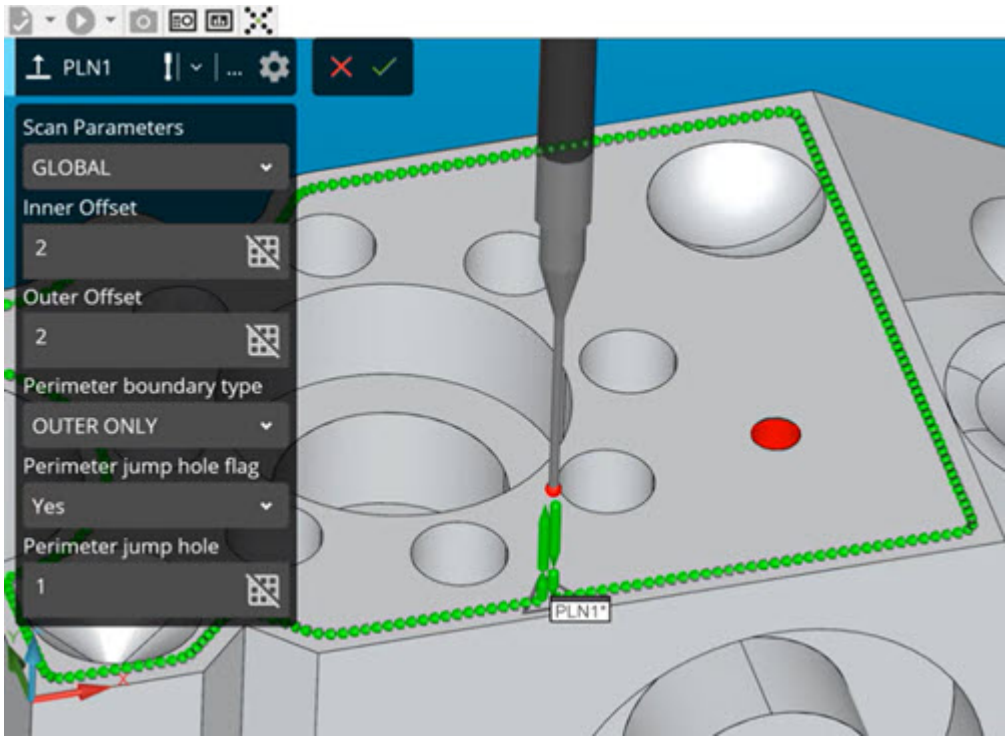
Measurement Strategy Editor dialog box showing the Smart Parameter options for a Plane feature.

5. Click the **Save As** button and type a unique **Group** name for the settings, and then click the **Close** button.

To use Smart Parameters from the **Measurement Strategy Widget**, follow these steps:

1. Select the Measurement Strategy **Group** from the **Measurement Strategy Editor** toolbar 
(**View | Toolbars**).

2. Press and hold the Shift button and click a surface to create a QuickFeature plane. PC-DMIS shows the **Measurement Strategy Widget** automatically when you create a QuickFeature.



QuickFeature Plane feature showing the Measurement Strategy Widget with Smart Parameter options.

You can see from the status of the **Smart Parameter** button in the example above that the functionality is off.

3. Click the **Smart Parameter** button to turn the functionality on. The **Smart Parameter** buttons for the **Inner Offset** and **Outer Offset** settings work together. If you click one on or off, PC-DMIS turns the Smart Parameters functionality on or off for both.

4. Select the **Perimeter boundary type** option from the list. The options are **INNER ONLY**, **OUTER ONLY**, and **INNER AND OUTER**.

5. For the **Perimeter Jump hole** option, click the **Smart Parameters** button to turn the Smart Parameters functionality on or off.

6. Click the **Apply** button to create the feature.

Setting Up Sensor Mapping

You can use the **Edit | Preferences | Feature - Sensor Mapping menu** item to open the **Sensor Mapping** dialog box.

With the **Sensor Mapping** dialog box open, you can then use QuickFeatures to populate this dialog box and then map those features to specific sensors (probes).

Once you click **Done**, the mapped features are added into the measurement routine with the appropriate `LOADPROBE` commands.

- For more information on QuickFeatures, see "Creating QuickFeatures" in the "Creating Auto Features" chapter.
- For more information on sensor mapping, see "Mapping Features to Sensors" in the "Using Inspection Plans in PC-DMIS" appendix.

Defining Colors on Imported CAD Entities

To define the default colors for imported CAD entities (points, curves, surfaces, and datums), use the **Import Options** dialog box, described in "Setting Import Options".

Understanding File Locations

The default file locations (path locations) for various user-specific settings and other files have changed in PC-DMIS 2010 MR2 and later to comply with newer Windows operating system standards. Before PC-DMIS 2010 MR2, most of this information was stored inside of the PC-DMIS installation directory. This topic shows where these files are now stored based on each file's role.

In the descriptions of the file locations, *<user name>* is the user name that you use to log on to Windows.

You can use the PC-DMIS Settings Editor application to back up, restore, or clear user-specific files and settings. Rather than manually delete or restore individual files on your own, we recommend that you use the tools that the PC-DMIS Settings Editor provides. For more information, refer to the PC-DMIS Settings Editor documentation.

For specific information about data files, see "Understanding Data Files".

Public Documents

Understanding Data Files

The entries in the PC-DMIS Settings Editor application store most of the settings in PC-DMIS. However, PC-DMIS also stores information in data files, which have a .dat extension.

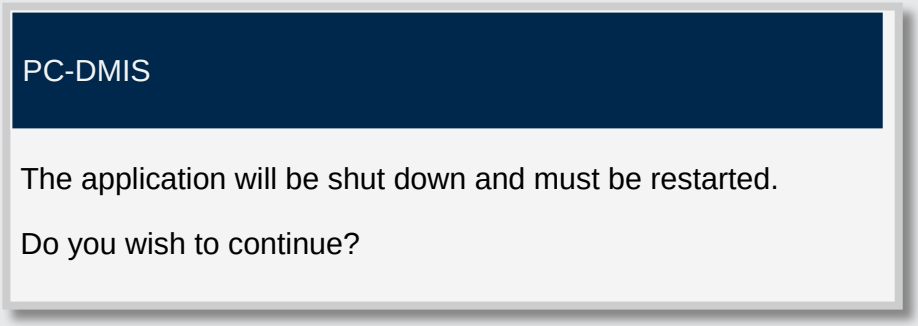
You can edit some of these files in a text editor, but you can only edit many of them within PC-DMIS. You can delete some data files if you want to return the respective PC-DMIS functionality to its original state.

The information below details many of the data files that are available, their file locations, whether you can edit them in a text editor, and where they're stored on the computer. In the descriptions of the file locations, <*user name*> is the user name that you use to log on to Windows.

PC-DMIS complies with current operating system standards required by Windows about where it stores user files.

When you first run PC-DMIS, it copies several .dat files from your folder where you installed PC-DMIS into your AppData user folder. From then on, PC-DMIS uses the user-specific file in that folder. However, if you have Administrator rights, you can modify the original factory-based file if needed.

Starting with PC-DMIS 2023.1, PC-DMIS creates device-specific folders in the AppData user folder. The software creates and updates these folders whenever you switch your device from the **Edit | Select Environment** menu option. When you select a new device, PC-DMIS saves the currently active .dat files to the previous device's folder and then it must restart. Before it restarts, PC-DMIS displays this prompt:



Click **Yes** to restart the application. When PC-DMIS starts up again, it copies the new device's .dat files from the relevant folders and applies them. This ensures that any device-specific window layouts, toolbars, and menu items are correctly recalled and applied each time you change your device.

Prior to PC-DMIS 2023.1, it might have been necessary for you to use the Settings Editor to perform a "Reset User" operation to restore certain functionality (for example, to restore DCC-related commands when you switch from a portable to a stationary CMM). With this new method of how PC-DMIS handles .dat files, this is no longer necessary. For details on how to configure and use the PC-DMIS Environment Configurator, see the "Environment Configurator" section in the PC-DMIS Core documentation.

An asterisk character (*) by the file name in the descriptions below indicates that the original, factory-based file exists in your installation directory.

You can use the PC-DMIS Settings Editor application to back up, restore, or clear user-specific files and settings. Rather than manually delete or restore individual files on your own, we recommend that you use the tools that the PC-DMIS Settings Editor provides. For more information, refer to the PC-DMIS Settings Editor documentation.

Manually moving or copying a data file to a different version of PC-DMIS is not recommended or supported.

For more information about file locations, see "Understanding File Locations".

colors.dat

This file stores your modified Edit window colors. PC-DMIS generates this file only if you modified any Edit window colors. When you exit PC-DMIS, it creates this file.

You cannot edit this file in a text editor.

If you delete this file, your Edit window colors revert to their default settings.

For information about how to define colors, see "Defining Edit Window Colors" in the "Setting Your Preferences" chapter.

File location: C:\Users\<*user name*>\AppData\Local\Hexagon\PC-DMIS\2026.2

CustomMenuItem.dat

This file contains information for the default items and user-defined items in the **User Defined Commands** list on the **Menu** tab in the **Customize** dialog box (**View | Toolbars | Customize**).

You cannot edit this file in a text editor.

If you delete both CustomMenuItem.dat and toolbar.dat, PC-DMIS removes any user-defined customizations made in the **Customize** dialog box and any custom toolbars. PC-DMIS regenerates custom items if you load a toolbar.dat file that has custom items.

For more information, see "Customizing the User Interface" in the "Navigating the User Interface" chapter.

File location: C:\Users\<*user name*>\AppData\Local\Hexagon\PC-DMIS\2026.2

DefaultDimensionColors.dat

PC-DMIS automatically creates and modifies this file whenever you modify the **Edit Dimension Colors** dialog box (**Edit | Graphic Display Window | Dimension Colors**).

This file contains dimension color information that:

- Defines the dimension's color limits
- Determines whether tolerance colors display in two directions
- Defines the colors that PC-DMIS uses for dimensions that are still within tolerance with percentages from 1 to 40
- Defines the color that displays when a dimension is out of tolerance with a negative value
- Defines the color that displays when a dimension is out of tolerance with a positive value

- Determines whether PC-DMIS displays tolerances as a percentage of the deviation in the Dimension Colors window (color bar)

You cannot edit this file in a text editor.

File location: C:\ProgramData\Hexagon\PC-DMIS\2026.2

elogo.dat *

This file controls the format of the Edit window's footer on the last page.

You can edit this file in a text editor.

DO NOT DELETE THIS FILE. If you delete this file, PC-DMIS erases the footer from the last page of the Edit window.

For more information, see "Modifying the Edit Window's Headers and Footers" in the "Using the Edit Window" chapter.

File location: In the directory where you installed PC-DMIS.

executebarstate.dat

This file contains the layouts of toolbars and dockable windows during measurement routine execution. PC-DMIS switches back and forth when it reloads these two files (gbarstate.dat and executebarstate.dat) and when you start and finish measurement routine execution.

You cannot edit this file in a text editor.

If you delete this file, PC-DMIS restores a default layout.

File location: In the directory where you installed PC-DMIS.

gbarstate.dat

This file contains the layouts of toolbars and dockable windows within the measurement routine (but not during execution).

You cannot edit this file in a text editor.

If you delete this file, PC-DMIS restores the default layout.

File location: C:\Users\<*user name*>\AppData\Local\Hexagon\PC-DMIS\2026.2

header.dat *

This file controls the format of the Edit window's header on all pages but the first page.

You can edit this file in a text editor.

DO NOT DELETE THIS FILE. If you delete this file, PC-DMIS erases the header from the affected pages of the Edit window.

For more information, see "Modifying the Edit Window's Headers and Footers" in the "Using the Edit Window" chapter.

File location: In the directory where you installed PC-DMIS.

illumination.dat

This file is used for vision machines. It stores the defined illumination quick sets. Illumination quick sets contain information about the machines lamps, which bulbs are on, and their brightness.

You cannot edit this file in a text editor.

If you delete this file, any custom quick sets are lost, although PC-DMIS recreates this file with a few default quick sets.

File location: C:\ProgramData\Hexagon\PC-DMIS\2026.2

layout#.dat

These files store information about a specific layout stored on the **Window Layouts** toolbar. There is one file for each stored layout, similar to the gbarstate.dat file. PC-DMIS automatically increments "#" for each new layout.

You cannot edit these files in a text editor.

If you delete a specific layout#.dat file, PC-DMIS removes the related layout button from the **Window Layouts** toolbar.

For more information, see "Window Layouts Toolbar" in the "Using Toolbars" chapter.

File location: C:\Users\<*user name*>\AppData\Local\Hexagon\PC-DMIS\2026.2

layouttoolbar.dat

This file contains a list of layouts when you use the **Window Layouts** toolbar to save a layout.

You cannot edit this file in a text editor.

If you delete this file, PC-DMIS removes your layouts from the **Window Layouts** toolbar.

File location: C:\Users\<*user name*>\AppData\Local\Hexagon\PC-DMIS\2026.2

LIGHTINGMATERIALS.DAT

This file defines the relative path to the default system-defined lighting and materials settings in default.txt. This appears as DEFAULT on the **Archive** tab in the **CAD and Graphic Setup** dialog box (**Edit | Graphic Display Window | Lighting, Materials**). Note that default.txt is not human readable.

The comments at the beginning of this file explain the file's format. In the file, the characters "L", "M", and "U" specify the list in which each item appears ("L" for Lighting, "M" for Material, and "U" for User Recall).

You can edit this file in a text editor.

DO NOT DELETE THIS FILE. If you delete this file, it causes the **CAD and Graphic Setup** dialog box to not know anything about the lighting or material files. You would then need to manually recreate the file or reinstall PC-DMIS.

File location: In the directory where you installed PC-DMIS.

logo.dat *

This file controls the format of the Edit window's header on the first page.

You can edit this file in a text editor.

DO NOT DELETE THIS FILE. If you delete this file, PC-DMIS erases the header from the first page of the Edit window.

For more information, see "Modifying the Edit Window's Headers and Footers" in the "Using the Edit Window" chapter.

File location: In the directory where you installed PC-DMIS.

MACHINE.DAT *

This file defines virtual machine definitions. Virtual machines are animated in the Graphic Display window as a representation of the real machine.

DO NOT DELETE THIS FILE. Instead, use the usermachine.dat file to customize MACHINE.DAT entries.

DO NOT DELETE THIS FILE. If you delete this file, the machine models become unavailable.

File location: In the directory where you installed PC-DMIS.

menu_<language>.dat

This file stores customized menus for the user. In the file name, <language> is the three-letter language code for the language you use to display PC-DMIS.

You cannot edit this file in a text editor.

If you delete this file, PC-DMIS removes any customized menus.

File location: C:\Users\<*user name*>\AppData\Local\Hexagon\PC-DMIS\2026.2

MessageBoxOptions.dat

This file stores a list of the warning messages that you have turned off.

You cannot edit this file in a text editor.

If you delete this file, all warning messages reappear.

File location: In the directory where you installed PC-DMIS.

PROBE.DAT *

This file defines the components that are available in PC-DMIS when you use the **Probe Utilities** dialog box (**Insert | Hardware Definition | Probe**) to create a probe assembly.

DO NOT DELETE THIS FILE. Instead, use the usrprobe.dat file to create or display customized probe hardware.

DO NOT DELETE THIS FILE. If you delete this file, those components become unavailable.

File location: In the directory where you installed PC-DMIS.

PROBECHANGER.DAT

This file defines virtual probe changer definitions. Virtual probe changers are animated in the Graphic Display window and appear within the volume space for collision detection. It is a representation of the actual probe changer.

DO NOT DELETE THIS FILE. Use the tools that PC-DMIS provides to define your animated probe changer.

DO NOT DELETE THIS FILE. If you delete this file, the probe changer models are unavailable.

File location: In the directory where you installed PC-DMIS.

QUICKFIX.DAT *

This file displays all of the quick fixture items that are available to add into the Graphic Display window.

You can edit this file in a text editor.

DO NOT DELETE THIS FILE. If you delete this file, PC-DMIS erases the library of quick-fixture items that are available, which makes it impossible to work with these files.

File location: In the directory where you installed PC-DMIS.

ReportingToolbar.dat

This file contains a list of the saved report templates and custom reports on the **Reporting** toolbar.

You cannot edit this file in a text editor.

If you delete this file, PC-DMIS removes any saved items from the **Reporting** toolbar.

File location: In the directory where you installed PC-DMIS.

TablesOnly.dat

This file defines the available virtual tables. It contains a list of tables and defines each table's width, length, and height, separated by commas. The values are in millimeters.

You can edit this file in a text editor.

To edit this value and show the virtual table, see "Defining Machines" in the "Defining Hardware" chapter.

File location: C:\ProgramData\Hexagon\PC-DMIS\2026.2

TemplRepPickerList.dat

This file contains a list of the report templates that you added to the **Report Templates** dialog box. To open the dialog box, click the **Template Selection** icon on the **Report** toolbar in the Report window (**View | Report Window**).

You can edit this file in a text editor.

If you delete this file, PC-DMIS removes those templates from the **Report Templates** dialog box, but it does not delete the actual report templates.

File location: In the directory where you installed PC-DMIS.

tool.dat

This file defines the required calibration artifacts when you want to calibrate a probe.

You cannot edit this file in a text editor.

File location: C:\ProgramData\Hexagon\PC-DMIS\2026.2

toolbar.dat

This file contains all of the customized toolbars definitions (buttons) and names. PC-DMIS creates this file when you customize or create any toolbars.

You cannot edit this file in a text editor.

If you delete this file, PC-DMIS removes any customized toolbars.

File location: C:\Users\<*user name*>\AppData\Local\Hexagon\PC-DMIS\2026.2

UserLightingMaterials.dat *

PC-DMIS automatically creates this file whenever you use the **Archive** tab in the **CAD and Graphic Setup** dialog box (**Edit | Graphic Display Window | Lighting, Materials**) to save a custom user configuration of lighting and material settings. As with the LIGHTINGMATERIALS.DAT file, it defines relative paths to any custom configuration settings files that you saved.

You can edit this file in a text editor.

File location: In the directory where you installed PC-DMIS.

usermachine.dat

This file defines custom animated machines. You can also copy machines (listed as items) from MACHINE.DAT, paste the information into this file, and customize the machines either

directly inside the file or from the **Load Virtual Machine** dialog box (**Insert | Hardware Definition | Machine**). Whenever you access that dialog box later, PC-DMIS reads this file in addition to the MACHINE.DAT file when it displays the available machines.

If you delete this file, PC-DMIS removes any custom machines.

For more information, see "Editing the usermachine.dat Data File" in the "Defining Hardware" chapter.

File location: C:\ProgramData\Hexagon\PC-DMIS\2026.2

usrprobe.dat *

You must manually create this file. You can then copy the probe information from PROBE.DAT, paste it into this file, and customize that information as needed. PC-DMIS then reads both this file and the PROBE.DAT file when it displays probes in the **Probe Utilities** dialog box (**Insert | Hardware Definition | Probe**).

If you delete this file, PC-DMIS removes customized probe information.

File location: C:\ProgramData\Hexagon\PC-DMIS\2026.2

userquickfix.dat

This file defines the custom quick fixtures in the **Available fixtures** list in the **Quick Fixture** dialog box (**Insert | Hardware Definition | Quick Fixture**). You can also copy fixtures (listed as items) from QUICKFIX.DAT and paste the information into this file. You can then customize them directly inside the file, or you can use the **Quick Fixture** dialog box to create new custom fixtures. Whenever you access that dialog box later, PC-DMIS reads this file and the QUICKFIX.DAT file when it displays the available fixtures.

If you delete this file, PC-DMIS removes any custom fixtures.

File location: C:\ProgramData\Hexagon\PC-DMIS\2026.2

Defining Default Environment

You can set a default environment to open PC-DMIS with that environment.

To set a default environment or switch environment, follow these steps:

1. Before you open a measurement routine, from the Home page, select **Edit | Environment Configuration | Switch Environment**. This opens the **PC-DMIS Environment** dialog box.

2. From the **Select an environment** list, select the environment.

3. To set the selected environment as a default environment, click **Set as Default**.

You can set a default environment to always open PC-DMIS with that default environment. To clear the default environment, select the default environment from the **Select an environment** list and then click **Clear Default**.

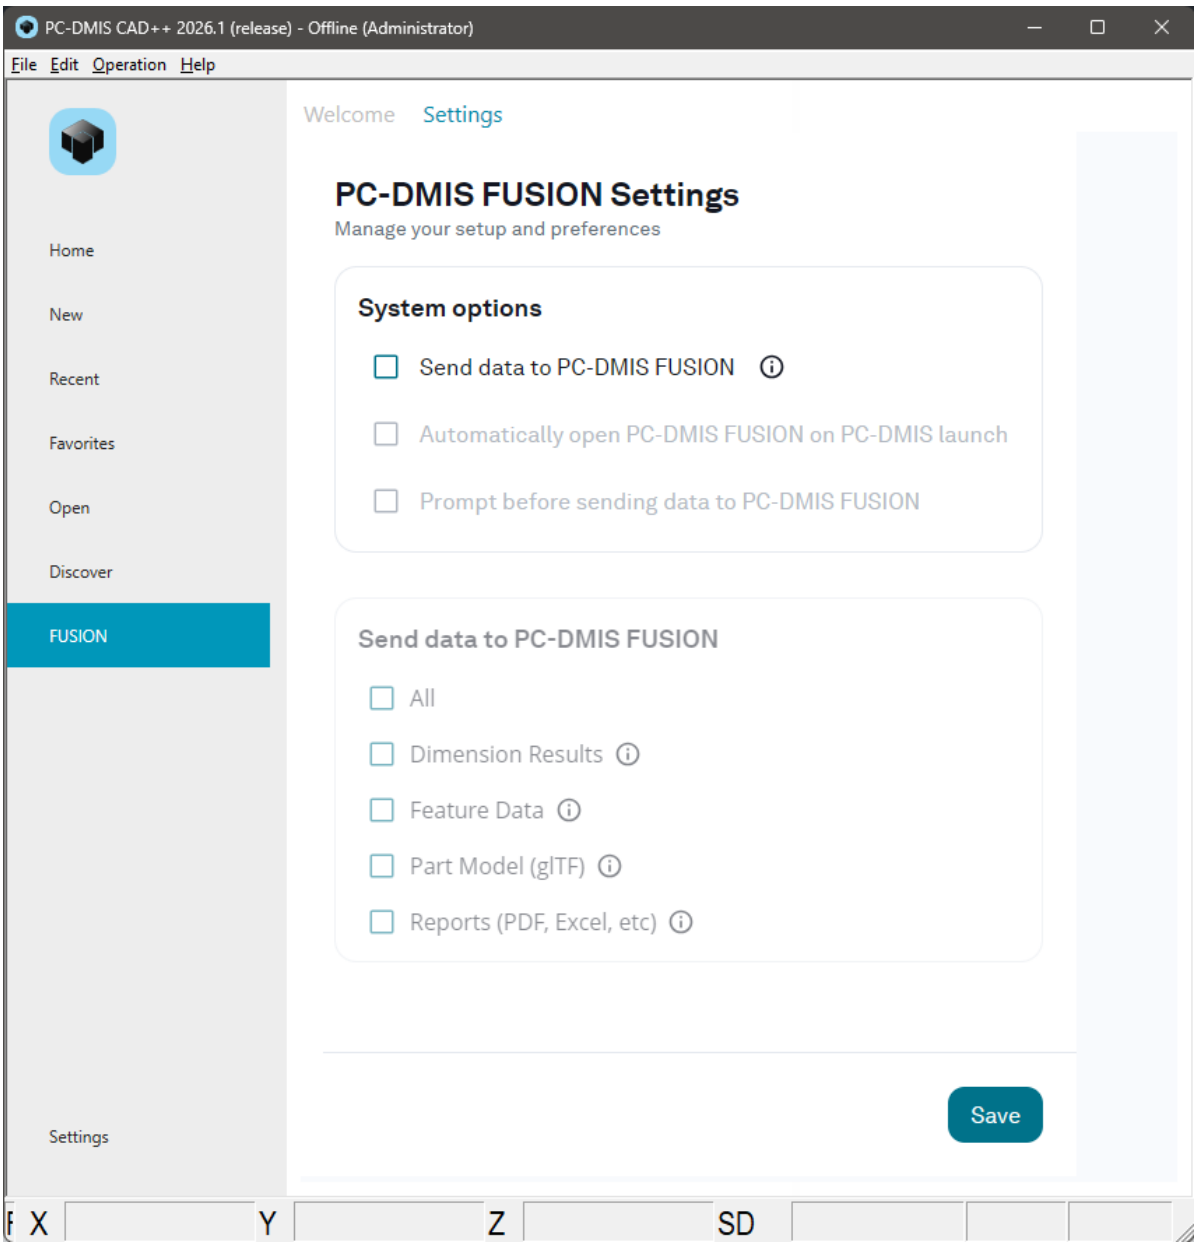
4. Click **Yes** at the prompt to switch environment. The software then restarts with the new environment settings.

You can use the **/envFile** switch to run PC-DMIS with selection of an environment or with the default environment.

If you create a shortcut that includes the name of an environment, PC-DMIS runs with that specific environment (such as **/envFile: Online**).

PC-DMIS FUSION Settings

From the Home page's left pane, when you click on the **FUSION** view and select the **Settings** tab, the **PC-DMIS FUSION Settings** screen appears with these options.



PC-DMIS FUSION Settings

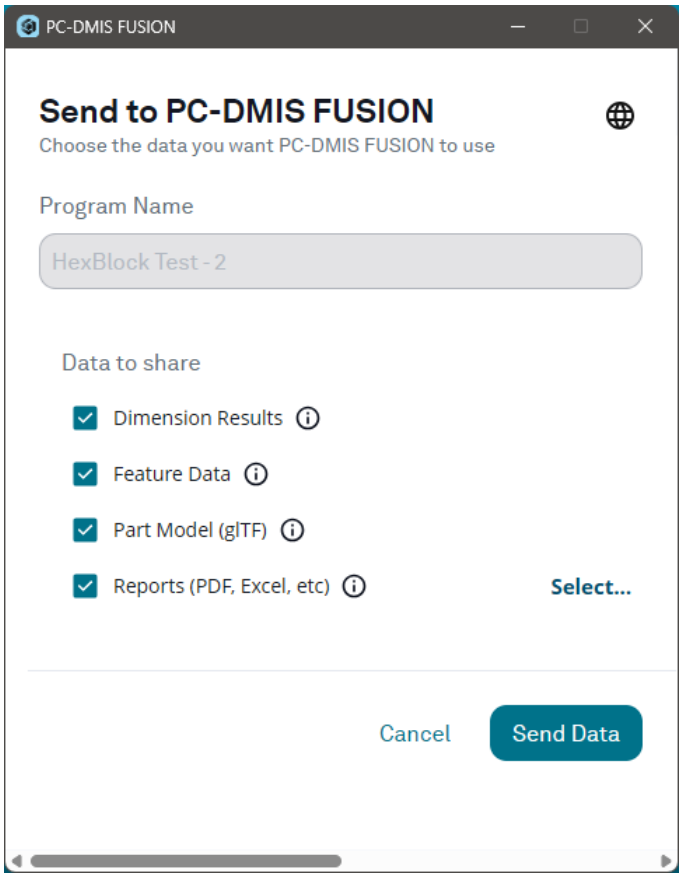
These options determine whether to send data to PC-DMIS FUSION and what data to send. PC-DMIS sends only what you choose to send, and all sent data remains on your computer.

To access the settings on this screen, you must run PC-DMIS as an administrator.

System Options

- **Send data to PC-DMIS FUSION** - This enables the other settings on this screen. The transmission of data occurs after PC-DMIS finishes execution of a measurement routine.

- **Automatically open PC-DMIS FUSION on PC-DMIS launch** - This starts the PC-DMIS FUSION application whenever you start PC-DMIS.
- **Prompt before sending data to PC-DMIS FUSION** - This provides a **Send to PC-DMIS FUSION** dialog box that prompts you to choose what data to send to PC-DMIS FUSION.



Send Data to PC-DMIS FUSION

All - This selects all the check boxes below. For each of these check boxes, you can view the information tooltip for detailed information on what PC-DMIS sends to PC-DMIS FUSION.

Dimension Results - This sends various pieces of dimension data necessary for the Sample Report, Statistics Report, and Insights.

Feature Data - This sends feature data (id, type, and other parameters) necessary for drawing features on the CAD Report.

Part Model (glTF) - This sends a light weight version of your part model. Your native CAD model is not sent.

Reports - This sends any PDF, Excel, or RTF reports that your measurement routine generates to PC-DMIS FUSION. If you have multiple reports generated from your execution, you can click **Select** on the right to send only those reports that you specify.

Editing the CAD Display

Editing the CAD Display: Introduction

PC-DMIS lets you edit the display of the CAD in the Graphic Display window.

The main topics in this chapter describe how to edit the CAD display. These include:

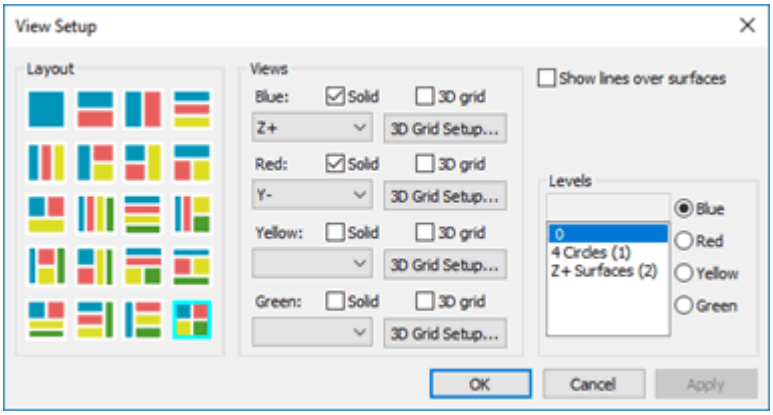
- Setting Up the Screen View
- Setting Up CAD and Graphics
- Working with CAD Levels
- Making CAD 3D by Using the Create Levels Window
- Working with CAD Groups
- Working with CAD Model Views
- Managing and Positioning On-Screen Elements
- Switching Between Curve and Surface Modes
- Drawing Surfaces
- Highlighting CAD Elements
- Displaying Mouse Coordinates in Screen Counter Text
- Repainting the Screen
- Changing Screen Modes
- Changing Screen Colors
- CAD GD&T Tab
- Changing Trihedron Settings
- Scaling the Drawing
- Rotating the Drawing
- Using the Rotation Widget
- Changing Rotation and Other Motion Options

- Showing and Hiding Graphics
- Working with CAD GD&T Callouts
- Working with Assemblies of Parts
- Creating a CAD Section Cut
- Working with a Machine Assembly
- Viewing CAD Information
- Verifying CAD Information
- Using Screen Captures of the Graphic Display Window
- Editing CAD Elements
- Editing CAD Vectors
- Selecting Features Using the Graphic Display Window
- Identifying Features by Using Tooltips
- Automatically Positioning Feature ID Labels
- Editing Dimension Colors
- Editing Feature Appearance
- Showing, Animating, and Moving Path Lines
- Graphical Hit Selection Method
- Deleting CAD Elements
- Deleting Features
- Deleting Dimensions
- Transforming a CAD Model
- Working with CAD Coordinate Systems
- Checking and Fixing Point Nominal Deviation
- Modifying Display Symbols
- Changing CAD Tolerances
- Centering the Probe on the Screen
- Viewing Clearance Planes

Setting Up the Screen View

The **Edit | Graphic Display Window | View Setup** option opens the **View Setup** dialog box. Click the **View Setup** icon from the **Graphic Modes** toolbar to also display this dialog box.

Use the **View Setup** dialog box to specify the number of views (maximum of four) of the part that PC-DMIS displays in the Graphic Display window. You can also determine the orientation of each view and if the particular view appears as a wireframe or a solid.



View Setup Dialog Box

To quickly change how the part appears in the "blue" view, you can click the icons on the **Graphic View** toolbar.

To store your view for later use, you can create and recall the view. See "Working with Viewsets" in the "Inserting Report Commands" chapter.

Changing Layout and Views

To change the screen layout and the orientation of the views, do the following:

1. Open the **View Setup** dialog box (**Edit | Graphic Display Window | View Setup**).
2. From the **Layout** area, select the desired screen style. For example, to split the screen into two different views of the part image, click on button two or three (in the first row). The window splits horizontally or vertically, based on the button you choose.
3. From the list box, select the desired view orientation for each window to display. For example, to view the part image from the Z+ direction, simply select **Z+** from the drop-down list box. If you want to view the same image from the Y- axis, select **Y-**. All

of the display options only affect how PC-DMIS displays the part image. They do not affect the measured data or inspection results.

4. If you want to display your part in the selected view of your part as a solid, select the **Solid** check box. You can leave the check box blank to display the part as a wireframe model.

5. Click either the **Apply** button or the **OK** button.

    - If you click **Apply**, PC-DMIS re-draws the Graphic Display window to reflect the current settings. This lets you preview your changes.

    - If you click **OK**, PC-DMIS closes the **View Setup** dialog box and applies the changes to the Graphic Display window. At any time before you click **OK**, you can click **Cancel** to close the dialog box and revert the views to what they were.

To redefine the sizes of the views in the Graphic Display window:

1. Position the pointer on the line separating the windows. The single arrow cursor changes to a double arrow.

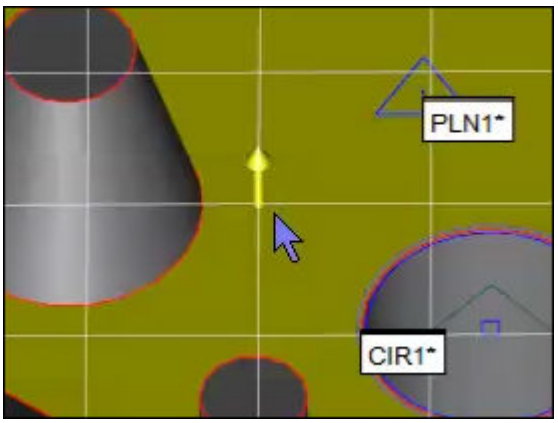
2. Click and drag the pointer to the desired location to change the view size.

This procedure works in either the horizontal or vertical position. You can then select the **Scale to Fit** option to re-scale the drawing so that it fits within the new window. For more information, see "Scaling the Drawing".

The software can be in any mode when you change the view size.

Adding a 3D Grid

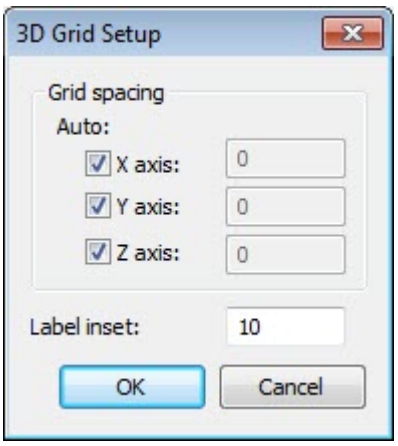
From the **View Setup** dialog box, select a **3D Grid** check box and click **Apply** to turn on the 3D grid for the selected view. The origin of the 3D grid is always located at the part's current alignment. If you enable a grid, and attempt to create a QuickFeature point (Vector, Edge, and Angle), the software snaps the point to the nearest intersection on the grid:



Example showing the Vector Point snapping to an intersection.

For information on creating QuickFeatures, see "Creating QuickFeatures by Hovering over CAD Elements" in the "Creating Auto Features" chapter.

From the **View Setup** dialog box, the **3D Grid Setup** button brings up the **3D Grid Setup** dialog box where you can modify the grid spacing and label inset.

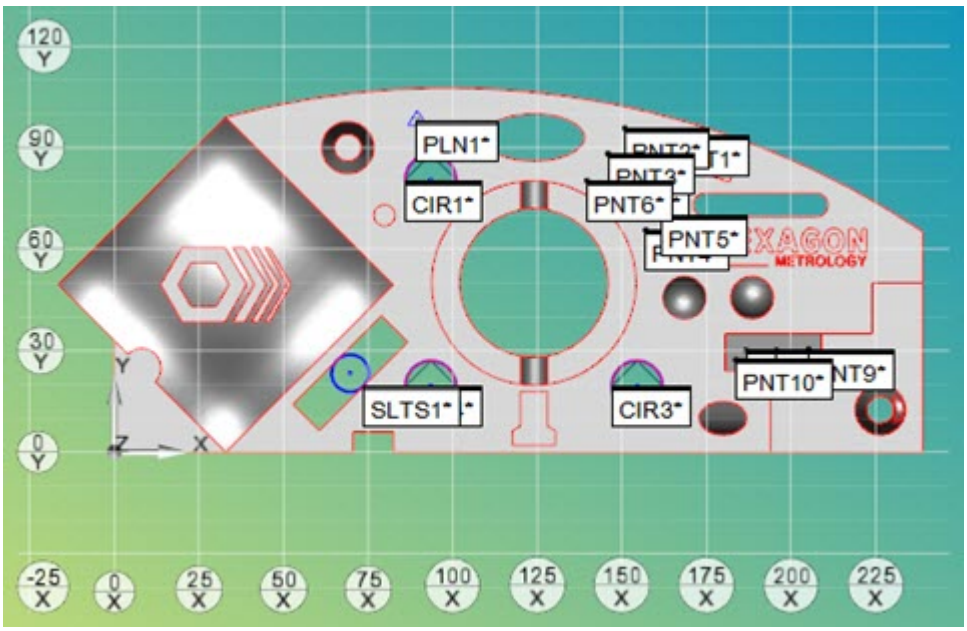


3D Grid Setup Dialog Box

Modify the grid line spacing by typing a value in the **X axis**, **Y axis**, and **Z axis** boxes or mark the **Auto** check box for that axis to have PC-DMIS automatically compute reasonable spacing.

Grid line labels are placed around the outside of the window. These lines follow the current alignment defined in the Edit window. You can move these labels along the lines by changing the value shown in the **Label Inset** box. This value determines the pixel buffer size that PC-DMIS places between the outer edge of the Graphic Display window and the 3D grid labels. You can choose any integer value between 0 and 1000.

Click **OK** to display the 3D grid in the Graphic Display window.



Example showing a 3D grid with a Label Inset of 10 pixels in the X-Y Plane.

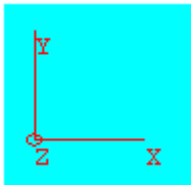
There are three possible grids that can be drawn:

X-Y

Y-Z

Z-X

PC-DMIS draws only one grid at a time. The grid drawn depends on the axis plane rotated closest to your screen (determined by the axis indicator). For example, the following axis indicator from the Graphic Display window shows the X-Y axis plane facing the user; PC-DMIS draws the X-Y axis grid.



Example of the axis indicator showing the X-Y plane.

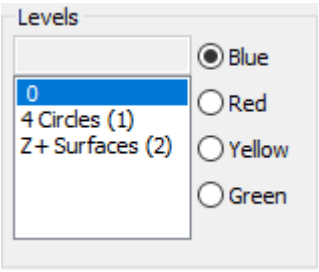
The color of the 3D grid can be modified from the **Screen Color** dialog box. See "Changing Screen Colors".

Showing lines over surfaces

This check box applies to solid view only. Select this check box to cause points and lines that hide behind surfaces to show through. This option is useful for looking at measured features that are behind surfaces. For example, suppose a measured line in your part is

slightly underneath the CAD surface. Selecting this check box will force the measured line to be visible.

Viewing CAD Levels



View Setup Dialog Box - Levels Area

You can view predefined levels of CAD elements in an associated "view" when you click on the level from the list. Then click the **Blue**, **Red**, **Yellow**, or **Green** option button to select the view.

By default, even if you haven't defined a level, PC-DMIS always displays a hidden 0 level. The 0 level is a default level that contains all the CAD elements in the CAD model. To create and work with CAD levels, see the "Working with CAD Levels" topic.

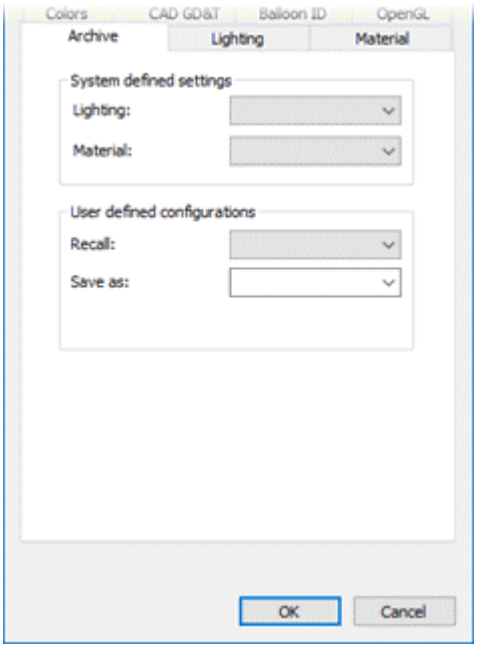
Setting Up CAD and Graphics

The **CAD and Graphic Setup** dialog box gives you a set of tools that allows you to further manipulate the display of CAD models (such as your part model) inside the Graphic Display window. These models include your part model, probe model, machine model, and other fixture models.

You can also use the dialog box to change other properties that affect how things are drawn on the screen.

You can open the dialog box by doing one of the following:

- From the **View | Toolbars | Graphic Modes** toolbar, click the **CAD Lighting** icon .
- From the **Edit** menu, point to **Graphic Display Window**, and choose **Lighting, Materials**.



CAD and Graphic Setup Dialog Box

This dialog box contains these tabs:

Archive - This tab saves and recall these CAD configurations for later use.

Lighting - This tab defines and enables light sources, their colors, their directions, light models, and CAD transparency.

Material - This tab applies texture mapping to the surfaces of your CAD models. You can also change the colors and brightness of the materials making up the textures.

Clip Planes - This tab defines up to four Clipping Planes that hide your part model in the clipped area. You can use this feature to cut your part model to show cross sections and cutaway views.

Trihedron - This tab modifies the main alignment trihedron's size as well as the color of each axis and component of the trihedron symbol.

Symbols - This tab sets the properties for the display of the following:

- Wireframe and surface objects
- Point symbols
- Path lines

Wireframe - This tab defines the color and width of surface edges.

Colors - This tab defines the colors for the following:

- The screen's background color
- The highlight color
- The mouse-over highlight color

- The 3D grid color
- The Vision's Field of View (FOV) color.

CAD GD&T - This tab defines the colors and other options for CAD GD&T callouts.

Pan, Zoom, Rotate - This tab defines how PC-DMIS interprets mouse gestures for pan, zoom, and rotate in the Graphics Display window.

Balloon ID - This tab uses a Microsoft Excel file to map characteristic IDs to balloon numbers.

OpenGL - This tab defines the OpenGL options that affect the display of the model in solid view mode.

These four buttons are at the bottom of the dialog box:

OK - Accepts your changes and closes the dialog box.

Cancel - Rejects your changes and closes the dialog box.

Save System Defaults - Saves your changes as the new default lighting and material settings. This overwrites the default settings that came with PC-DMIS.

Restore System Defaults - This brings back the original lighting and material settings that came with PC-DMIS.

Any modifications you make to the **CAD and Graphic Setup** dialog box take place in real time in the Graphic Display window. This lets you immediately see the effects of your selected changes. Until you click **OK**, however, the changes you make are only temporary.

Settings to appropriately display CAD models

PC-DMIS renders CAD models best when the CAD geometry, including the surface features, is set to transparent. This is accomplished by selecting the **Enable transparency** check box on the **Lighting** tab of the **CAD and Graphics Setup** dialog box.

If the transparent CAD model needs to be more visible, lower the transparency:

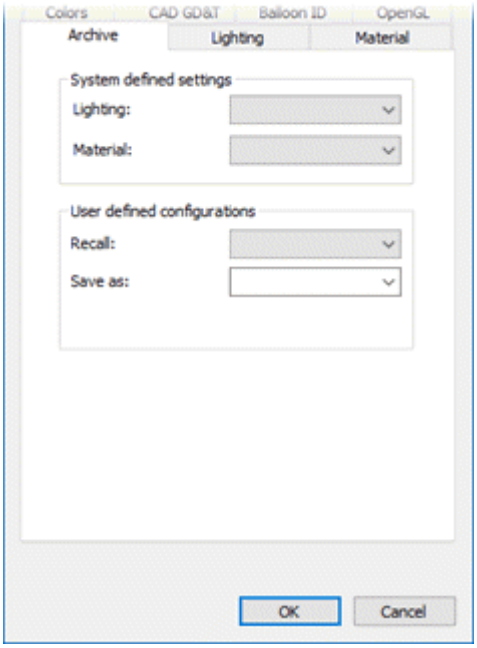
1. Access the **CAD and Graphic Setup** dialog box (**Edit | Graphic Display Window | Lighting, Materials**).
2. From the **Lighting** tab, set the **Transparency** slider to a lower value, such as 50%.

To produce a better and more accurate rendering of your model:

1. From the **CAD and Graphic Setup** dialog box, click the **OpenGL** tab.
2. From the **OpenGL** tab, select the **High quality transparency** check box.
3. From the **Lighting** tab, select the **Single layer** check box.

4. Set the **Transparency** slider as needed, such as 70%.

Archive Tab



CAD and Graphic Setup Dialog Box - Archive Tab

The **Archive** tab of the **CAD and Graphic Setup** dialog box contains two areas, the **System defined settings** area and the **User defined configurations** area.

The **System defined settings** area lets you select from system defined lighting and material settings. These are stored in a configuration file named LightingMaterials.dat in the directory where you installed PC-DMIS.

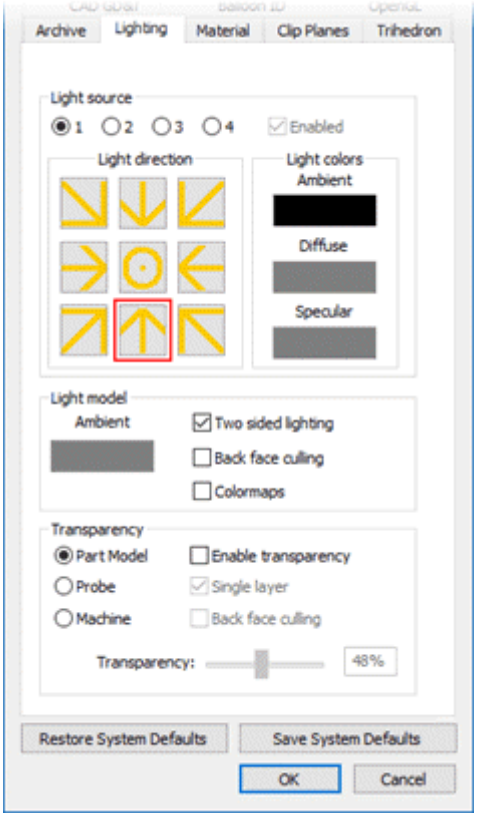
The **User defined configurations** area lets you save and recall your own custom lighting and materials configurations. The software stores them in the default.txt file located in the \Models\LightingMaterials sub directory where you installed PC-DMIS.

To save a custom defined configuration:

1. Make any changes you want in the other tabs of the **CAD and Graphic Setup** dialog box.
2. Click in the **Save as** box. A **Save Now** button appears.
3. Type a name for your saved configuration.
4. Click the **Save Now** button.

To recall a user-defined configuration, select the saved configuration from the **Recall** list.

Lighting Tab

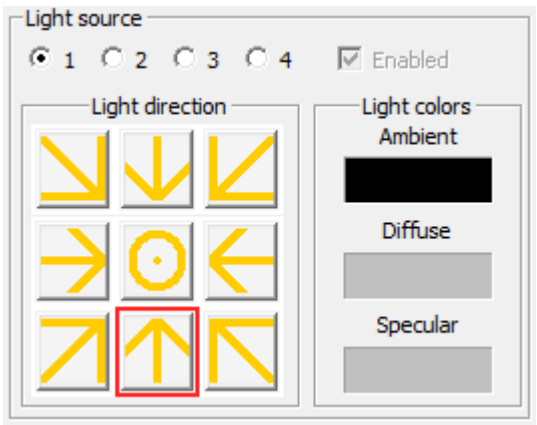


CAD and Graphic Setup Dialog Box - Lighting Tab

The **Lighting** tab of the **CAD and Graphic Setup** dialog box consists of three areas that allow you to define your light sources, your light model, and transparencies.

Light source:

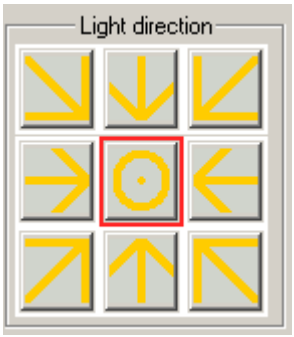
The **Light source** area defines up to four light sources, each specifying a light direction and color. You can click the **Enabled** check box and select the appropriate number to create a new light source.



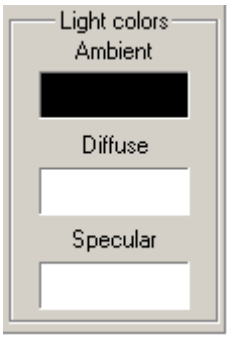
Lighting Tab - Light source Area

With the exception of the first light source, which remains always enabled, the **Enabled** check box lets you turn on or off the current light source.

Once you enable a light source, an active **Light direction** button becomes selected with a red outline. These buttons define the direction from which the light originates.



The center light direction button acts as if the light comes from the direction you are located as if shining through your computer screen onto the CAD part. The other direction buttons define light coming from other angles.



The **Light colors** section lets you change the **Ambient**, **Diffuse**, or **Specular** color for the current light source. To change the color, perform the following steps:

1. Click on the colored rectangle beneath each type of light. This action opens the **Color** dialog box.

2. From the **Color** dialog box, select the color.

Light source **1** has gray as the default color for **Diffuse** and **Specular**, while the other three light sources use black as the default color.

Ambient illumination is light that has been scattered so much by the environment that its direction is impossible to determine - this light seems to come from all directions. Backlight in a room has a large ambient component, since most of the light that reaches your eye has bounced off many surfaces. A spotlight outdoors has a tiny ambient component; most of the light travels is the same direction, and since you are outdoors, very little of the light reaches your eye after bouncing off other objects. When ambient light strikes a surface, it is scattered equally in all directions.

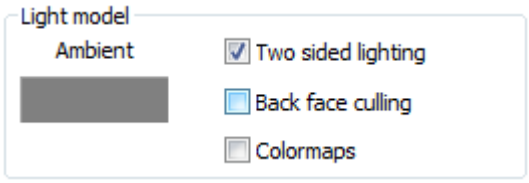
Diffuse light comes from one direction, so it is brighter if it comes squarely down on a surface than if it barely glances off the surface. Once it hits a surface, however, it is scattered equally in all directions, so it appears equally bright, no matter where the eye is

located. Any light coming from a particular position or direction probably has a diffuse component.

Specular light comes from a particular direction, and it tends to bounce off the surface in a preferred direction. A laser beam bouncing off a mirror produces almost 100 percent specular reflection. Shiny metal or plastic has a high specular component, and chalk or carpet has almost none. You can think of specular light as "shininess".

If you disable a light source, the **Light direction** and **Light colors** features become unavailable for selection.

Light model:



Lighting Tab - Light model Area

The **Light Model** area defines information applied to the entire scene, regardless of the light source.

Two sided lighting - This check box determines whether or not the front and back faces of surfaces should be lighted. You should select this check box for imported IGES files and for some other CAD formats when the surface normals are not correct.

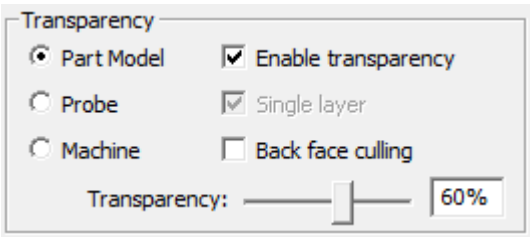
Back face culling - This check box determines whether or not PC-DMIS should cull, or hide, the back faces of surfaces. You should select this check box for IGES files, and some other CAD formats when the surface normals are not correct.

Colormaps - This check box determines whether or not PC-DMIS applies the lighting properties on the **Lighting** tab to colormaps.

- if you mark this check box, the software applies the lighting properties to colormaps whenever it renders the CAD model.
- If you clear this check box, the software does not apply the lighting properties; the colormap colors have a flat appearance, but the colormap colors exactly match the color scale that the colormap uses.

Ambient – This box defines the ambient color applied to the entire scene. Click on the box to change colors.

Transparency:



Lighting Tab - Transparency Area

Working with simulated probes or machines on your screen can be difficult if they block your sight to your part model. To reduce this problem, the **Transparency** area lets you make certain objects transparent inside the Graphic Display window. In this way, you can see your part model or other CAD objects even if your probe or machine is in the way.

You can make these objects transparent inside the Graphic Display window:

- Part model
- Probe
- Machine

You can also turn on or off the part model's transparency with the **Part Model Transparency** icon ( ) on the**Graphic View** toolbar.

Once you have enabled transparency for a simulated machine, you can then select features and other items on your part with a click on your part model *through the transparent machine*.

Once you select the **Enable transparency** check box, you can select the other items in the **Transparency** area. When you enable transparency for an object, the other settings in this area control how the transparency is to be shown.

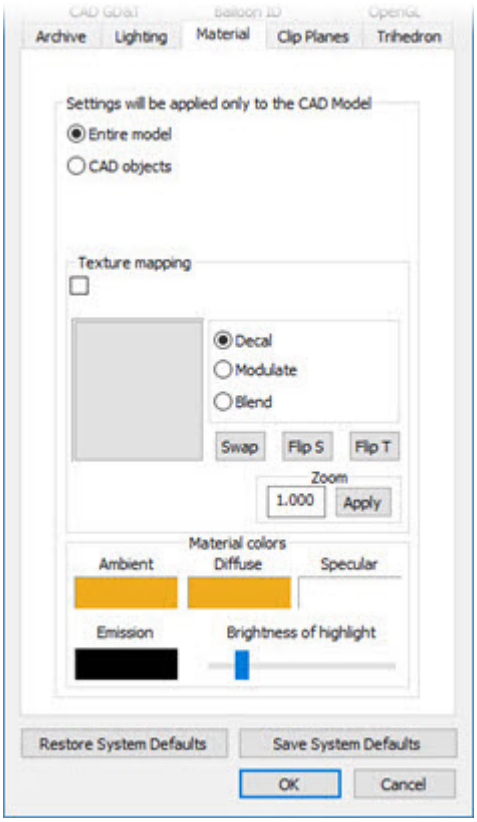
Single layer - This check box is only enabled when the **High quality transparency** check box from the **OpenGL** tab is enabled and checked. If you select the **Single layer** check box, only the top-most transparent surface of the selected model (CAD Model, Probe, or Machine) is rendered. In effect, this check box hides the internal features of a transparent model even though other models can still be viewed through the transparent model. Note that rendering is faster when this option is selected.

Back face culling - This check box causes PC-DMIS to not draw the back faces of surfaces for the selected transparent object.

Transparency - This slider lets you determine the percentage of transparency for the selected object. Moving the slider to the left makes the display object more opaque, while moving the slider to the right makes it more transparent. The value (0 - 100) can also be updated in the **Transparency** box to the right of the slider.

Material Tab

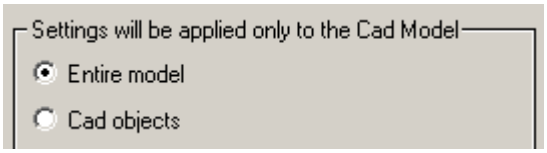
From the **Edit** menu, point to **Graphic Display Window**, choose **Lighting, Materials** and select the **Material** tab.



CAD and Graphic Setup Dialog Box - Material Tab

The **Material** tab of the **CAD and Graphic Setup** dialog box consists of settings that you can apply to CAD objects that make up the imported CAD part model or the entire part model altogether.

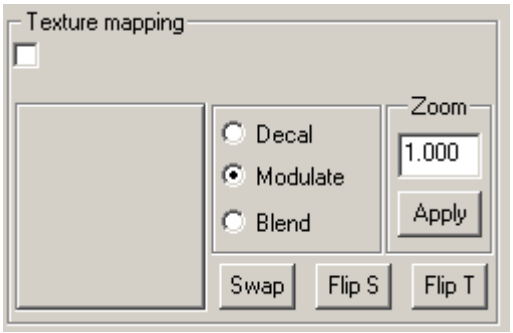
The first area of this tab contains two option buttons that allow you to determine the "active selection", either **Entire model** or **CAD objects**.



Entire model – This option applies the settings to the entire CAD model.

CAD objects – This option applies the settings to specific selected CAD objects that make up the entire model.

Texture mapping



The **Texture mapping** area defines the texture that you want to apply to the active selection. PC-DMIS automatically applies the texture image as often as necessary to cover the entire active selection.

The check box displays the current bitmap name once you select a bitmap file to use for the texture. This check box is always selected when the active selection is a CAD object.

The large gray square area under the check box displays the current texture.

To apply a texture to your part:

1. Click the gray square area to open the standard **Open** dialog box.
2. You can use the **Open** dialog box to navigate and select a valid bitmap file. A bitmap file must have a width and height of 2 to some power. For example, 2 to the 5th power is 32 and 2 to the 4th power is 16. So, if your bitmap is 32 X 16 pixels, it would be a valid bitmap. If you had something like 32 X 20, PC-DMIS would display an error message.
3. PC-DMIS displays a preview of the selected texture inside the gray square area.
4. Click **Open** to accept the texture.

To apply the check box to the active selection, click the **Enable** check box as needed.

The other items in the **Texture Mapping** area determine how PC-DMIS should apply the texture and surface colors:

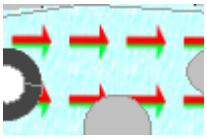
Decal prevents any of the surface's color from being emitted, so you can only see the texture's color.

Modulate and **Blend** use OpenGL algorithms to determine the final display colors.

Zoom controls the "zoom" factor applied to the current texture. Values greater than 1.0 zoom *into* the texture, repeating the texture less often. Values less than 1.0 zoom *out of* the texture, repeating the texture more often. For example, a value of 2.0 makes the bitmap twice the size (repeat half as often), and a value of 0.5 makes the bitmap half the size (repeat twice as often).

The buttons **Flip T**, **Flip S**, and **Swap** determine the orientation of the texture. The texture is a two dimensional image, the orientation is described in terms of **S** and **T**. In the images below, a custom texture with an arrow drawn atop helps to visualize what happens:

The original texture looks like this, an arrow pointing to the right with the top half of the arrow red and the bottom half of the arrow green:



Click **Swap** on the original to switch the orientation so that **S** becomes **T** and **T** becomes **S**. This causes the arrow to point up but to also flip the bottom and top of the arrow:

 (Swap example)

Click **Flip S** on the original to change the direction of **S**. This causes the arrow to point to the left:

 (Flip S example)

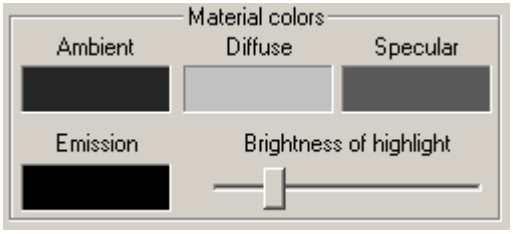
Click **Flip T** on the original to change the direction of **T**. This causes the arrow to flip, making the bottom and top switch places:

 (Flip T example)

You can click these buttons in different combinations to get a variety of orientations for your texture.

Click **Apply** to see any changes you made to texture orientations or other material colors.

Material colors



The **Material colors** area defines the color information that you want to apply to the entire CAD model.

The **Ambient**, **Diffuse**, and **Specular** function similarly to those already explained in the **Light Colors** area of the **Lighting** tab. See "Lighting Tab".

Emission - Materials may have an emissive color, which simulates light originating from an object. In the OpenGL lighting model, the emissive color of a surface adds intensity to the object, but is unaffected by any light sources. Also, the emissive color does not introduce any additional light into the overall scene.

Brightness of highlight - This slider controls the intensity of the highlight when looking at a curved surface.

Applying Textures to the Entire CAD Model

1. From the **Edit** menu, point to **Graphic Display Window**, and choose **Lighting, Materials**.

2. Click on the **Material** tab.
3. Select the **Entire model** option.
4. Under **Texture mapping**, select the gray square area. An **Open** dialog box appears.
5. Select a valid bitmap file.
6. Click **Open**. The texture appears in the dialog box.
7. Click the check box for the bitmaps in the **Texture mapping** area. The texture covers the entire CAD model.
8. Perform additional customization on the texture as needed from the other options on the dialog box.
9. Click **OK** to accept the finished texture.

Applying Textures to Selected CAD Objects

1. From the **Edit** menu, point to **Graphic Display Window**, and choose **Lighting, Materials**.
2. Click on the **Material** tab.
3. Select the **CAD objects** option. An empty list appears along with a **Clear** and a **Remove** button.
4. Under **Texture mapping**, select the gray square area. An **Open** dialog box appears.
5. Select a valid bitmap file.
6. Click **Open**. The texture appears in the dialog box.
7. Click on surfaces on the CAD model. PC-DMIS applies the surfaces you clicked with the current texture. The previously empty list now shows the individual CAD items that have textures applied to them.

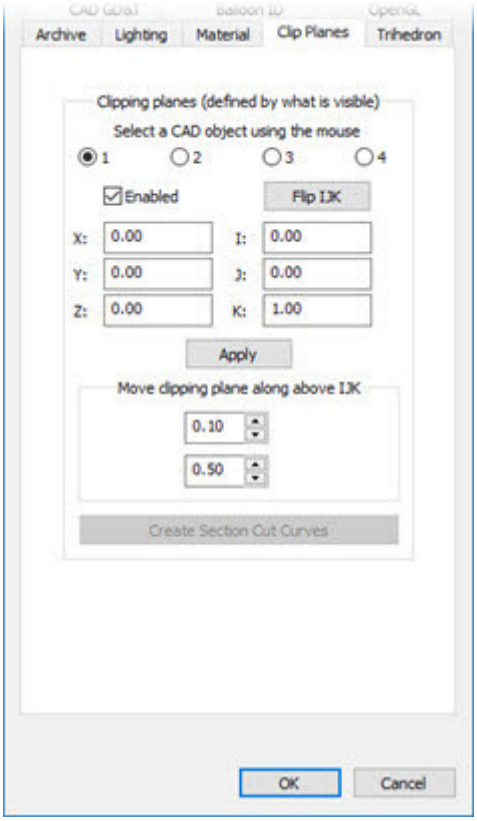
Removing Textures from Selected CAD Objects

1. Select **Edit | Graphic Display Window | Lighting, Materials**.
2. Select the **Material** tab.

   Once you apply a texture to a CAD object, the number representing that CAD object appears in a list.

- To remove textures from all selected CAD objects, click the **Clear** button.
- To remove textures from individual CAD objects, select the objects from the list and click **Remove**.

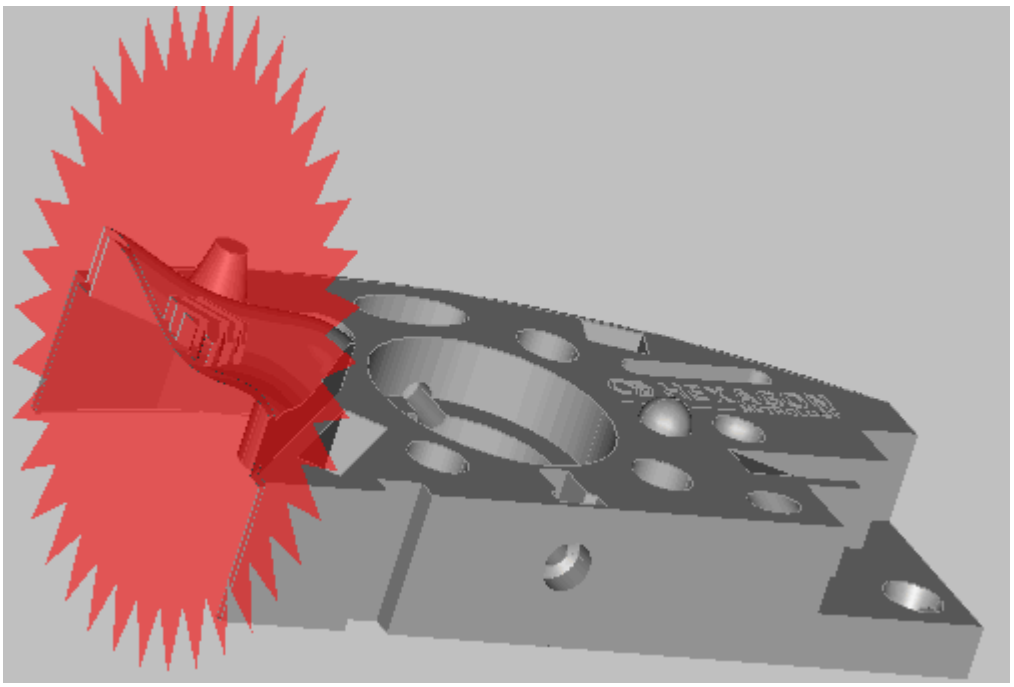
Clip Planes Tab



CAD and Graphic Setup Dialog Box - Clip Planes Tab

The **Clip Planes** tab of the **CAD and Graphic Setup** dialog box allows you to define up to four planes, called "clipping planes" that you can use to hide the display of your part model on one side of the plane. Your part model on the other side of the plane remains visible. These planes allow you to create cross sections of your part model.

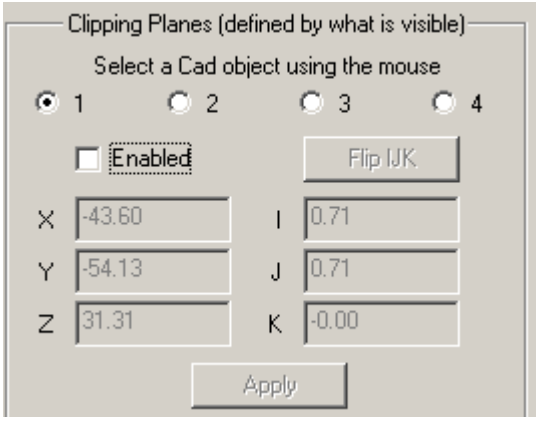
Clipping Planes appear in the Graphic Display window as round saw-like symbols.



Example of a clipping plane creating a cross section of the Hexagon test block

Defining a Clipping Plane

You need only two pieces of information to define your clipping plane: an XYZ location and an IJK vector. The IJK vector points in the direction of what remains visible.



There are two ways to define this information:

- You can click on your part in the Graphic Display window, and PC-DMIS takes the point that you clicked as the clipping plane's location. Once you click a location, PC-DMIS automatically enables your clipping plane and sets the vector to the surface normal at the location. You can then modify the IJK vector as desired.
- You can select the **Enabled** check box and then manually type in the XYZ location and IJK vector.

The XYZ and IJK values are in the active part alignment coordinate system and not the CAD coordinate system.

The **Flip IJK** button flips the vector so that it points in the opposite direction.

Once you have your clipping plane modified to where you want it, click **Apply** to see your changes. PC-DMIS hides all portions of your part model pointing away from your chosen clipping plane vector.

Clearing the **Enabled** check box disables the current clipping plane. Disabled clipping planes have a yellow color. The ability to place and move your clipping plane is also disabled. Enabled clipping planes have a red color.

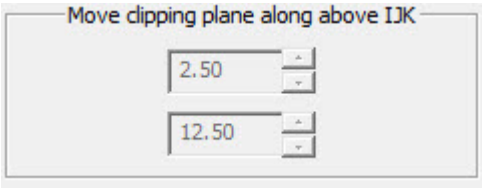
You can define multiple clipping planes by selecting a new clipping plane option button and then following the above instructions.

Adjusting a Clipping Plane

Once you have the clipping plane inserted, you can adjust it by:

- Clicking the **Flip IJK** push button to invert the IJK. This is useful when surface vectors from a CAD selection were incorrect, a relatively common problem with IGES files.
- Manually editing XYZ location and IJK vector information by typing in new values.
- Using the **Move clipping plane along above IJK** area.

The **Move clipping plane along above IJK** area contains two rows of boxes and up and down arrow buttons. The boxes define increments that the clipping plane uses to move along the defined vector when you click the up or down arrow buttons for that box.

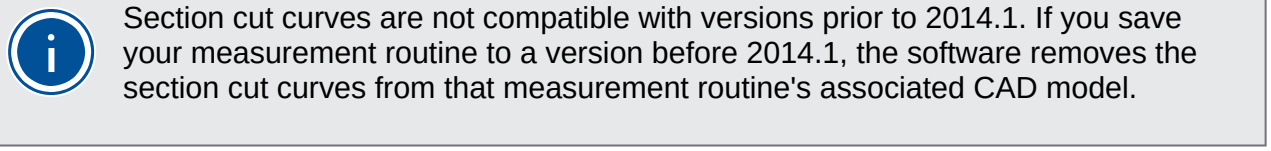


The top row allows you to move the clipping plane along the IJK vector in small adjustments.

The bottom row allows you to also move the clipping plane along the IJK vector, in larger increments.

Creating and Viewing Section Cut Curves

When you create a section cut, PC-DMIS generates a set of curves from where the clipping plane intersects the part. These section cut curves behave like any other curve in the CAD model. You can select and program the section cut curves so that your measurement routine measures them.



Section cut curves are not compatible with versions prior to 2014.1. If you save your measurement routine to a version before 2014.1, the software removes the section cut curves from that measurement routine's associated CAD model.

Creating Section Cut Curves

To create section cut curves (or polyline) from the intersection of the Clip Plane and the CAD:

1. From the **Edit** menu, point to **Graphic Display Window**, and choose **Lighting, Materials**.
2. Click the **Clip Planes** tab.
3. On your CAD model, click a CAD object.
4. From the **Clip Planes** tab of the **CAD and Graphics Setup** dialog box, select the **Enabled** check box to mark it.
5. Adjust the **X**, **Y**, **Z** and **I**, **J**, **K** values as needed.
6. Adjust the values for the **Move clipping plane along above IJK** as needed.
7. Click **Apply** to set the clipping plane and enable the **Create Section Cut Curves** button.
8. Click the **Create Section Cut Curves** button to create the section cut curves.
9. Click **OK** to close the dialog box.

Viewing Section Cut Curves

To view the section cut curve from the assembly tree view of the **CAD Assembly** dialog box:

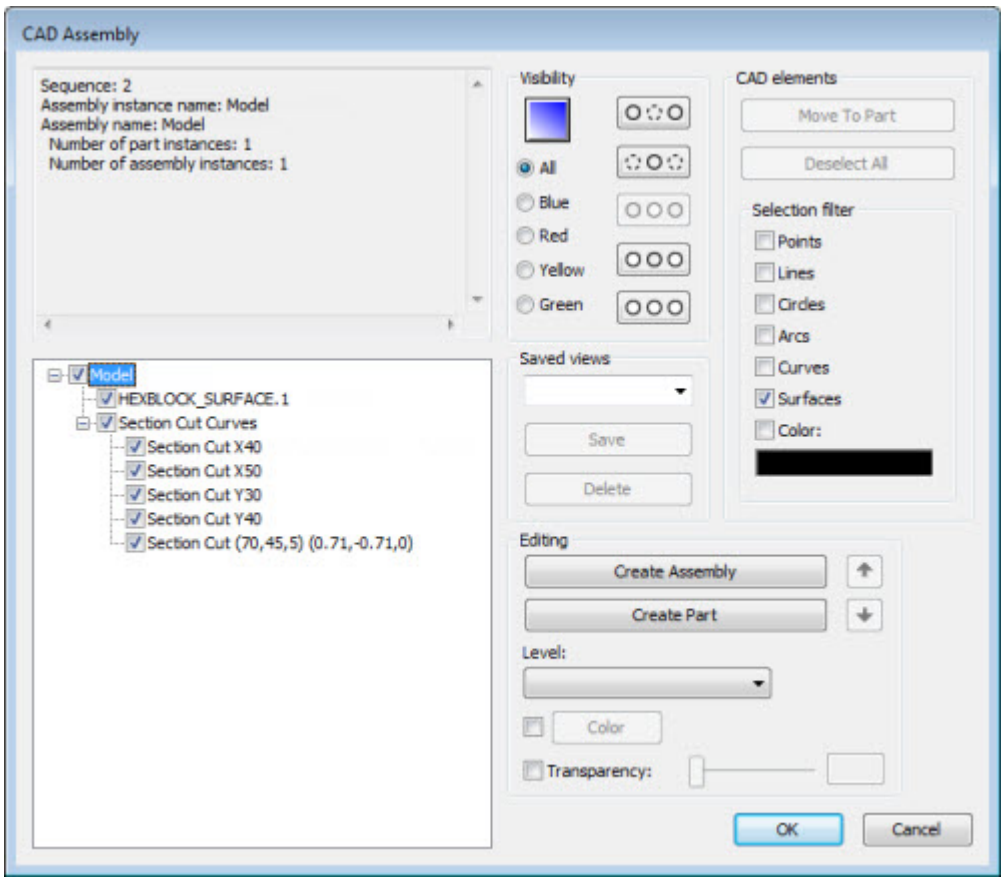
1. From the **Edit** menu, point to **Graphic Display Window**, and choose **CAD Assembly** to open the **CAD Assembly** dialog box.
2. From the assembly tree view, click the plus sign to expand the list of assembly components.
3. At the root of the assembly tree view is an assembly component named "Section Cut Curves". Click the plus sign to expand it and show the section cut curves.

4. The items that begin with "Section Cut" are followed with some descriptive text:

    - If the clipping plane is aligned with a trihedron axis, the descriptive text is that axis's character followed by the position of the plane along that axis. For example, a clipping plane located at X = 20, Y = 10, Z = -4 has an entry of "Section Cut Z-4"

    - If the clipping plane is not aligned with a trihedron axis, the descriptive text contains both the plane point and the vector values. For example, a clipping plane located at X = 80, Y = 40, and Z= -12 and a vector of 0.87, 0.0, 0.50 has an entry of "Section Cut (80,40,-12) (0.87,0,0.50)".

5. Mark or clear the check box next to each section cut to show or hide the curves in the Graphic Display window.



Example of the CAD Assembly dialog box with several created section cut curves

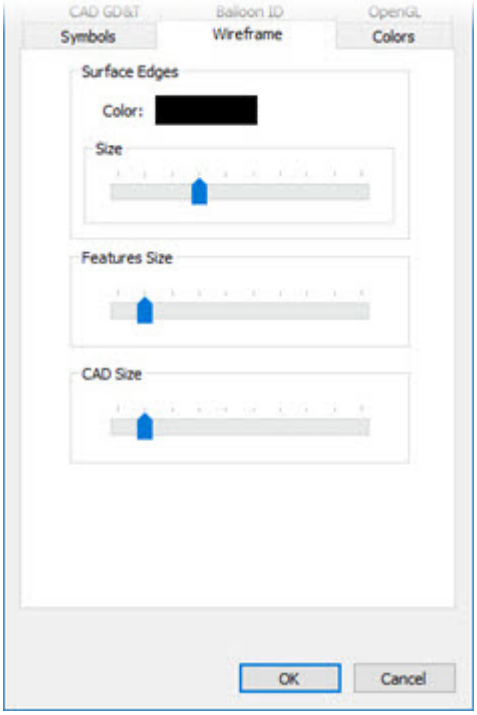
Trihedron Tab

See the "Changing Trihedron Settings" topic.

Symbols Tab

See the "Modifying Display Symbols" topic.

Wireframe Tab



CAD and Graphic Setup dialog box-Wireframe tab

The **Wireframe** tab of the **CAD and Graphic Setup** dialog box controls how to draw wireframe elements in the Graphic Display window.

Surface Edges area

You can have PC-DMIS draw bold lines around edges of surfaces. These lines are called "surface edges".

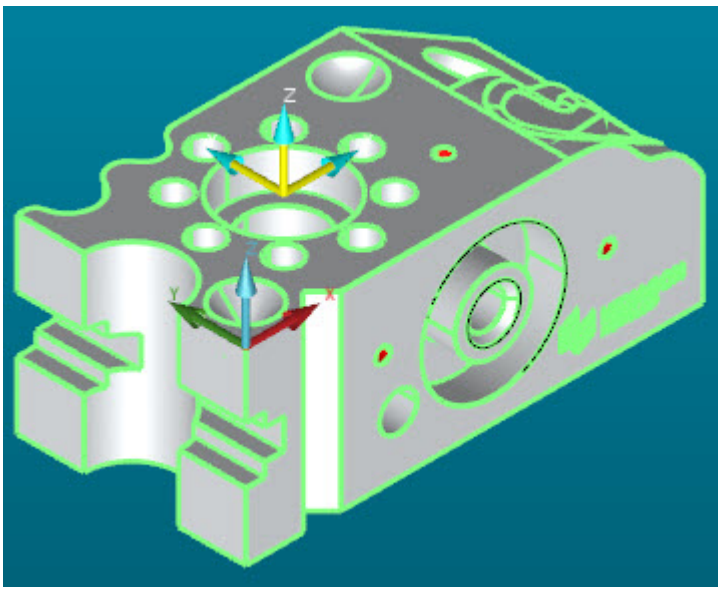
To show or hide the surface edges, from the Graphic View toolbar, click **Surface Edges** ( ).

This area controls how surface edges appear:

Color - This box opens the **Colors** dialog box, so that you can define the color of surface edges.

Size - This slider sets the width of surface edges.

This example shows surface edges with thick green lines, instead of the default black lines:

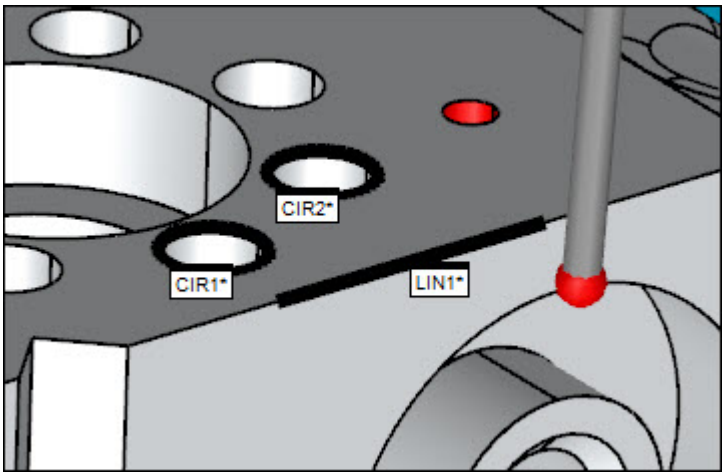


Example of the Color setting set to "Green" and the Size setting set to show thicker surface edges

Features Size area

This area contains a slider which sets the width of features that PC-DMIS draws on top of the CAD model in the Graphic Display window. For example, if you measure a line feature, PC-DMIS draws a line in 3D space at that location on the model.

This example shows two circle features and a line feature at a larger width:



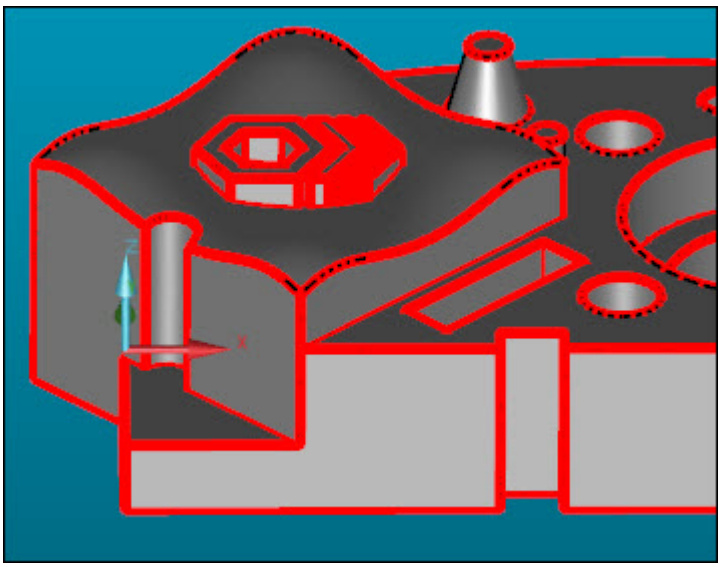
Example of the Figure Size setting set to show thicker feature widths

CAD Size area

This area contains a slider which sets the width of these items:

- CAD curves and CAD surfaces in a wireframe view
- Lines that render embedded CAD GD&T objects

This example shows part of a mixed solid and wireframe CAD model with larger wireframe lines based on this setting. (The CAD model's original format already had a red color for the wireframe lines.)

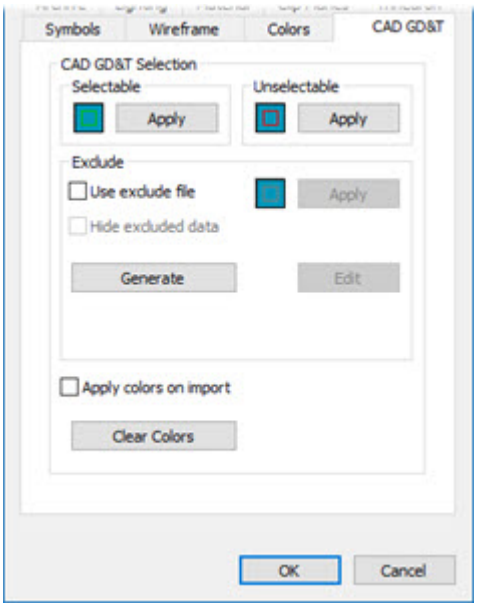


Example of the CAD Size setting that shows thicker wireframe and CAD GD&T object lines

Colors Tab

See the "Changing Screen Colors" topic.

CAD GD&T Tab



CAD and Graphic Setup Dialog Box - CAD GD&T Tab

The **CAD GD&T** tab of the **CAD and Graphic Setup** dialog box configures how CAD GD&T callouts appear in the Graphic Display window.

A CAD model with embedded CAD GD&T callouts typically has all of the dimensional requirements on it. However, some dimensional requirements you cannot measure (or should not measure) on a CMM.

This tab can help you indicate which dimensional requirements you want to include in the measurement routine when someone imports the CAD GD&T callouts as PC-DMIS features and dimensions and other commands. For information on how to work with GD&T callouts, see "Working with CAD GD&T Callouts".

The **CAD GD&T** tab consists of these areas and options:

CAD GD&T Selection area

These options configure the colors the software uses for CAD GD&T callouts in their different states.

- **Selectable** - This option defines the selectable color. These are CAD GD&T callouts that are valid for GD&T selection.
- **Unselectable** - This option defines the color for items that you cannot select. These are CAD GD&T callouts that are automatically invalid for GD&T selection. These include notes, surface finish, material specifications, and so forth.

Exclude area

You can use this area to manually exclude items from GD&T callouts that you could normally select. If you choose to exclude items, the lower part of this area lists the items that you have excluded. Excluded items are items that you have specifically identified as not wanted in the measurement routine. During CAD GD&T selection operations, PC-DMIS excludes those items.

This area also defines an optional exclude color for manually excluded items. You also have the option to hide excluded items entirely.

This area contains the following options:

Use exclude file - This check box tells PC-DMIS to use a .exclude file and exclude items you disabled from selection during CAD GD&T selection operations. These items take on the exclude color when you click **Apply**. The software lists the excluded items in the lower part of the **Exclude** area.

- The exclude file must remain in the same directory as the measurement routine.
- The exclude file's name must have the same name as the measurement routine. For example, if your measurement routine has the name of Circles.prg, the exclude file must have the name of Circles.exclude.

Color box - This opens the standard **Color** dialog box, so you can define the color for excluded items.

Hide excluded data - This check box hides any excluded items.

Generate - This button generates an exclude file from the CAD model. This text file contains all the embedded CAD GD&T callouts in the model. It has a filename of <measurement routine>.exclude, where <measurement routine> is the name of your

current measurement routine. PC-DMIS stores this file in the same directory as your measurement routine.

By default, all the lines in this text file are enabled for selection by a single quote character at the beginning.

A sample line might look something like this:

```
' "24", Diameter Dimension 'PMILW_DIM_hole(24)',
Characteristic ID: 24, Source seq: 2685, Sequence: 907
```

To make a line excluded from CAD GD&T selection, remove the beginning quote character.

Edit - This button opens the .exclude file inside of Notepad.

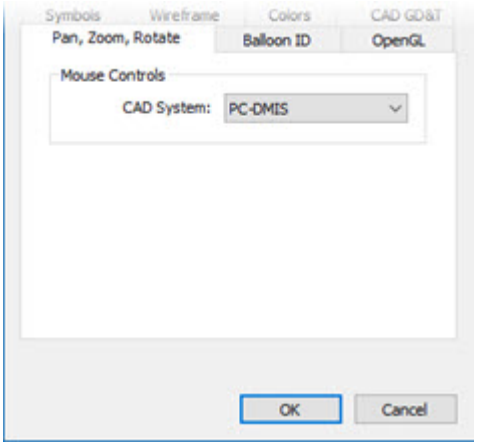
Apply Colors on Import - This check box is for convenience. It tells PC-DMIS to apply the selectable and unselectable colors defined here to the CAD model during import. The colors are applied automatically to the CAD GD&T objects at that time. Also, if you mark the **Use exclude file** check box above, PC-DMIS applies the exclude color to the imported model as well.

Clear Colors - This button resets all colors to their default values.

For information on how to work with the **Color** dialog box, see the "To Change a Color" topic.

Pan, Zoom, Rotate Tab

From the **Edit** menu, point to **Graphic Display Window**, and choose **Lighting, Materials**. Then click the **Pan, Zoom, Rotate** tab.



CAD and Graphic Setup Dialog Box - Pan, Zoom, Rotate Tab

The **Pan, Zoom, Rotate** tab defines how PC-DMIS interprets mouse gestures to perform pan, zoom, and rotate operations in the Graphic Display window.

From the **CAD Systems** list in the **Mouse Controls** area, you can choose the CAD system that PC-DMIS mimics for the pan, zoom, and rotate operations.

Common Controls

These mouse gestures are common to all **CAD System** options:

Left button -

Click to select an item.

Click and hold, then drag to box-select multiple items.

Click and hold, then right-click and hold, then drag to zoom the view to that box.

Mouse Wheel button -

Rotate the wheel forward or backward to zoom in and out.

Right button -

In **Translate Mode** ( ), right-click and hold, then drag to pan.

In **2D Rotate Mode** ( ), right-click and hold, then drag to do a 2D rotation.

In **3D Rotate Mode** ( ), right-click and hold, then drag to do a 3D rotation.

PC-DMIS

If you choose **PC-DMIS**, the software interprets mouse gestures like this:

Mouse Wheel button -

Click the wheel button and hold, then drag to do a 3D rotation.

Right button -

Right-click and hold, then drag to pan the view.

Right-click and hold, press Ctrl, and then drag to do a 3D rotation.

Right-click and hold, press Alt, and then drag to do a 2D rotation.

CATIA 5

If you choose **CATIA v5**, the software interprets mouse gestures like this:

Mouse Wheel button -

Click the wheel button and hold, then drag to pan.

Click the wheel button and hold, press Ctrl, and then drag to zoom in or out.

Click the wheel button and hold, then left-click and hold, then drag to do a 3D rotation.

Click the wheel button and hold, then left-click and release, then drag to zoom in or out.

Creo

If you choose **Creo**, the software interprets mouse gestures like this:

Mouse Wheel button -

Click the wheel button and hold, then drag to do a 3D rotation.

Click the wheel button and hold, press Shift, and then drag to pan.

Click the wheel button and hold, press Ctrl, and then drag left or right to do a 2D rotation.

Click the wheel button and hold, press Ctrl, and then drag up or down to zoom in or out.

NX

If you choose **NX**, the software interprets mouse gestures like this:

Middle button -

Click the wheel button and hold, then drag to do a 3D rotation.

Click the wheel button and hold, press Shift, and then drag to pan.

Click the wheel button and hold, press Ctrl, and then drag to zoom in or out.

SolidWorks

If you choose **Solidworks**, the software interprets mouse gestures like this:

Mouse Wheel button -

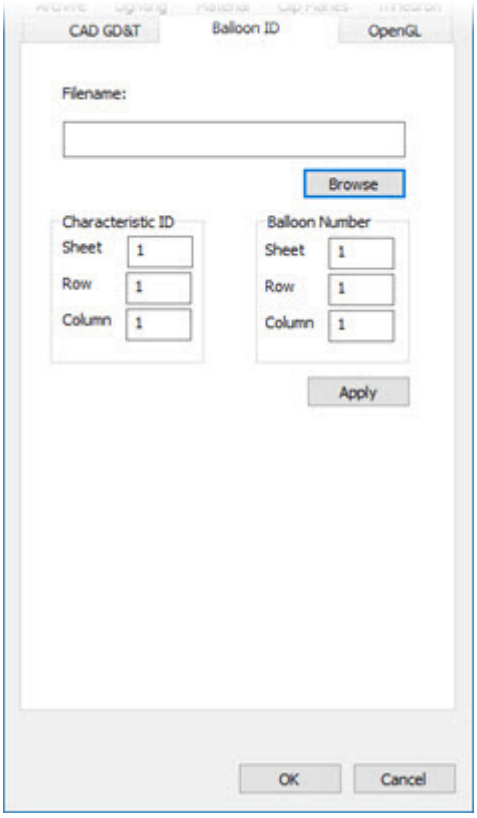
Click the wheel button and hold, then drag to do a 3D rotation.

Click the wheel button and hold, press Alt, and then drag to do a 2D rotation.

Click the wheel button and hold, press Shift, and then drag to zoom in or out.

Click the wheel button and hold, press Ctrl, and then drag to pan.

Balloon ID Tab



CAD and Graphic Setup Dialog Box - Balloon ID Tab

The **Balloon ID** tab uses a Microsoft Excel file to map characteristic IDs to balloon numbers. For information on showing the characteristic IDs, see the "Showing and Hiding CAD GD&T Characteristic IDs" subtopic under the "Working with CAD GD&T Callouts" topic.

You can use an Excel file with any of these file extensions: .xls, .xlsx, .xlsm

How It Works

Once you supply a pathway to an Excel file with data, and click **Apply** or **OK**, PC-DMIS uses an internal Excel reader to read the file.

Once you choose to display characteristic IDs, PC-DMIS reads the Excel file and uses the info on the **Balloon ID** tab to locate the starting characteristic ID.

For each ID in the defined characteristic ID column, PC-DMIS checks if that ID number is in the model.

If so, PC-DMIS looks up the corresponding balloon number and replaces that characteristic ID with the balloon number.

This does not replace the underlying characteristic IDs embedded in the model.

Items on the Tab

Filename - This box defines the full path to the Excel file. You can use the **Browse** button to select the folder.

- If this box contains a pathway to a valid Excel file, PC-DMIS uses the Excel file to determine what balloon number to show for each characteristic ID.
- If this box does not contain a pathway to a valid Excel file or is empty, PC-DMIS shows the default characteristic IDs.

Characteristic ID - This area defines the sheet, row, and column for the first cell in a column of characteristic IDs.

Balloon Number - This area defines the sheet, row, and column for the first cell in a column of balloon numbers.

Suppose you have an Excel file with this information on sheet 1:

	A	B
1	Characteristic ID	Balloon Number
2	20	1B
3	21	15B
4	22	20B
5	24	2B
6	25	3B
7	26	4B
8	27	5B
9	28	6B
10	29	21B

To replace the numbers, you would set these values in the **Characteristic ID** area:

Sheet - 1

Row - 2

Column - 1 (for column A)

And you would set these values in the **Balloon Number** area:

Sheet - 1

Row - 2

Column - 2 (for column B)

When PC-DMIS encounters the characteristic ID of 20 in the model, it would replace it with the balloon number of 1B, and so on.

OpenGL Tab

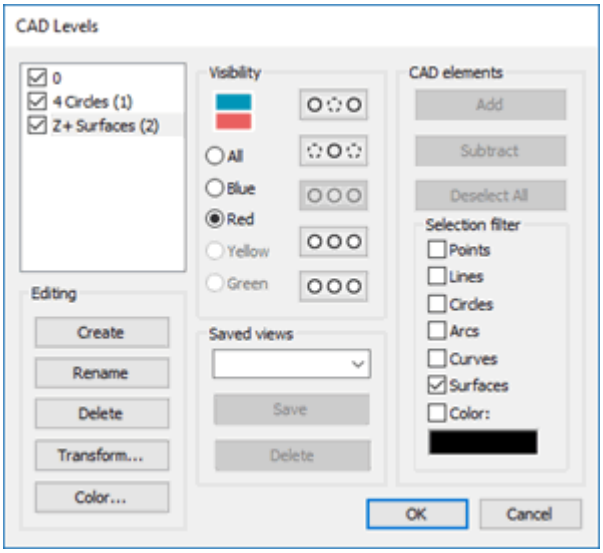
See "Changing OpenGL Options" in the "Setting Your Preferences" chapter.

Working with CAD Levels

A CAD level consists of a group of user-selected CAD geometries or elements selected from the Graphic Display window. The level information is saved with the .CAD file, so that if you import the .CAD into another measurement routine, the level information is available there too.

You can define which levels are displayed in each view of the Graphic Display window by using the **CAD Levels** dialog box (**Edit | Graphic Display Window | CAD Levels**). Once levels are defined, you can view the levels using either the **CAD Levels** dialog box or the **View Setup** dialog box (**Edit | Graphic Display Window | View Setup**).

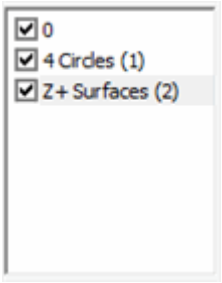
To open the **CAD Levels** dialog box, from the **Graphic Modes** toolbar, click the **CAD Levels** icon , or select **Edit | Graphic Display Window | CAD Levels**. This dialog box lets you define the CAD elements to assign to the levels. You can also use it to modify levels, delete levels, and view levels in the Graphic Display window:



CAD Levels Dialog Box

The dialog box contains these items:

Levels List



The list of levels in the upper-left area of the dialog box shows all the current levels in the CAD model. The list always contains the default level 0, a level that automatically contains all the CAD elements in the CAD file.

Here are some operations you can perform using the levels list:

- Double-click on a level from the list to select all CAD elements assigned to that level.
- Select a CAD element in the Graphic Display window, and press and hold Ctrl on the keyboard to select the corresponding level in the level list.
- Select the check box next to a level to show the selected level.
- Clear the check box to hide the selected level.

Visibility

The **Visibility** area provides option buttons and icon buttons that allow you to run visibility operations in order to change the hidden state of levels.

The colored icon at the top of this area shows your current screen layout. It corresponds with the icon used in the **Layout** area of the **View Setup** dialog box. See "Setting Up the Screen View".

The **Blue**, **Red**, **Yellow**, and **Green** options limit the visibility operation to only that "view" of the Graphic Display window. The **All** option applies the visibility operation to all views.

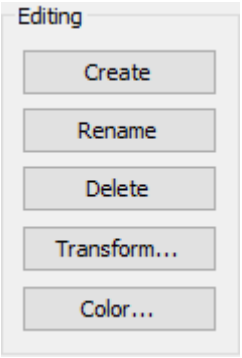
These command buttons have pictures on them that depict their action:

- **Hide** - Hides the level selected in the list.

- **Hide Siblings** - Hides all the levels except the level selected in the list.
- **Show** - Shows the level selected in the list.
- **Show Siblings** - Shows all the levels except the level selected in the list.
- **Show All** - Shows all the levels in the list.

These buttons are unavailable for selection until you select a level from the list of levels.

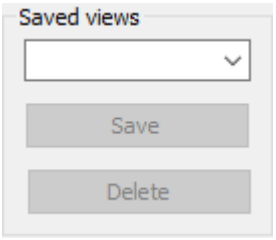
Editing



The **Editing** area allows you to modify CAD levels. For all buttons except **Create**, you need to first select a level from the levels list. The buttons affect that selected level.

- **Create** - Creates a new level in the CAD model. Initially, there are not any CAD elements assigned with this new level. You need to use the **Add** button in the **CAD Elements** section to add CAD elements selected from the Graphic Display window to the new level.
- **Rename** - Renames the selected level. You can also rename a level by clicking on a selected level in the list until the cursor appears.
- **Delete** - Deletes the selected level. PC-DMIS assigns any CAD elements that were on that level to the default level 0. You cannot delete the default level.
- **Transform** - Transforms the selected level. When you click this button, PC-DMIS displays the **CAD Transform** dialog box. See "Transforming a CAD Model" for information on using this dialog box.
- **Color** - Changes the color of all CAD elements in the selected level.

Saved Views

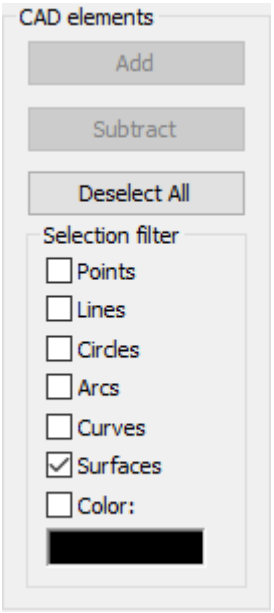


The **Saved Views** area stores the level visibility state in the CAD model. These are saved inside the .CAD file. Use the drop-down combo box to either select and recall a saved view or to specify a name for a new view.

This level visibility state does not include the number of graphics views. The number of graphics views can only be saved using viewsets. See "Working with Viewsets".

- **Save** - Saves the current level visibility state using the name entered in the combo box.
- **Delete** - Deletes the saved view selected in the combo box.

CAD Elements



The **CAD Elements** area modifies the level of the selected CAD elements. You can select (or deselect) CAD elements by simply clicking on or box-selecting them in the Graphic Display window. Selected elements are highlighted.

- **Add** - Adds the selected CAD elements to the selected level in the list.
- **Subtract**- Removes the selected CAD elements from the selected level in the list. The CAD elements are assigned the default level 0, but only if they are on the

selected level. If a selected CAD element is not on the selected level, then that CAD element is not modified.

- **Deselect All** - Clears any selected CAD elements on the Graphic Display window.
- **Selection Filter** - The check boxes in the **Selection Filter** area filter the type of CAD elements assigned to a CAD level. You can also use the **Color** check box in this area to filter your selection by the color of the CAD element. When you select the **Color** check-box, the color of the next CAD element that you select in the Graphic Display window is used as the filter color. For subsequent selections, you can only select CAD elements with that color.

Creating Levels

1. Access the **CAD Levels** dialog box.
2. Click **Create** from the **Editing** area. A new level number appears in the list of levels.
3. Select the new level, and rename it if desired. Even if you rename the level, PC-DMIS still shows the level number in parentheses.
4. Ensure that the CAD level is selected from the list.
5. From the Graphic Display window, select the CAD elements you want included in the CAD level. To limit which CAD element types are selectable, select the check boxes of CAD elements in the **Selection Filter** area.
6. Click the **Add** button. PC-DMIS assigns the selected elements to the selected level. Now when you show that level and hide other levels, PC-DMIS shows only those elements.
7. Click **OK** when finished to close the dialog box.

Modifying Levels

1. Access the **CAD Levels** dialog box.
2. Select the level from the level list.
3. To add elements to the level, select the CAD elements from the Graphic Display window, and click **Add**. PC-DMIS modifies the level accordingly.
4. To remove elements from the level, select the level, and display its assigned CAD elements. From the Graphic Display window, select the elements to remove, and click **Subtract**. PC-DMIS modifies the level accordingly.
5. Click **OK** when finished to close the dialog box.

Deleting Levels

1. Access the **CAD Levels** dialog box.
2. Select a level from the level list.

3. Click **Delete**. PC-DMIS deletes the level and assigns all CAD elements of that level to the 0 level.
4. Click **OK** when finished to close the dialog box.

Showing a Level for a Specific Layout Pane

1. Access the **CAD Levels** dialog box.
2. From list of levels, select the level to use, and ensure that its check box is selected.
3. From the **Visibility** area, select the **Blue**, **Red**, **Yellow**, or **Green** option button for the pane in which you want to view the level.
4. Either deselect the check boxes from other levels in the list of levels, or use the pictured **Hide Siblings** button in the **Visibility** area to hide other levels.
5. Click **OK** when finished to close the dialog box.

You can also view levels within the **View Setup** dialog box.

Making CAD 3D by Using the Create Levels Window

Note that the **Operation | Graphic Display Window | Make 3D** menu option and the associated Create Levels window were removed in PC-DMIS 2009. The functionality to create CAD levels is now contained in the **CAD Levels** dialog box. For more information, see the "Working with CAD Levels" topic.

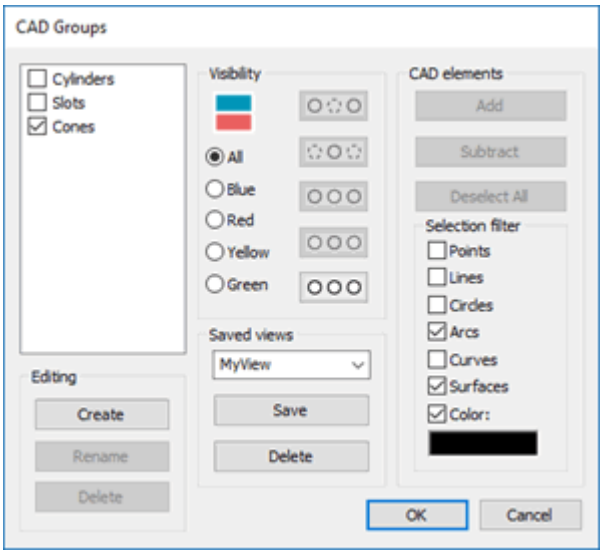
Working with CAD Groups

Similar to a CAD level, a CAD group consists of a group of user-selected CAD geometries called "elements" selected from the Graphic Display window.

However, CAD groups differ from CAD levels in these respects:

- CAD elements can belong to more than one CAD group, and there can be any number of these groups.
- CAD elements in a CAD group can span CAD levels.
- CAD elements in a CAD group can span across multiple assembly components.
- A CAD group's settings apply to all views of the graphical model.

Select **Edit | Graphic Display Window | CAD Groups** or from the **Graphic Modes** toolbar, click the **CAD Groups** button to open the **CAD Groups** dialog box.



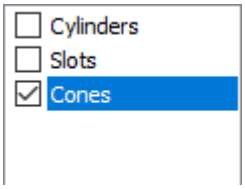
CAD Groups Dialog Box

This dialog box lets you define the CAD elements that are assigned to the groups. You can also use the dialog box to modify groups, delete groups, and view or hide groups in the Graphic Display window.

PC-DMIS saves CAD group information with the .CAD file, so that if you import the .CAD into another measurement routine, the group information is available there too.

The **CAD Groups** dialog box contains these items:

CAD Groups



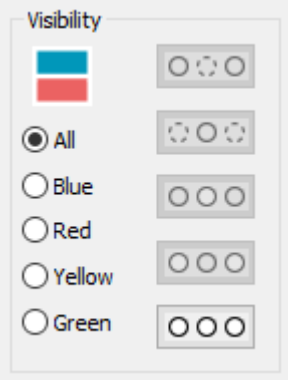
The list of CAD groups in the upper-left area of the dialog box shows all the current CAD groups in the CAD model. Because you can assign CAD elements to more than one group, this list lets you select (highlight) more than one group from the list at a time. So, for example, you could select a surface, then select two groups, and add that surface to both groups.

Here are some operations you can perform using the CAD Groups list:

- Double-click on a group from the list to select all CAD elements assigned to that group.
- Select a CAD element in the Graphic Display window and press and hold Ctrl on the keyboard to select the corresponding group in the group list.

- Mark the check box next to a group to show the CAD elements assigned to it.
- Clear the check box next to a group to hide the CAD elements assigned to it.

Visibility



The **Visibility** area provides option buttons and icon buttons that allow you to run visibility operations in order to change the hidden state of the CAD groups. If a CAD object belongs to more than one group, and at least one of the groups is hidden, that CAD object becomes hidden as well. So, even if the CAD object is visible in another group, it is still hidden.

The colored icon at the top of this area shows your current screen layout. It corresponds with the icon used in the **Layout** area of the **View Setup** dialog box. See "Setting Up the Screen View".

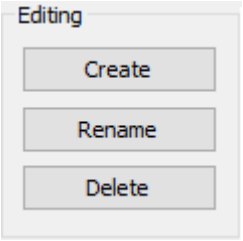
The **Blue**, **Red**, **Yellow**, and **Green** options limit the visibility operation to only that "view" of the Graphic Display window. The **All** option applies the visibility operation to all views.

These command buttons have pictures on them that depict their action:

- **Hide** - Hides the CAD group selected in the list.
- **Hide Siblings** - Hides all the CAD groups except the group selected in the list.
- **Show** - Shows the CAD group selected in the list.
- **Show Siblings** - Shows all the CAD groups except the group selected in the list.
- **Show All** - Shows all the CAD groups in the list.

These buttons have a dark gray background and are unavailable for selection until you select a CAD group from the CAD Groups list.

Editing

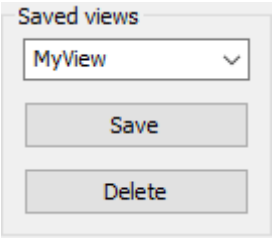


The **Editing** area allows you to modify CAD groups. For all buttons except **Create**, you need to first select at least one group from the CAD Groups list, and the buttons affect the selected group or groups.

- **Create** - Creates a new group. Initially, there are no CAD elements assigned to this new group. You need to select the CAD elements from the Graphic Display window and then use the **Add** button in the **CAD Elements** section to add the selected CAD elements to the new group.
- **Rename** - Renames the selected group. You can also rename a group by clicking on a selected group in the list until the cursor appears.
- **Delete** - Deletes the selected groups (but not the CAD elements in those groups).

No **Transform** or **Color** buttons are used with CAD groups. This is because the CAD elements can belong to more than one group.

Saved Views

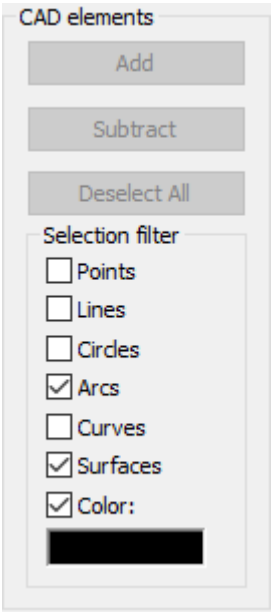


The **Saved Views** area stores the CAD group visibility state in the CAD model. These are saved inside the .CAD file. Use the drop-down combo box to either select or recall a saved visibility state or to specify a name for a new view.

This CAD group visibility state does not include the number of graphics views. The number of graphics views can only be saved using viewsets. See "Working with Viewsets".

- **Save** - Saves the current visibility state using the name that you typed in the combo box.
- **Delete** - Deletes the saved visibility state that you selected in the combo box.

CAD Elements



The **CAD Elements** area modifies the group using the selected CAD elements. You can select multiple CAD elements by pressing Ctrl and clicking on them or by box-selecting them in the Graphic Display window. Selected elements are highlighted.

- **Add** - Adds the selected CAD elements to the currently selected groups in the list.
- **Subtract** - Removes the selected CAD elements from the currently selected groups in the list. If a selected CAD element is not on the selected group, then that CAD element is not modified.
- **Deselect All** - Clears any selected CAD elements on the Graphic Display window.
- **Selection Filter** - The check boxes in the **Selection Filter** area filter the type of CAD elements assigned to a CAD group. You can also use the **Color** check box in this area to filter selection by the color of the CAD element. When you select the **Color** check-box, the color of the next CAD element that you select in the Graphic Display window is used as the filter color. For subsequent selections, you can select CAD elements only with that color.

Creating CAD Groups

1. Access the **CAD Groups** dialog box.
2. From the **Editing** area, click **Create**. A new group appears with "New Group" as the default name followed by a unique number.
3. Select the group and rename it if desired by clicking again on the group or using the **Rename** button.
4. Ensure that the CAD group is selected from the list.

5. From the Graphic Display window, select the CAD elements that you want to include in the CAD group. Your selection can span multiple part models as part of an assembly or multiple layers. To limit which CAD element types are selectable, select the check boxes of CAD elements in the **Selection Filter** area.

6. Click the **Add** button. PC-DMIS assigns the selected elements to the selected group. Now when you show that group and hide other groups, PC-DMIS shows only those elements.

7. Click **OK** when finished to close the dialog box.

Modifying CAD Groups

1. Access the **CAD Groups** dialog box.

2. Select the group from the CAD Groups list.

3. To add elements to the group, select the CAD elements from the Graphic Display window and click **Add**. PC-DMIS modifies the group accordingly.

4. To remove elements from the group, select the group and display its assigned CAD elements. From the Graphic Display window, select the elements to remove and click **Subtract**. PC-DMIS modifies the group accordingly.

5. Click **OK** when finished to close the dialog box.

Deleting CAD Groups

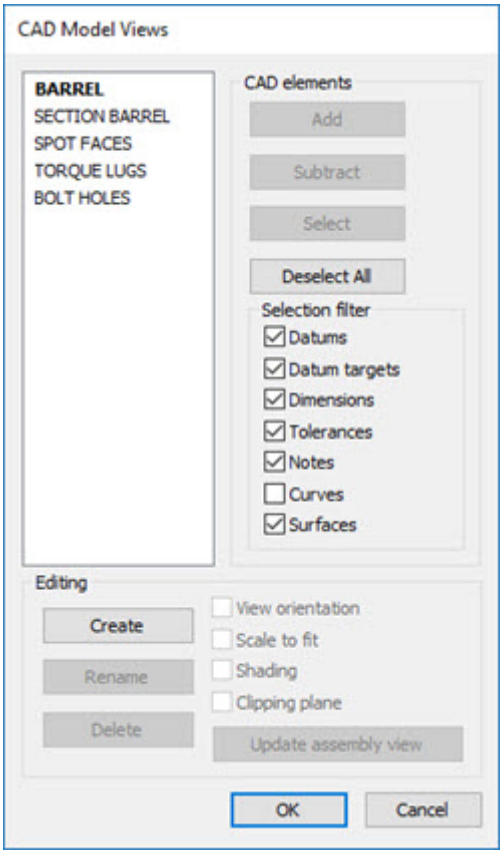
1. Access the **CAD Groups** dialog box.

2. Select a group from the CAD Groups list.

3. Click **Delete**.

4. Click **OK** when finished to close the dialog box.

Working with CAD Model Views



CAD Model Views Dialog Box

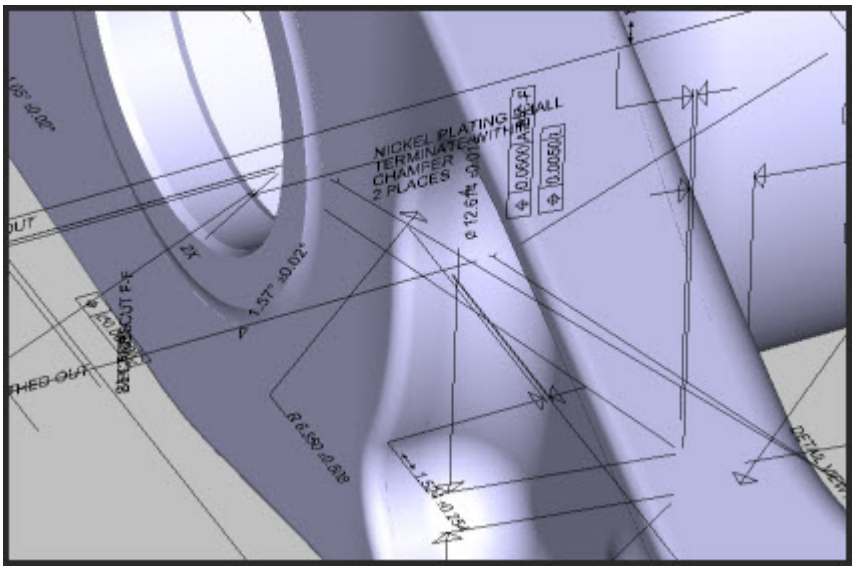
If a Model View is active, and you merge an imported CAD file, PC-DMIS adds all the visible geometry of the imported CAD model into the active Model View.

A single CAD model view (previously known as a "CAD capture") consists of one or more selected CAD elements stored in that view. Similar to CAD Groups, you can use the **CAD Model Views** dialog box (**Edit | Graphic Display Window | CAD Model Views**) to define multiple CAD model views and what CAD to store in each view. You can also activate or deactivate the CAD views to show or hide the stored CAD elements within it. It essentially controls the visibility of CAD elements. However, it does more than CAD Groups, because the dialog box can also control the following:

- Visibility of CAD elements
- Visibility of CAD assembly components
- Optional view orientation
- Optional scale-to-fit operation
- Optional rendering mode (shaded/wireframe, surface edges on/off)

- Optional clipping plane

Many CAD systems provide the ability to add views directly into the CAD model. When you import those models, you can access those views from the **CAD Model Views** dialog box.



Portion of a CATIA Model Showing CAD Model Views (the GD&T or other text-like CAD elements)

Creating CAD Views from the CAD Models View Dialog Box

This procedure assumes you haven't created any views yet.

1. Click **Create** to add **New Model View 1** into the list of views.
2. From the list, select **New Model View 1**.
3. From the Graphic Display window, ensure you have a visible part model.
4. You can use the **Editing** area to mark or clear the check boxes. These control whether or not the software saves the view orientation, scale to fit, shading, and clipping plane into the selected view.
5. From the part model, click on one or more CAD elements to highlight them.
6. Click **Add** to add the selected CAD elements to the selected view.
7. If you want to rename the view to something else to better reflect its the stored CAD elements, click **Rename** and type a new name.
8. Continue creating CAD model views as needed. The next time you click **Create**, the software increments the number in the newly added view (for example, **New Model 2**).

Activating CAD Views from the CAD Model Views Dialog Box

From the list of created views, double-click on a CAD view to activate that view. When you activate a view, the software does the following:

- It highlights the view in the list and shows CAD elements that are in the activated view in the Graphic Display window.
- It updates the visible CAD assembly components to the state stored in the view.
- Based on the selected options, it can change the view orientation, perform a scale-to-fit operation, change the shading, and enable a clipping plane.
- It temporarily hides all other CAD elements and CAD assembly components.

You can also activate a CAD view from the list on the **CAD Setup** toolbar. For information, see the "CAD Setup Toolbar" topic in the "Using Toolbars" chapter.

About the CAD Model Views Dialog Box

List - The list shows all the views in the CAD model. To activate a view, double-click on the view in the list. The activated view has a bold font face. To deactivate a view, double-click on the activated item in the list. If a CAD model view contains embedded CAD GD&T callouts, this icon ( ) appears next to that item in the list. For information on CAD GD&T callouts, see the "Working with CAD GD&T Callouts" topic.

Create - This button creates a new CAD model view and adds any visible CAD GD&T elements into it.

Rename - This button renames the selected view name.

Delete - This button deletes the selected view. It does not delete any CAD elements.

Add - This button adds selected CAD elements to the selected view.

Subtract - This button removes the currently selected CAD elements from the selected view. It does not delete any CAD objects.

Select - This button selects all CAD elements contained in the selected view.

Deselect All - This button deselects all selected CAD objects.

Selection filter - The check boxes in this area filter selected CAD elements when you box-select them so that the software only selects the selected object types.

View orientation - If marked, this check box stores the current view orientation into the selected view. If cleared, and you activate the model view, the orientation view does not change. If you change the orientation and then mark this check box again, it uses the new orientation.

Scale to fit - If marked, this check box performs a scale-to-fit operation when you activate the view.

Shading - If marked, this check box stores the current shading (solid or wireframe) and the current surface edges state (on or off) into the selected view. When you later activate the view, it uses the stored shading regardless of the current Graphic Display window's shading. If you clear this check box and you activate the view, the shading uses whatever the Graphic Display window uses. To change the stored shading state, you can clear and mark this check box again to tell the view to use the current Graphic Display window shading.

Clipping plane - If marked, this check box stores the current clipping plane into the selected view. If you import a model that has a clipping plane defined in its view, that clipping plane temporarily exists in the model for that view. If you then clear the **Clipping plane** check box, the clipping plane is permanently removed. This check box remains disabled until you define a clipping plane. For information on creating and using a clipping plane, see the "Clip Planes Tab" topic.

Update from assembly - This button updates the selected view with the assembly view defined in the **CAD Assembly** dialog box. For information on manipulating the assembly view in that dialog box see, "Working with Assemblies of Parts".

Managing and Positioning On-Screen Elements

The Graphic Display window holds more than just the CAD drawing of your part. It can also display feature ID labels, Datum Definition labels, Dimension Info text boxes, and Point Info text boxes. All these elements bring organization to your report. However, if you have too many of them displayed, they may cover or clutter your part drawing.

Fortunately, you can move your mouse pointer over an element to reposition it. When your mouse pointer changes to a cross-hair, click on the element and drag it to a new location. PC-DMIS then draws a leader-line from the ID label or text box to its corresponding feature.

You can also have PC-DMIS dynamically reposition all your labels and text boxes around your part drawing even when you change the zoom level for your part's display. Select the **Automatic label positioning** check box from the **General** tab of the **Setup Options** dialog box. See "Automatic Label Positioning" in "Setting Your Preferences".

If things still look cluttered, you can also control the visibility state of these various elements using shortcut menus. See "Feature Shortcut Menu" and "Box-Select Shortcut Menu" in "Using Shortcut Keys and Shortcut Menus".

You can only position elements in the active view. If you have a split screen showing additional views of the part, the IDs remain as before in the other views.

Switching Between Curve and Surface Modes

From the **Operation | Graphic Display Window | Change Curve/Surface Mode** menu, you can choose between Curve Mode or Surface Mode. These make a models curves (the wireframe model) or its surfaces visible and available for selection.

From the **Graphic Modes** toolbar, you can also use the **Curve Mode** and **Surface Mode** icons with the **Program Mode** icon to take offline hits on your CAD model's wireframe or surface entities.

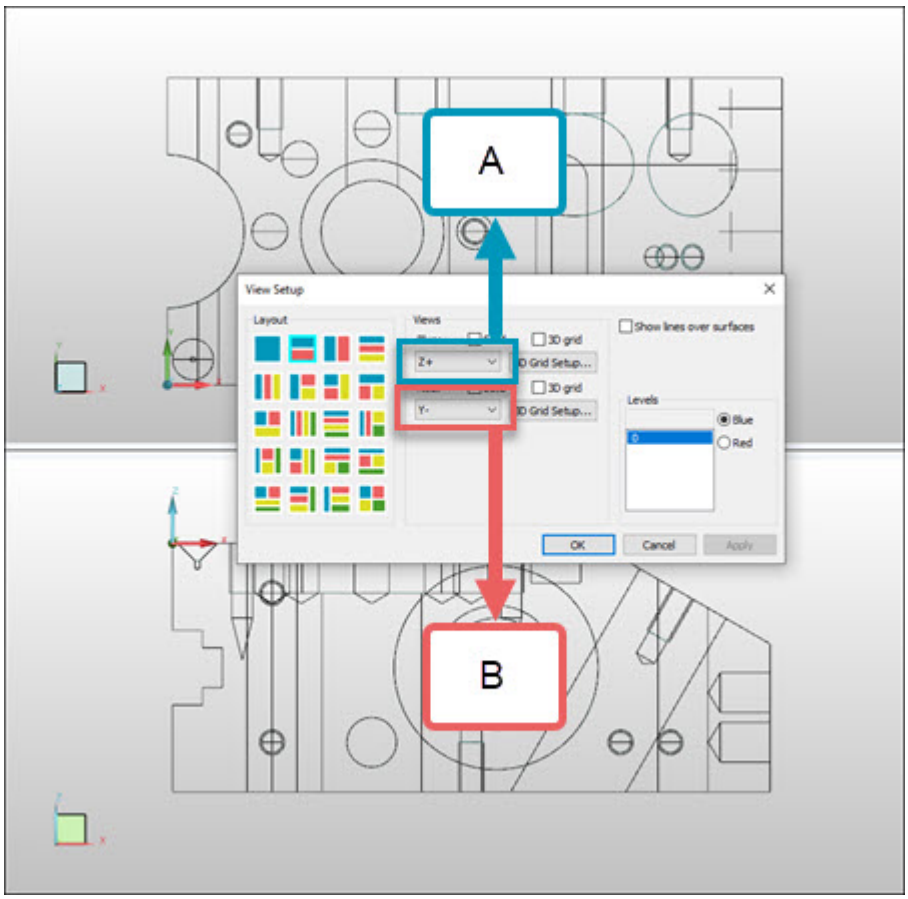
You must have the optional package called "Curves and Surfaces" purchased for your system in order to access these modes.

Curve Mode

The **Curve Mode** option makes a wireframe's model of curves and lines selectable when you click on the CAD data in the Graphic Display window. You must import a wireframe model for this option to become available. This mode works well for all measured features.

You need two graphic views to take hits in Curve Mode. You can set up multiple graphic views from the **View Setup** dialog box. For information on how to do this, see "Setting Up the Screen View".

The picture below illustrates this feature. The top half of the screen (A) shows the model in the Z+ view. The bottom half of the screen (B) shows the model in the Y- view. If your workplane is the Z+ plane, you can then use top half of the screen (A) to take hits, and use the bottom half of the screen (B) to set the probe's depth.



Sample Graphic Display window split to show two different wireframe views of the part

The following list references the above screen as it discusses the Curve Mode mouse operations you can use to set your probe's depth and take hits to insert measured features into your measurement routine. The information below assumes that Z+ is your workplane. You must also set PC-DMIS in Program Mode for these to work:

Operation: Right-click

Screen to Use: B

Description: This sets the approximate animated probe depth at the current mouse pointer position. Use this to create Move Points when you create measurement routines in Offline Mode. See "Inserting a Move Point Command" in "Inserting Move Commands".

Operation: Right-click + drag

Screen to Use: B

Description: This sets the depth for your next inserted hits on the nearest wireframe entity when you release the mouse button. Use this to set the depth for measured lines, circles, and cylinders.

Operation: Left-click

Screen to Use: A

Description: This selects the nearest line or circle and takes equally-spaced hits at the current depth setting based on the settings in the **General** tab of the **Setup Options** dialog box. See "Other Edit Boxes for the General tab" in "Setting Your Preferences".

Operation: Left-click + drag

Screen to Use: A

Description: This takes a single hit at the current depth setting on a line, arc, or circle. The hit direction depends on which side of the wire you release your mouse. Always approach from the side of the wire the machine would approach from.

Operation: Left-click + hold and release

Screen to Use: A

Description: This delayed click takes a hit at the pointer's position at the current depth setting. Use this method to take hits on a plane. Be sure to hold the mouse steady when you hold down the button so that when you release it, a valid hit is taken normal to the surface at the pointer's position.

For example, to define a Measured Cylinder feature in the Z+ view in **Curve Mode** follow these steps, and see the movie below:

1. In screen B (in the Y- view), right-click drag, to set the depth for the first level of hits.
2. In screen A (in the Z+ view), left-click on the cylinder to insert four hits for the first level.
3. In screen B, right-click + drag again, to set the depth for the second level of hits.
4. In screen A , left-click again on the curve to insert four more hits. You now have eight hits in two sets, with each set at different depths.
5. Press the End key to create the Measured Cylinder feature.

Surface Mode

The **Surface Mode** option makes a solid model's surfaces selectable when you click on the CAD data in the Graphic Display window. You must import a solid model for this option to become available. To take a hit, click on any surface. PC-DMIS pierces the surface and captures the X, Y, Z, I, J, and K information; the hit is recorded at the pointer's position. Select the correct number of hits to define the feature and then press the End key. PC-DMIS guesses the feature type. This mode works best for creating point, line, and

plane features. While you can also use this mode with circular features (circles, cylinders, cones, and spheres), it may be difficult to select hits at a constant cross section or depth, especially for inside features. In these cases, you may want to use Curve Mode.

For information on using these modes with scans, see the "Scanning Your Part" chapter.

Drawing Surfaces

The **Operation | Graphic Display Window | Draw Surfaces** option allows you to display surfaces on the screen. Note that you must first select the **Solid** check box in the **View Setup** dialog box. For information on the **View Setup** dialog box, see the "Setting Up the Screen View" topic.

To turn off the display of surfaces, select this option again.

Highlighting CAD Elements

You can hold down Shift key and move your mouse pointer over your part to see a highlight of the different CAD elements in your imported part model.

To create QuickFeatures from CAD elements, hold down the Shift key, hover over the CAD element and then click on it. This only functions with contact Auto features. For more information, see "Creating QuickFeatures by Hovering Over CAD Elements" in the "Creating Auto Features" chapter.

To change this mouse-over highlight color, see "Highlight" under "Changing Screen Colors" in this chapter.

Displaying Mouse Coordinates in Screen Counter Text

If you mark either the **Show CAD** or **Show Part** check boxes in the **Probe Readouts Setup** dialog box, PC-DMIS provides a continuous update of the location of your mouse pointer's location in the Probe Readouts window as it moves over the part model. If you move the mouse cursor away from the part over an empty space in the Graphic Display window, PC-DMIS displays its last known location when it was over the part.

In previous versions, this information was displayed in the upper right-hand corner of the Graphic Display window. In this new consolidated design, it now appears displayed in the Probe Readouts window.

For related information, see these topics:

- "Setting Up the Probe Readouts Window" topic in the "Setting your Preferences" chapter.
- "Using the Probe Readouts Window" topic in the "Using Other Windows, Editors, and Tools" chapter.

Repainting the Screen

Select the **Operation | Graphic Display Window | Repaint the Screen** option to redraw the Graphic Display window.

Changing Screen Modes

PC-DMIS allows you to switch between these Screen Modes. The different modes tell PC-DMIS how to interpret mouse clicks.

Using Translate Mode

The **Operation | Graphic Display Window | Change Screen Mode | Translate** option places PC-DMIS into Translate Mode. This mode allows you to move and zoom in or out on the part while in the Graphic Display window. The following functions are available in translate mode:

- Shrink the size of the part within the Graphic Display window.
- Enlarge the size of the part within the Graphic Display window.
- Select a portion of the part within the Graphic Display window.
- Reposition the part within the Graphic Display window.

Shrinking the Part Image within the Graphic Display Window

To shrink (or zoom out of) the entire image of the part, rotate your mouse's wheel button away from you. PC-DMIS centers the zoom-out operation at the pointer's location.

Enlarging the Part Image within the Graphic Display Window

To enlarge (or zoom in on) the entire image of the part, rotate your mouse wheel button towards you. PC-DMIS centers the zoom-in operation at the pointer's location.

Enlarging a Portion of the Part Image within the Graphic Display Window

To enlarge (or zoom in on) a specified section of the part:

1. Place the pointer at a corner of the selection area.
2. Drag both the right and left buttons simultaneously over a portion of the Graphic Display window.
3. When the box contains the proper geometry, release both buttons to have PC-DMIS zoom in on the selected area.

Once you reach a certain point, the image doesn't enlarge any further.

Repositioning the Part Image within the Graphic Display Window

To change the position of the part image within the Graphic Display window:

1. Position the pointer over the part image.
2. Drag the pointer to a new position and then release it.

Using 2D Rotate Mode

You can select **Operation | Graphic Display Window | Change Screen Mode | 2D Rotate** to rotate the part in two dimensions. You can rotate the part a full 360 degrees, or any fraction of 360 degrees.

When you rotate, the software displays an icon to show the center of rotation. For more information see "Center of Rotation" in the "Rotating the Drawing" topic.

The following sections describe the different ways to rotate a drawing in two dimensions.

Rotating a drawing only changes the display. It does not change the origin or datums of the part.

Rotating 2D by Dragging

To drag the pointer and rotate around the imaginary center of the current view:

1. From the **Graphics Modes** toolbar, click the **2D Rotate Mode** icon.
2. Move the pointer in the Graphic Display window (in any area other than at the center).
3. Right-click and drag the pointer about the center of the view to redraw the image dynamically.
4. Release the button to keep the current rotation.

To rotate your part from within any mode, press Alt + right-click and drag the mouse. This does not work if you have the **Rotate** dialog box for 3D rotation open.

Rotating 2D to an Element (Square up the Drawing)

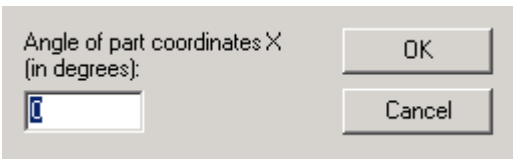
To "square-up" the part to the screen, from the **Graphic Modes** toolbar, select the **2D Rotate Mode** icon, and then right-click on a CAD element. PC-DMIS rotates the drawing so that the selected element is parallel to the closest screen axis (vertical or horizontal).

You can square-up the drawing to the closest X, Y, or Z axis at any time, even if you don't have the **Rotate** dialog box open. Click twice on the Graphic Display window with your mouse wheel button.

Rotating 2D by a Factor

To rotate by a precise factor, similar to the "Scaling the Model by a Factor" topic, do the following:

1. From the **Graphic Modes** toolbar, select the **2D Rotate Mode** icon .
2. In the Graphic Display window, press Shift and then right-click to show a small dialog box.

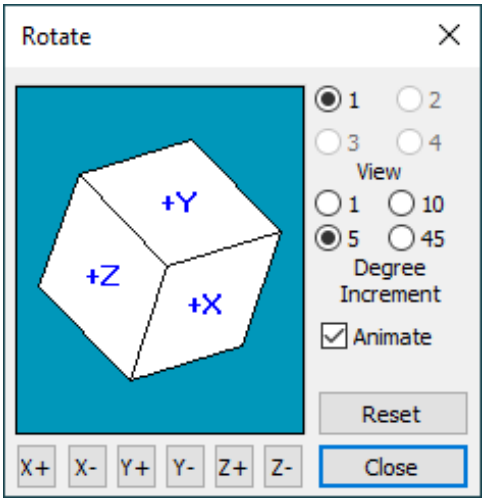


3. Type the angle (in degrees) into the **Angle of part coordinates X** box.

4. Click **OK** to close the box and perform the 2D rotate of the part in the Graphic Display window.

Using 3D Rotate Mode

You can select **Operation | Graphic Display Window | Change Screen Mode | 3D Rotate** to display the **Rotate** dialog box. With this dialog box, you can rotate a part drawing in three dimensions, up to 45 degrees per rotation.



Rotate Dialog Box

When you rotate, the software displays an icon to show the center of rotation. For more information see "Center of Rotation" in the "Rotating the Drawing" topic.

The "Rotate 3D using Rotate Dialog Box", "Rotate 3D by Dragging", and "Rotate 3D to an Element" topics below describe three different ways to rotate a drawing in three dimensions.

For additional information on how to rotate a drawing, see "Rotating the Drawing".

Rotate 3D by Dragging

You can drag the pointer to rotate the part:

1. From the **Graphic Modes** toolbar, selecting the **3D Rotate Mode** icon to open the **3D Rotate** dialog box.

2. Right-click and drag the pointer.

To rotate your part with or without the **Rotate** dialog box open, press Ctrl + right-click, and drag the pointer. Also, you can do this if you hold the wheel button and drag the pointer.

Rotate 3D using Rotate Dialog Box

To rotate the drawing using the dialog box, do the following:

1. From the **Graphic Modes** toolbar, select the **3D Rotate Mode** button ( ) to open the **3D Rotate** dialog box.
2. From the **3D Rotate** dialog box, select the view to be altered (numbered as 1-4 option buttons).
3. Select the **Degree Increment** (1, 5, 10, or 45) option to determine the rotation amount in degrees.
4. Click on one of the axis buttons (**X+**, **X-**, **Y+**, **Y-**, **Z+**, or **Z-**) to rotate the drawing by the defined increment around the selected axis.
5. Click **Close** to display the changes to the CAD image in the Graphic Display window.

Reset - This button snaps the rotation of the drawing in the **Rotate** dialog box and in the Graphic Display window to the closest axis.

Animate - If you select this check box, PC-DMIS dynamically re-draws the part in the Graphic Display window as it is rotated inside the dialog box. If you clear this check box, and then use a rotation button in the dialog box, the rotation of the actual part on the screen does not take place until you release the clicked button.

Rotate 3D to an Element (Square up the Drawing)

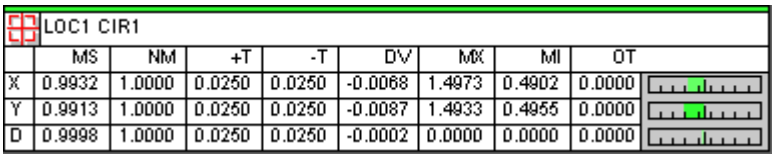
To "square-up " the part to the screen,

1. From the **Graphic Modes** toolbar, select the **3D Rotate Mode** icon
2. Right-click on a CAD element. PC-DMIS rotates the drawing and makes the selected feature parallel to the closest screen axis (vertical, horizontal, or perpendicular to the screen).

You can square-up the drawing to the closest X, Y, or Z axis at any time, even if you don't have the **Rotate** dialog box open. Click twice on the Graphic Display window with your mouse wheel button.

Text Box Mode

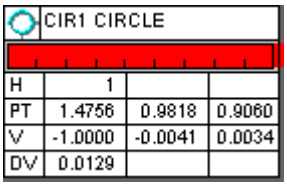
This button places PC-DMIS into a mode that lets you manipulate feature IDs, scan points, and CAD GD&T callouts. You can also use this mode to quickly create and modify Dimension Info and Point Info text boxes.



LOC1 CIR1

	MS	NM	+T	-T	DV	MX	MI	OT
X	0.9932	1.0000	0.0250	0.0250	-0.0068	1.4973	0.4902	0.0000
Y	0.9913	1.0000	0.0250	0.0250	-0.0087	1.4933	0.4955	0.0000
D	0.9998	1.0000	0.0250	0.0250	-0.0002	0.0000	0.0000	0.0000

Sample Dimension Info Box



CIR1 CIRCLE

H	1		
PT	1.4756	0.9818	0.9060
V	-1.0000	-0.0041	0.0034
DV	0.0129		

Sample Point Info Box

To create these text boxes, use the shortcut menus that appear when you right-click or box-select feature IDs or features. For more information, see the "Inserting Dimension Info Boxes" and "Inserting Point Info Boxes" topics in the "Inserting Report Commands" chapter.

The following shortcut menus are available inside Text Box Mode:

- Right-click on the feature, feature's ID label, or text box to display a shortcut menu for that feature. For more information, see "Feature Shortcut Menu" in the "Using Shortcut Keys and Shortcut Menus" appendix.
- Right-click on a Dimension info or Point Info box to display a shortcut menu for that text box. For more information, see "Feature Shortcut Menu" in the "Using Shortcut Keys and Shortcut Menus" appendix.
- Right-click on a CAD GD&T callout to display a shortcut menu for that callout. For more information, see "Feature Shortcut Menu" in the "Using Shortcut Keys and Shortcut Menus" appendix.
- Box-select one or more features to display a shortcut menu. For more information, see "Box-Select Shortcut Menu" in the "Using Shortcut Keys and Shortcut Menus" appendix.
- Right-click on a scan point and use the **Move Cursor To** menu to jump to that point. For more information, see the "Feature Shortcut Menu" topic in the "Using Shortcut Keys and Shortcut Menus" chapter.

When your pointer isn't over a feature or text box, you can perform the normal Translate Mode operations to zoom and rotate the part with the right mouse button. For additional information, see "Translate Mode".

Tips

- You can create a DIMINFO or a POINTINFO box regardless of the current mode with the mouse. Double-click on a feature or feature ID label. PC-DMIS automatically creates an info box based on current **Edit Dimension Info** or **Edit Point Info** dialog box settings. For example, suppose you created a Dimension Info box for a feature. If you double-click subsequent feature labels, the software creates additional Dimension Info boxes for those features. It uses the same settings selected the last time someone used the **Edit Dimension Info** dialog box.
- You can use your pointer to identify the feature associated with a particular label. From the Graphic Display window, move your pointer over either a feature or a feature's ID label. PC-DMIS highlights the feature on the CAD drawing.

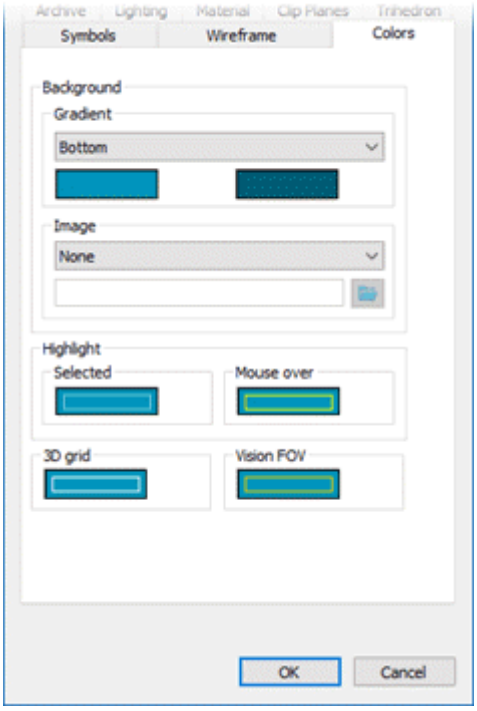
Program Mode

Select **Operation | Graphic Display Window | Change Screen Mode | Program** to learn and edit measurement routines using CAD data from IGES files.

You can use Program Mode to create measured features from a wireframe or surface CAD model. While in Program Mode, you take hits on the model with an animated probe simulating taking hits with the CMM in Guess Mode. This capability is available in either the Offline or Online mode of PC-DMIS.

For more information on how to use graphics to create measurement routines, refer to the "Working in Offline Mode" appendix.

Changing Screen Colors



CAD and Graphic Setup Dialog Box - Colors Tab

The **Colors** tab of the **CAD and Graphic Setup** dialog box determines the display settings of the Graphic Display window.

These display settings include:

- Background color
- Background Gradient color
- Background Image
- Highlight colors for feature selection and mouse-over
- 3D Grid color
- The Vision module's Field of View (FOV) color

If you want to change the color of components in your part model, use the **CAD Assembly** dialog box. For more information, see "Working with Assemblies of Parts".

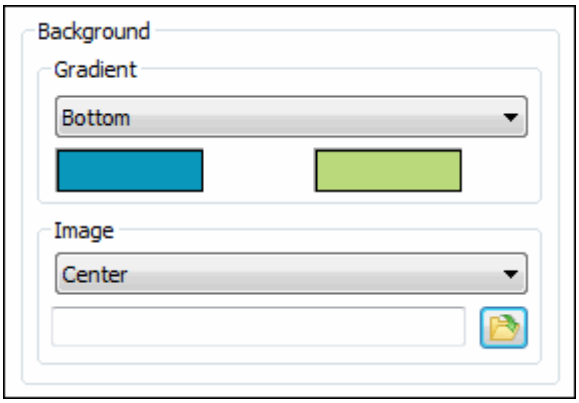
To Change a Color

To change the colors:

1. Access the **Colors** tab on the **CAD and Graphic Setup** dialog box (**Edit | Graphic Display Window | Screen Color**).

2. Under **Background**, **Gradient**, **Highlight**, **Mouse Over Highlight**, **3D Grid**, **Vision FOV**, or **CAD GD&T**, click on the rectangular color box to open the **Color** dialog box.
3. Choose a new color for the option you selected. In most cases, PC-DMIS immediately displays the selected color change and provides a preview of the change.
4. Click **OK**. The **Color** dialog box closes and returns to the **Screen Color** dialog box.
5. If you changed a **CAD GD&T** color, you need to click the **Apply** button next to it to preview it.
6. When finished, click the **OK** button on the **CAD and Graphic Setup** dialog box to accept your changes and close the dialog box.

Background

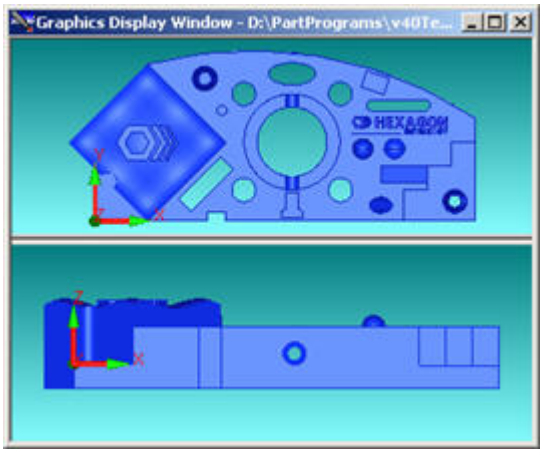


The **Background** area allows you to change the background screen color or set an image as the background. PC-DMIS also uses the color or image as the background for any Geometric Tolerances displayed in the Graphic Display window. Follow the directions discussed in "To Change a Color" to set the background color.

Setting the Gradient Background Color

The **Gradient** area lets you define a secondary background gradient color. When you set the gradient to something other than **None** in the list, a rectangular color box appears. You can click that box to define a secondary gradient color. Then, when setting the screen's background, PC-DMIS starts from the setting location (for example, the Bottom) and displays the secondary gradient color, and then gradually changes from that color to the primary gradient color as it draws the colors near the other end of the screen.

For example, a **Bottom** gradient setting might look like this:



Example that shows gradient colors.

The available items in the **Gradient** list are:

- **None** - No secondary gradient. The screen's background will be the solid primary color.
- **Bottom** - The secondary gradient color starts at the bottom of the screen and gradually changes to the primary color as it nears the top.
- **Right** - The secondary gradient color starts at the right side of the screen and gradually changes to the primary color as it nears the left side.
- **Top left** - The secondary gradient color starts at the top-left side of the screen and gradually changes to the primary color as it nears the bottom right side.
- **Top right** - The secondary gradient color starts at the top right side of the screen and gradually changes to the primary color as it nears the bottom-left side.
- **Bottom Left** - The secondary gradient color starts at the bottom-left side of the screen and gradually changes to the primary color as it nears the top-right side.
- **Bottom Right** - The secondary gradient color starts at the bottom-right side of the screen and gradually changes to the primary color as it nears the top-left side.

Setting an Image as the Background

The **Image** settings area sets an image as the background. To do this, from the **Image Mode** drop-down list, set the image to something other than **None**. This enables the **File Navigation** text box and the **Open File** button . Then, do one of the following:

- Manually enter the path to the image file in the **File Navigation** text box then click **OK** on the **CAD and Graphic Setup** dialog box.

  or:

- Click **Open File** to display the **Open** dialog box, navigate to the image file and then select it. Click **Open** from the **Open** dialog box, and then click **OK** on the **CAD and Graphic Setup** dialog box.

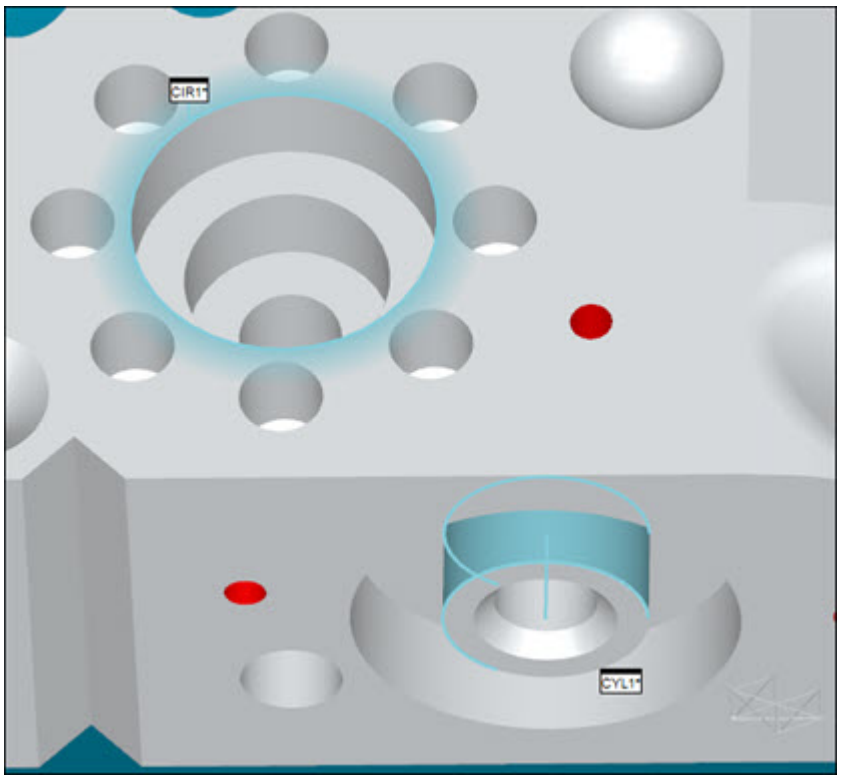
The background image is drawn based on the image mode selected:

- **None** - No background image is displayed.
- **Center** - The image is centered in the Graphic Display window and is not scaled.
- **Top left** - The image is positioned at the top-left of the Graphic Display window and is not scaled.
- **Top right** - The image is positioned at the top-right of the Graphic Display window and is not scaled.
- **Bottom left** - The image is positioned at the bottom-left of the Graphic Display window and is not scaled.
- **Bottom right** - The image is positioned at the bottom-right of the Graphic Display window and is not scaled.
- **Fit** - The image is scaled to fit just inside the Graphic Display window, preserving the image's aspect ratio.
- **Stretch** - The image is scaled to fill the entire Graphic Display window, not preserving the image's aspect ratio.
- **Fill** - The image is scaled to fill the entire Graphic Display window, preserving the image's aspect ratio.
- **Tile** - The image is drawn repeatedly over the entire Graphic Display window and is not scaled.
- **Tile mirrored** - The image is drawn repeatedly over the entire Graphic Display window with every other image being mirrored. The images are not scaled.

Highlight

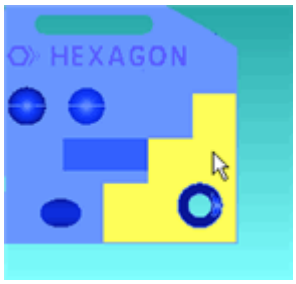
The **Highlight** area allows you to change the color PC-DMIS uses for items that you select or when you hover your pointer over surfaces or curves. To change the color, follow the directions discussed in the "To Change a Color" topic.

Selected - This option controls the color that PC-DMIS uses when you select geometric features from the CAD model. You typically need to select features from the CAD model for operations like constructions and dimensions. PC-DMIS also automatically selects features one by one as it executes them.



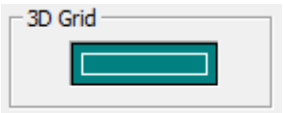
A selected circle (2D feature) and a selected cylinder (3D feature)

Mouse over - This option controls the highlight color that PC-DMIS uses when you move the pointer over geometric features on the CAD model. PC-DMIS typically uses this color when you create QuickFeatures. (For details on how to create QuickFeatures, see "Creating QuickFeatures" in the "Creating Auto Features" chapter.) PC-DMIS also uses this color for the line you drag to create a Quick Scan. (For information on the Quick Scan functionality, see "Creating Quick Scans" in the "Scanning" chapter of the PC-DMIS CMM documentation.)



The default mouse-over color during a QuickFeature operation

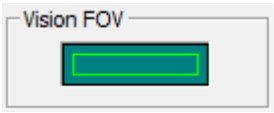
3D Grid



The **3D Grid** area allows you to change the color used for the 3D grid in the Graphic Display window. Follow the directions discussed in "To Change a Color".

For more information on the 3D Grid, see "Adding a 3D Grid".

Vision FOV

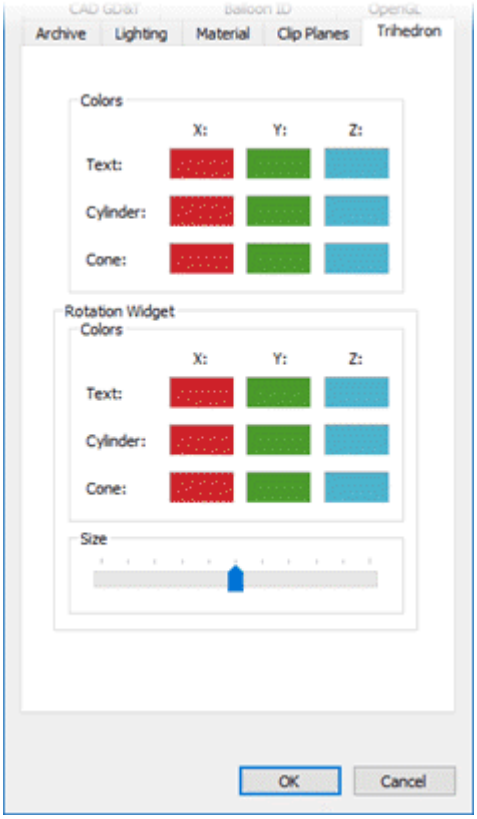


The **Vision FOV** area lets you change the color used for the Field of View (FOV) when using the PC-DMIS Vision module. Follow the directions discussed in the "To Change a Color" topic. For information on the FOV and the Vision module, see the PC-DMIS Vision documentation.

Changing Trihedron Settings

A trihedron is an XYZ symbol in the Graphic Display window that shows the intersection of three planes. It defines the coordinate system's origin, and shows the current orientation when you rotate the part.

The **Edit | Graphic Display Window | Trihedron** menu item displays the **Trihedron** tab of the **CAD and Graphic Setup** dialog box. You can use this tab to change the colors for the different components that make up the trihedron and to size the rotation widget.



CAD and Graphic Setup Dialog Box - Trihedron Tab

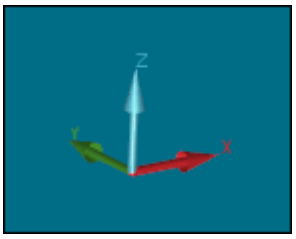
You can change colors for these trihedrons with these areas:

- **Colors** - This affects the standard part alignment trihedron.

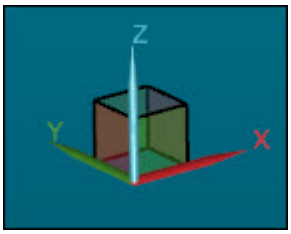
- **Rotation Widget Colors** - This affects the rotation widget trihedron. For more information on this widget, see "Using the Rotation Widget".

Original Colors

The original colors for the part alignment symbol and the rotation widget are red (X), green (Y), and blue (Z):



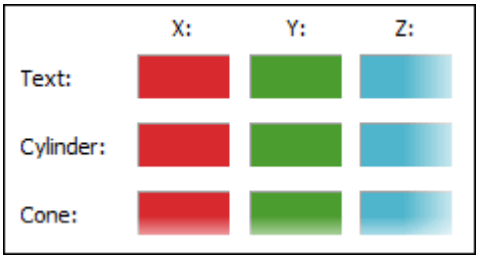
Example showing the original colors of the part alignment trihedron.



Example showing the original colors of the rotation widget.

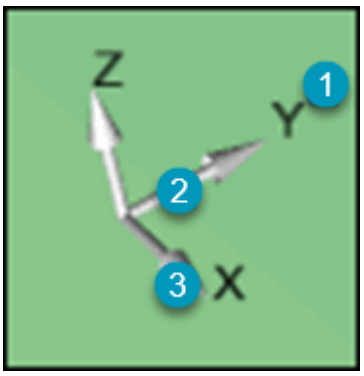
Colors area

The **Colors** area contains a grid of colored boxes.



These grids of boxes represent the different components for each of the three axes of the two trihedrons.

- **Text** - This sets the colors of the "X", "Y", or "Z" letters (or text) displayed on the trihedrons (1 in image below).
- **Cylinder** - This sets the color of the X, Y, or Z axis line (or cylinder) on the trihedrons (2 in image below).
- **Cone** - This represents the color of the X, Y, or Z arrow head (or cone) on the trihedrons (3 in image below).



You can click on a colored box to change that component's color.

Rotation Widget area

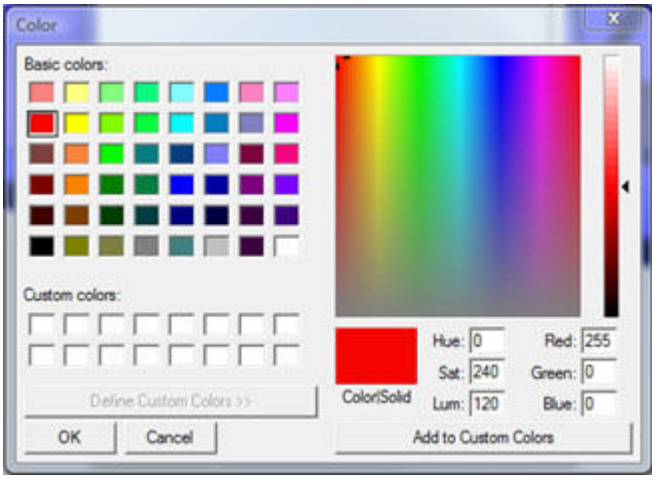
The colored boxes in this area work the same way as the colored boxes in the **Colors** area above, except that they affect the rotation widget.

The **Size** slider changes the relative size of the rotation widget.

> You can temporarily change the size with the mouse pointer. Hover your pointer over a face on the rotation widget until it highlights that face. Then rotate the mouse wheel. The size change remains until you close the measurement routine. To make the size change permanent, first open the **Trihedron** tab, resize the widget, and then click **OK**.

Changing Colors

You can change these colors by clicking on one of the colored boxes and choosing a new color from the **Color** dialog box:



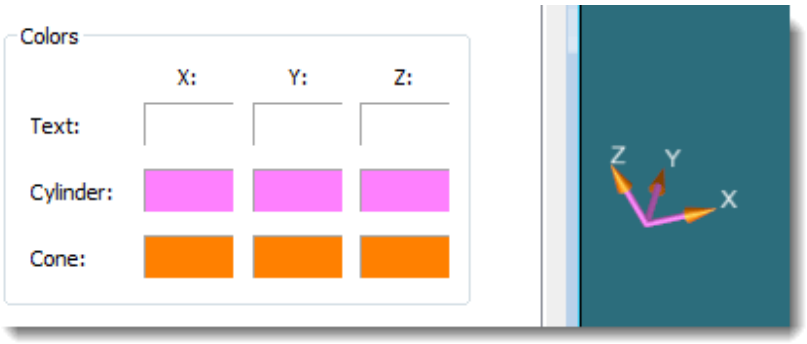
Color Dialog Box

As soon as you click **OK**, the **Color** dialog box closes, and PC-DMIS updates the trihedron color in the Graphic Display window.

When you click **OK** on the **CAD and Graphic Setup** dialog box, PC-DMIS stores the color information in the JSON file. All measurement routines then use these colors for that trihedron.

Example

This example shows a modified alignment trihedron. If you change its **Text** colors to white, **Cylinder** colors to pink, and **Cone** colors to orange, the trihedron looks like this:



Example showing a modified trihedron.

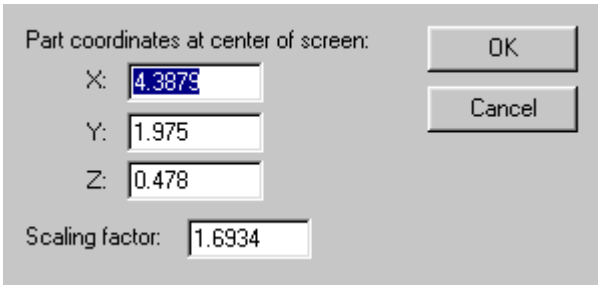
Scaling the Drawing

You can scale the CAD drawing to fit the size of your selected view(s) in the Graphic Display window, or you can scale by a factor. These options are helpful whenever the image becomes too large or too small.

Scaling the Model to Fit the View

The **Operation | Graphic Display Window | Scale to Fit** menu option re-displays the part image to fit entirely within the Graphic Display window. This option is helpful whenever the image becomes too large or too small. To alter the part image so all features and CAD elements are visible, select the **Scale to Fit** menu option.

Scaling the Model by a Factor



Scale Drawing Dialog Box

Scaling a drawing alters the part's image in the Graphic Display window. This option does *not* alter the CAD data in any way. The Scale Drawing option is *not* available from the menu bar, and it only functions when PC-DMIS is in Translate Mode.

To use this option:

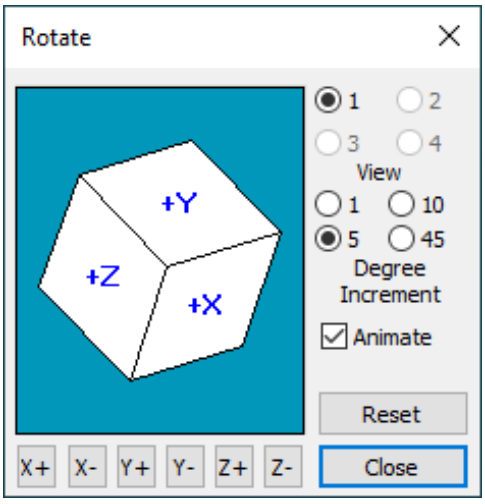
1. Click the **Translate** mode icon from the **Graphic Modes** toolbar. For more information on the screen modes, see "Changing Screen Modes".
2. Press Shift and right-click to open the **Scale Drawing** dialog box.
3. Type the **X**, **Y**, **Z** part coordinates to display in the center of the screen.
4. Type the desired value for the **Scaling factor**. This is an actual scale factor, not a relative scale factor.

A scale factor of 0.5 scales the part to half its actual size. A scale factor of 2.0 scales the part to twice its actual size. A scale factor of 1.0 scales the part to its actual size.

You can also scale the graphical image within the Graphic Display window by right-clicking above or below an imaginary horizontal line that splits the Graphic Display window.

Rotating the Drawing

Select **Operation | Graphic Display Window | Rotate** to display the **Rotate** dialog box.



Rotate Dialog Box

This dialog box allows you to rotate a part drawing in three dimensions. You can rotate up to 45 degrees per rotation for each view of the part. You can also activate this option from the **3D Rotate Mode** button ( ) on the **Graphic Modes** toolbar.

To rotate the drawing using the **Rotate** dialog box, do the following:

1. Select the view to be altered (1-4).

2. Determine the amount of rotation by selecting the degree increment (1, 5, 10, or 45).
3. Click on the desired axis button to rotate the drawing in the indicated direction.
4. An icon shows the point of rotation. For information, see "Center of Rotation Icon" below.

Click the **Reset** button to snap the rotation of the drawing in the **Rotate** dialog box and in the Graphic Display window to the closest axis.

If you select the **Animate** check box, PC-DMIS dynamically re-draws the part in the Graphic Display window as it is rotated.

For additional information on rotating, see "3D Rotate Mode".

To quickly rotate your part with or without the **Rotate** dialog box open, press Ctrl + right-click and drag the mouse. If your mouse has a center wheel button, hold the wheel button and drag the mouse. Also, you can double-click the wheel button at any time to perform the same action as the **Reset** button on the **Rotate** dialog box: it snaps the rotation to the closest axis.

Determining the Point of Rotation with a CAD Model

If you have a CAD model in the Graphic Display window, there are two ways to determine the point of rotation. Which way to use depends on where your pointer is when you first click the right mouse button. Either your pointer is over the Graphic Display window background, or it is over the part's CAD.

- If the pointer is *over the Graphic Display background*, the part rotates about the part's origin.
- If the pointer is *over the part*, the part rotates about the point on the part directly below the pointer.

Determining the Point of Rotation without a CAD Model

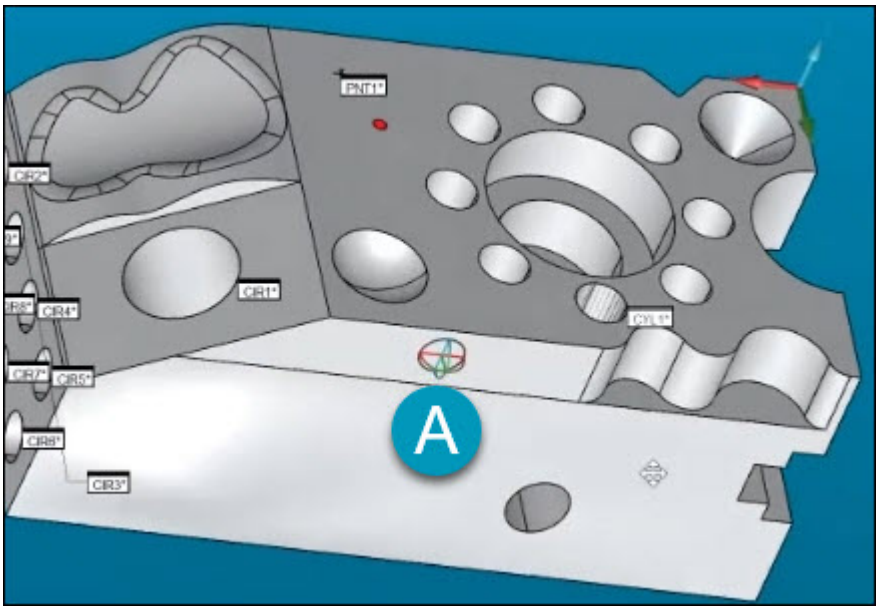
If you don't have a CAD model in the Graphic Display window, PC-DMIS can rotate about a user-defined point instead. This may be useful when there are relatively large distances between measured objects or CAD objects.

- If the **Rotate** dialog box is active, PC-DMIS treats the screen center position as if you clicked there.
- If PC-DMIS cannot find a pierced point, it instead uses the closest display object (pixel) and rotates about that point. If the closest object is a CAD object, then the point PC-DMIS uses is the closest point on the closest CAD object.

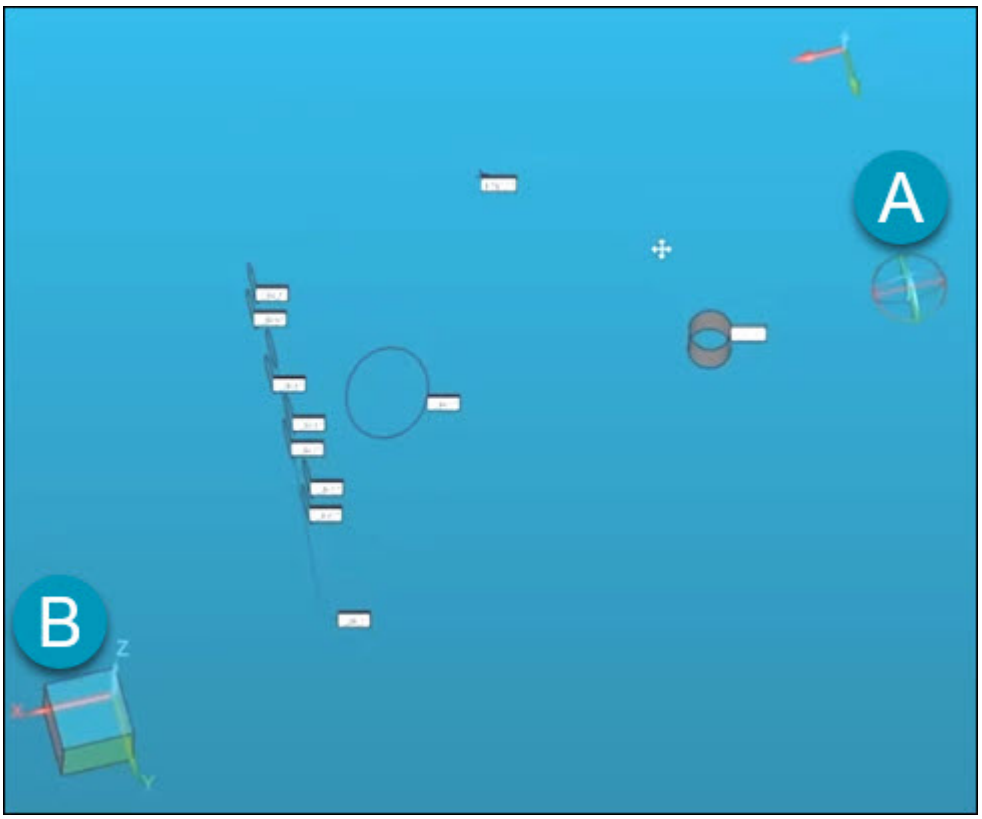
Center of Rotation Icon

A colored, spherical, wire-frame icon indicates the current center of rotation:

Center of rotation Icon



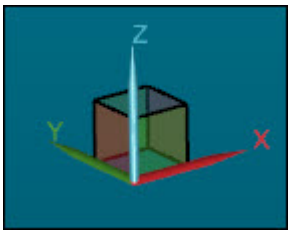
Graphic Display window with center of rotation icon (A) on the part.



Graphic Display window with center of rotation icon in space (A) and Rotation Widget (B).

- Like the Rotation Widget, the center of rotation icon uses the same colors as the trihedron. For information, see "Changing Trihedron Settings".
- The size of the center of rotation icon matches the size of the Rotation Widget. For information, see "Using the Rotation Widget".

Using the Rotation Widget



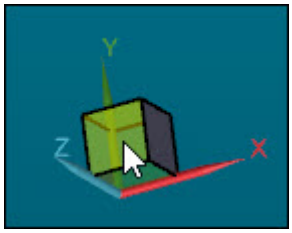
The Rotation Widget is another trihedron with a cube that you can show or hide in the bottom-left corner of each view of the Graphic Display window. The trihedron shows the current rotation of the CAD model. You can also use it to rotate and scale to fit the CAD model.

To show or hide this widget, use from the **Graphic Items** toolbar, use the **Show Rotation Widget** icon ( ). For more information on this toolbar, see "Graphic Items Toolbar" in the "Using Toolbars" chapter.

You can temporarily change the size with the mouse pointer. Hover your pointer over a face on the rotation widget until it highlights that face. Then rotate the mouse wheel. The size change remains until you close the measurement routine. To make the size change permanent, first open the **Trihedron** tab, resize the widget, and then click **OK**.

The Cube

The Rotation Widget contains a translucent colored cube. When you hover over a cube face, it highlights that face on the cube with the mouse-over color discussed in the "Highlight" topic.



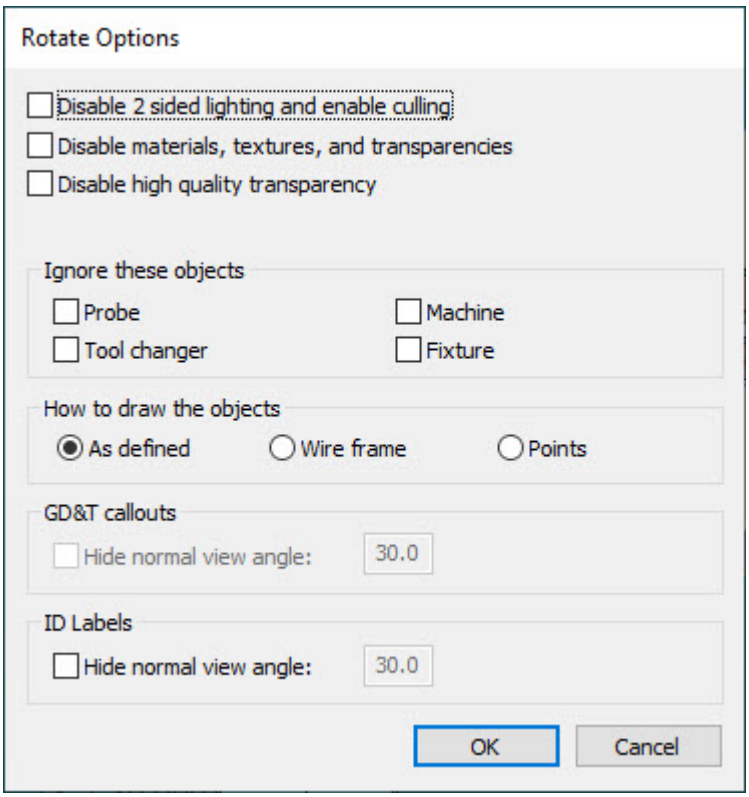
- You can click on any cube face to rotate the model to show that face.
- You can double-click on the cube face to rotate the model and scale the model to fit the window.

The default colors for this trihedron are the same as those that the alignment trihedron uses. You can change the colors on the **Trihedron** tab of the **CAD and Graphic Setup** dialog box. For information, see "Changing Trihedron Settings". For information, see "Trihedron tab".

Changing Rotation and Other Motion Options

You can use the **Rotate Options** dialog box to modify how PC-DMIS displays CAD models. You can access the dialog box by doing one of the following:

- From the **Edit** menu, point to **Graphic Display Window**, and choose **Rotate Options**.
- From the **Graphic Modes** toolbar, click the **Rotate Options** icon .



Rotate Options Dialog Box

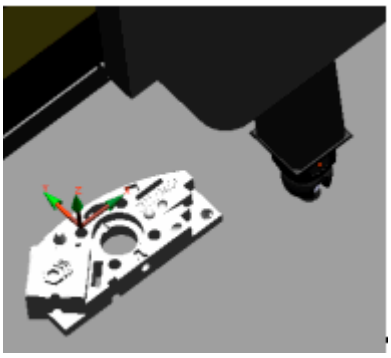
This dialog box controls whether or not certain items get drawn and how they get drawn inside the Graphic Display window when you rotate your part model. The options on this dialog box can help speed up the display of your rotation. PC-DMIS does not apply these settings globally to all measurement routines; instead, they are only applied to your current measurement routine. This allows you to set different rotation options for each measurement routine.

If you are using *3Dconnexion 3D Mouse* device, this dialog box behaves just like the **Pan, Zoom, Rotate Options**dialog box but with a different dialog box title. *3Dconnexion 3D Mouse* devices extend the functionality described for rotation to zooming and panning as well. For information, see the "Configuring 3Dconnexion 3D Mouse Devices" topic in the "Getting Started: An Overview" chapter.

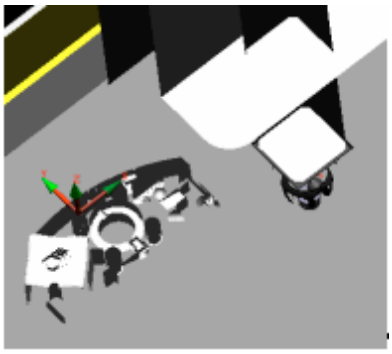
Changing Animation Speeds: If you want to modify your offline animation speeds, see the **Execution** area on the **Animation** tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**). In addition, see the "Executing and Debugging Measurement Routines Offline" topic in the "Working in Offline Mode" chapter.

Disable 2 Sided Lighting and Back Face Culling

Selecting this check box disables two sided lighting and uses back face culling during rotation. The resulting lighting effects will roughly display only half of the CAD elements. See the comparison below.



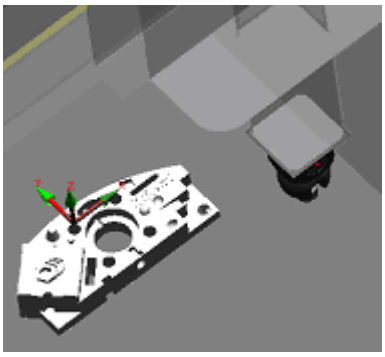
Before Rotation



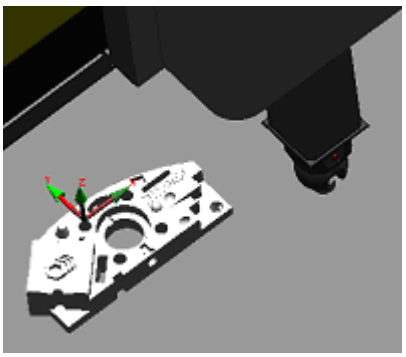
During Rotation – Disable 2 sided lighting and back face culling

Disable Materials, Textures, and Transparencies

Selecting this check box disables the rendering of applied materials, textures, and transparencies during rotation. See the comparison below.



Before Rotation with Transparency



During Rotation - No transparencies

Disable High Quality Transparency

If high-quality transparency is enabled, it will be temporarily disabled when the graphic is rotated, zoomed, or panned. This can be particularly helpful for very complex models that take a long time to render using high-quality transparency.

Animate Speed

You can set this value by using the slider or typing a decimal value. It applies to all measurement routines. This decimal value determines the relative speed of the animated rotation of the part in the Graphic Display window when you click one of the seven view buttons on the **Graphic View** toolbar (**View | Toolbars | Graphic View**).

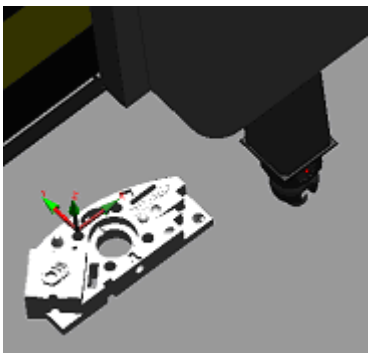
The default value is 1. This represents a normal rotation speed. Smaller values provide slower rotations, larger values produce quicker rotations.

The minimum allowed value is 0.1 and results in a very slow rotation.

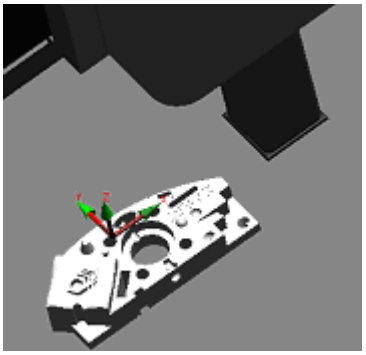
The maximum allowed value is 10 and results in an instantaneous rotation for view changes.

Ignore These Objects

Selecting this check box disables the display of specified objects. Objects will be ignored during rotation for those object types that are selected using the associated check boxes. You can choose to ignore probes, machines, changers, or fixtures. The example below hides the probe during rotation.



Before Rotation



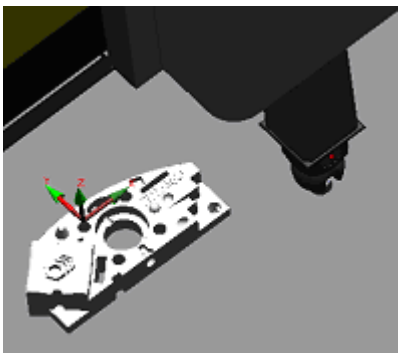
During Rotation - Ignore Probe

How to Draw Objects - As Defined

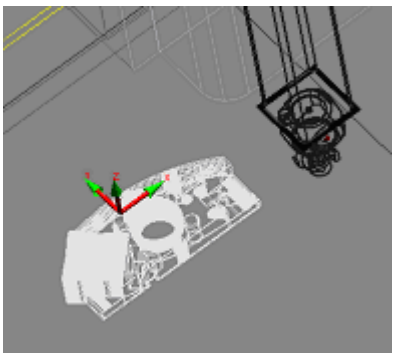
Selecting this option draws objects as originally defined during rotation.

How to Draw Objects - Wireframe

Selecting this option draws objects as wireframes during rotation. See the comparison below.



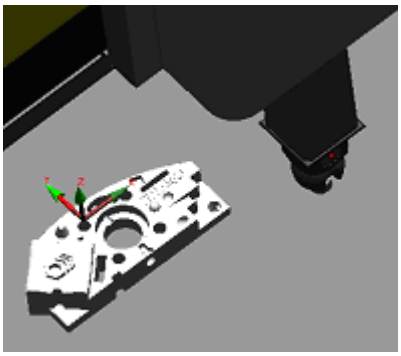
Before Rotation



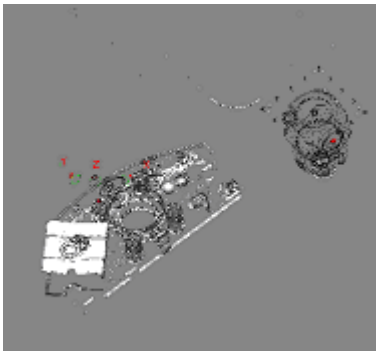
During Rotation - Draw Wireframe

How to Draw Objects - Points

Selecting this option draws objects as points. The **Points** option gives a representation of the objects using points. See the comparison below.



Before Rotation with Transparency



During Rotation – Draw Points

GD&T Callouts Area

The **GD&T callouts** area lets you control the display of GD&T callouts within an imported CAD model. It helps reduce screen clutter by making such callouts temporarily hidden as they reach or approach a view angle parallel to your current view angle. This option is disabled if your part model doesn't have any embedded GD&T callouts.

Do not confuse these GD&T callouts with the Geometric Tolerance dimensions that are created inside PC-DMIS. The GD&T callouts are essentially CAD objects themselves. These were not created inside PC-DMIS. Rather, they were created by the CAD software used to create the model and are stored with the model.

Hide normal view angle - This option tells PC-DMIS to hide the callouts when they cross a threshold of degrees parallel to your view angle. The box to the right of the check box lets you specify the threshold of degrees parallel to your view angle. The default value is 30.

Suppose you have a GD&T callout that points to a cylinder feature on the top of your part. Now, suppose you type a value of 45 degrees in the box. When you 3D rotate the part, the callout remains visible until the rotation of the part meets or exceeds 45 degrees.

If you want to always show the callouts, clear the check box.

ID Labels Area

The **ID Labels** area behaves the same as the GD&T callouts area, except that instead of GD&T callouts, it affects ID labels, such as feature ID labels, dimension info boxes, and point info boxes. It helps reduce screen clutter by making these labels temporarily hidden as they reach or approach a view angle parallel to your current view angle.

For more information on the items in this area, see the "GD&T Callouts Area" topic.

Showing and Hiding Graphics

You can choose to show or hide various labels and graphical objects inside the Graphic Display window with the **Graphic Items** toolbar (**View | Toolbars | Graphic Items**). Hiding some of these objects from time to time may de-clutter the Graphic Display window so that it's easier to perform certain operations.

These are the items you can show or hide:

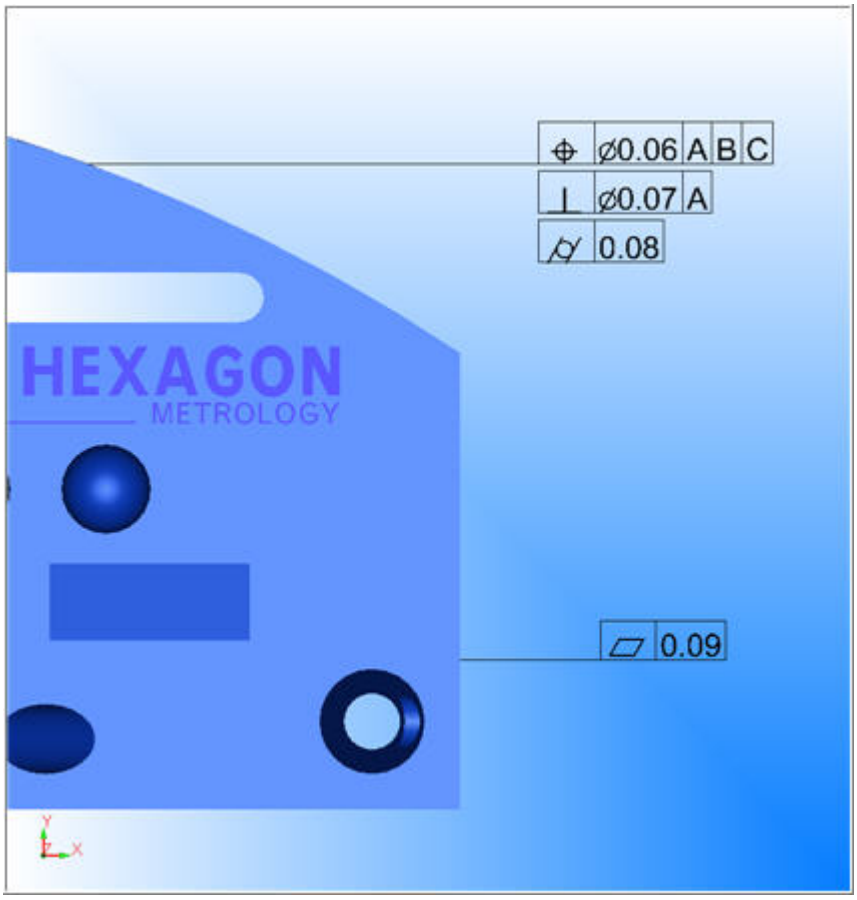
- CAD models
- GD&T
- Characteristic IDs
- Rotation Widget
- Feature Labels

- Point Info Labels
- Dimension Info Labels
- Cross Sections
- Label IDs
- Probe
- Machine
- Tool Changer
- Fixture
- Clearance Plane
- ClearanceCube

For information on the **Graphic Items** toolbar, see "Graphic Items Toolbar" in the "Using Toolbars" chapter.

Working with CAD GD&T Callouts

PC-DMIS lets you work with CAD GD&T callouts that are part of your CAD model in the Graphic Display window. You can show and hide these callouts, reposition them, change their view options, filter them, and import them into your measurement routine.



Sample CAD GD&T Callouts Displayed in the Graphic Display window

These CAD GD&T callouts are not actual Geometric Tolerances or Feature Control Frames. Instead, CAD GD&T callouts reside directly in your CAD model and appear as CAD elements. They do not initially perform any function in PC-DMIS other than providing visual information in the Graphic Display window. For details on Geometric Tolerances and Feature Control Frames, see "Introduction to Geometric Tolerances and Feature Control Frames".

To work with CAD GD&T callouts, your license must include the **CAD** and **GD&T Selection** options, or **CAD++**. Also, your CAD model must use a supported format. Supported formats include: CATIA v5, CATIA v6, Creo, NX, SolidWorks, and STEP AP242.

PC-DMIS also partially supports CAD GD&T callouts in IGES files. The IGES file must contain the following:

- 2D drawings with GD&T callouts
- A 3D model that corresponds to the 2D drawings

During the import process, PC-DMIS attempts to match the 2D GD&T callouts to the 3D features on the IGES model. Once PC-DMIS matches 2D callouts to the 3D features, you can then import the embedded callouts as features and FCF dimensions.

Showing or Hiding CAD GD&T Callouts

To show and hide the callouts, from the **Graphic Items** toolbar, click the **Show GD&T** icon ( ). If you want the callouts to always appear in newly created measurement routines, from the PC-DMIS Settings Editor, in the **Options** section, set the `ShowCADGDT` entry to **TRUE**.

Showing or Hiding CAD GD&T Notes

To show or hide GD&T notes, from the **Graphic Items** toolbar, click the **Show GD&T Notes** icon ( ).

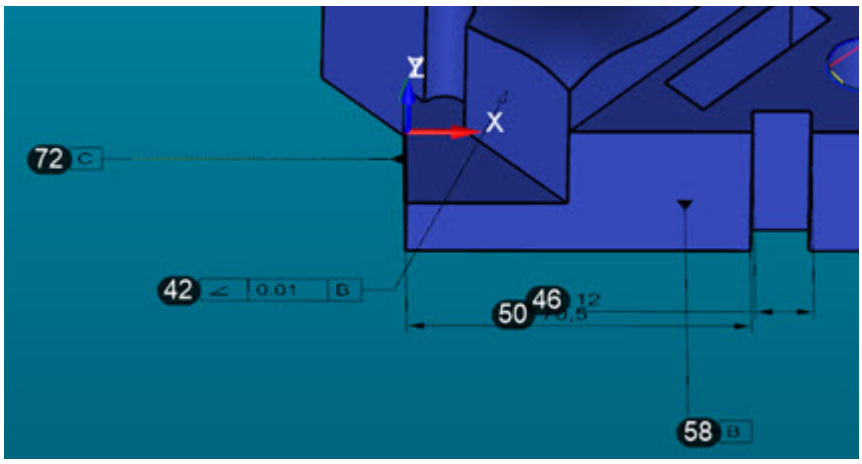
GD&T notes contain information embedded directly within the CAD model.

You cannot import them as commands into the Edit window.

Showing or Hiding CAD GD&T Characteristic IDs

You can use the **Characteristic IDs** icon ( ) on the **Graphic Items** toolbar to show and hide CAD GD&T characteristic IDs on CAD GD&T callouts. A characteristic ID on a callout is a unique identifier assigned to the CAD GD&T by the native CAD software. You can only see a characteristic ID if its corresponding CAD GD&T is also visible.

For information on the **Characteristic IDs** icon on the **Graphic Items** toolbar, see "Graphic Items Toolbar" in the "Using Toolbars" chapter of the PC-DMIS Core documentation.



Example of Characteristic IDs

You can modify the font size with the **Graphic Font** on the **Font Setup** dialog box. The font **Color** on that dialog box controls the background color of the characteristic ID. The foreground color automatically uses black or white to maintain good contrast.

> For information on the **Font Setup** dialog box, see "Customizing User Interface Fonts" in the "Setting Your Preferences" chapter.

You can use an Excel sheet to map different values to each characteristic ID and show those instead. To do this, use the **Balloon ID** tab on the **CAD and Graphic Setup** dialog box.

> For information on the **Balloon ID** tab, see the "Balloon ID Tab" topic.

> Don't confuse these characteristic IDs with the characteristic IDs PC-DMIS uses when you import a CAD GD&T callout. That type of characteristic ID comes from the native CAD model's PMI. For additional information on characteristic IDs in feature names, see "Use Characteristic ID Naming" in the "Setting Your Preferences" chapter.

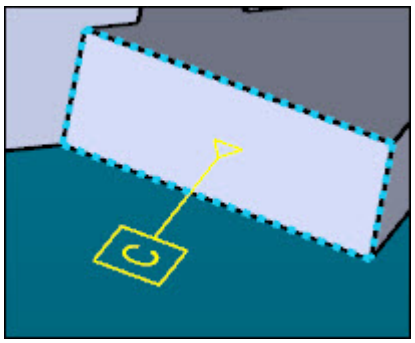
Viewing Associated CAD Elements

If you have the **CAD Information** dialog box open (**View | CAD Information**) and you click on a CAD GD&T callout, the software highlights the associated CAD element.

Inside the **CAD Information** dialog box, you can then click on links inside of curly braces to zoom in on specific CAD elements.

For more information on the **CAD Information** dialog box, see "Viewing CAD Information".

Another way to view associated CAD elements is to press Shift and position your mouse pointer over the GD&T callout. PC-DMIS highlights both the callout and all CAD elements linked to the callout:



Example of highlighting the surface for datum C

Associating CAD GD&T Callouts with CAD Elements

When you import a part with embedded CAD GD&T callouts, PC-DMIS does its best to link it to the correct CAD element. If PC-DMIS links something incorrectly, you can fix it with the **Associate CAD elements** shortcut menu.

To access this menu, from the **Graphic Modes** toolbar, click the **GD&T Selection Mode (from CAD)** button ( ). Then right-click on a CAD GD&T callout and choose **Associate CAD Elements** to open the **Associate CAD Elements** dialog box.

This dialog box shows the current associated CAD elements in the **Elements** list:

Associate CAD Elements dialog box with two associated elements

You can click on any element to zoom to that element in the Graphic Display window.

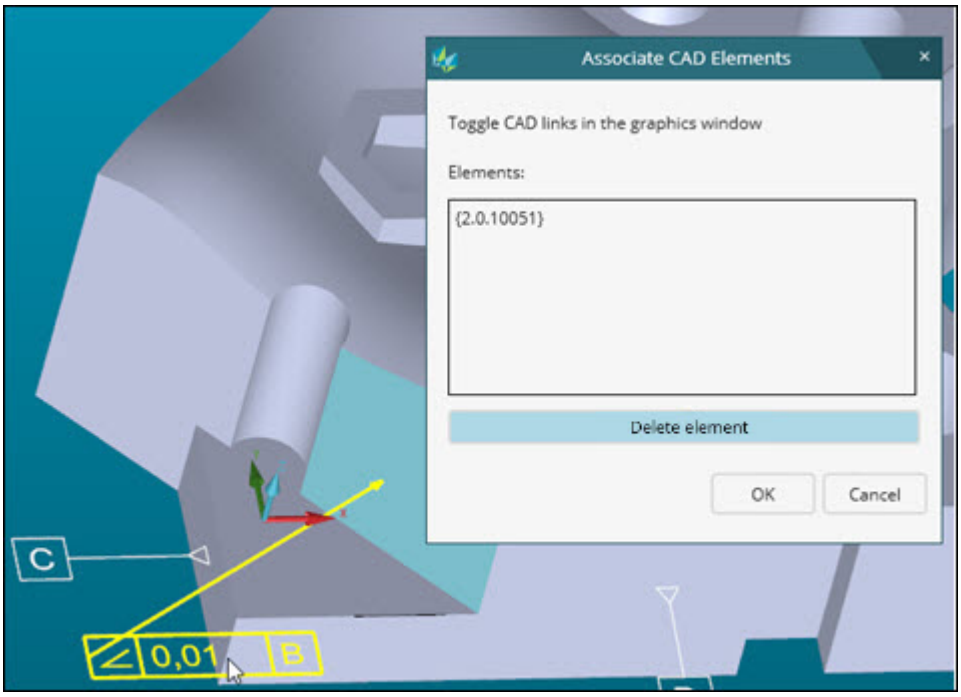
To remove an association:

1. Select the **Associate CAD elements** shortcut menu to see the current association in the **Associate CAD Elements** dialog box.
2. From the **Elements** list, select the element.
3. Click the **Delete element** button to remove the item from the **Elements** list.

4. Click **OK** to confirm the change.

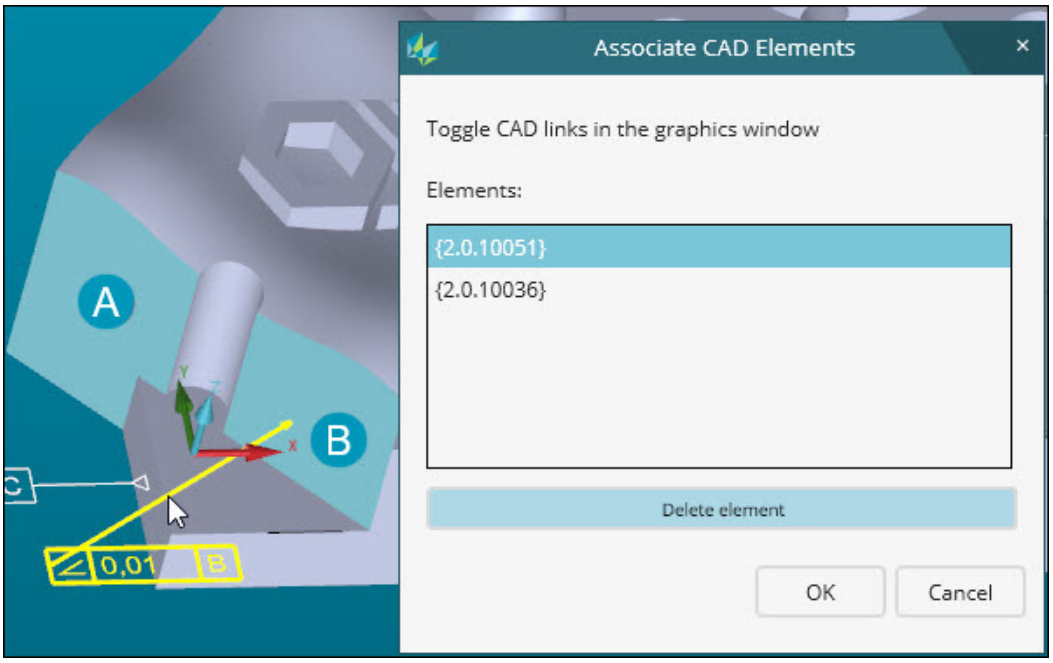
To add a new association:

1. Choose the **Associate CAD elements** shortcut menu to see the current association in the **Associate CAD Elements** dialog box.



GD&T callout initially associated to a single element

2. With the dialog box open, from the CAD model, click on a CAD element. PC-DMIS highlights the selected CAD element and adds it into the **Elements** list.



GD&T callout now associated to both elements (A and B)

3. Click **OK** to confirm the change.

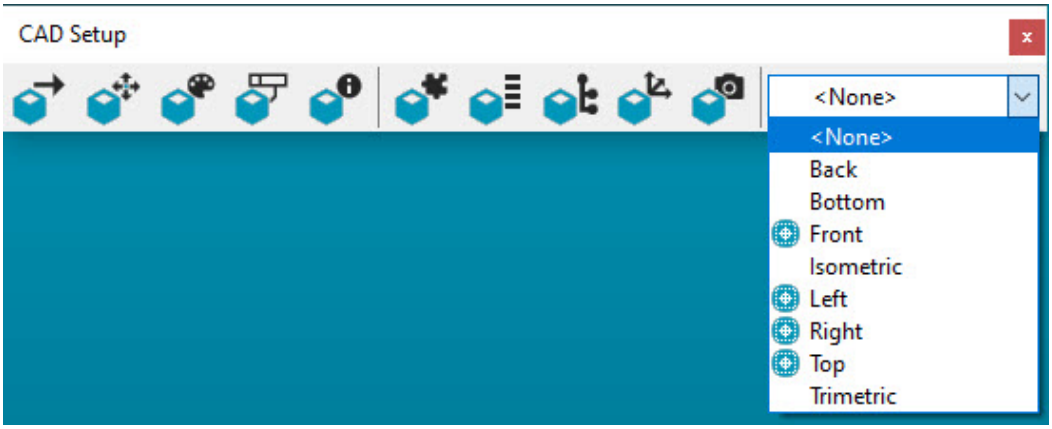
Associating CAD GD&T Callouts with Existing PC-DMIS Features

Similar to creating and removing associations between GD&T callouts and CAD elements, you can also add or remove an association between CAD GD&T callouts and existing features from your measurement routine. This can be helpful if you do not want to use the default Auto Feature method to measure a feature. For example, you may want to create constructions instead.

To associate a CAD GD&T callout with an existing PC-DMIS feature, do this:

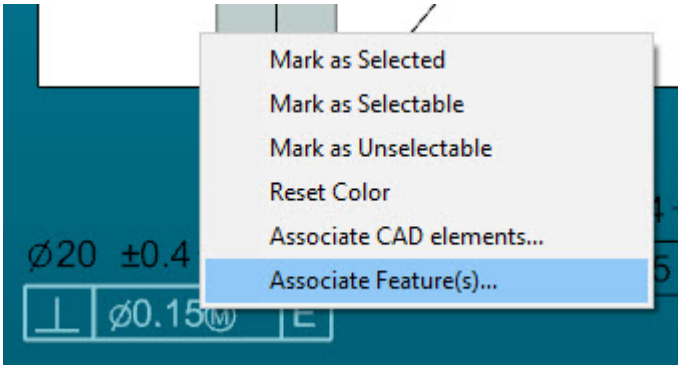
1. From the **Graphic Modes** toolbar, click the **GD&T Selection Mode (from CAD)** button ( ).

2. From the **CAD Setup** toolbar (**View | Toolbars | CAD Setup**), select the view associated with the features from the **CAD Model View** list. The view you select must have the PMI displayed as shown.



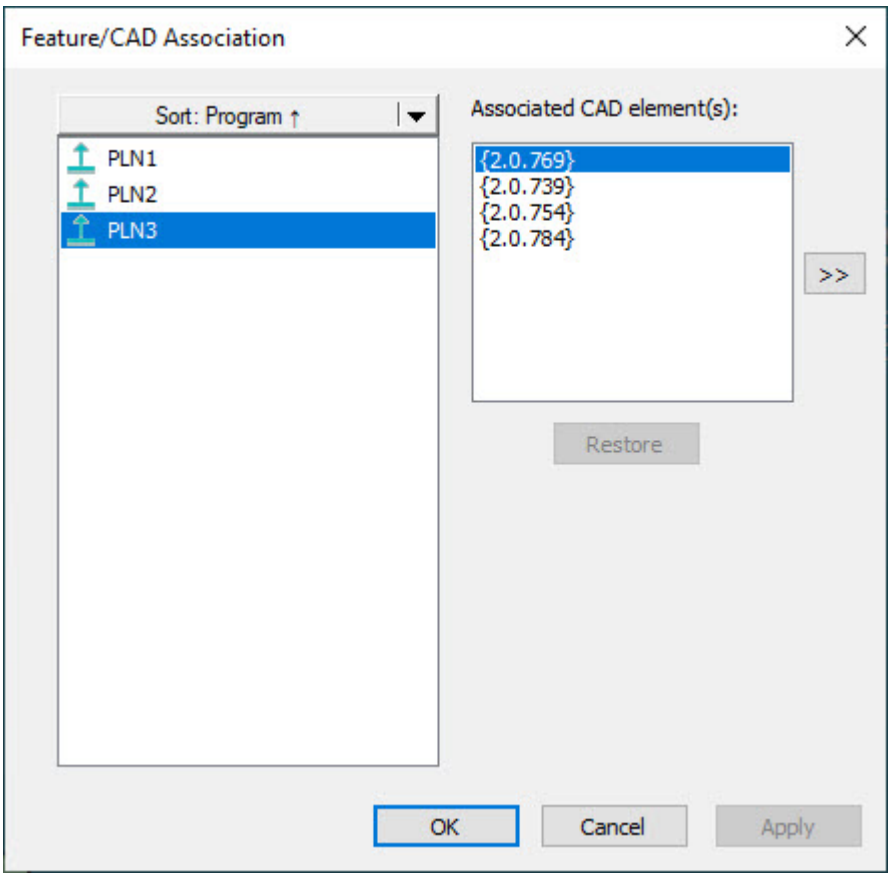
Example of view options with PMI in CAD and displayed (Front, Left, Right, and Top)

3. Right-click on a CAD GD&T callout in the Graphic Display window and select the **Associate Feature(s)** option.



PMI menu with the Associate Feature(s) option selected

4. The **Feature/CAD Association** dialog box opens. Select a feature from the **Features** list on the left to view its associated CAD feature elements in the **Associated CAD element(s)** list on the right. PC-DMIS highlights all associated feature elements in the Graphic Display window.



Feature/CAD Association dialog box

5. Click **OK** to save your changes.

To remove an association between a CAD GD&T Callout and a feature, do this:

1. Right-click on a CAD GD&T callout in the Graphic Display window and select the **Associate Feature(s)** option.

2. Select a feature from the Feature list on the left to view the associated feature elements in the **Associated CAD element(s)** list on the right. PC-DMIS highlights all the elements associated with the selected feature on the CAD model in the Graphic Display window.

3. Click any of the highlighted features in the Graphic Display window to temporarily remove them from the **Associated CAD element(s)** list. This also removes their association with the selected feature in the **Feature** list causing PC-DMIS to no longer highlight the selected feature in the Graphic Display window.

   You can also select the feature element from the **Associated CAD element(s)** list and click the **>>** button to remove the association.

   Click the **Restore** button to insert the feature element back into the **Associated CAD element(s)** list. This restores its association with the selected feature and PC-DMIS highlights the element in the Graphic Display window again.

4. Click **OK** to save any changes you made.

Once you click **OK**, any associations you removed are permanent. If you need to recreate the association, you must perform the steps to associate a CAD GD&T callout with a CAD feature and select the feature element that you removed.

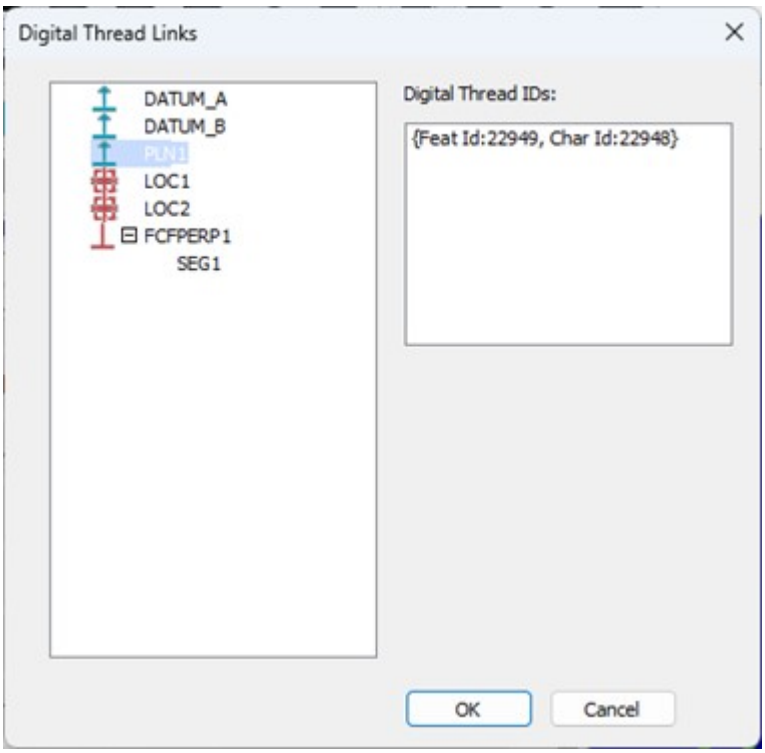
Once you associate a feature with a CAD surface, PC-DMIS recognizes it when it consumes the GD&T callout and uses the pre-existing, associated feature rather than inserting a new feature into the measurement routine.

Viewing GD&T Digital Thread IDs

When you import a CAD file, PC-DMIS reads the digital thread IDs (Feature ID and Character ID) from the CAD data and stores them internally. When you create features and dimensions using the associated PMI, PC-DMIS inserts these IDs into the corresponding PC-DMIS commands. As a result, when you export the data, the digital thread IDs are preserved and included in the output.

Digital thread IDs are available for CAD data imported from a .qif file, or from a STEP file that contains UUIDs for the features and characteristics. PC-DMIS includes digital thread ID information only in QIF report.

To view the associated digital thread IDs for a feature or dimension, select **Operation | Graphic Display Window | GD&T Selection | View GD&T Digital Thread Ids** to open the **Digital Thread Links** dialog box. From the **Features** list on the left, select a feature or dimension to view its associated digital thread IDs in the **Digital Thread IDs** area.



Example showing the digital thread IDs (feature ID and character ID) for a selected plane feature.

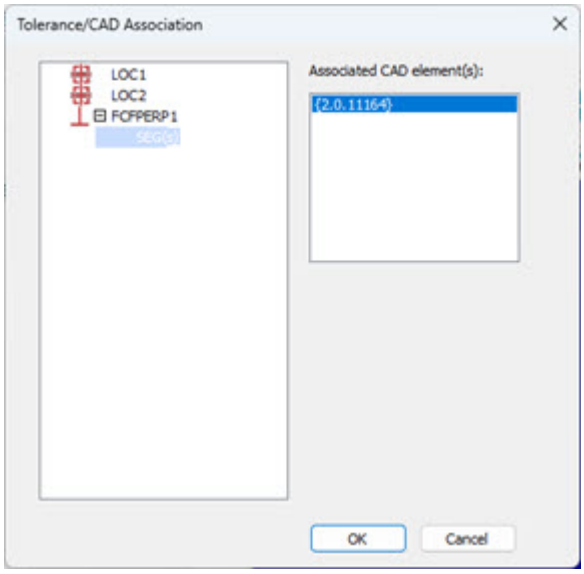
Associating GD&T Digital Thread IDs with Dimensions

You can associate GD&T digital thread IDs with dimensions that you create manually. To associate GD&T digital thread IDs with dimensions, follow these steps:

> If the dimension references measured or constructed features, make sure you associate those features with the required CAD elements before you associate the dimension. For information on how to associate features, see "Associating CAD GD&T Callouts with Existing PC-DMIS Features" in the "Working with CAD GD&T Callouts" topic in the PC-DMIS Core documentation.

1. From the **Graphic Modes** toolbar, click the **GD&T Selection Mode (from CAD)** button ( ).
2. Right-click on a CAD GD&T callout in the Graphic Display window and select **Associate Tolerance(s)** to open the **Tolerance/CAD Association** dialog box.
3. Select a dimension from the **Dimension** list and then click the CAD GD&T callout in the Graphic Display window that you want to associate with the selected dimension.

   PC-DMIS displays the associated CAD element in the **Associated CAD element(s)** area.



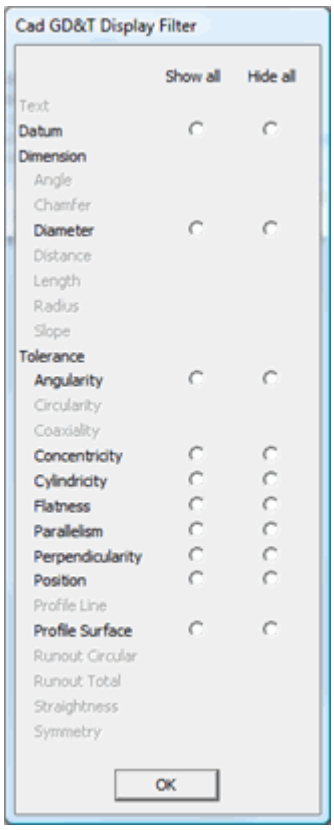
4. Click **OK** to save your changes.

Moving CAD GD&T Callouts

To reposition a CAD GD&T callout, from the **Graphic Modes** toolbar, turn on Text Box Mode ( ), and then drag the callout to a new location.

Filtering CAD GD&T Callouts

1. From the **Graphic Modes** toolbar, turn on Text Box Mode ( ).
2. Right-click on a GD&T callout, and from the shortcut menu, select **CAD GD&T Display Filter** to show the **CAD GD&T Display Filter** dialog box. This dialog box shows a list of CAD GD&T information and two columns of option buttons (**Show all** and **Hide all**).
3. For each item you want to show or hide, click **Show all** or **Hide all** to immediately toggle the visibility state of that GD&T callout.



4. Click **OK** to close the dialog box and store the current filtered state until accessed and modified later.

Showing or Hiding Individual Callouts

From the **Graphic Modes** toolbar, turn on Text Box Mode ( ), right-click on a GD&T callout, and select one of the Show or Hide ID menu items.

Importing CAD GD&T Callouts

PC-DMIS can import selected GD&T callouts as dynamically-generated FCF dimensions or datum definitions.

1. From the **Graphic Items** toolbar, click the **Show GD&T** icon ( ), to ensure that the GD&T callouts are visible.

> You can hide all the label types, so that they don't fill up the screen during the import process. To do this, from the **Graphic Items** toolbar, click the **Show All Label IDs** icon ( ).

2. Do one of the following:

- *Select* **Operation | Graphic Display Window | GD&T Selection | Select All GD&T**. This option selects all embedded CAD GD&T callouts and converts them into Edit window commands.
- *Select* **Operation | Graphic Display Window | GD&T Selection | Select GD&T in Current View**. This option selects only the embedded CAD GD&T callouts that are visible and converts them into Edit window commands.
- *Select* **Operation | Graphic Display Window | GD&T Selection | Select GD&T in Active CAD Model View**. This option creates GD&T dimensions from the embedded CAD GD&T callouts stored inside an active CAD model view. This menu remains grayed out until you make a view active. To make a view active, from the **CAD Model Views** dialog box (**Edit | Graphic Display window | CAD Model Views**), from the list of views, double-click on a model view. For information on CAD Model Views, see "Working with CAD Model Views".

- Enable the **GD&T Selection Mode (from CAD)** ( ) icon on the **Graphic Modes** toolbar. Then *click on a single item*. In the Edit window, PC-DMIS generates all necessary commands that make up the specific datum definition or FCF dimension. These commands are temporary. PC-DMIS removes them if you click **Cancel**. From the **Geometric Tolerance Command** dialog box that appears, make any changes to the FCF dimension. Click **OK** to accept the dimension and make referenced temporary commands permanent. Temporary commands that are not referenced are removed.

  Even if PC-DMIS is not in **GD&T Selection Mode (from CAD)**, as long as PC-DMIS is in a supported mode and the callout is visible, you can press Shift and click on the callout to import it. Supported modes include Translate Mode, 2D Rotate Mode, and 3D Rotate Mode.

- Enable the **GD&T Selection Mode (from CAD)** ( ) icon on the **Graphic Modes** toolbar. Then *box-select multiple callouts*. In the Edit window, PC-DMIS generates all necessary commands that make up the selected datum definitions or FCF dimensions.

If the selected CAD GD&T callouts don't have geometry features, they are incomplete. You cannot import incomplete GD&T callouts into the measurement routine. PC-DMIS shows incomplete or invalid callouts in the **Invalid GD&T** tab of the **CAD GD&T Selection Information** dialog box.

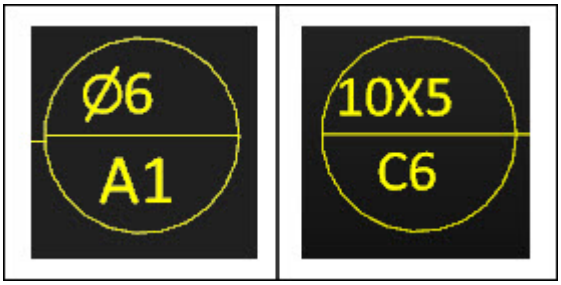
If the measurement routine's GD&T standard does not support the selected CAD GD&T callout, PC-DMIS adds an operator comment stating that the geometric tolerance command was not created. It then lists the IDs of the features that it did add to the routine. For information on the routine's GD&T standard, see the "Setup Options: Geometric Tolerances Tab" topic in the "Setting Your Preferences" chapter.

If you hold down Shift before you click on or box-select the CAD GD&T callout item, the software generates the FCF datum definitions and commands in the Edit window without showing the **Geometric Tolerance Command** dialog box.

By default, if you hold down Shift and click (or double-click) on a GD&T callout item, PC-DMIS displays the measurement strategy widget. You can use this widget to change a feature's main parameters. For more information on this widget, see "Using the Measurement Strategy Widget" in the "Creating Auto Features" chapter.

Datum Target Areas

You can import rectangular and circular datum target areas if they are aligned to an axis. The following picture shows some sample datum target areas:



The left shows a circular area, while the right sample shows a rectangular area

When you import a datum target area, the software creates the following in the Edit window:

- A High Point feature
- A workplane that corresponds to the target area surface normal

Regions of Interest (ROI)

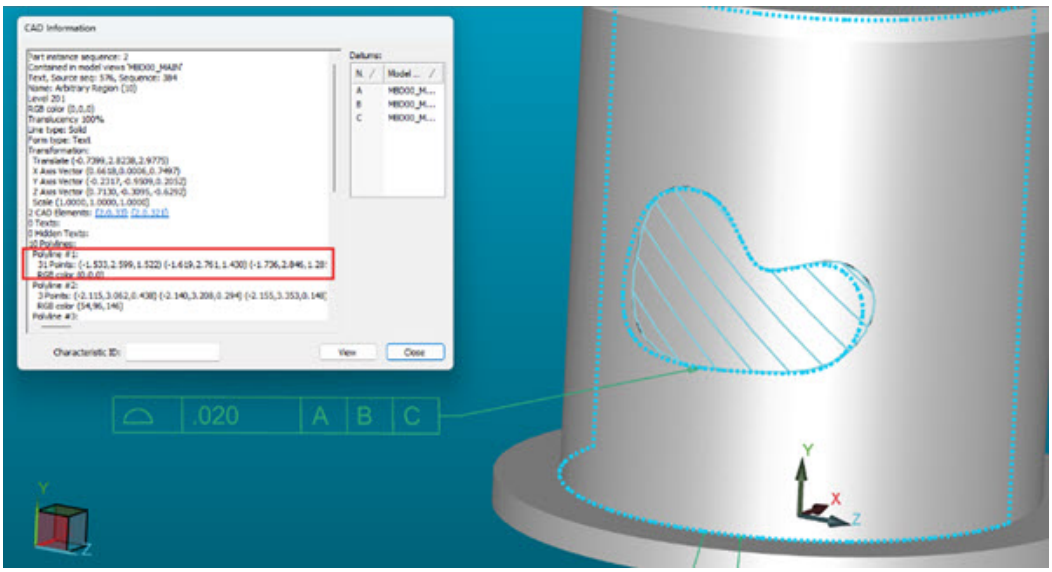


Image showing a surface profile within a specified region of interest, the associated CAD elements, and the CAD Information dialog, with the polyline information highlighted

You can import a surface profile tolerance with a restricted region of interest, if the region's outer boundary is defined as a CAD polyline. The associated CAD elements must be the polyline and the underlying CAD surface. PC-DMIS uses the polyline points as the boundary points of a Patch scan, limiting the extent of measurement to the region within the polyline.

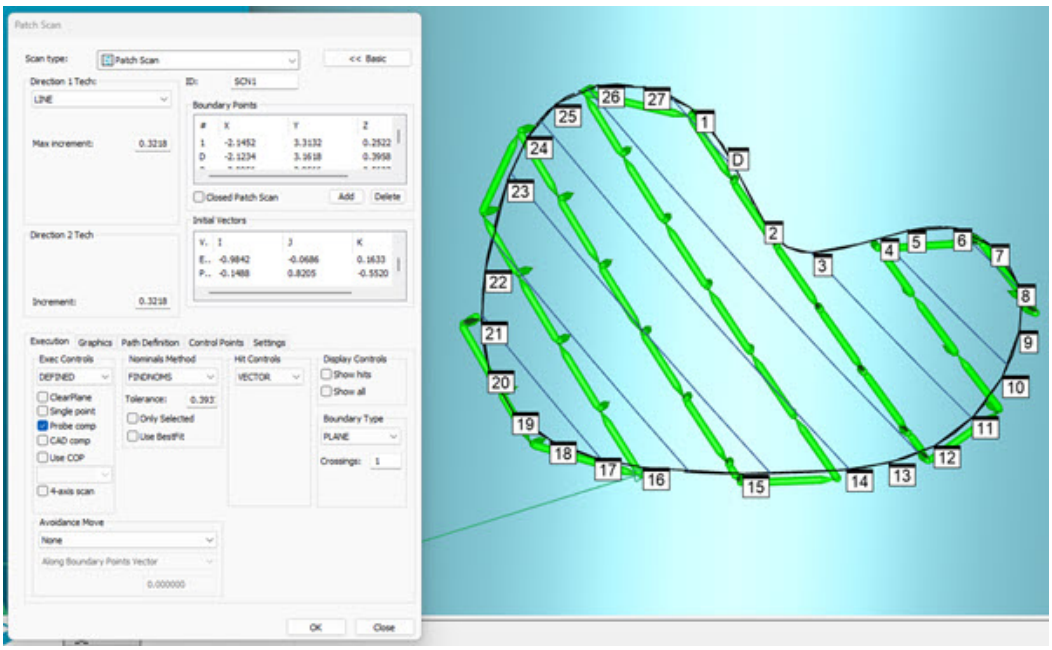

Image showing the Patch scan's boundary points and the path lines of the generated scan

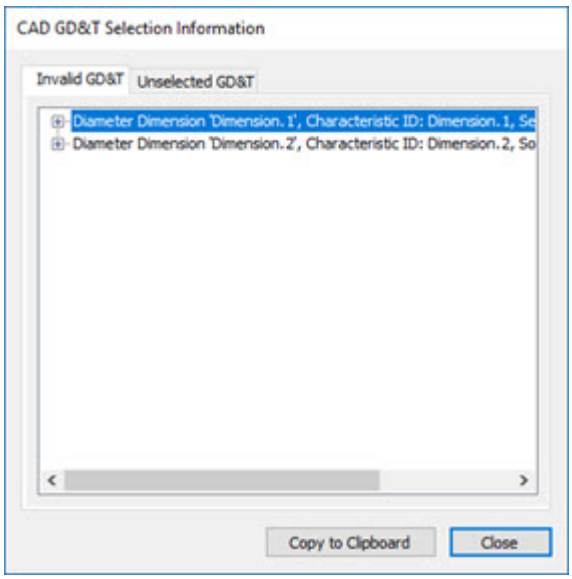
Use Characteristic ID Naming

When you import callouts, you can have the features use their native characteristic IDs instead of PC-DMIS's default feature naming. For more information see "Use Characteristic ID Naming" in the "Setting Your Preferences" chapter.

Viewing Invalid GD&T Callouts

The **Operation | Graphic Display Window | GD&T Selection | View Invalid GD&T for Selection** menu option opens the **Invalid GD&T** tab on the **CAD GD&T Selection Information** dialog box. This tab also appears after you import CAD GD&T callouts as Edit window commands and some callouts were incomplete or invalid.

This tab analyzes all the CAD GD&T callouts to locate invalid callouts. Invalid callouts are those that the software cannot solve for selection. The dialog box then displays these callouts in a list.



CAD GD&T Selection Information dialog box - Invalid GD&T tab

You can expand an object to see a description of why the software cannot solve the object for selection.

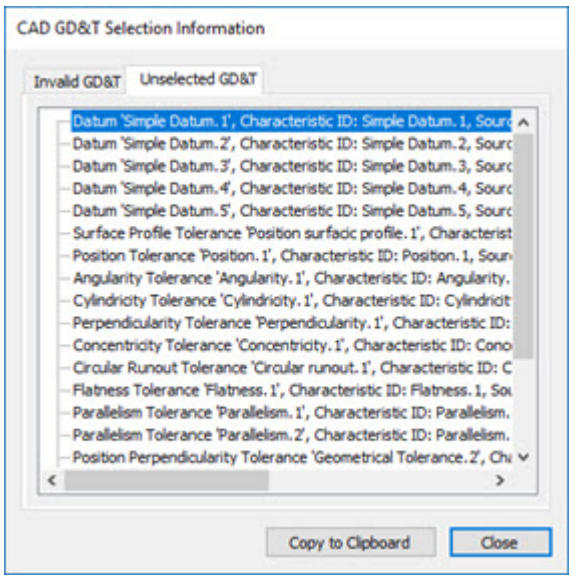
You can click on an object to highlight the object in the Graphic Display window. You can double-click on an object to highlight and scale the object. These make it easier to locate.

The **Copy to clipboard** button copies the text of the contents to the Clipboard.

> This option cannot detect all the reasons why the software cannot solve an object for selection. This means objects may not appear in this dialog box that it cannot solve.

Viewing Unselected GD&T Callouts

The **Operation | Graphic Display Window | GD&T Selection | View GD&T Not Selected** menu option opens the **Unselected GD&T** tab on the **CAD GD&T Selection Information** dialog box.



CAD GD&T Selection Information dialog box - Unselected GD&T tab

This tab analyzes all the CAD GD&T callouts to locate unselected callouts. Unselected callouts are those that you have not selected using GD&T selection. That is, these callouts don't have corresponding measurement routine commands.

Once you import them with GD&T selection, they no longer appear in this tab. For information on GD&T selection, see the "Importing CAD GD&T Callouts" subtopic above.

You can click on an object to highlight the object in the Graphic Display window. You can double-click on an object to highlight and scale the object. These make it easier to locate.

The **Copy to clipboard** button copies the text of the contents to the Clipboard.

Setting CAD GD&T Callout Colors

You can set the colors the software uses for valid and invalid CAD GD&T callouts in the Graphic Display window. For information on how to do this, see "CAD GD&T Tab" under "Setting Up CAD and Graphics".

Marking CAD GD&T Callouts with Colors for Selected, Selectable, or Unselectable

You can set CAD GD&T Callouts to different colors to better communicate the state of the current callout (selected, selectable, or unselectable).

For more information, see "CAD GD&T Callouts Shortcut Menu" in the "Using Shortcut Keys and Shortcut Menus" appendix.

Excluding CAD GD&T Callouts

You can use .exclude files to exclude items that PC-DMIS would normally accept as selectable CAD GD&T callouts. One reason to do this is to only display callouts that apply to a specific measurement device.

1. Choose **Edit | Graphic Display Window | CAD GD&T** to access the **CAD GD&T** tab on the **CAD and Graphic Setup** dialog box.

2. From the **Exclude** area, click **Generate** to create an .exclude file based on the available CAD GD&T callouts.
3. Click **Edit** to open the .exclude file in a text editor.
4. For any item that you want to exclude, remove the single quote character at the front of the line.
5. Mark the **Use exclude file** check box.
    - In the **Exclude** area, click **Apply** if you want to color the excluded CAD GD&T callouts.
    - Click **Hide excluded data**, if you want to hide the items you chose to exclude.
6. Click **OK**.

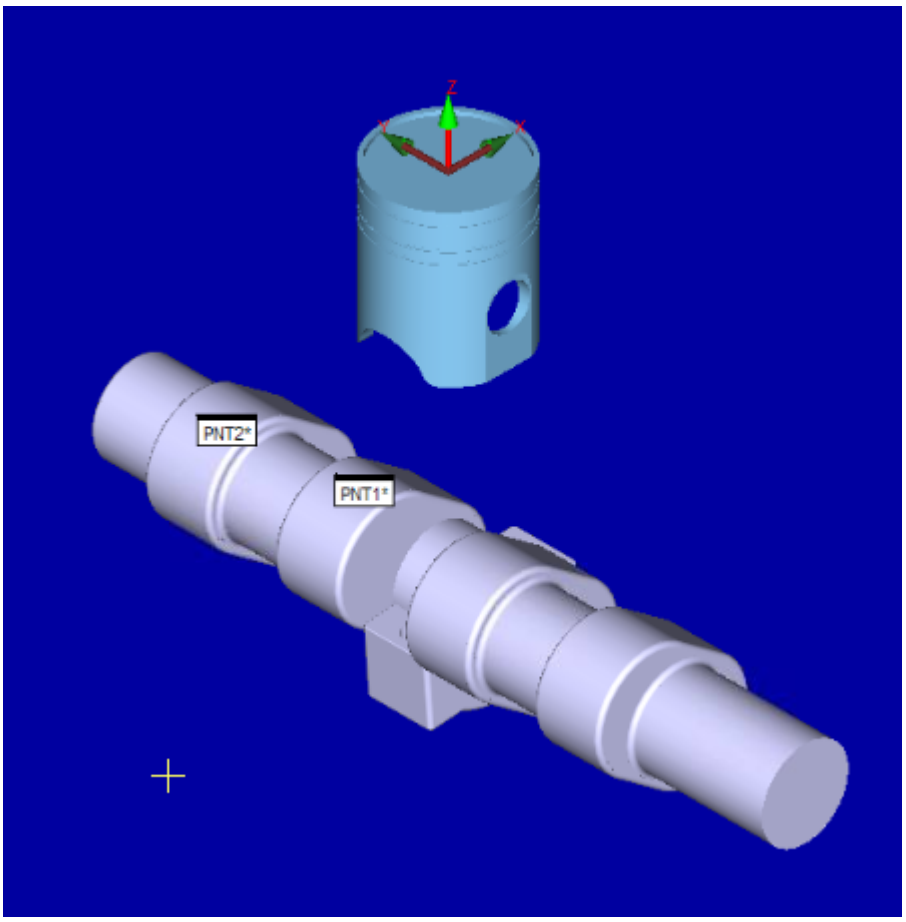
For information on .exclude files, see the "CAD GD&T Tab" topic in this chapter.

Instead of using the **Generate** button to create the .exclude file, you can also manually create your own .exclude file. To do this:

1. Create a text file with the same name as your measurement routine. Give the text file the **.exclude** filename extension.
2. Use a text editor, and type the Characteristic IDs to exclude on separate lines. You only need to type the IDs. If an ID has a space in it, put quotes around the ID. For example, an ID of A 1 should be "A 1".
3. Save your changes, and place the .exclude file in the same directory as the measurement routine.

Working with Assemblies of Parts

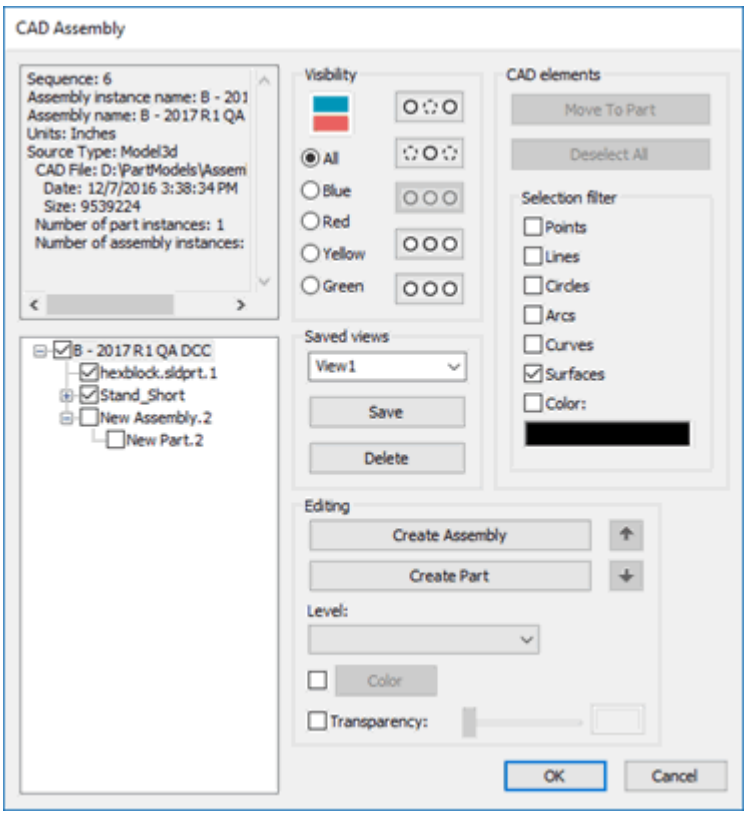
A CAD Assembly consists of two or more imported part models merged together in the Graphic Display window. For example, the graphic below shows an assembly of two visible parts.



A Sample CAD Assembly

You can have multiple parts and even multiple assemblies together in a single .cad file.

To work with assemblies, open the **CAD Assembly** dialog box. From the **CAD** toolbar, select the **Assembly** icon , or select **Edit | Graphic Display Window | CAD Assembly**.

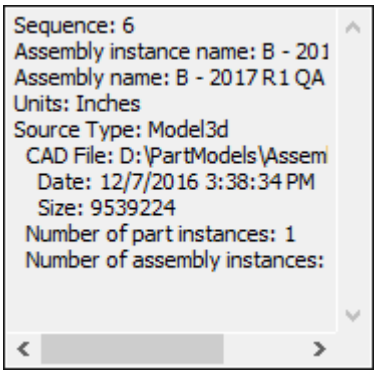


CAD Assembly Dialog Box

The **CAD Assembly** dialog box contains a list of all imported and merged parts, assemblies, and CAD section cuts used in the Graphic Display window. You can use this dialog box to view, edit, and manage assemblies of parts. You can also resize this dialog box, and the software remembers the last used size and position the next time it opens.

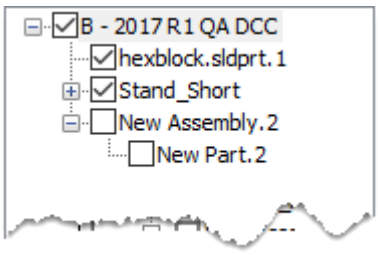
This dialog box contains these options:

Information Box



The gray box at the top of the dialog box displays information about the item currently selected on the Assembly Tree View. The information changes depending on the item selected.

Assembly Tree View



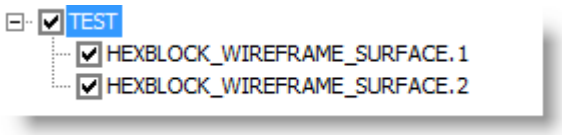
The left side of the dialog box has a tree view that represents the CAD assembly structure. Each item in the tree view represents an assembly component.

- If you select a component from the tree view, PC-DMIS displays information about that item in the gray box above the list.
- If you double-click a component in the assembly, PC-DMIS selects and highlights the component in the Graphic Display window. Conversely, with the **CAD Assembly** dialog box open, if you press and hold the Alt key and then left-click a CAD object in the Graphic Display window, PC-DMIS selects its corresponding component in the tree view. This helps to identify which CAD objects belong to which assembly component.

Each component has its own check box to show or hide that component immediately within the Graphic Display window.

- If you mark a check box, PC-DMIS shows that component.
- If you clear a check box, PC-DMIS hides that component (and any children components, regardless of their visibility state).
- Once you mark a check box, you can use the buttons in the **Visibility** area to change the visibility state of that component or of its sibling or children components.

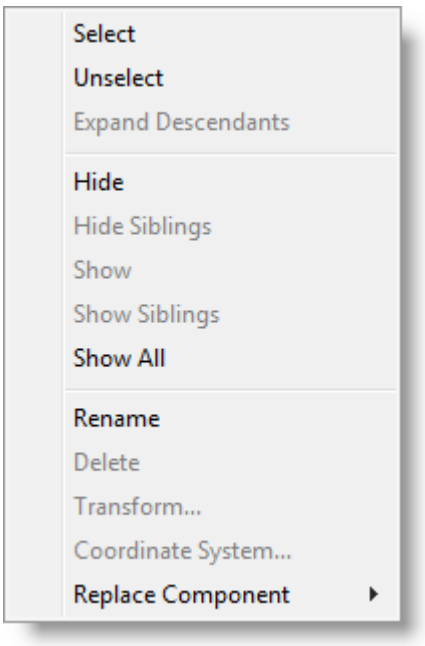
Your original imported image name has the number 1 appended to its name. Any CAD transformation that creates a new instance of this same CAD file are then incremented to have a unique number. See "Transforming a CAD Model".



Mirrored CAD File names with unique numbers inside a CAD Assembly Tree View

For information on SectionCutCurve entries, see "Creating and Viewing Section Cut Curves".

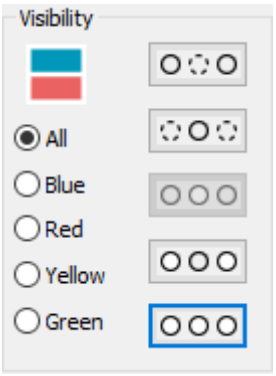
A shortcut menu appears when you right-click in the tree view. The shortcut menu contains these items:



- **Select** - This item functions as if you had double-clicked on the assembly component.
- **Unselect** - This item deselects the assembly component in the Graphic Display window.
- **Expand Descendants** - This item expands an assembly to show a list of child parts making up the assembly.
- **Hide** - This item hides the selected component.
- **Hide Siblings** - This item hides all of the components except the selected component at the same level on the assembly tree.
- **Show** - This item shows the selected component.
- **Show Siblings** - This item shows all of the components except the selected component at the same level on the assembly tree.
- **Show All** - This item shows all the components on the assembly tree.
- **Rename -** This item renames the selected component in the assembly.
- **Delete** - This item deletes the selected component from the assembly and removes it from the Graphic Display window. You cannot delete the root tree view component.
- **Transform** - This item displays the **CAD Transform** dialog box. This dialog box allows you to transform (translate, scale, and rotate) a single component in the assembly. You cannot transform the root tree view component. For more information, see "Transforming a CAD Model".

- **Coordinate System** - This item displays the **CAD Coordinate System** dialog box. This dialog box lets you create and manage different coordinate systems. For more information, see "Working with CAD Coordinate Systems".
- **Replace Component** - This item allows the selected assembly component to be replaced with another CAD model. This model can either be an imported CAD model or a model connected with the DCI. The submenus have the same structure as the **File | Import** and **File | Direct CAD Interface** menu options respectively. The new model replaces whatever model is associated with the selected node. The new model on the node retains any transformation that was applied to the previous model. For information on how to import model files, see "Importing CAD Data or Feature Data" in the "Using Advanced File Options" chapter.

Visibility



The **Visibility** area provides option buttons and icon buttons that allow you to run visibility operations in order to change the hidden state of assembly component groups.

The colored icon at the top of this area shows your current screen layout. It corresponds with the icon used in the **Layout** area of the **View Setup** dialog box. See "Setting Up the Screen View".

The **Blue**, **Red**, **Yellow**, and **Green** options limit the visibility operation to only that "view" of the Graphic Display window. The **All** option applies the visibility operation to all views.

These command buttons have pictures on them that depict their action:

Hide - This button hides the selected component.

Hide Siblings - This button hides all of the components except the selected component at the same level on the assembly tree.

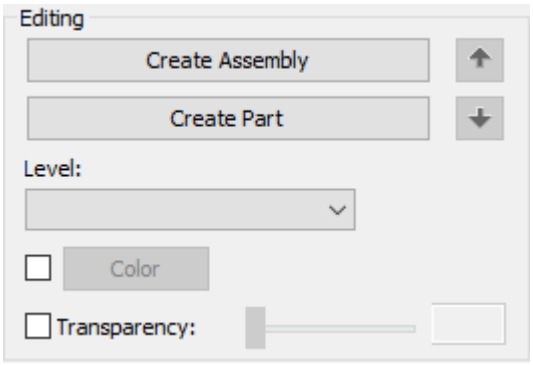
Show - This button shows the selected component.

Show Siblings - This button shows all of the components except the selected component at the same level on the assembly tree.

Show All - This button shows all the components on the assembly tree.

Only the hide and show properties are applied to individual views. The **Color** and **Transparency** settings in the **Editing** area are always applied to all views.

Editing



The **Editing** area lets you edit the currently selected component from the **Assembly Tree View**.

Create Assembly - This button creates a new assembly node in the currently selected assembly. Initially, the node is empty, but you can then move other assembly components into it by using the up and down arrow buttons ( ) on those components.

Create Part - This button creates a new part node in the currently selected assembly. Initially, the node is empty, but you can move CAD objects into it by using the Move to Part button in the CAD Elements area.

Up Arrow - This button moves the part or assembly component in the tree view up into the assembly just above it in the list.

Down Arrow - This button moves the part or assembly component in the tree view down into the assembly just below it in the list.

Color - This check box enables the **Color** button and displays the **Color** dialog box. This dialog box lets you apply a color to the selected tree view component. This check box also enables or disables the display of the selected color. Once you choose the initial color, you can click the **Color** button thereafter to modify the color used. This overrides any colors set for CAD elements using the **Edit CAD Elements** dialog box until the assembly component no longer uses a color or is removed from the **CAD Assembly** dialog box. For more information, see "Editing CAD".

Level - This list lets you assign the CAD objects within the selected assembly component to a predefined CAD level. This action overrides any CAD level assignments that were set using the **CAD Levels** dialog box until the assembly component is removed from the level

or from the assembly within the **CAD Assembly** dialog box. For more information, see "Working with CAD Levels".

Transparency - This check box applies the selected transparency percentage to the selected tree view component. You can drag the slider or change the value manually in the box to change the transparency percentage.

You cannot perform some edit operations on the root-level component (usually the part name used in your measurement routine) or DCI components. Those operations that you cannot use are disabled when you select these types of components.

Save Views

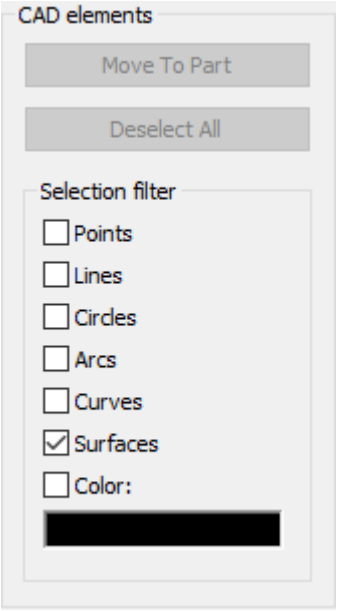
The **Saved Views** area lets you manage different visibility states of the **Assembly Tree View**.

Save - This button saves the current visibility state, giving it the name specified in the current **Saved Views** box. You must click the **OK** button to permanently save your view. PC-DMIS stores saved views in the .cad file associated with the measurement routine.

Delete - This button deletes the stored visibility state of the name selected from the **Saved Views** box.

To load a stored visibility state, select it from the **Saved Views** list. The check boxes in the **Assembly Tree View** are immediately modified according to the loaded view.

CAD Elements



The **CAD Elements** area lets you select CAD objects and move them to a different part. You can select or deselect CAD objects within the Graphic Display window. To do that, click on them individually, or for multiple CAD objects, drag a box around them.

Move To Part - This button moves the selected CAD objects to the currently selected part in the **Assembly Tree View**.

Deselect All - This button deselects all previously selected **CAD** objects.

Selection Filter - This area lets you filter the CAD objects that PC-DMIS can select. If an item is selected, PC-DMIS has the ability to select that type of CAD object when you click or box-select CAD objects in the Graphic Display window.

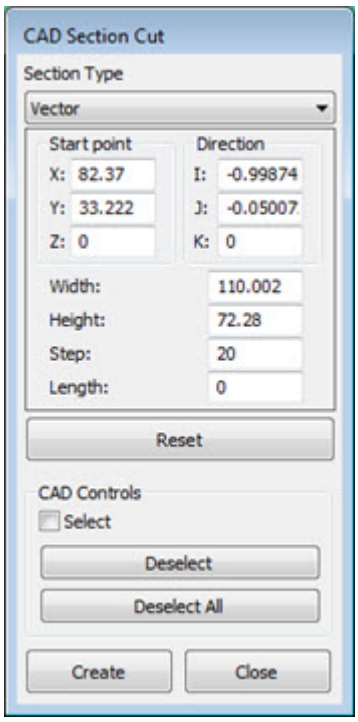
You can also filter the selection by the color of the CAD object. If you select the **Color** check box, the color of the next CAD object that you select in the Graphic Display window is then used as the filter color. For subsequent selections, you can only select CAD elements with that color.

Creating a CAD Section Cut

The **CAD Section Cut** function creates a CAD curve polyline defined by the contour of the CAD model.

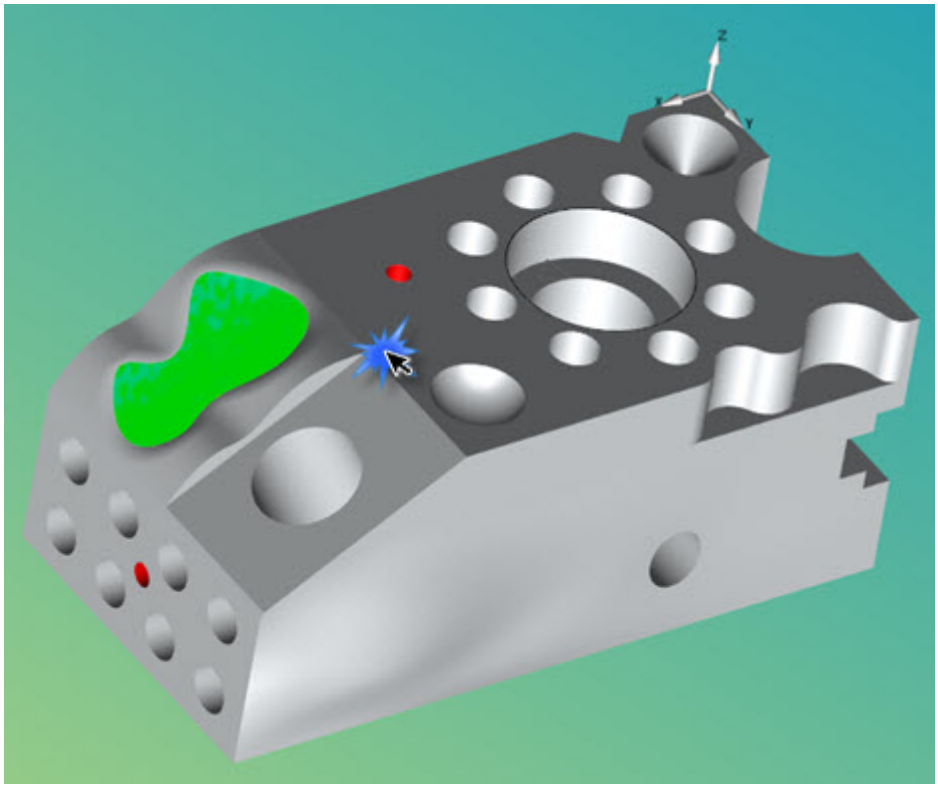
To create a CAD Section Cut:

1. From the main menu, select **Edit | Graphic Display Window | CAD Section Cut** to open the **CAD Section Cut** dialog box.

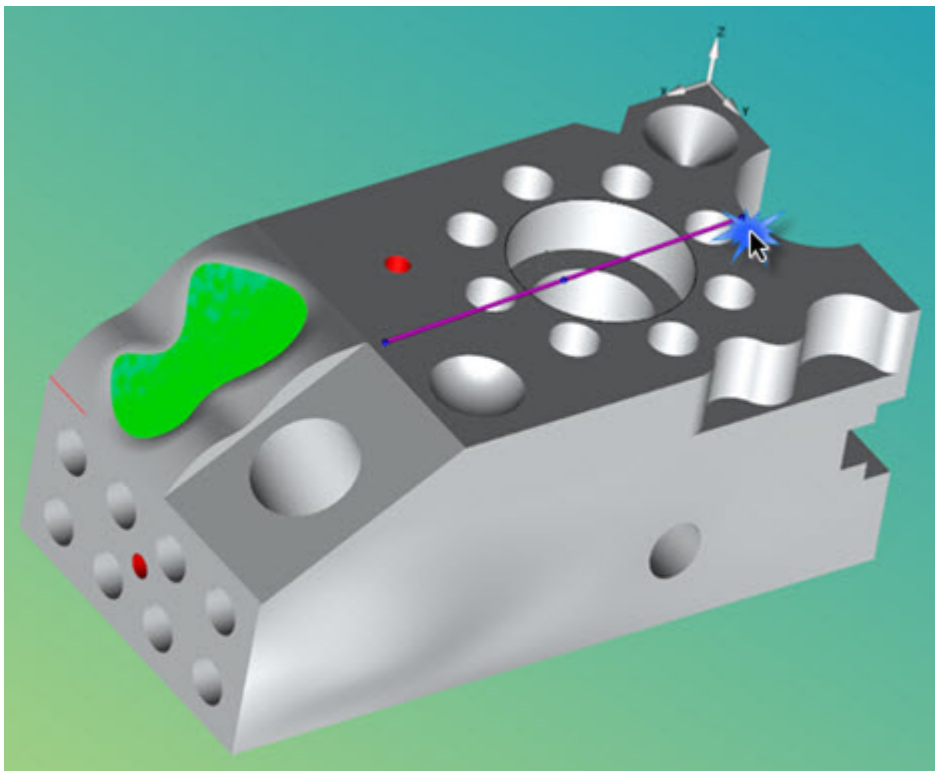


2. Select the type of section cut you want to define from the **Section Type** list. For details on these options, see the topic "Cross Section".

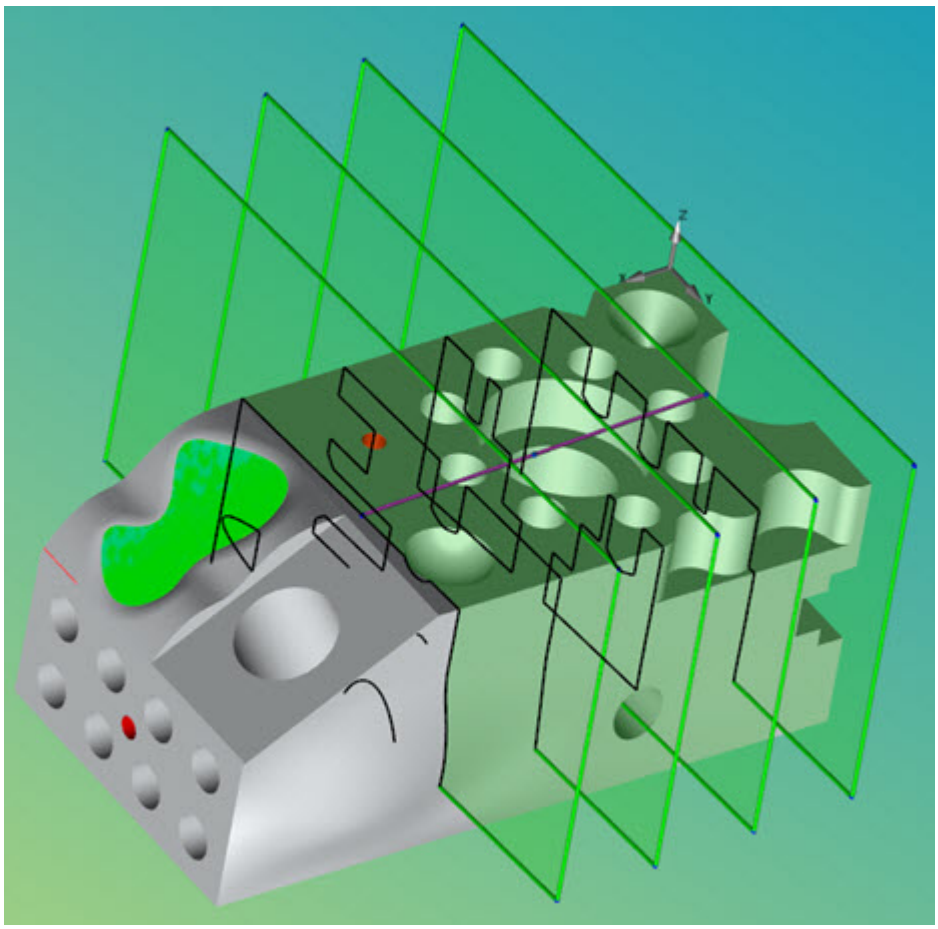
3. Click the surface where the section cut is to start.



4. Move your cursor to where the section cut is to end and click.

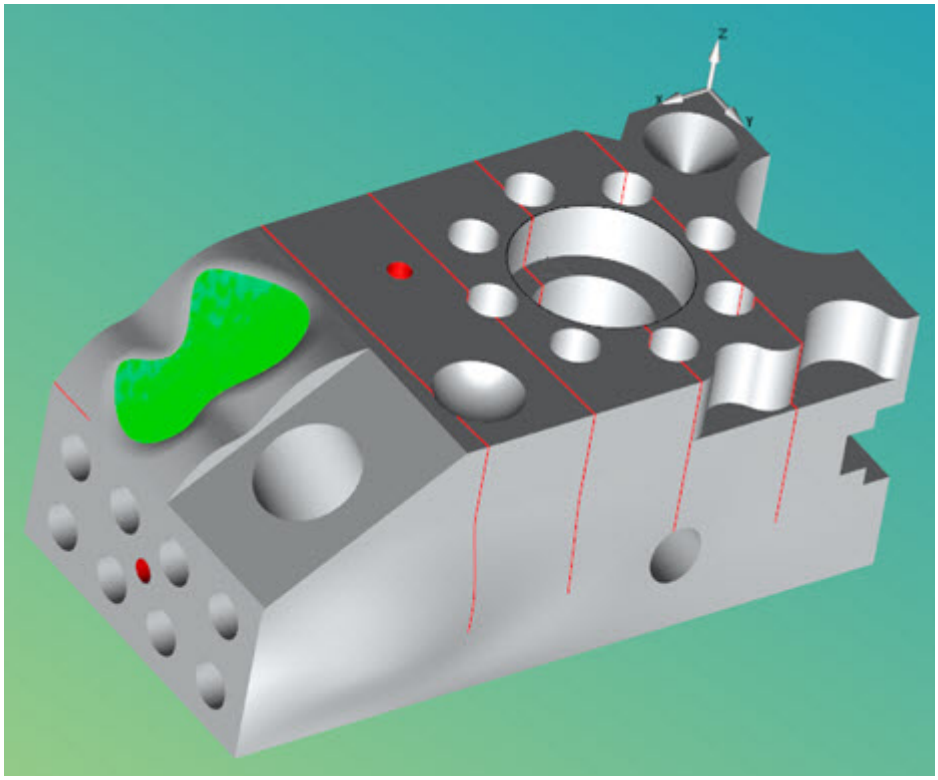


5. The CAD Section Cut is generated.



From the **CAD Section Cut** dialog box, edit the properties. Click and drag any of the section cut handles in the Graphic Display window to manipulate the properties.

6. Click **Create** to finalize the CAD section cuts.

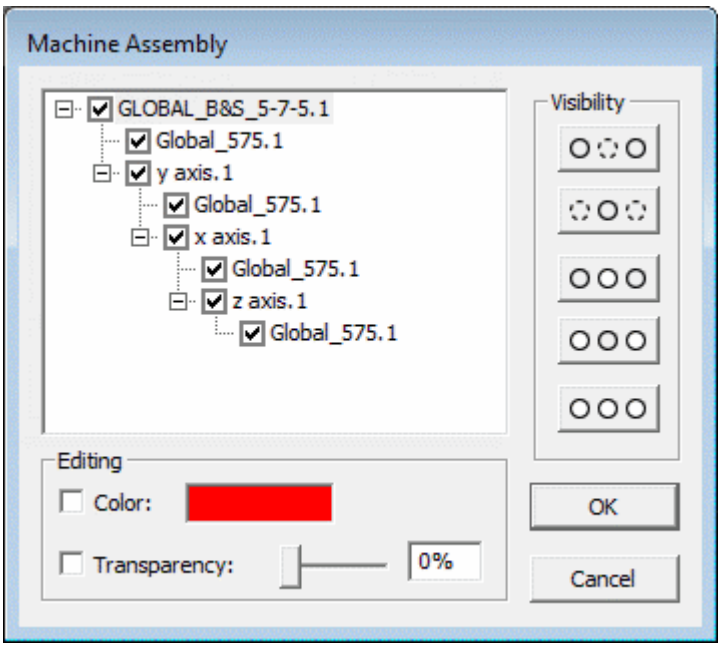


Once created, the CAD section cuts can be viewed in the **CAD Assembly** dialog box (**Edit | Graphic Display Window | CAD Assembly**).

7. Click **Close** when done.

Working with a Machine Assembly

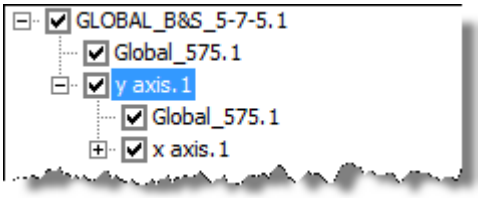
The **Edit | Graphic Display Window | Machine Assembly** displays the **Machine Assembly** dialog box. This gives you the tools to show and hide different components of your defined machine in the Graphic Display window.



Machine Assembly Dialog Box

This dialog box contains these options:

Assembly Tree View



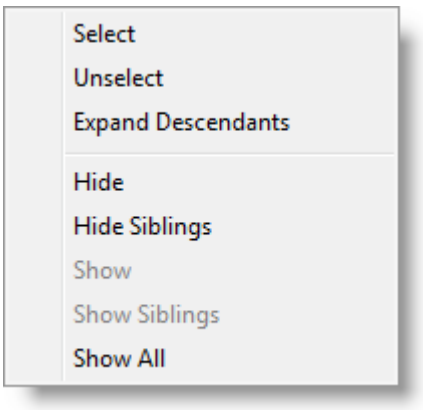
The tree view represents the machine's assembly structure. Each item in the tree view represents an assembly component.

- If you double-click on a component in the assembly, PC-DMIS selects and highlights that CAD object in the Graphic Display window. Conversely, with the dialog box open, if you select a CAD object in the Graphic Display window, PC-DMIS selects its corresponding component in the tree view. This makes it easy to identify which CAD objects belong to which assembly component.

Each component has its own check box to show or hide that component immediately within the Graphic Display window.

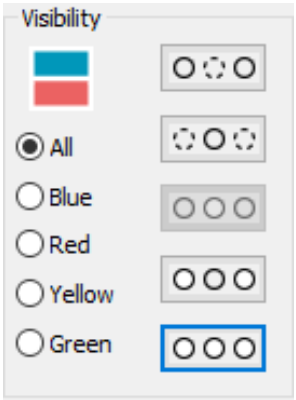
- If you mark a check box, PC-DMIS shows that component.
- If you clear a check box, PC-DMIS hides that component (and any children components, regardless of their visibility state).
- Once you mark a check box, you can also change the visibility state of that component or of its sibling or children components by using the buttons in the **Visibility** area.

A shortcut menu appears when you right-click in the tree view. It contains these items:



- **Select** - This functions as if you had double-clicked on the assembly component.
- **Unselect** - This deselects the assembly component in the Graphic Display window.
- **Expand Descendants** - This expands an assembly to show a list of child parts making up the assembly.
- **Hide** - This hides the selected component.
- **Hide Siblings** - This hides all of the components except the selected component at the same level on the assembly tree.
- **Show** - This shows the selected component.
- **Show Siblings** - This shows all of the components except the selected component at the same level on the assembly tree.
- **Show All** - This shows all the components on the assembly tree.

Visibility

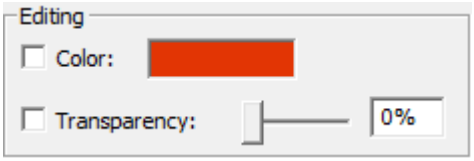


The **Visibility** area provides convenient buttons to change the hidden state of assembly component groups. Select the Hide button to hide the selected component.

- **Hide** - This hides the selected component.
- **Hide Siblings** - This hides all of the components except the selected component at the same level on the assembly tree.

- **Show** - This shows the selected component.
- **Show Siblings** - This shows all of the components except the selected component at the same level on the assembly tree.
- **Show All** - This shows all of the components on the assembly tree.

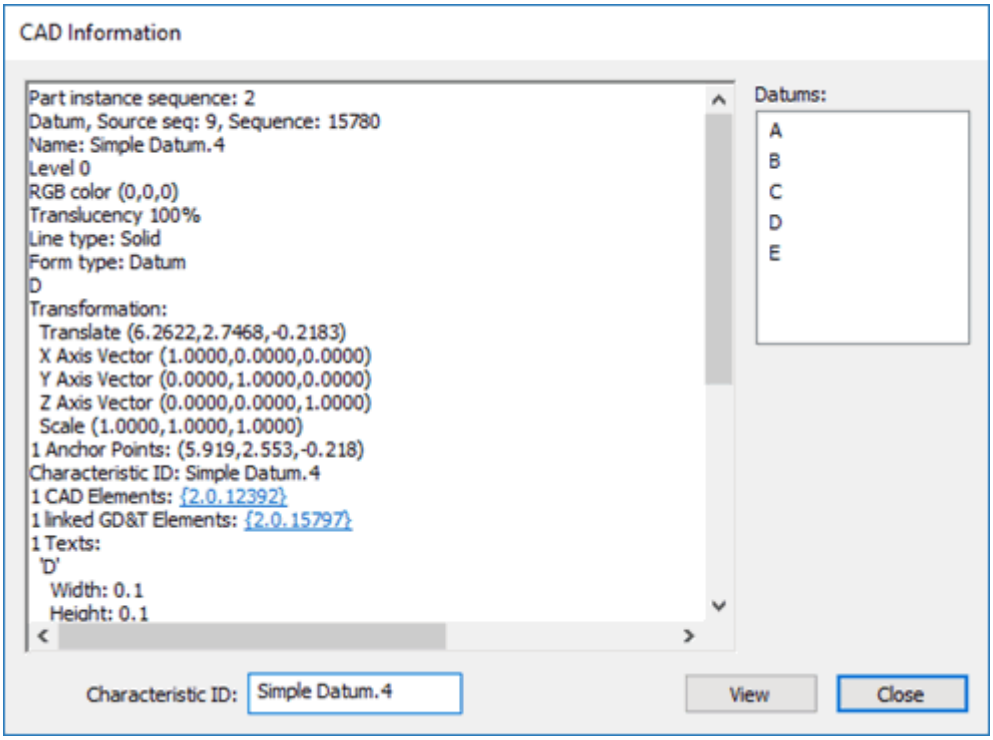
Editing



The **Editing** area lets you edit the currently selected component from the **Assembly Tree View**.

- **Color** - This check box enables the **Color** button and displays the **Color** dialog box. This dialog box lets you apply a color to the selected tree view component. This check box also enables or disables the display of the selected color. Once you choose the initial color, you can click the **Color** button thereafter to modify the color used.
- **Transparency** - This check box applies the selected transparency percentage to the selected tree view component. You can drag the slider or change the value manually in the box to change the transparency percentage.

Viewing CAD Information



CAD Information Display Box

The **View | CAD Information** menu option opens the **CAD Information** dialog box. This dialog box shows detailed CAD information for any CAD element you select from the Graphic Display window.

If you click on a CAD GD&T Callout, the following occurs:

- The software highlights the associated CAD element in the Graphic Display window.
- The CAD information in the dialog box includes curly braces with a link that zooms to that CAD element.

Datums - This list shows all the datums in the CAD model. You can click on a datum to have the Graphic Display window highlight it and rotate to it.

Characteristic ID - This ID box shows the Characteristic ID for a CAD GD&T object when you click on that CAD GD&T object in the Graphic Display window.

You can also use this box to do case-insensitive searches of CAD GD&T objects. To perform this search, type an ID in the box, and press Tab to have PC-DMIS show the CAD GD&T object with that ID.

- PC-DMIS also uses partial matches. For a partial match, PC-DMIS shows the first object with that ID in its Characteristic ID. You can press Enter to find the next partial match. You can keep pressing Enter to cycle through all available matches.

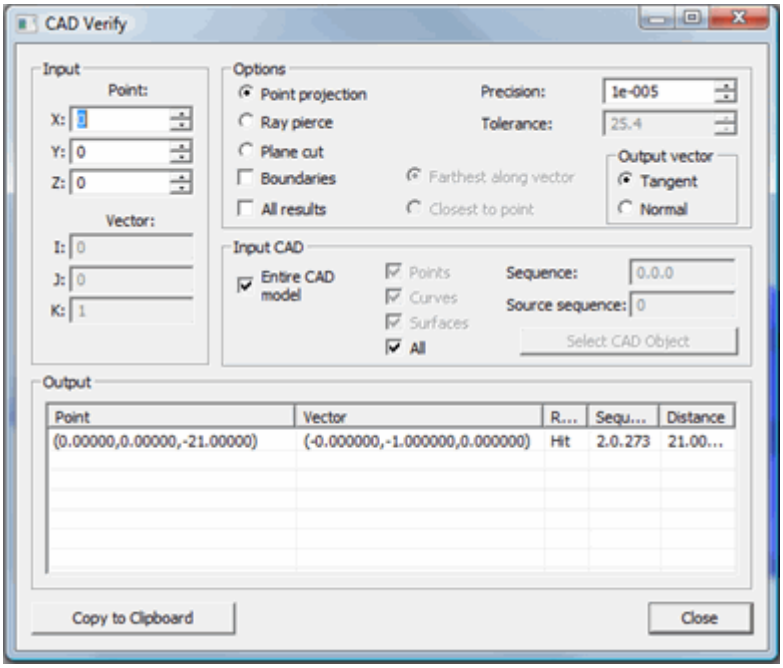
- If there is no matching CAD GD&T object with that ID, the value in the ID reverts to what it was.

You can manually revert an ID to its previous value if you press Escape before the box loses focus. The box loses focus whenever you click on something else you can interact with or if you press Tab or Enter.

Suppose you have some CAD GD&T objects, and two of them have Characteristic IDs of 23 and 125. If you type 2 in this box, PC-DMIS shows the object with 23 in its ID. In this example, both 23 and 125 are partial matches for 2, but 23 is earlier in the list of objects. You can then press Enter to have PC-DMIS show the next partial match of 125.

View - This button causes the selected datum to flash a few times in the Graphic Display window.

Verifying CAD Information



CAD Verify Dialog Box

You can use the **View | CAD Verify** menu item to verify that the CAD model is accurate based on the CAD native coordinate system. PC-DMIS displays a **CAD Verify** dialog box that allows you to perform different operations on the CAD model imported into the Graphic Display window. You can easily resize the **CAD Verify** dialog box to a larger size as needed.

The dialog box contains the following areas and items:

Input area

This area specifies the **XYZ** position and the **IJK** vector associated with it which are used to verify the CAD model. PC-DMIS disables the **IJK Vector** boxes if the **Point projection** option is selected.

Options area

This area determines what operation PC-DMIS performs on the CAD model. You can also specify options that control the behavior of the operations and the resulting output. The input point and vector in these options refer to the information entered into the **Input** area.

Point Projection - This projects the input point onto the CAD model. A *closest distance* algorithm is used to project the point.

Ray pierce - This option pierces the CAD model using a line. The input point and vector define the line.

Plane cut - This option intersects the CAD model using a plane. The input point defines a point on the plane and the vector specifies the plane's normal vector. For surfaces, only the surface boundaries are intersected with the plane.

Boundaries - This check box determines whether or not surface boundaries are used. If you select this check box and the CAD entity is a surface, only the surface boundaries are used. This does not affect curve geometry.

All results - This check box determines whether or not to get results for all the CAD entities in the model. If you don't select this check box, only the "best" result is displayed. The best result depends on the operation selected.

- For **Point projection**, the best result is the CAD point closest to the input point.
- For **Ray pierce**, the best result is either the intersection point farthest along the ray vector or closest to the input point. You can specify which intersection point is displayed. See "Farthest Along Vector" below.
- For **Plane cut**, the best result is the intersection point closest to the input point.

Farthest Along Vector - This option displays the intersection point farthest along the ray vector.

Closest to Point - This option displays the intersection point closest to the input point.

Resolution - This box controls the precision of the result. The result remains within the resolution value. The minimum resolution is 0.0000001.

For Direct CAD Interface models, the precision only affects the number of displayed decimal places. The actual CAD system controls the precision of the operations and cannot be modified from within PC-DMIS.

Tolerance -This box defines a tolerance value to limit the display to only those items that fall within the specified limits.

- If you select **Point projection** and **All results**, you can specify a **Tolerance** value. PC-DMIS then displays all CAD entities within the tolerance distance.
- If you select **Ray pierce** and **All results**, you can specify a **Tolerance**. For curve geometry and surface boundaries, PC-DMIS displays any curve within the tolerance distance of the ray vector.

Output Vector - This area controls the displayed vector for surface boundaries and curves. (For surface points within its boundaries, the displayed vector is always the surface normal.)

- Select **Tangent** to display the curve point's tangent vector.
- Select **Normal** to display the curve point's normal vector. For curves, the normal vector is the inverse of the second-derivative vector. For surfaces, the normal vector is simply the surface normal.

Input CAD area

This area lets you choose the CAD entities you want tested.

Entire CAD Model - This check box determines whether PC-DMIS tests the entire CAD model or only selected CAD entities.

- If you select this check box, PC-DMIS enables other check boxes that allow you to define which entity types to test in the entire CAD Model: **Points**, **Curves**, **Surfaces**, or **All**.
- If you clear this check box, only specific CAD entities are tested. See "Sequence/ Source Sequence" below.

Points - This check box tests for all points on the entire CAD model.

Curves - This check box tests for all curves on the entire CAD model.

Surfaces - This check box tests for all surfaces on the entire CAD model.

All - This check box tests for all points, curves, and surfaces on the entire CAD model.

Sequence / Source Sequence - These boxes let you define a single CAD entity. You can fill in these boxes and then click the **Select CAD Object** button. PC-DMIS turns the item red and causes it to flash a few times.

Alternately, you can test multiple CAD entities by selecting them one at a time from the Graphic Display window, or by box-selecting a group of entities.

Output area

The **Output** area contains the results of the verification in a table format with points making up the rows. PC-DMIS displays all the points in the Graphic Display window. Selected points from this list are highlighted in the Graphic Display window. To update the information in the **Output** area, select a new option and press TAB.

This list describes the column headings in the **Output** area:

Point - This column shows the resulting CAD point from the input point and the CAD.

Vector - This column shows the resulting CAD vector from the input point and the CAD.

Result - This can be either **Hit** or **Miss**.

For **Point projection**,

- **Hit** means that the projection point was on the interior of the CAD entity.
- **Miss** means that the projection point was on the extremities of the CAD entity. For curves, the extremities are the end-points. For surfaces, the extremities are the boundaries.

For **Ray pierce**,

- **Hit** means that the ray vector directly intersected the CAD entity.
- **Miss** means that the ray vector passed close to, but did not directly intersect, the CAD entity.

For **Plane cut**,

- **Hit** means that the plane directly intersected the CAD entity.
- **Miss** means that the plane passed close to, but did not directly intersect, the CAD entity.

Sequence - This column shows which CAD entity the point is on. The sequence is a unique identifier assigned to each CAD entity.

Distance - This column shows the distance between the input point and the output point.

Copy to Clipboard

This button copies the **Output** area's results to the Windows Clipboard. If you selected specific points, only information for those points is copied. Otherwise, the entire output is copied.

Using Screen Captures of the Graphic Display Window

You can take screen captures of the Graphic Display window and then send them to the Clipboard, send them to the report, or save them to your computer. You can also add a captured image into the PC-DMIS Edit window as an external object. For more information, see "Inserting External Objects" in the "Adding External Elements" chapter.

Sending Screen Captures to the Clipboard

The **Operation | Graphic Display Window | Screen Capture To | Clipboard** menu option captures the Graphic Display window and copies the screen capture to the clipboard. The image remains on the clipboard until another screen is captured, or you close the measurement routine.

To view an image captured to the clipboard, paste it into a supporting application such as Microsoft Paint or Microsoft Word.

Sending Screen Captures to the Report

See "Screen Captures" in the "Using the Edit Window" chapter.

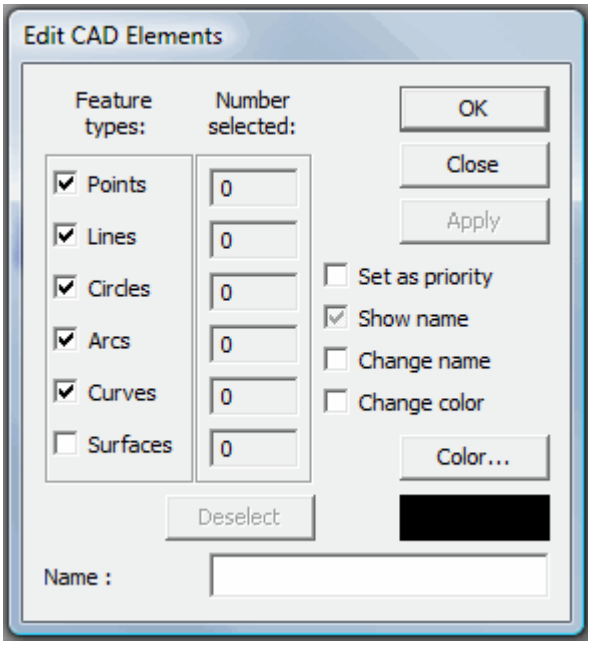
Sending Screen Captures to a File

The **Operation | Graphic Display Window | Screen Capture To | File** menu option captures the Graphic Display window and opens a **Save As** dialog box so you can save the screen capture as a bitmap file to a folder on your computer.

Editing Screen Captures

By itself, PC-DMIS does not have the ability to edit or format a captured image. However, you can use any image editor software to edit or format your screen captures.

Editing CAD Elements



Edit CAD Dialog Box

The **Edit CAD Elements** dialog box (**Edit | Graphic Display Window | CAD Elements**) allows you to alter the priority, element name, display of name, or color for different CAD elements in the CAD file.

To use this dialog box:

1. From the **Feature types** area, select the desired CAD element feature types to change.
2. From the Graphic Display window, select the CAD elements to change.
3. To select multiple CAD elements, box-select the desired CAD elements. When you release the mouse, PC-DMIS highlights the current selected elements and indicates the number of features in the **Number Selected** box. You can choose additional elements in the same manner. If needed, click the **Deselect** button to clear the screen of any highlighted elements.
4. Once the desired elements are selected and highlighted, mark the check box of the operation you want to perform:
    - **Set as priority**
    - **Show name**
    - **Change name**
    - **Change color**

5. See the "Dialog Box Description" subtopic below for any additional instructions and information on the individual operations.

6. Click **Apply** or **OK**.

In order for this option to work, you must create CAD levels. See "Setting Up the Screen View" for more information.

Dialog Box Description

The dialog box contains these items:

Feature types - Determines what feature types to edit. The available types are:

- Points
- Lines
- Circles
- Arcs
- Curves
- Surfaces

Number selected - Shows the number of selected CAD elements for each type.

Deselect - Deselects any highlighted CAD elements.

Name - Specifies a name for the selected CAD elements.

Set as priority - Determines the surfaces PC-DMIS checks first when calculating nominal values. For more information see "About Priority Surfaces" below.

Show name - Shows or hides the CAD element feature name (if provided by the CAD designer) associated with the selected CAD elements.

Change name - If marked, this changes the name of the selected CAD elements to the name provided in the **Name** box.

Change color - Draws the selected CAD data in the color shown in the box near the **Color** button once you click **Apply** or **OK**. To change the current color, select the **Color** button.

Color - Defines a color to apply to selected CAD elements by displaying a basic **Color** dialog box.

Once you click **OK** on this dialog box, it becomes the selected color in the **Edit CAD Elements** dialog box.

About Priority Surfaces

You can use the **Set as Priority** check box on the **Edit CAD Elements** dialog box to define a prioritized set of CAD surfaces for Find Noms (find nominals) processing. These are called "priority surfaces".

Prioritizing surfaces speeds up the calculation of nominal values as it allows PC-DMIS to determine which surfaces to check first. There is no limit to the number of surfaces that you can select. The order that you select the surfaces determines the order of the search.

Whenever you open the **Edit CAD Elements** dialog box and select the **Set as Priority** check box, PC-DMIS automatically selects the previously stored set of surfaces.

Setting Priority Surfaces

1. Select **Edit | Graphic Display Window | CAD Elements**.
2. If the **Set as priority** check-box is not marked, mark it now. PC-DMIS highlights any surfaces that are already prioritized.
3. Select surfaces in the Graphic Display window to add or remove them to this list.
4. Click **Apply** or **OK** button to update the measurement routine with the changes made to the list of priority surfaces.

Storing a New Set of Priority Surfaces

1. Open the **Edit CAD Elements** dialog box (**Edit | Graphic Display Window | CAD Elements**).

2. Select the **Set as Priority** check box. If you've already defined a set of surfaces, PC-DMIS selects them in the Graphic Display window.
3. With the **Set as Priority** check box selected, click the **Deselect** button and then click the **Apply** button. This essentially tells PC-DMIS to clear any stored surfaces.
4. Deselect the **Set as Priority** check box.
5. Select the new set of surfaces to store.
6. Select the **Set as Priority** check box.
7. Click the **Apply** button.
8. Click **OK**.

Box-Selecting and Priority Surfaces

When you box-select with the **Auto Features** dialog box open, PC-DMIS selects all CAD surfaces of the feature type inside the box.

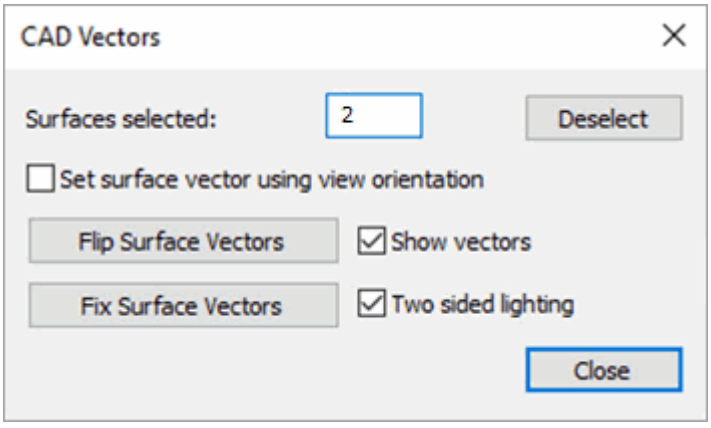
To limit which surfaces PC-DMIS selects inside the box, you can specify the priority surfaces. That is, if you've defined priority surfaces using the **Edit CAD Elements** dialog box, when you box-select from a surface Auto feature, PC-DMIS considers only the priority surfaces for that feature.

PC-DMIS uses priority surfaces for other functionalities, including Find Noms.

For more information on how to box-select to create features, see "Box Selecting to Create Multiple Auto Features" in the "Creating Auto Features" chapter.

Editing CAD Vectors

The **Edit | Graphic Display Window | CAD Vectors** menu item opens the **CAD Vectors** dialog box. With this dialog box, you can display and manipulate surface vectors.



CAD Vectors Dialog Box

Surfaces selected

With the dialog box open, click on a CAD surface in the Graphic Display window to select or deselect that surface. You can also drag a box across a portion of your part to box-select several surfaces at once. PC-DMIS highlights any selected surface and shows the number of selected surfaces in the **Surfaces selected** box.

Deselect

The **Deselect** button clears all selected CAD surfaces.

Set surface vector using view orientation

When you select this check box, the software flips the normal vector to make it point towards you as you select CAD surfaces.

For example, deselect the **Two sided lighting** check box, select the **Set surface vector using view orientation** and then click on a dark-colored CAD surface in the Graphic Display window. The software flips the surface normal towards you and away from the CAD model.

Flip Surface Vectors

The **Flip Surface Vectors** button flips your surface vectors, which causes the vector arrows to point in the opposite direction. PC-DMIS then clears the selected surfaces, and then redraws them with the flipped surface vector the next time you select them.

Show vectors

If you select the **Show vectors** check box, PC-DMIS displays a green arrow on each selected CAD surface to represent its vector.

Fix Surface Vectors

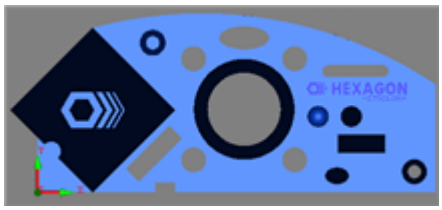
Some surfaces, when you initially select them, may have improper vectors. A proper vector points away from the part.

The **Fix Surface Vectors** button uses internal mathematical algorithms to correct selected surface vectors, which automatically causes the vector arrows to point in the proper direction. PC-DMIS then clears the selected surfaces. The next time you select them, they will appear with the corrected surface vector.

To fix the surface vectors of the entire CAD model, follow these steps:

1. Select the **Show Graphic Window as Solid** icon ( ) from the **Graphic View** toolbar to display your CAD model in Solid view.
2. Select the **Edit | Graphic Display Window | Lighting, Materials** menu item. The **CAD and Graphic Setup** dialog box opens.
3. Select the **Lighting** tab.
4. Clear the **Two sided lighting** check box.

5. Click the **OK** button. In the Graphic Display window, notice how some of the CAD surfaces appear dark. This is a visual indication that the surface normal for that surface is pointing in the wrong direction.



6. Select **Edit | Graphic Display Window | CAD Vectors**. The **CAD Vectors** dialog box opens.

7. Click the **Fix Surface Vectors** button. If the algorithm can fix all of the surface vectors, PC-DMIS changes the dark surfaces to the part's usual color, signifying that the surface vectors now point in the proper direction outside the part. If any of the surfaces remain with a dark shade, you can select those surfaces and manually flip their vectors by using the **Flip Surface Vectors** button.

To fix only specific surfaces on the model, follow the above procedure, but before you click **Fix Surface Vectors**, select the specific surfaces.

Two sided lighting

This check box determines whether the software lights the front and back faces of surfaces. For details on how to change CAD and graphics lighting settings, see the "Lighting Tab" topic in the "Setting Up CAD and Graphics" section of this documentation.

Close

This button closes the dialog box and clears any selected vectors.

Selecting Features Using the Graphic Display Window

You can use the Graphic Display window to select features and elements in the Graphic Display window (for example, to print, create coordinate systems, construct new features, calculate dimensions, and so on).

You can select features in any of these five basic ways:

- Use the ID(s)
- Use meta-character matching
- Select the last ID(s)
- Box-select ID(s)

- Select features in Online mode

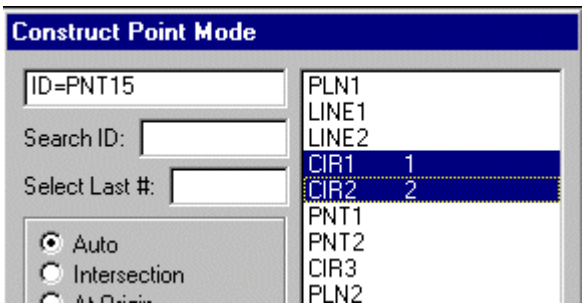
Selected features are indicated by the current highlight color. To deselect a selected (or highlighted) feature, click the selected feature once. To re-select it, click the feature again.

Selecting Features Using the ID(s)

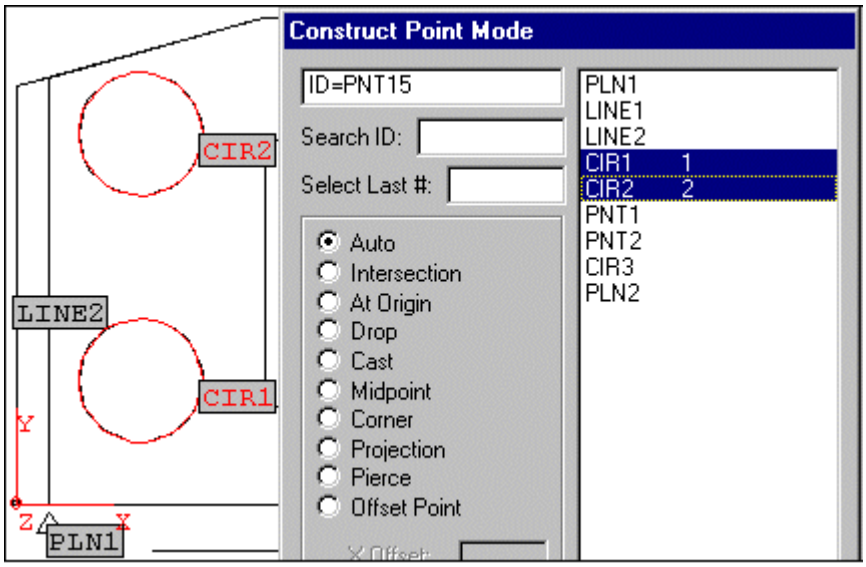
This selects the desired feature using the ID.

1. Type the ID(s) assigned to the feature(s) in the **Search ID** box.

2. Click on the desired ID from the list of features. PC-DMIS automatically assigns each feature a number in order of selection indicated to the right of the feature ID.



3. While in the Graphic Display window, move the cursor over the feature desired and click the left mouse button. (Note that the feature you selected in the Graphic Display window is now highlighted (or selected) in the feature window.)



Selecting Features Using Meta-Character Matching

This selects features using a meta-character. Meta-characters are characters that act as wildcard characters for other alphanumeric characters. There are two meta-characters available in PC-DMIS. They are the:

1. Asterisk (*)
2. Question mark (?)

Both are described below in greater detail.

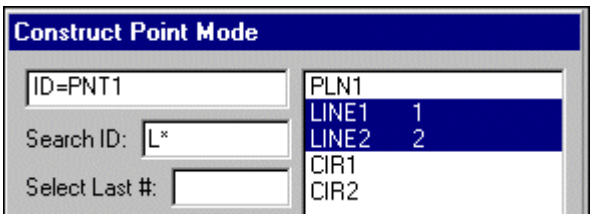
The Asterisk (*) Meta Character

***** The asterisk meta-character (*) matches, or takes the place, of any character or characters in a search.

For example, imagine these features are available in the feature list:

- PLN1

- LINE1
- LINE2
- CIR1
- CIR2



Asterisk (*) meta-character

To select all the line features (LINE1 and LINE2), in the **Search ID** box type **L***, and then press the Tab key. PC-DMIS selects all features beginning with "L".

To use the asterisk (*) meta-character in your feature selection:

1. Place your cursor in the **Search ID** box.
2. Type your search criteria using the asterisk (*).
3. Press the Tab key.

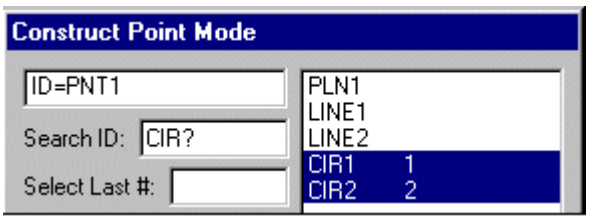
PC-DMIS selects the features that meet the search criteria.

You can use the asterisk (*) meta-character multiple times in any one search. You can also use it with the question mark (?) meta-character.

The Question Mark (?) Meta Character

? - The question mark meta-character (?) acts in the same way as the asterisk (*), except that the question mark meta-character matches *only 1* alphanumeric character. For example, suppose in your list of features, you have the following:

- PLN1
- LINE1
- LINE2
- CIR1
- CIR2



Question mark (?) meta-character

For example, if you want to select all the circle features (CIR1 and CIR2) using the question mark (?) meta-character, in the **Search ID** box, type **CIR?** and press the Tab key. PC-DMIS looks for all features that meet the search criteria, which in this case, is a feature with an ID 4 characters long with the first 3 characters being "CIR".

To use the question mark (?) meta-character:

1. Place your cursor in the **Search ID** box.
2. Type search criteria using the question mark (?).
3. Press Tab.

PC-DMIS selects the features that meet the search criteria.

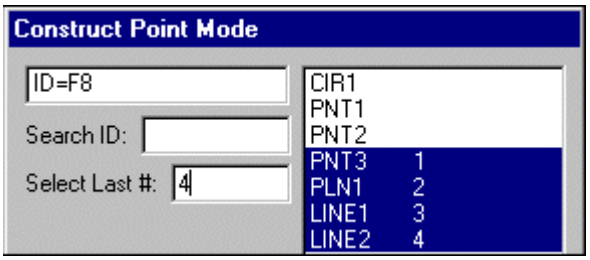
You can use the question mark (?) meta-character multiple times in any one search. You can also use it with the asterisk (*) meta-character.

Selecting the Last ID(s)

There are several alternative methods for selecting features in the feature list box, located in many dialog boxes. This instructs PC-DMIS to use the last 'number' of features in the current operation.

To select the last number of features:

1. From the dialog box, place your cursor in the **Select Last #** box.
2. Type the *last* number of features to be used. For example, to create a line from the last four features measured type **4** in the box.

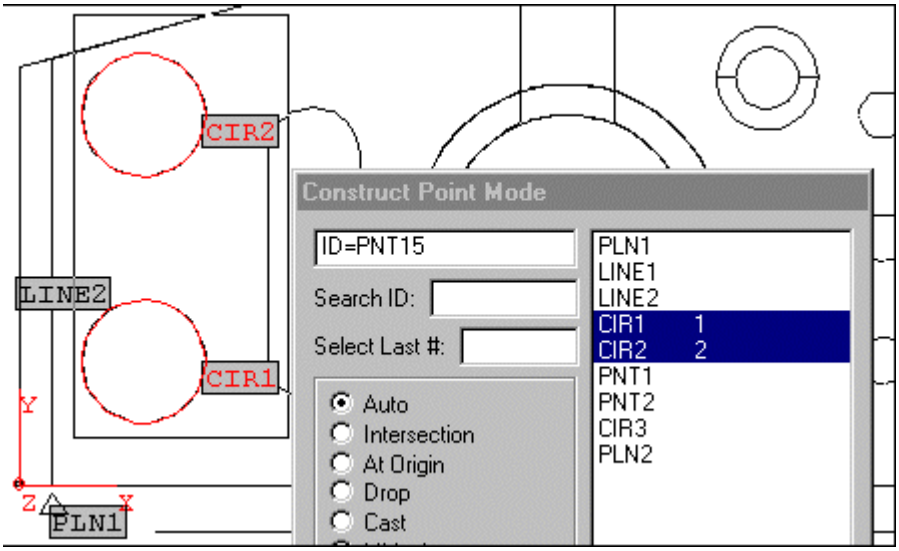


Select Last ID

Box-Selecting ID(s)

Another way to select features is to use the left mouse button to draw a "box" around the features. This is called "box-selecting". To do this:

1. Place the mouse pointer at one corner of where the box is to be drawn, and hold down the left mouse button.
2. Drag the mouse pointer to the opposite corner of the "box". PC-DMIS draws the box outline on the screen as you drag the mouse.
3. When the "box" is satisfactory, release the left mouse button. PC-DMIS highlights all the elements in the box, and lists them in the feature list box.



Box-Selecting CIR1 and CIR2

This option also allows you to modify the contents of the box as indicated in the list. To either add or delete a feature from the set, click on the feature to be changed (either in the Graphic Display window, or the dialog box's list of features).

Overview of Box-Selecting Sheet Metal Feature IDs

The ability of PC-DMIS to "box-select" feature identifications now allows a union of sheet metal features between two selected groups. This functionality makes the selection of multiple three-dimensional objects much easier. Additionally, if any CAD objects are box-selected and then a CAD object is chosen without box selection, those objects that were box-selected become permanent selections in addition to the single selection.

For specific information on how to use this capability, see "Box-Selecting to Create Multiple Auto Features" in the "Creating Auto Features" chapter.

Selecting Features in Online Mode

With PC-DMIS in Online mode, use the active tip as a pointer, and trigger the probe when the tip is close to the feature needed.

Editing a Feature ID

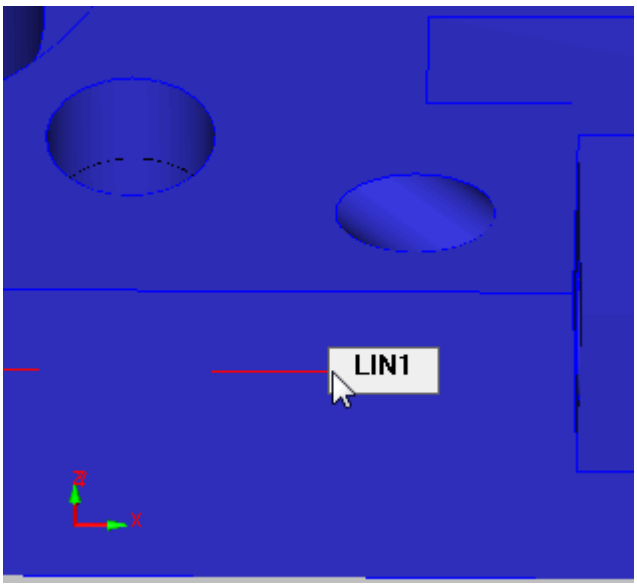
Edit ID Dialog Box

To change a feature's identification, double-click on the desired feature ID in the feature list. PC-DMIS displays the **Edit ID** dialog box. This dialog box allows you to rename the selected feature's ID.

Never use any of the mathematical characters (-, +, /, or *) in an ID. This causes problems when you attempt to use the ID inside PC-DMIS expressions. For the full list of ID rules, see "Setup Options: ID Setup tab" in the "Setting Your Preferences" chapter.

Identifying a Feature by Using Tooltips

You can also identify a feature without having to show feature IDs. Instead, PC-DMIS can display a small tooltip that appears when you briefly hover your mouse pointer over the feature inside the Graphic Display window. The tooltip remains visible until you move the mouse pointer off of the tooltip.



Sample Tooltip of a Line Feature

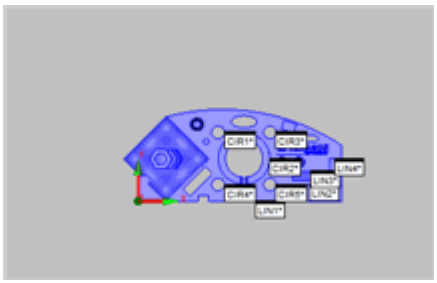
You may find this useful when you have a large measurement routine, and you want to keep your feature ID labels turned off to improve performance, yet you still need a way to quickly identify a feature.

- Click on the tooltip to toggle the feature's ID label in the current view.
- Right-mouse click to display a shortcut menu with the same options available when you right-click on a feature inside Text Box Mode.

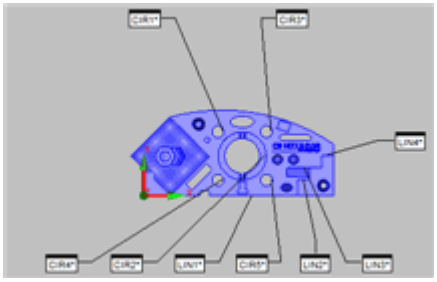
These tooltips are not available when PC-DMIS performs path operations (Animate Path, Edit Path, and other path operations), when in Quick Fixture Mode, or in any mode where you use the mouse button or keyboard buttons at the same time (such as during a Pan, Zoom, or Rotate operation).

Automatically Positioning Feature ID Labels

PC-DMIS provides you with these methods to automatically position feature ID labels in the Graphic Display window with leader lines so that they point to the features they reference instead of resting directly on the feature. This moves the labels to the edge of your CAD view so that you can more easily see the part or feature.



Example that shows the ID labels without automatic positioning.



Example that shows ID labels with automatic positioning.

Method 1 - Use the Setup Options Dialog Box

Access the **Setup Options** dialog box (**Edit | Preferences | Setup**), and from the list of check boxes on the **General** tab, enable the **Automatic label positioning** check box. This method keeps repositioning your labels whenever you perform pan, zoom, or rotate operations on the part. It only functions with the main CAD view if you have multiple split views.

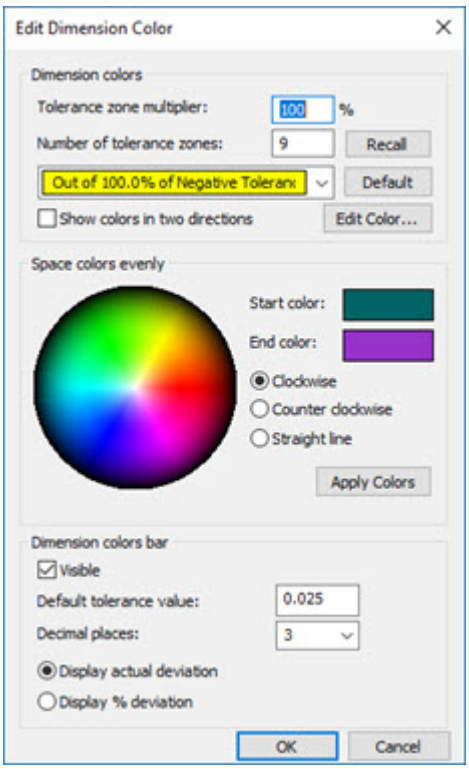
Method 2 - Use the Feature ID Label Shortcut Menu

Right-click on a feature ID label, and from the shortcut menu, select **Automatic Label Positioning**. This method, different from method 1, works in the current CAD view, not just the main CAD view. Also, it only positions the labels once. So, if you perform pan, zoom, or rotate operations, the labels are not repositioned.

Editing Dimension Colors

Select the **Edit | Graphic Display Window | Dimension Colors** menu option to open the **Edit Dimension Colors** dialog box. This dialog box defines the colors and tolerance zones for your entire tolerance band.

You can also right-click the **Dimension Colors Bar** that is visible in the Graphic Display window to open the **Edit Dimension Colors** dialog box.



Edit Dimension Colors Dialog Box

Defining Dimension Colors

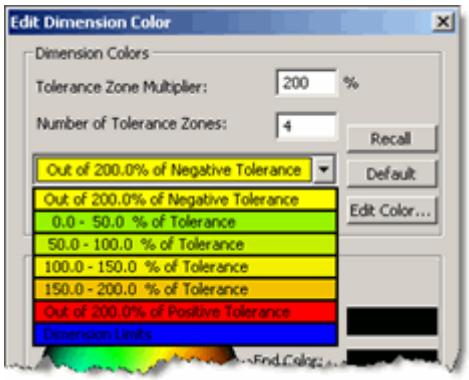
1. Set the **Tolerance zone multiplier** value as needed.
2. Type a value in the **Number of tolerance zones** box to define the number of tolerance zones.
3. If desired, select the **Show colors in two directions** check box to extend your color range to the -Tol value.
4. Pick the colors for the tolerance zones in one of two ways:
    - *Method 1* - Select each tolerance zone one at a time from the tolerance zone drop-down list, and click the **Edit** button to set a specific color for each zone.
    - *Method 2* - Use the color wheel to select the start and end tolerance zone colors, and allow PC-DMIS to define colors for the other zones.
5. Click **Apply Colors**.
6. Modify the options for the **Dimension colors bar** as desired.
7. Click **OK**.

Dialog Box Description

Tolerance zone multiplier - This value increases the negative and positive tolerance by the percentage specified. This value provides you with greater control over the tolerance range for your tolerance zone. This allows your range of colors to extend into the out-of-tolerance zone and lets you visually see how much something is out of tolerance.

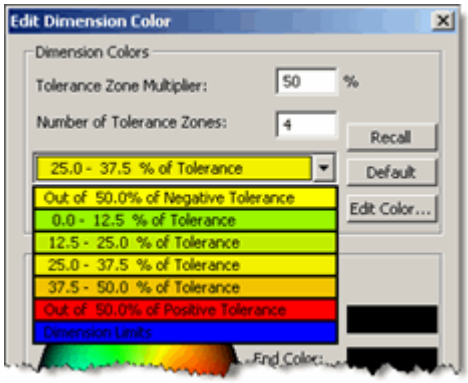
If this option is set to 200%, the range of tolerance zones is 2.0*(-Tol) through 2.0*(+Tol).

For example, if you give this option a value of 200%, the tolerance zone doubles its normal range:



Example that shows the Tolerance Zone Multiplier set to 200%.

If you type 50%, the zone is half its normal range:



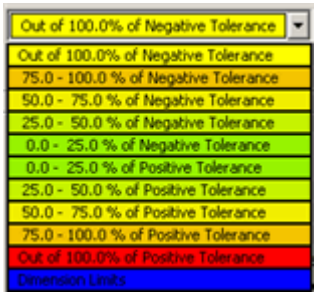
Example that shows the Tolerance Zone Multiplier set to 50%.

The default value is 100%.

Number of tolerance zones - This value determines the number of tolerance zones for your measurement routine. Tolerance zones divide your entire tolerance band by this number to create the different zones. Each tolerance zone has a unique color associated with it.

Tolerance zones - This list contains all the tolerance zones. You can select a specific zone from this list to manipulate its color in detail. The **Dimension Limits** item from this list is used to create a border at the absolute positive or negative limit of the feature tolerance. The color used for this corresponds to the color used to draw the tolerance band.

Show colors in two directions - This option determines whether or not your tolerance zones for the current measurement routine display the same color range in two directions, one heading towards the **Positive Out of Tolerance** range and the other heading towards the **Negative Out of Tolerance** range. This effectively expands the lower dimension color range to –Tol instead of zero.



Example showing tolerances displayed in two directions.

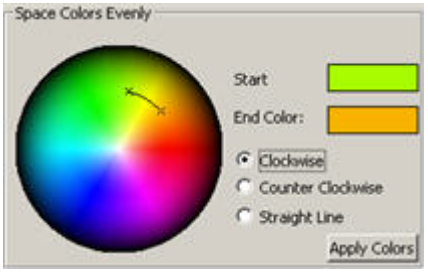
You can then use the **Edit** button to define the negative dimension colors and positive dimension colors separately.

Recall - This button returns the colors to the default setting.

Default - This button overrides the previous default color settings with the current values.

Edit Color - This button opens a **Color** dialog box so that you can change the color associated with the currently-selected tolerance zone.

Color Wheel - The color wheel provides you with a quick way to define colors for all your tolerance zones. It lets you pick the colors for the first and last tolerance zones. A small x appears on the color wheel for each color selected. The remaining tolerance zone colors are spaced evenly between the start and end colors. The direction of the spacing depends upon the option selected.



Example showing the Color Wheel with selected start and end colors.

Clockwise - This option sets the end color to have the same brightness as the start color and spaces the colors in a clockwise direction.

Counter clockwise - This option sets the end color to have the same brightness as the start color, but spaces the colors in the counter-clockwise direction.

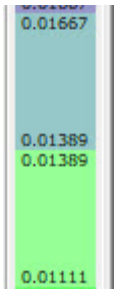
Straight line - This option spaces the colors from the start color to the end color, regardless of the brightness, in a straight line direction.

Apply Colors - This button applies any color changes you made without closing the dialog box, which allows you to immediately test your color selection.

Visible - This check box lets you show or hide the **Dimension Colors Bar** once you click **OK**. For information on the **Dimension Colors Bar**, see the "Using the Dimension Colors Window" topic in the "Using Other Windows, Editors, and Tools" chapter.

Default tolerance value - This box lets you change the default tolerance value for the **Dimension Colors Bar**.

Decimal places - This value changes the number of decimal places displayed in the **Dimension Colors Bar** in the Graphic Display window.



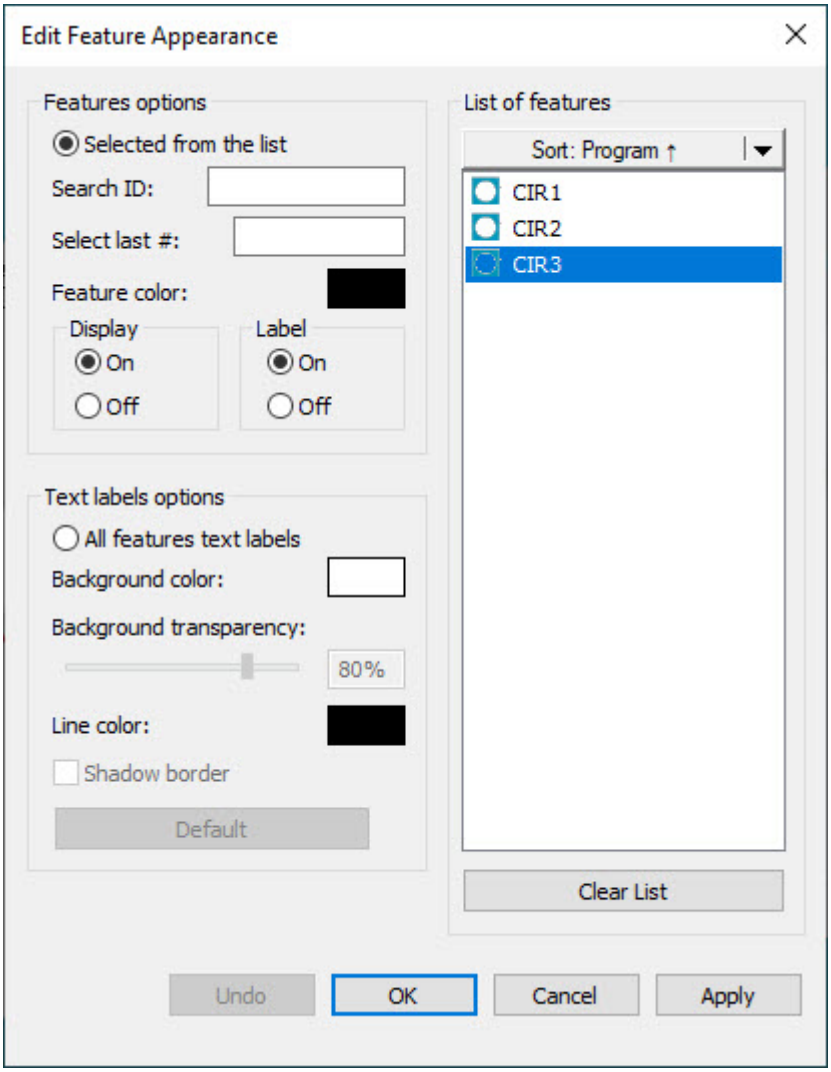
Example of the Dimension Colors Bar with five decimal places.

Note that this value does not affect the decimal places used by the **Dimension Color Key** object used in reporting. The decimal places for the Dimension Color Key object in reporting are hard coded to three decimal places.

Display actual deviation - This option displays tolerances as the actual deviation in the **Dimension Colors Bar**.

Display % deviation - This option displays tolerances as a percentage of the deviation in the **Dimension Colors Bar** for the current measurement routine.

Editing Feature Appearance

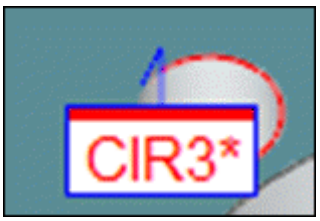


Edit Feature Appearance Dialog Box

Select the **Edit | Graphic Display Window | Feature Appearance** menu option to open the **Edit Feature Appearance** dialog box. You can use this dialog box to alter feature identifications (termed "feature IDs") within a measurement routine, feature colors, and feature ID labels.

The following example shows how to modify a legacy feature ID label and a feature with the **Edit Feature Appearance** dialog box. Various colors demonstrate the different parts of the label.

- Red - A modified **Feature color**. By default, the colored bar at the top of the ID label also changes to match the color of the circle.
- White - The default **Background color**.
- Blue - A modified **Line color**.



Example showing a feature ID label and a feature with a modified appearance.

Editing Feature IDs

Double-click the desired feature in the list box to edit a previously-assigned feature name. The software opens the **Edit ID** dialog box which you can use to type a new identification.

Edit ID Dialog Box

You can also change feature IDs in the Edit window. Highlight the desired ID, and type a new identification. If you type an ID that another feature already uses, PC-DMIS displays a message and keeps the previous ID.

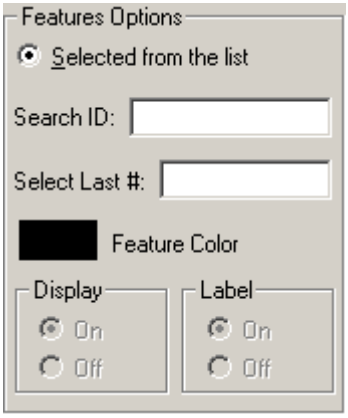
Never use any of the mathematical characters (-, +, /, or *) in an ID. This causes problems when you attempt to use the ID inside PC-DMIS expressions. For the full list of ID rules, see "Setup Options: ID Setup tab" in the "Setting Your Preferences" chapter.

This dialog box contains two main areas:

- **Features options** - You can use this area to modify the display of the part's features.
- **Text labels options** - You can use this area to modify the feature ID labels in the Graphic Display window.

To change the graphic options for features or feature ID labels, select the desired options from the dialog box, click **Apply** and then **OK**.

Features Options Area



The **Features Options** area allows you to change the color of selected part features and whether or not selected features or feature ID labels are displayed in the Graphic Display window. To use the items in this area, you must first select one or more items from the **List of Features** and then click the **Selected from the list** option. This enables the other items in this area.

The **Search ID** and **Select Last #** boxes are discussed in the "Search ID" and "Select Last #" topics in the "Navigating the User Interface" chapter.

The **Feature Color** option allows you to set the color for a specified feature's identification. This option works in the same manner as the **Edit Color** option (see the **Edit CAD** dialog box found in "Editing CAD").

To Change the Color of a Feature:

1. Select the feature to be altered from the **List of Features**.
2. Select the **Feature Color** option. PC-DMIS automatically displays the **Color** dialog box.
3. Click on the desired color, or define a new one using the **Custom Color** box.
4. Click the **OK** button. PC-DMIS returns to the **Edit Feature Appearance** dialog box. The new color is displayed in the **Feature Color** box.
5. Click the **Apply** button and PC-DMIS automatically changes the color of the feature in the Graphic Display window. The top border of the feature ID label also changes to match the feature color.

The **Display** area contains **On** and **Off** options that control the display of features in the Graphic Display window. This option is useful when you want to focus on only a portion of geometrical features the part contains at a time.

To Determine the Display of Selected Features:

1. Select the feature or features that you want to turn on or off.

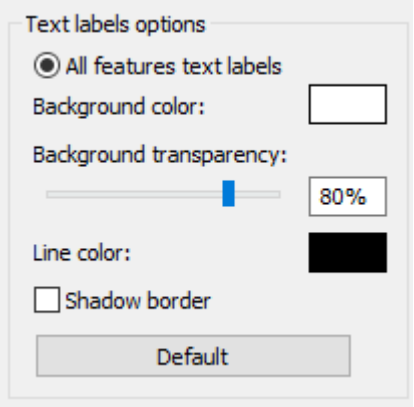
2. From the **Display** area, select either the **ON** or the **OFF** option.
3. Click the **Apply** button. PC-DMIS displays or conceals the features.
4. If the changes made are to your satisfaction, click the **OK** button. PC-DMIS closes the dialog box and saves the changes.

The **Label** area contains **On** and **Off** options that control the display of feature IDs in the Graphic Display window. This option is useful when a portion of the part drawing becomes cluttered with several feature IDs. You can hide Specific IDs, allowing other IDs to be more easily viewed.

To Determine the Display of Selected Feature ID Labels:

1. Select the feature label or labels that you want to turn on or off.
2. From the **Label** area, select either the **ON** or the **OFF** option.
3. Click the **Apply** button. PC-DMIS displays (or conceals) the feature labels.
4. If the changes made are to your satisfaction, click the **OK** button. PC-DMIS closes the dialog box and saves the changes.

Text Label Options Area



The **Text Label Options** area lets you set the graphic options for all feature ID labels. To use the features in this area, you must first select the **All features text labels** option. PC-DMIS automatically selects all the features from the **List of Features**.

Background Color
This box opens a **Color** dialog box so that you can change the label's background color.

Background Transparency
This slider or the box to its right adjusts the transparency level of the label's background color. The value can be from 0 (opaque) to 100 (completely transparent).

Line Color
This box opens a **Color** dialog box so that you can change the label's border color.

Shadow border
This check box displays a small shadow under the label.

Example Feature ID labels set to a pink background color with 50% transparency

You can set the default graphic options for future labels. To do this, select the desired graphic options and then click the **Default** button.

You can also change these items by right-clicking on a feature's ID label and selecting the **Change Appearance** menu option from the resulting shortcut menu. See "Feature Shortcut Menu" in "Using Shortcut Keys and Shortcut Menus".

Showing, Animating, and Moving Path Lines

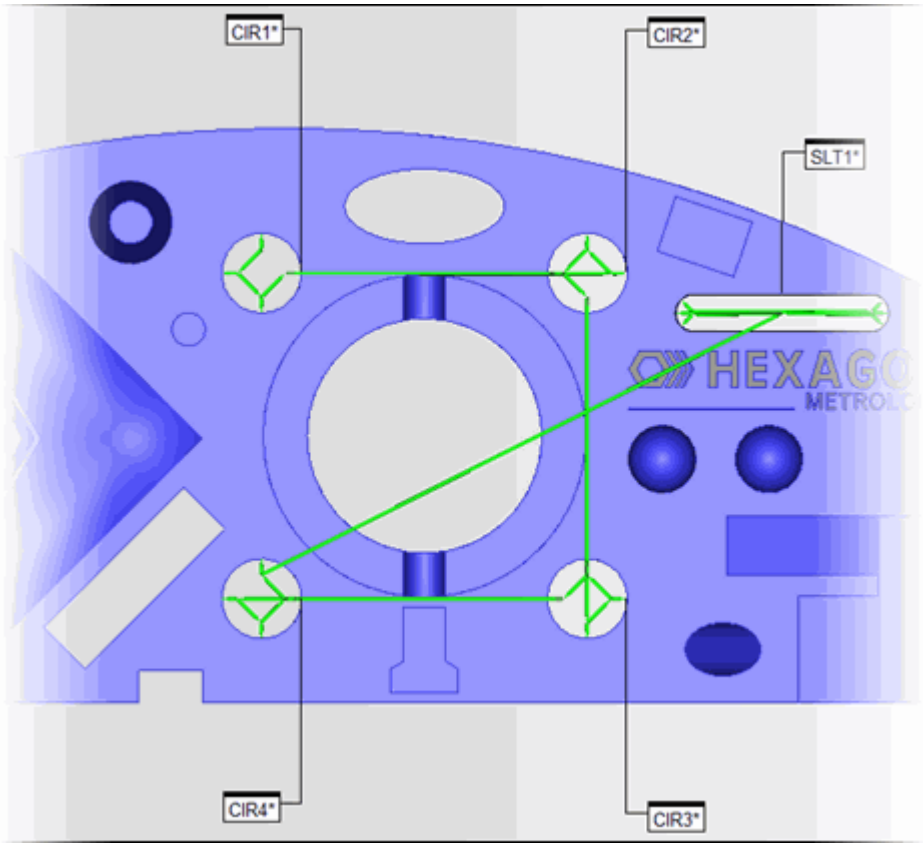
PC-DMIS can generate colored lines on the CAD model in the Graphic Display window that show the path your probe will take during execution as it measures marked features. These lines are called path lines. Path lines help you preview the path your probe will take and troubleshoot possible collision areas.

The software only generates the probe's path lines for features that follow a `MODE/DCC` command. If your measurement routine doesn't have a `MODE/DCC` command, you won't see any path lines.

The **Animate Path**, **Regenerate Path**, **Optimize Path**, and **Collision Detection** options are not available for Portable devices.

Viewing All Path Lines

To view path lines, select **View | Path Lines**. PC-DMIS checks each command and draws the path lines accordingly. You can press Esc to cancel this process at any time.



This example shows the probe's route drawn on the part's graphical image

Viewing Path Lines from a Cursor's Position

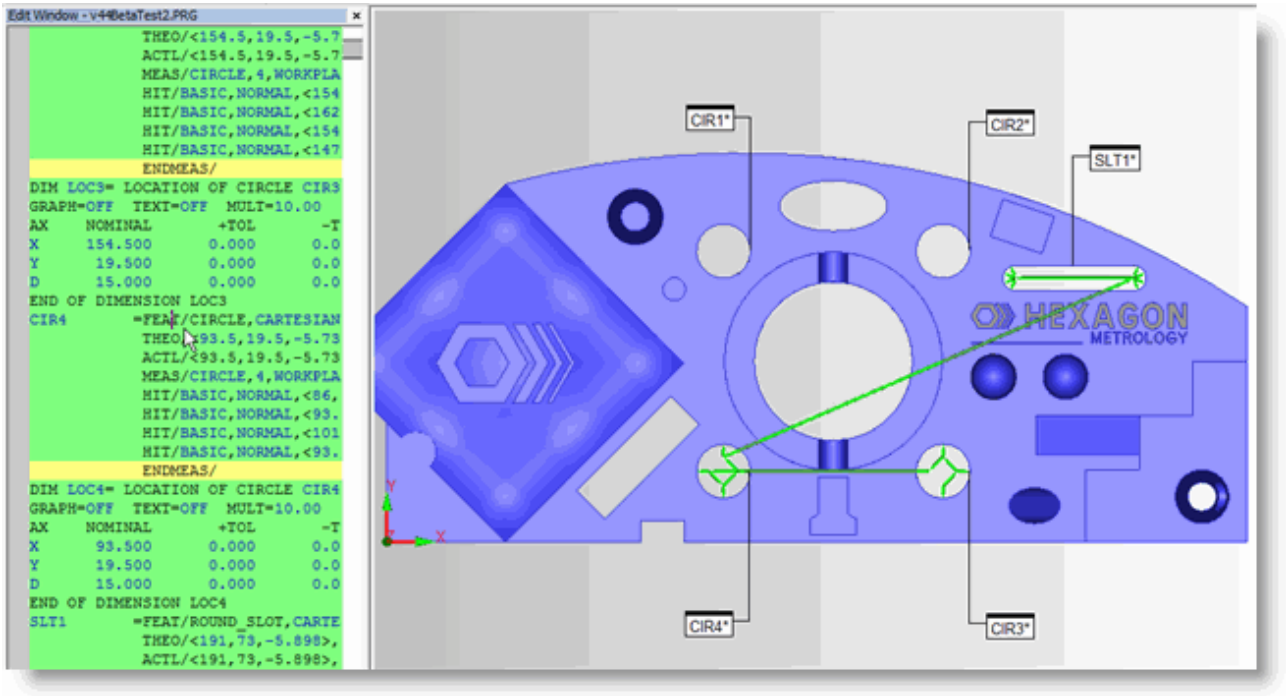
This only works if the Edit window is in Command Mode.

You can select **View | Path Lines from Cursor** to limit the displayed path lines to focus on the following:

- The feature where the cursor resides.
- The feature that precedes it.
- The feature that follows it.

You may find this most useful when stepping through a measurement routine.

For example, suppose your measurement routine has these features in this order: CIR1, CIR2, CIR3, CIR4, and SLT1. If you clicked on item CIR4 in Command Mode, the Graphic Display window draws path lines for CIR3, CIR4, and SLT1.



Example showing path lines drawn for the clicked feature, CIR4, its preceding feature, CIR3, and its following feature, SLT1

To modify the number of features that display their path lines within **Path Lines from Cursor** mode, edit the value in the **Create Path Feature Count** box located in the **Animation** tab of the **Setup Options** dialog box. The default value is 1, which means that PC-DMIS draws path lines for one feature preceding the current feature and one feature following the current feature. See the "Setup Options: Animation tab" topic in the "Setting Your Preferences" chapter.

The **Path Lines from Cursor** mode does not function with **Auto Insert Moves** operation (**Operation | Graphic Display Window | Clearance Moves | Auto Insert Moves**). If you perform an **Auto Insert Moves** operation, PC-DMIS reverts to displaying all the path lines. See "Inserting Clearance Moves Automatically" in the "Inserting Move Commands" chapter.

Viewing Path Lines for a Range of Selected Items

Another way of limiting the displayed path lines is to select a range of one or more features in the Edit window and show path lines used for only those selected features.

To do this:

1. In the Edit window, select the range of features.
    - If in Command Mode, click and drag the selection or click on the first feature, press Shift and then click on the second feature to establish the range of features.
    - If in Summary Mode, click on the first feature, press Shift and then click on the second feature to establish the range of features.
    - In either mode, you can press Ctrl and click to select non-sequential features.

2. Right-click in the Edit window. A shortcut menu appears.
3. From the shortcut menu, choose **Path | Path Lines**. PC-DMIS draws the path lines on the screen for the selected features. A check box appears next to the shortcut menu item.

If you want to select a different range of features, you need to right-click in the Edit window and, from the shortcut menu, clear the **Path | Path Lines** menu item. You can then re-select the **Path Lines** shortcut menu item for the new selection.

Changing a Path Line's Size

To change the size of your path lines:

1. Choose **Edit | Graphic Display Window | Display Symbols** to open the **CAD and Graphic Setup** dialog box.
2. Click the **Symbols tab**.
3. Modify the **Fixed Size** value.

During execution or collision detection operations, or during a part translation or rotation, PC-DMIS draws the path lines as simple lines (without the defined diameter) in order to speed up these operations.

Changing a Path Line's Color

By default, the software shows path lines in a green color.

To change the color:

1. Access the **Setup Options** dialog box
2. Click the **Animation** tab.
3. From the **Path Lines Color** box, choose a color.

See the "Setup Options: Animation tab" topic in the "Setting Your Preferences" chapter.

You can use the **Path** toolbar on the **QuickMeasure** toolbar (**View | Toolbars | QuickMeasure**) to work with common path line options. For more information, see the "CMM QuickMeasure Toolbar" topic in the PC-DMIS CMM documentation.

Animating the Path

The **Animate Path** option is not available for Portable devices.

The **Operation | Graphic Display Window | Animate Path** menu option animates the path of the probe on the part. The **Animate Path** option only simulates the movement of the probe. It does not execute the measurement routine.

To make **Animate Path** available for selection:

1. Mark the desired features.
2. Select the **View | Path Lines** menu item. The **Animate Path** option is then available for selection.

   The software only generates the probe's path lines for features that follow a `MODE/DCC` command. If your measurement routine doesn't have a `MODE/DCC` command, you won't see any path lines.
3. Select the **Animate Path** menu item. PC-DMIS displays the **Execution** dialog box and automatically begins animating the path with a simulated probe tip.

   - To stop the animation at any time, press the Esc key or click **Stop** on the **Execution** dialog box.
   - To continue a stopped animation, click **Continue** .
   - You can also press the Enter key to toggle between stop and continue when animating the path.
   - You can click on a path line to select that feature in the Edit window. This also provides an opportunity to add a move point along that path line. For more information on how to use move points to move a path line, see "Moving Path Lines".

Regenerating the Path

The **Operation | Graphic Display Window | Regenerate Path** menu option erases the current path lines and re-draws them.

You may want to regenerate your path when you've made changes to a measurement routine, and you want your path lines to reflect the current state of the measurement routine.

Notes

- **Regenerate Path** is only accessible *after* you mark features in the Edit window *and* you select the **View | Path Lines** option.

  The software only generates the probe's path lines for features that follow a `MODE/DCC` command. If your measurement routine doesn't have a `MODE/DCC` command, you won't see any path lines.

- **Regenerate Path** is not available for Portable devices.
- You can press Esc to cancel the regeneration at any time.
- If you insert a move before a PH9 wrist change, the location of the wrist change does not move until you choose **Regenerate Path**.

Optimizing the Path

For information on how to create an optimized path for your probe from the **Optimize Path Workflow** dialog box (**Edit | Optimize Path** or **Operation | Graphic Display Window | Optimize Path**), see the "Optimizing the Path" topic in the "Using Inspection Plans in PC-DMIS" appendix.

Detecting Collisions

The **Collision Detection** option is not available for Portable devices.

The **Operation | Graphic Display Window | Collision Detection** menu option (CD) displays the **Collision Detection** dialog box. The CD module detects collisions between the probe and CAD surfaces. It ignores all CAD curves, lines, and points. As a result, only CAD files that fully describe the part using surfaces are suitable for collision detection. (The CD algorithm doesn't use the actual surface definitions, but rather the surface tessellations [or graphical approximations], which are also used to render solid views using the OpenGL graphics language.)

Changing Animation Speeds: If you want to modify your offline animation speeds, see the **Execution** area on the **General** tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**). In addition, see the "Executing and Debugging Measurement Routines Offline" topic in the "Working in Offline Mode" chapter.

Viewing Collisions for a Range of Selected Items

You can also limit the collision detection items by selecting a range of one or more features in the Edit window, and perform the collision detection on only those selected features.

To do this:

1. In the Edit window, select the range of features. Either click and drag the selection (if in Command Mode), or click on the first feature, press the Shift key on your keyboard, and then click the second feature to establish the range of features. (If in Summary Mode, you can also press the Ctrl key instead of the Shift key on your keyboard.)

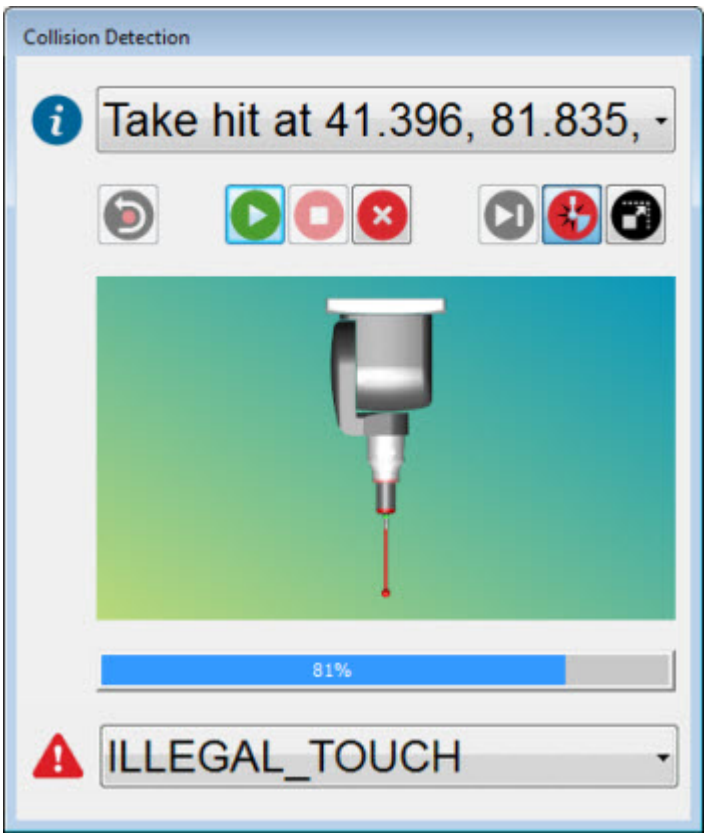
2. Right-click in the Edit window. A shortcut menu appears.

3. Choose **Selected Items Collision Detection**. PC-DMIS automatically performs the collision detection on those features and draws path lines as PC-DMIS processes the features. A check box then appears next to the shortcut menu item.

If you want to immediately select a different range of features, you need to right-click in the Edit window, clear the **Selected Items Collision Detection** first, and then re-select it for the new selection.

Collision Detection Dialog Box Options

Collisions are shown in the **Collision Detection** dialog box (**Operation** | **Graphic Display Window** | **Collision Detection**).



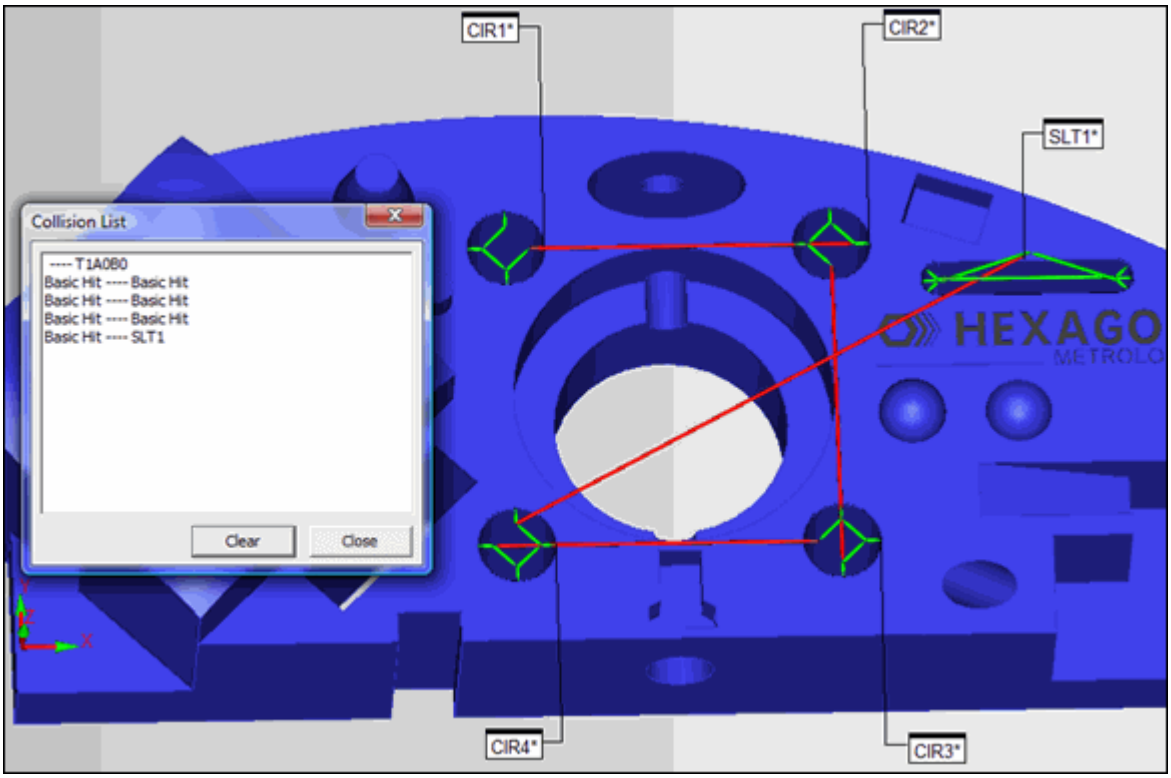
Collision Detection Dialog Box

Most of the items in this dialog box function like those in the **Execution** dialog box. For information on those items, see "Using the Execution Dialog Box" in the "Using Advanced File Options" chapter.

The following items only apply to collision detection:

- **Stop On Collision** - If selected (highlighted), the probe animation collision detection stops if a collision occurs.
- **Probe Display** - Immediately below the icons on the dialog box in the probe display area. The probe is shown using a green color. If a collision occurs, the portion of the probe that collides is shown in red. The same color scheme is used to draw the probe on the screen, as well as in the **Collision Detection** dialog box.
    - You can enlarge or shrink the drawing of the probe just as you would the part on the Graphic Display window by right-clicking above or below an imaginary horizontal line.
    - You can 3D rotate the drawing of the probe by holding down Ctrl key on your keyboard and the right-mouse button while dragging the mouse.
- **Scale to Fit** - Shrinks or enlarges the drawing of the probe so that it fits back into the probe display area of the dialog box.

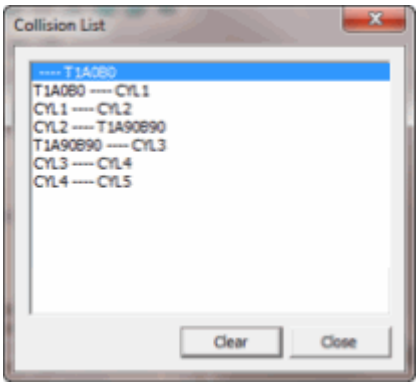
When PC-DMIS has finished running Collision Detection, it redraws the path lines in the Graphic Display window. PC-DMIS indicates where collisions have occurred by drawing affected path line segments in red (RGB color of 255,0,0). In addition, PC-DMIS displays a **Collision List** dialog box helping you to quickly locate collision problems in your measurement routine.



Example of the Graphic Display window showing the path lines and collisions (red lines).

Displaying a Collision List

The **Collision List** dialog box is displayed as soon as you select **Operation | Graphic Display Window | Collision Detection** menu option to start collision detection. This is helpful when collision detection needs to be stopped, identified collisions can be reviewed up to that point.



Collision List Dialog Box

This dialog box displays a list of collisions for the measurement routine. The Graphic Display window also highlights those path lines in red. If the Edit window is in Command Mode, you can click on an item on the **Collision List** dialog box to locate the command in the Edit window where collision was detected. You can then modify the measurement routine to fix the collision problem.

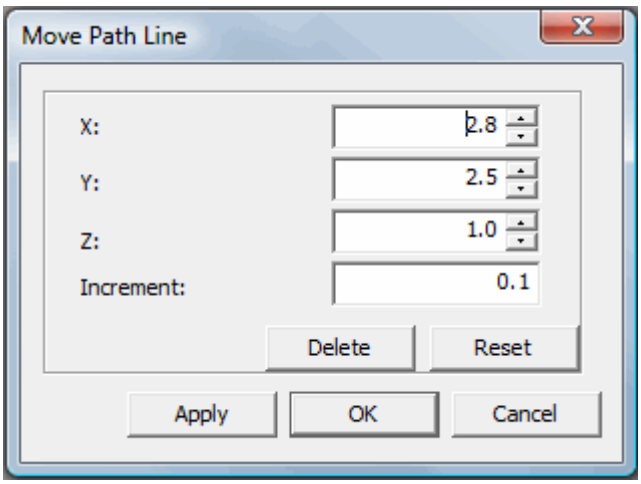
If you want to remove one or more items from the **Collision List** dialog box, select the item or items, and click the **Clear** button. You may find this useful if you want to remove an item you've already corrected or if you want to focus on a subset of a large list of detected collisions.

Moving Path Lines

Once you enable path lines and see them on your screen, you can change the route the probe follows as it moves between features. To do this, place PC-DMIS in Translate Mode and click on a highlighted path line. PC-DMIS splits the path line near where you clicked and adds a `MOVE/POINT` command at that location. Use the **Move Path Line** dialog box to adjust the move point location.

This method only works on the path lines *between* features. You can use a different method to reposition path lines *within* Auto features. For information, see "Show Hit Targets" in the "Creating Auto Features" chapter.

If you click on a path line between features and the **Move Path Line** dialog box still doesn't open, you may need to enable this functionality. To do this, from the **Setup Options** dialog box (**Edit | Preferences | Setup**), on the **Animation** tab, mark the **Path Line Moving Enabled** check box. For more information, see "Setup Options: Animation tab" in the "Setting Your Preferences" chapter.



Move Path Line Dialog Box

The dialog box contains **X**, **Y**, and **Z** axis boxes, allowing you to type a specific move point location, or you can use the **Increment** value with the small up and down arrows next to each axis box.

- When you click the up arrow, PC-DMIS adds the increment value to the current value.
- When you click the down arrow, PC-DMIS subtracts the increment value from the current value.

The selected path line is adjusted automatically in the Graphic Display window.

- **Delete** - This button deletes the selected move point. This button only becomes active when you click on or near a move point located along the path line.
- **Reset** - This button sets the path line back to normal as long as you haven't clicked **OK** or **Apply**.
- **Apply** - This button functions the same as the **OK** button except that the dialog box remains open, which allows you to continue to work with additional path lines.
- **OK** - This button accepts your changes and inserts a `MOVE/POINT` command into the Edit window at the appropriate location to reflect the adjusted path line and then closes the dialog box.

If you need to adjust the move point later, simply click on the point on the path line. The **Move Path Line** dialog box opens again, which allows you to change the values for the `MOVE/POINT` . Alternately, you can press F9 on the `MOVE/POINT` command inside the Edit window, and then use the **Move Point** dialog box to change the values.

It's often handy to rotate the part while you adjust path lines. The **Move Path Line** dialog box permits you to do 2D and 3D rotate operations with the standard Alt + right-click drag and Ctrl + right-click drag methods, respectively.

The only way to remove a path line modification is to delete the inserted `MOVE/POINT` command from the Edit window.

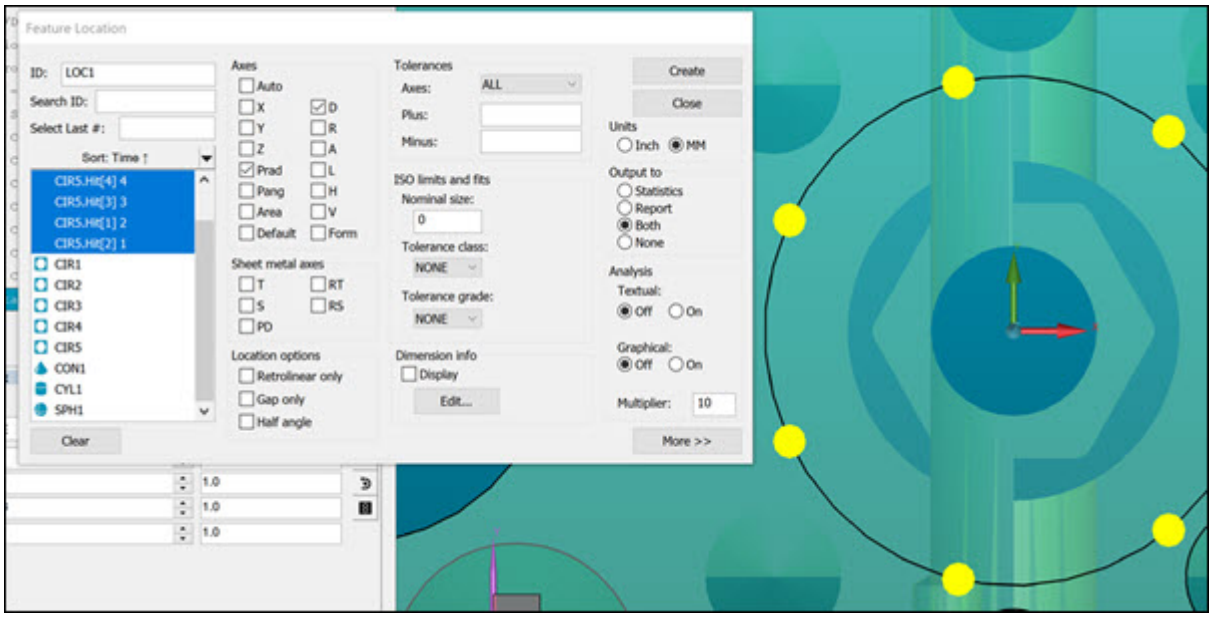
Graphical Hit Selection Method

The Graphical Hit Selection method allows you to select existing feature or scan hits in the Graphic Display window, and then use them as inputs for Alignments, Constructions, and Dimensions.

This provides an alternate way to select inputs for those types of commands.

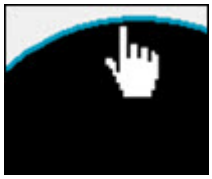
Once you have created the feature or scan hits:

1. Open the relevant dialog box to create your Alignment, Construction, or Dimension.
2. Select the feature or features from the Graphic Display window or from the **Feature List**. When you select the items from the **Feature List**, the software highlights them in the Graphic Display window.



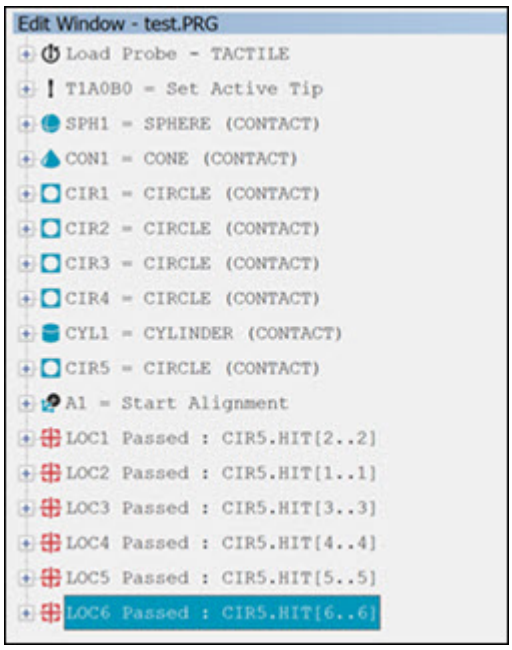
Dimension example using the Graphical Hit Selection method, selecting 6 circles from the Feature List

After you select the feature or scan, the cursor changes to show the hits you can select.



Once you select the item from the Graphic Display window, the software adds it to the **Feature List** of the opened dialog box.

3. Click **Create** on the dialog box to add the command to the Edit window's measurement routine.



Notes on hit properties:

Hits are drawn in black.

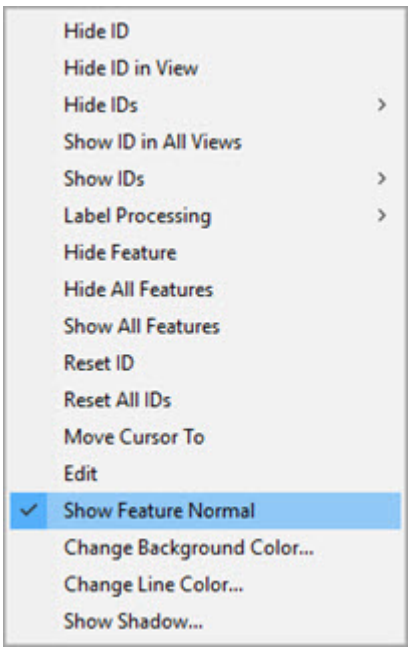
You can define or view the hit selection color from the **Colors** tab on the **CAD & Graphics Setup** dialog box (**Edit | Graphic Display Window | Screen Color**).

You can define or view how hits are drawn in the Graphic Display window from the **Point Symbols** section of the **Symbols** tab on the **CAD & Graphics Setup** dialog box (**Edit | Graphic Display Window | Display Symbols**).

Show Feature Normal Option

To assist in the selection of hits, the **Show Feature Normal** option is available. You can find it on the right-click menu in the Graphic Display window.

To access it, right-click any feature label in the Graphic Display window. The pop-up menu displays a list of options, including the **Show Feature Normal** option.



Graphic Display pop-up menu with the Show Feature Normal option selected

When you select the **Show Feature Normal** option, the software performs these operations:

- Saves the state of all CAD views
- Rotates and translates the feature to normal in the selected view
- Zooms to fit on the selected feature in the selected view
- Flashes the feature in all views

The software displays the CAD model with the transparency value as defined by the **Enable transparency** setting. You can find this setting in the **Transparency** section of the **CAD and Graphic Setup** dialog box (**Edit | Graphic Display Window | Lighting, Materials**).

De-selecting the **Show Feature Normal** option returns all views to the states they were in before the option was last enabled.

Alignment Example

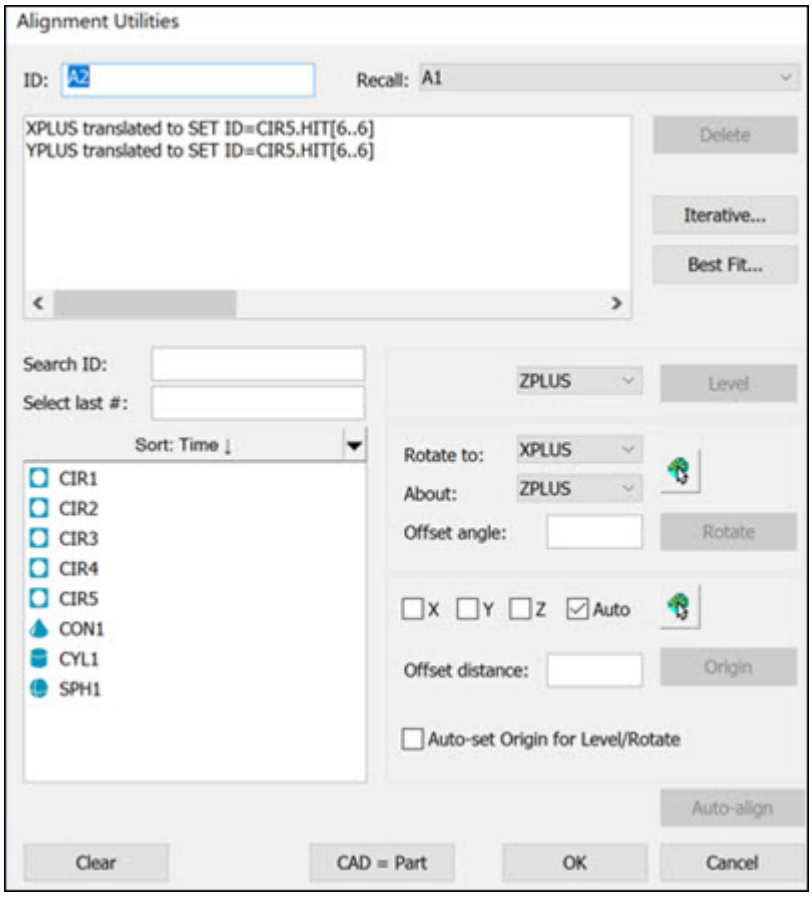
Use the Graphical Hit Selection method to select feature and scan hits as inputs when you create an alignment.

> **!** You cannot use feature or scan hits as inputs for Best Fit and Iterative alignments.

To select feature or scan hits with the Graphical Hit Selection method:

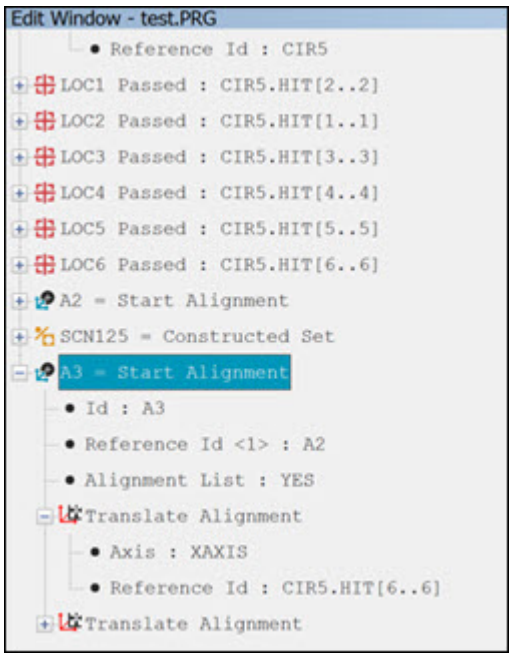
1. Create the feature or scan hits.

2. Click **New Alignment** from the **Alignments** toolbar (**View | Toolbars | Alignment**) or from the menu (**Insert | Alignment | New**). PC-DMIS displays the **Alignment Utilities** dialog box.



3. Select the items to use as inputs from the **Feature List** in the dialog box or select them from the Graphic Display window. For details, see "Graphical Hit Selection Method".

4. After you select all the items, click **Create**. The software displays the new alignment in the measurement routine.



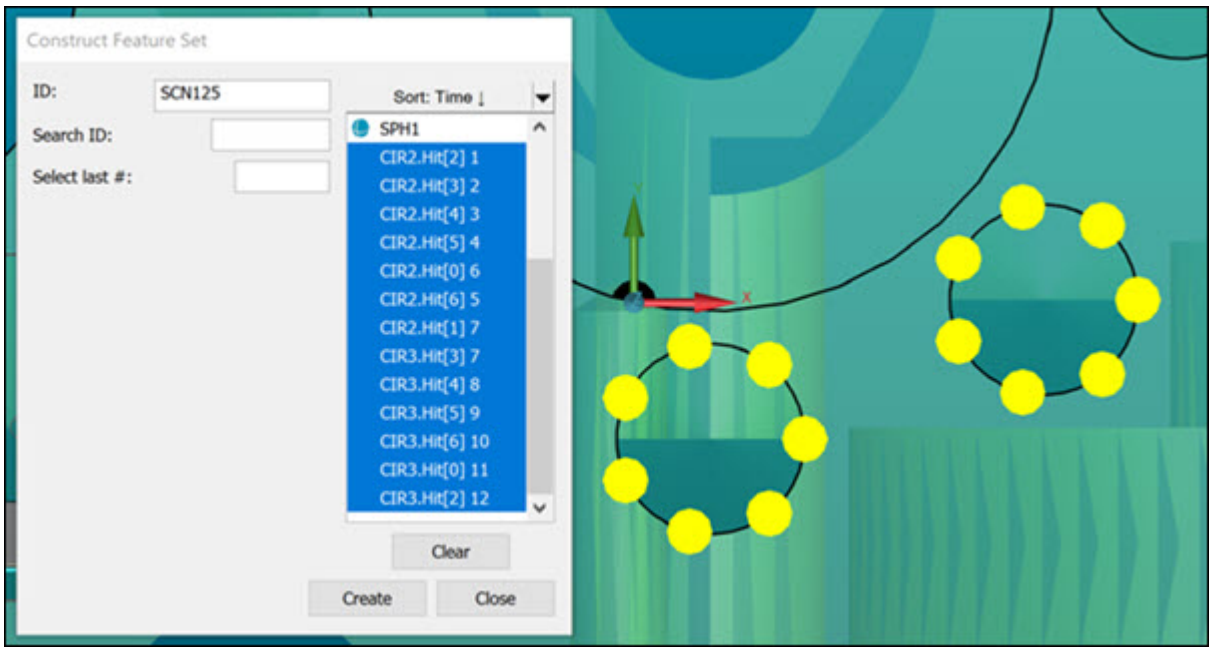
Construction Example

Use the Graphical Hit Selection method to select feature and scan hits as inputs when you create a construction.

Hits can only be selected individually. Multiple hit selection is not currently supported.

To select feature or scan hits with the Graphical Hit Selection method:

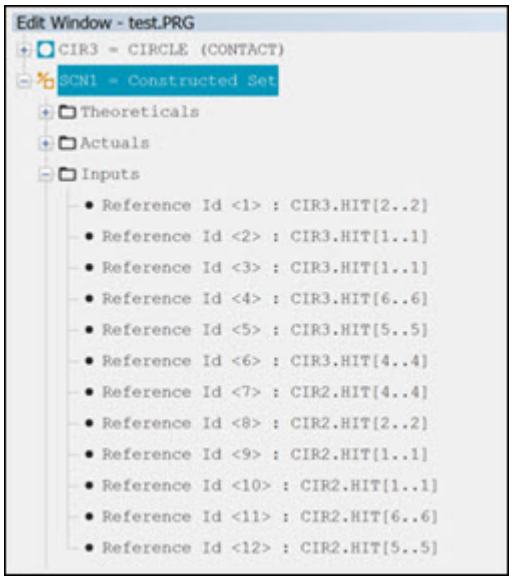
1. Create the feature or scan hits.
2. Click the construction type (for example, the **Constructed Feature Set** option) from the **Constructed Features** toolbar (**View | Toolbars | Constructed Features**) or from the menu (**Insert | Feature | Constructed | Set**). PC-DMIS displays the construction's dialog box.



Construction dialog box with features selected and highlighted in the Graphic Display window.

3. Select the items to use as inputs from the **Feature List** in the dialog box or select them from the Graphic Display window. For details, see the "Graphical Hit Selection Method" topic in the PC-DMIS Core documentation.

4. After you select all the items, click **Create**. The software displays the new construction in the measurement routine.



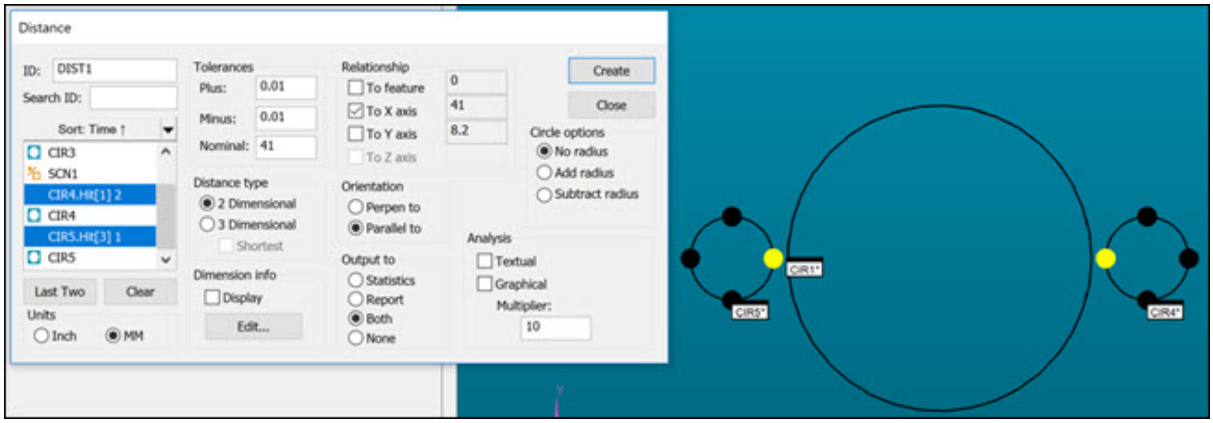
Dimension Example

Use the Graphical Hit Selection method to select feature and scan hits as inputs when you create a dimension.

Dimension types where points are not valid inputs will not display feature or scan hits.

To select feature or scan hits with the Graphical Hit Selection method:

1. Create the feature or scan hits.
2. Click the dimension type (for example, the **Distance** option) from the **Dimension** toolbar (**View | Toolbars | Dimension**) or from the menu (**Insert | Dimension**). PC-DMIS displays the dimension's dialog box.

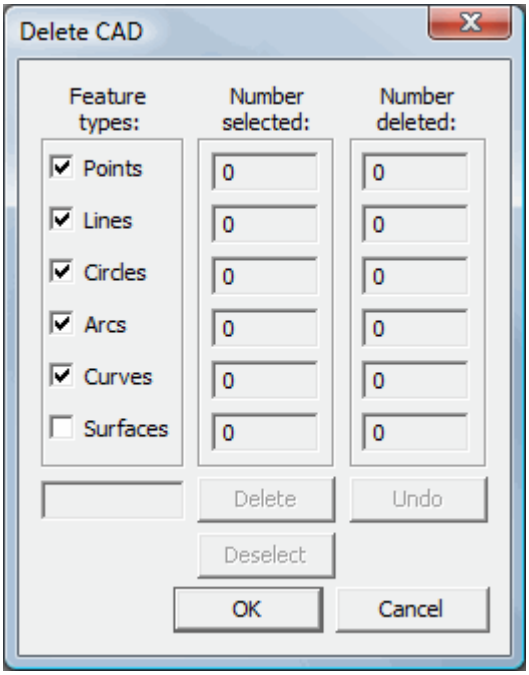


Dimension Distance dialog box with features selected and highlighted in the Graphic Display window

Dimension types where points are not valid inputs will not display Feature or Scan Hits.

3. Select the items to use as inputs from the **Feature List** in the dialog box, or select them from the Graphic Display window. For details, see "Graphical Hit Selection Method".
4. After you select all the items, click **Create**. The software displays the new dimension in the measurement routine.

Deleting CAD Elements



Delete CAD Dialog Box

The **Edit | Delete | CAD Elements** menu option displays the **Delete CAD** dialog box.

You can use this dialog box to permanently remove the CAD elements of selected features from the CAD model in the Graphic Display window.

This can help simplify an imported CAD file before building a measurement routine. For example, a CAD file may contain text or other descriptive information that has no impact on the inspection of the part.

To use this dialog box:

1. From the **Feature types** area, mark the CAD element feature types you want to delete.
2. From the Graphic Display window, press Ctrl + Click (or box-select) to highlight the CAD elements you want to remove.
3. Click **Delete** or press the Delete key to preview the deletion. At this point, the items are only temporarily removed, and you can click **Undo** to restore the temporary deletion.
4. Click **OK** to permanently delete the selected CAD elements.

Dialog Box Description

The dialog box contains these items:

Feature types - Determines what feature types to delete. The available types are:

- Points
- Lines
- Circles
- Arcs
- Curves
- Surfaces

Number selected - Shows the number of selected CAD elements for each type.

Deselect - Deselects any highlighted CAD elements.

Number deleted - Displays the number of features that have been deleted. The numbers in these fields change, depending on the features selected in the **Feature types** area.

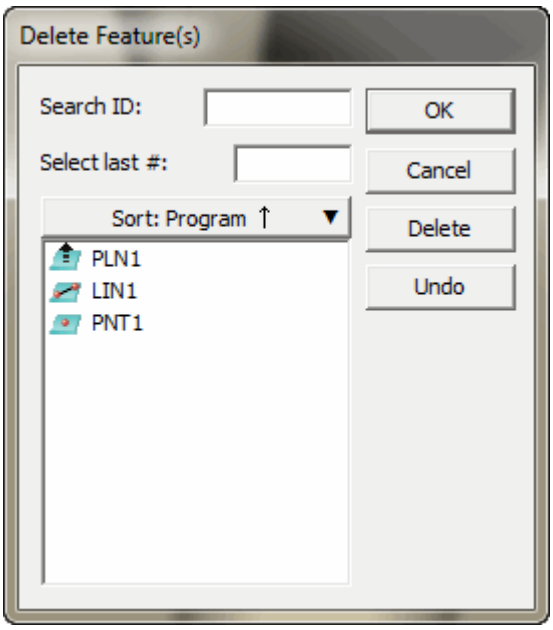
Delete - Deletes selected nominal features. If this dialog box is open, you can also press the Delete key to delete the CAD elements. Until you click **OK**, this is only temporary.

Undo - Restores the recently deleted nominal features. This only works for items that are temporarily deleted. To restore permanently deleted CAD elements, you need to re-import the entire model file.

Deleting Features

PC-DMIS allows you to delete existing features in two ways:

- You can select features in the Edit window and press the Delete key on your keyboard.
- You can use the **Delete Features** dialog box, discussed below.



Delete Features Dialog Box

The **Delete Features** dialog box (**Edit | Delete | Features**) permanently removes measured, auto, or constructed features from the measurement routine. You should use this option when you want to remove a number of unnecessary features. The **Delete Features** dialog box only lists those features above the current cursor position in the Edit window.

Select the features to delete, and then click **Delete** to mark them for deletion. Click **OK** to delete items marked for deletion.

Search ID - Selects matching features after you press Tab.

Select last # - Selects a number of features from the end of the list.

Delete - Marks the selected items for deletion by placing a text fragment of "del" next to selected features in the list. This deletion is not permanent until you click **OK**.

Undo - Restore all the features that are marked for deletion after clicking **Delete**. This button does not restore deleted dimensions once you click **OK**.

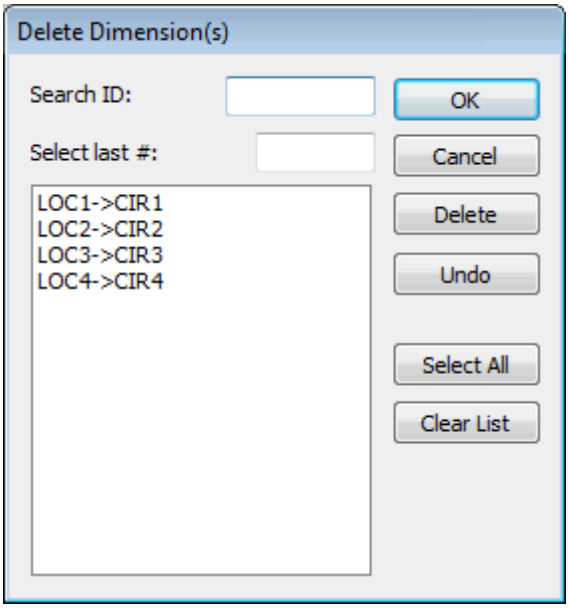
When measured features are removed from the Graphic Display window, PC-DMIS automatically removes any dimensions or datums associated with them from the measurement routine.

Deleting Dimensions

PC-DMIS allows you to delete existing dimensions in two ways:

- You can select dimensions in the Edit window and press the Delete key on your keyboard.

- You can use the **Delete Dimensions** dialog box, discussed below.



Delete Dimensions Dialog Box

The **Delete Dimensions** dialog box (**Edit | Delete | Dimension**) lets you permanently remove any dimensions from the measurement routine. Use this option when you need to remove a number of unnecessary dimensions. The **Delete Dimensions** dialog box only lists those features above the current cursor position in the Edit window.

Select the dimensions to delete, and then click **Delete** to mark them for deletion. Click **OK** to delete items marked for deletion.

Search ID - This box selects matching dimensions after you press Tab.

Select last # - This box selects a number of dimensions from the end of the list.

Delete - This button places a text fragment of "del" next to selected dimensions in the list to mark them for deletion. You can select all the dimensions from the list by clicking **Select All**. This deletion is not permanent until you click **OK**.

Undo - This button restore all the dimensions that are marked for deletion after clicking **Delete**. This button does not restore deleted dimensions once you click **OK**.

Select All - This button selects all the features in the list. For

Clear List - This button clears any selected features from the list.

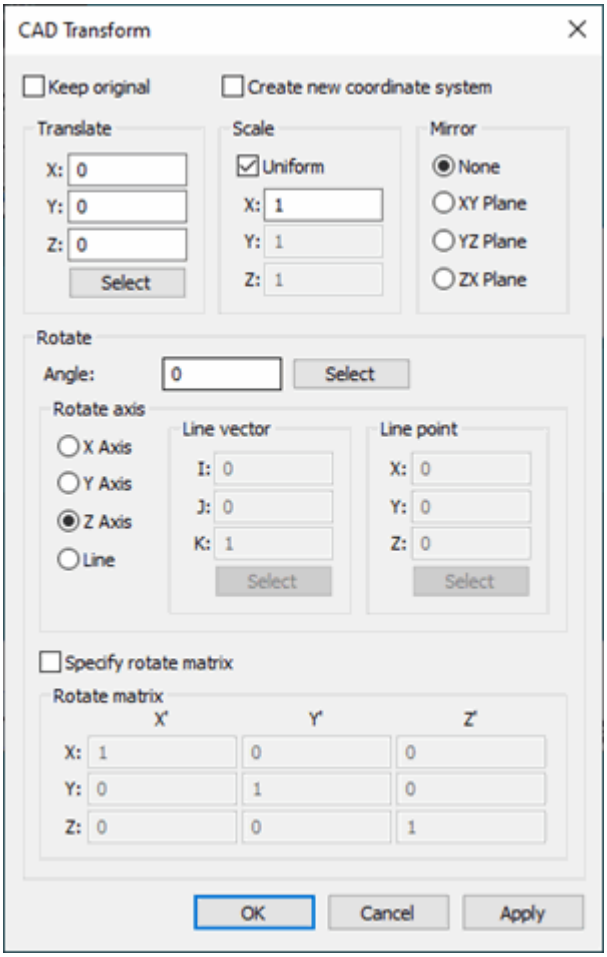
Transforming a CAD Model

You can transform (translate, scale, and rotate) your CAD model. Also, if desired, you can keep a copy of the original, unmodified CAD model as well as create a new coordinate system for the transformed model.

To transform your CAD model, open the **CAD Transform** dialog box (**Operation | Graphic Display Window | Transform**). Use the items in the dialog box as needed, and then click **OK** or **Apply**.

You can also click the **CAD Transform** button from the **CAD Setup** toolbar or from the **CAD** dropdown toolbar on the **QuickMeasure** toolbar to open the **CAD Transform** dialog box.

Performing a CAD transform operation does not transform any existing learned features. This operation essentially renders them useless. You may want to perform a **File | Save As** operation to create a backup of your measurement routine and CAD model before you proceed.



CAD Transform Dialog Box

Keep original - This check box lets you keep a copy of the original, unmodified CAD model.

Create new coordinate system - This check box lets you create a new coordinate system from the newly-translated CAD model. For more information, see "Working with CAD Coordinate Systems".

Translate - This area defines the XYZ offsets to translate the model. You can type the specific location to which you want PC-DMIS to move the coordinate system. If you do not know the coordinates, you can use the **Select** button to select a specific CAD entity to which the coordinate system moves. See "Transforming by Selecting" below.

Scale - This area defines how the CAD model is scaled. This can be useful for fixing models that are not scaled correctly due to improper measurement-unit identification. For example, if the model is sized for millimeter units but you want it scaled for inch units, you can scale the model by 25.4.

The **Uniform** check box uniformly scales the model. If you want to scale a selected axis of the model, clear the **Uniform** check box. Leave the value as 1 for axes that you do not want scaled, and change the axis that you want scaled. You can also scale axes by negative values. This is useful if you want to mirror an axis. In this case, enter -1 for that axis.

Mirror - In this section, you can mirror the CAD view of a part. Mirroring provides the same functionality as using **Scale** with -1 specified for the mirroring axis. Mirroring your CAD model is particularly useful when measuring automotive parts that have identical left- and right-hand pieces. If CAD information is available for the right side of a part, you can mirror the appropriate axis, and create a CAD view of the left side of the part.

The **Mirror** option does *not* create a new measurement routine in the mirrored image. If you want to mirror your measurement routine instead, see the "Mirror" topic in the "Using Basic File Options" chapter, and follow the instructions.

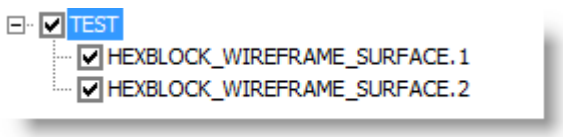
To mirror the CAD data, do the following:

1. Select the axis you want to mirror. If you want to keep your old CAD data so that after mirroring you have CAD data for both the symmetrical halves, select the **Keep original** check box.

2. Click **Apply** or **OK**. PC-DMIS mirrors the CAD drawing in the specified axis and displays the image in the Graphic Display window.

Mirrored Elements in CAD Assemblies

If you open the **CAD Assembly** dialog box, you can see that your original imported image name has the number 1 appended to its name. Any CAD transformation that creates a new instance of the same CAD file (such as a mirror operation) is then incremented to have a unique number. See "Working with Assemblies of Parts".



Example showing a mirrored CAD file names with unique numbers inside the CAD Assembly tree view.

Hidden Assembly Components During a Mirror Operation

If you hide elements of your CAD assembly prior to mirroring your CAD data, hidden components are still mirrored, but their mirrored counterparts also continue to remain hidden in the Graphic Display window until their visibility state is modified in the **Assembly Tree View** of the **CAD Assembly** dialog box.

Rotate - This area controls how the CAD model is rotated. Type the angle you want to rotate the model by in the **Angle** box. You can type the specific location to which you want PC-DMIS to move the coordinate system. If you do not know the coordinates, you can use the **Select** button to select a specific CAD entity to which the coordinate system moves. See "Transforming by Selecting" below.

Rotate axis - This area defines the line about which the CAD model is rotated. The model rotates about this line by the specified angle. The direction of rotation follows the right-hand rule. You can use one of the coordinate-system axes as the line to rotate about by selecting the appropriate **X**, **Y**, or **Z** axis option button. If you do not want to rotate about one of the coordinate system axes, you can rotate about an arbitrary line by selecting the **Line** option button. This enables the **Line vector** and **Line point** areas. Fill these areas out to determine the point and vector that comprise the arbitrary line.

Right-Hand Rule: If you extend the thumb on your right hand in the direction of the line vector, and curl your other fingers into your palm, your fingers indicate the direction of positive angle rotation.

Rotate matrix - As you determine your CAD model's new transformation, this area automatically gets filled out with the values to use in a 3 X 3 matrix. This 3 X 3 matrix rotates the CAD model. Usually, you won't need to fill out anything in this area as it is generally for informational purposes only.

For the Advanced User:

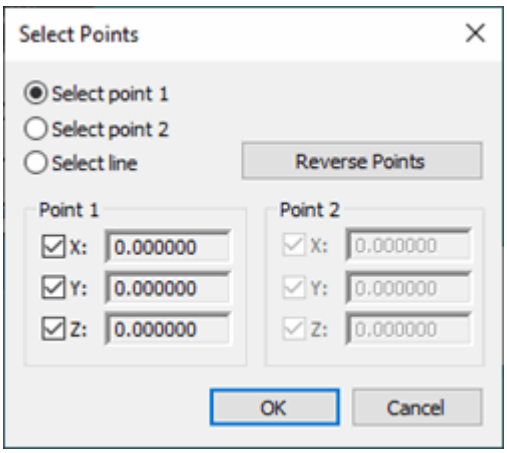
You can select the **Specify rotate matrix** check box to type the values for the rotation matrix manually. The columns specify the axes for the rotation. These restrictions apply:

- Each axis of the matrix must be orthogonal to the other two axes. Thus, each axis pair must form a 90-degree angle.
- Each axis must be unit length. That is, the length of the axis must be one.

When you apply the transformation, if either of these restrictions is not met, a message appears and indicates the problem, and PC-DMIS automatically corrects the rotation matrix.

Transforming by Selecting

When you click the **Select** button, PC-DMIS displays the **Select Points** dialog box.



Select Points Dialog Box

Instead of typing an offset value, you can use this dialog box to select an offset by picking a CAD entity from the Graphic Display window.

Select point 1 - This option defines the translation location. With this option selected, click on a desired CAD entity. This anchors the point to that location.

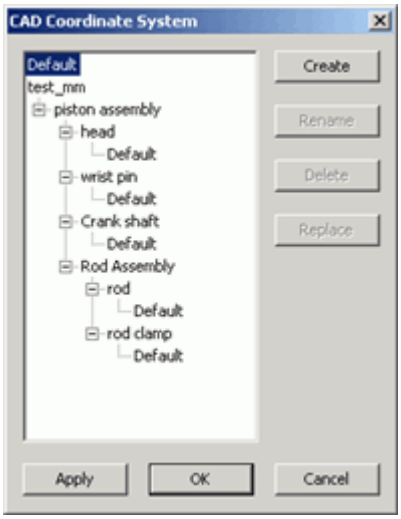
Select point 2 - This option specifies the angle with respect to point 1 and the axis of rotation. With this option selected, click on a second CAD entity on your CAD model to define the angle.

Select line - Instead of selecting two points for your translation, this option lets you select a single line. PC-DMIS then sets the values of the **Point 1** and **Point 2** areas to match the start and end points of the selected line.

Reverse Points - This button switches the XYZ values of Point 1 with the XYZ values of Point 2.

Point 1 and Point 2 - These areas define the XYZ center point of the CAD entity selected with the **Select point 1** and **Select point 2** options. Use the check boxes in these areas to selectively update the X, Y, or Z value of the point, which enables you to specify points where there is no actual geometry for you to click on. For example, for Point 1, suppose you wanted the X and Y value of one point but the Z value of a different point. To do this, clear the **Z** check box and then select one point. Then clear the **X**, **Y** check boxes, select the **Z** check box, and select the other point.

Working with CAD Coordinate Systems



CAD Coordinate System Dialog Box

The **Edit | Graphic Display Window | CAD Coordinate System** menu option displays the **CAD Coordinate System** dialog box. The **CAD Coordinate System** dialog box lets you create or select new coordinate systems for your CAD model.

The **Coordinate System** list on the left side of the dialog box shows all the coordinate systems in the CAD model. The coordinate systems listed first are the global coordinate systems. The **Default** coordinate system is always listed.

If the CAD model is an assembly of component parts then following the global coordinate systems, PC-DMIS lists all the coordinate systems contained in that assembly. These are listed in a tree view structure. To expand the tree view, click on a plus symbol (+). PC-DMIS displays the component parts' assembly coordinate systems. The **Default** coordinate system is always listed for each part component in the assembly. This coordinate system defines the part's default local coordinate system.

When you first open the **CAD Coordinate System** dialog box, PC-DMIS checks to see if the current active coordinate system matches a coordinate system in the list:

- If it finds a match then PC-DMIS selects it from the list.
- If it doesn't match any of the coordinate systems then PC-DMIS uses the **Default** coordinate system at the top of the list. This can happen if you transformed the CAD without creating a coordinate system (for more information, see the "Transforming a CAD Model" topic).

To Select and Use Coordinate Systems

To use an existing coordinate system:

1. Select the coordinate system from the **Coordinate System** list. PC-DMIS shows that coordinate system in the Graphic Display window. If you select an assembly component, PC-DMIS selects the first coordinate system in that component instead.

2. Click **Apply** or **OK**. The selected coordinate system becomes the new active coordinate system, and PC-DMIS redraws the CAD to reflect its new position.

To Create a Coordinate System

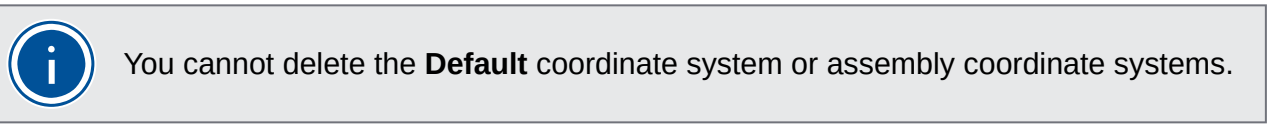
To create a coordinate system at the current CAD model's position, click the **Create** button. You can use the **CAD Transform** dialog box to change the CAD model's position. For more information on how to transform a CAD model, see the "Transforming a CAD Model" topic.

To Rename a Coordinate System

To rename a coordinate system, select the coordinate system from the list, and click the **Rename** button. Type the new name.

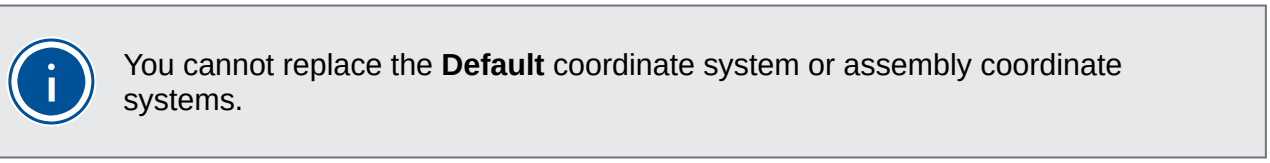
To Delete a Coordinate System

To delete a coordinate system, select the coordinate system from the list, and click the **Delete** button. PC-DMIS deletes the selected coordinate system.

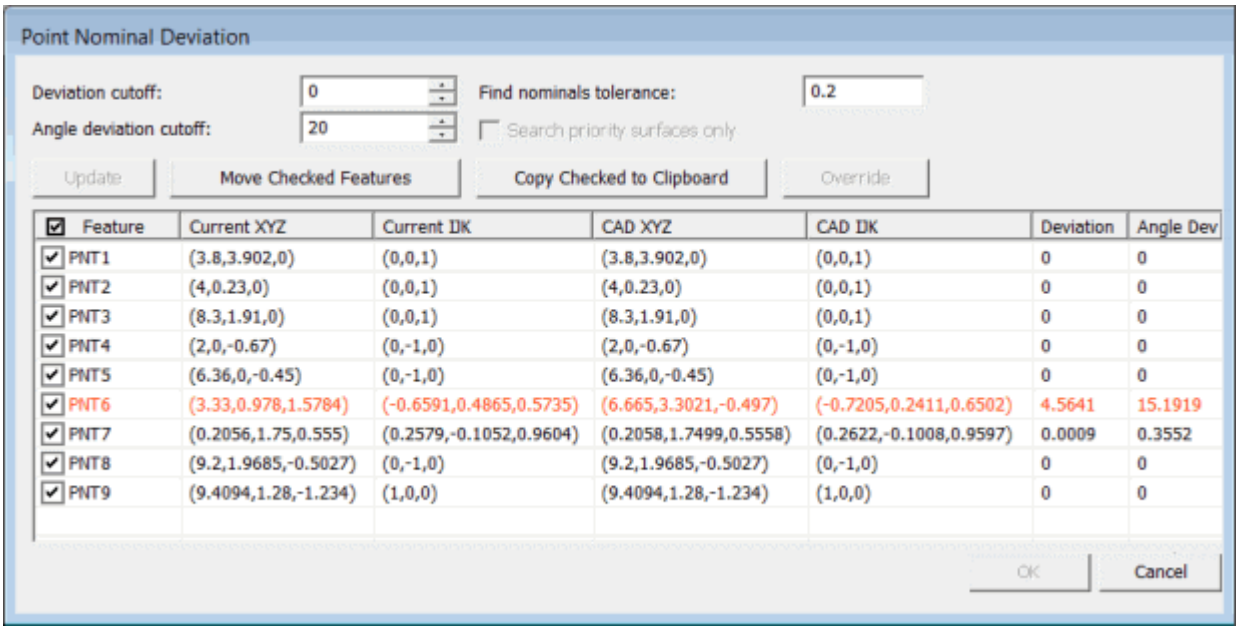


To Replace a Coordinate System

To replace or overwrite an existing coordinate system with the current CAD model's position, select a coordinate system from the list, and click the **Replace** button.



Checking and Fixing Point Nominal Deviation



Point Nominal Deviation Dialog Box

The **Edit | Graphic Display Window | Point Nominal Deviation** menu option displays the **Point Nominal Deviation** dialog box. Use this re-sizable dialog box to compare certain point measurements against a CAD model to check for changes or updates made to the CAD model. Essentially, you define a tolerance value, and PC-DMIS looks at the nominals for any point features in your measurement routine and compare them against the CAD model.

PC-DMIS lists all of the points. It lists any points that deviate beyond the defined tolerance value in a red/orange color; you can then adjust them as needed.

The **Point Nominal Deviation** dialog box contains the following options:

Deviation cutoff - This box filters the point features that display. The distance between a point feature's theoretical position and the CAD model nominal position is its deviation. Only points whose deviation is greater than or equal to the deviation cutoff are listed.

Angle deviation cutoff - This box controls the nominal CAD position. The CAD surface normal and the point vector must be within this angle. The range for this angle is 0–90 degrees.

Find nominals tolerance - This box defines the tolerance value that are allowed for each point feature. Points with a deviation that exceeds this tolerance value turn red.

Search priority surfaces - This check box specifies whether or not PC-DMIS only uses priority surfaces when searching for a solution. You can define priority surfaces using the **Set as priority** check box in the **Edit CAD Elements** dialog box. See the "Editing CAD" topic for more information on how to do this. If you clear this check box, and PC-DMIS

cannot find an acceptable value within the defined priority surfaces, it checks all of the other surfaces on the CAD model.

Update - This button lists all of the points on the CAD model.

Move Checked Features - This button updates the XYZ and IJK values of those point features whose check boxes you have selected to match the CAD model's XYZ and IJK values.

Copy Checked to Clipboard - This button copies the information about all of the selected points to the Clipboard. For an example, see "Clipboard Example".

Override - Sometimes the best point that the algorithm finds is incorrect. When you select a single feature, the **Override** button becomes available. Click this button to display the **Override** dialog box, which you can use to override the found point with a different point. For more information, see "Using the Override Dialog Box".

Feature - This column displays the name of the ID of the feature. The column's header contains a check box. Selecting or clearing this check box selects or clears the check boxes for all point features in the list.

Current XYZ - This column displays the feature's current theoretical position.

Current IJK - This column displays the feature's current theoretical vectors.

CAD XYZ - This column displays the feature's nominal position if it were moved onto the CAD.

CAD IJK - This column displays the feature's nominal vector if it were moved onto the CAD.

Deviation - This column displays the distance between the feature's current theoretical position and its corresponding nominal CAD position.

Angle Dev - This column displays the angle deviation between the feature's current theoretical vector and its corresponding nominal CAD vector.

Clipboard Example

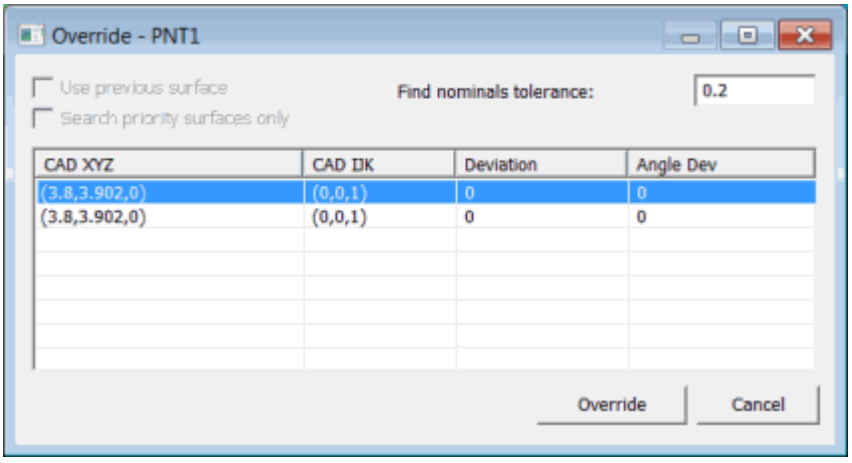
```
Feature     Current XYZ          Current
IJK              CAD XYZ                CAD
IJK                  Deviation   Angle Dev
PNT1       (3.8,3.902,0)         (0,0,1)                  (3
.8,3.902,0)           (0,0,1)                  0           0

PNT2       (4,0.23,0)            (0,0,1)                  (4
,0.23,0)              (0,0,1)                  0           0
PNT3       (8.3,1.91,0)          (0,0,1)                  (8
.3,1.91,0)            (0,0,1)                  0           0
PNT4       (2,0,-0.67)           (0,-1,0)                 (2
,0,-0.67)             (0,-1,0)                 0           0
PNT5       (6.36,0,-0.45)        (0,-1,0)                 (6
.36,0,-0.45)          (0,-1,0)                 0           0

PNT6       (3.33,0.978,1.5784)   (-0.6591,0.4865,0.5735)
 (6.665,3.3021,-0.497)   (-0.7205,0.2411,0.6502)
 4.5641      15.1919
PNT7       (0.2056,1.75,0.555)   (0.2579,-0.1052,0.9604)
 (0.2058,1.7499,0.5558)  (0.2622,-0.1008,0.9597)
 0.0009      0.3552
PNT8       (9.2,1.9685,-0.5027)  (0,-1,0)                 (9
.2,1.9685,-0.5027)    (0,-1,0)                 0           0
PNT9       (9.4094,1.28,-1.234)
 (1,0,0)                  (9.4094,1.28,-1.234)    (1,0,0)
              0           0
```

Example showing the points copied to the Clipboard (best viewed in full screen).

Using the Override Dialog Box



Override Dialog Box

The **Override** dialog box appears when you select the **Override** button in the **Point Nominal Deviation** dialog box. It shows a list of all of the CAD nominal points that correspond to the selected feature from all surfaces within the Find Nominals Tolerance search zone. PC-DMIS initially sorts these points from the smallest to the largest deviation.

Usually, the first point that is listed is the point used in the **Point Nominal Deviation** dialog box. Each point is graphically represented with a cross-hair in the Graphic Display window.

Selecting a point in the list highlights that point as well as any curve or surface on which the point lies in the Graphic Display window. Once you find the desired point, click the **Override** button. The **Override** dialog box closes and the **Point Nominal Deviation** dialog box reappears, showing the updated point value.

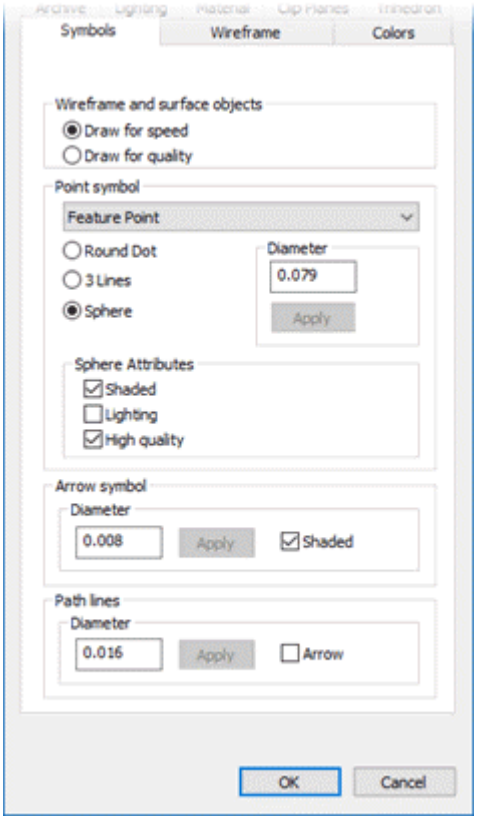
Use previous surface - You should use this check box when you override several points. For example, if you know that points for several features should all lie on the same surface but the algorithm incorrectly put the points on different surfaces, you would override the first feature as usual. Then on the second and subsequent overrides, you could select the **Use previous surface** check box. This would cause PC-DMIS to only show the points found on the surface of the previous override.

Find nominals tolerance - This box functions the same as the box with the same name in the **Point Nominal Deviation** dialog box, but with different results. PC-DMIS searches the CAD for nominal points that correspond to the selected feature. It searches in a spherical zone around the current theoretical position of the selected feature. This box defines the size of that spherical search zone. The value regulates the amount of CAD that PC-DMIS evaluates while generating this point override list.

The **Search priority surfaces only** check box is discussed in the table above.

Modifying Display Symbols

You can select **Edit | Graphic Display Window | Display Symbols** (or the **Display Symbols** icon from the **Graphic Modes** toolbar) to display the **Symbols** tab on the **CAD and Graphic Setup** dialog box.



CAD and Graphic Setup dialog box - Symbols tab

This tab lets you change how PC-DMIS displays different symbols in the Graphic Display window. The initial values for the settings on the **Symbols** tab come from the measurement routine file (.prg). If no settings information exists in the measurement routine, then the initial values for the settings come from the JSON file or from hard-coded defaults.

Available symbols you can modify include **Wireframe and Surface objects**, the **Point Symbol**, the **Arrow Symbol**, and **Path Lines**. Corresponding areas exist on the **Symbols** tab. Whenever you make a change to one of the check boxes or option buttons, PC-DMIS applies that change automatically so you can see what effect it has. PC-DMIS only saves your changes once you click the **OK** button. To see changes to the symbols' sizes, click the appropriate **Apply** button.

Draw for speed - This option turns off anti-aliasing for wireframe and surface objects. This option optimizes the drawing speed of CAD objects in the Graphic Display window.

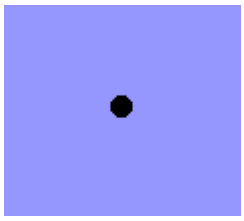
Draw for quality - This option turns on anti-aliasing for wireframe and surface objects. This option optimizes the drawing quality of CAD objects in the Graphic Display window.

Point Symbol - This list defines the type of Point to modify. You can choose **Scan Point**, **CAD Point**, or **Feature Point**. The default item is **Feature Point**.

Diameter / Width in Pixels - This box defines the size of the point symbol. The **Round Dot** symbol uses the **Width in Pixels** value. **3 Lines** and **Sphere** use the **Diameter** value. This diameter value is in measurement routine units. Note that the maximum size for **Round Dot** is based on the computer's physical video card. If the size exceeds the limits

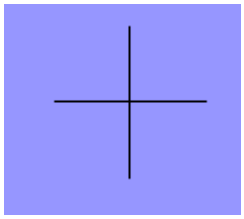
of the current computer's video card, PC-DMIS displays the symbol at the largest size available to the current system's video card.

Round Dot - This option displays the point symbol as a round dot.



Example Round Dot symbol

Three Lines - This option displays the point symbol as a three-lined cross hair.



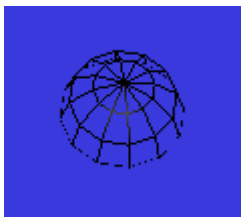
Example Three Lines symbol

Sphere - This option displays the point symbols as a sphere. This is the slowest symbol for PC-DMIS to draw, especially if you have all the attributes selected. These check boxes become available if you select the Sphere symbol. They provide you with additional attributes to further control the display of a sphere symbol in the Graphic Display window:

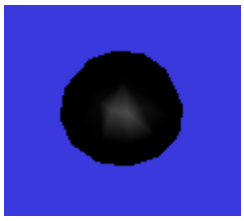
- **Shaded** - This check box produces a shaded (opaque) sphere symbol.
- **Lighting** - This check box adds OpenGL lighting to the sphere symbol.
- **High Quality** - This check box produces a smoother-looking sphere symbol.

While these check boxes improve the image quality of the sphere symbol, they also cause a slight increase in the time it takes to draw the sphere symbols whenever the screen gets refreshed.

Shaded, High Quality



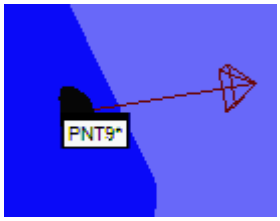
Lighting, High Quality



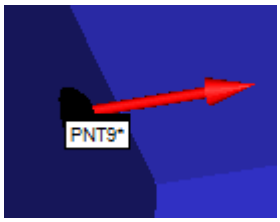
Shaded, Lighting, High quality

Arrow Symbol - This box controls the diameter size (in measurement routine units) of the arrows displayed in the Graphic Display window. The size of the actual arrow in the display only changes if you select the **Shaded** check box.

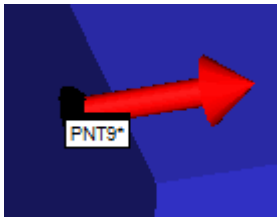
Shaded - This check box shades arrow symbols so that it draws arrows as cylinder tubes with a set diameter. If not selected, the software draws arrows as simple lines without size.



Not Shaded

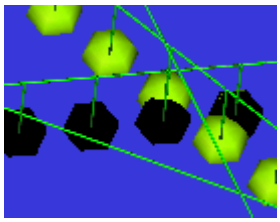


Shaded

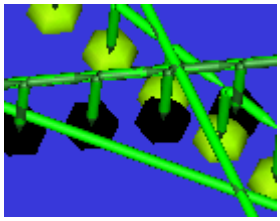


Increased Diameter

Path Lines - The **Diameter** value in this area controls the fixed diameter size (in measurement routine units) of the path lines. Fixed size means the path lines do not change size on the screen when you zoom in or out on part model.

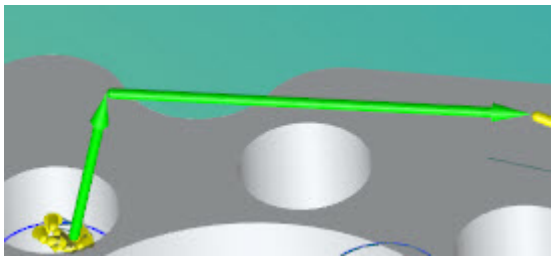


Default Size

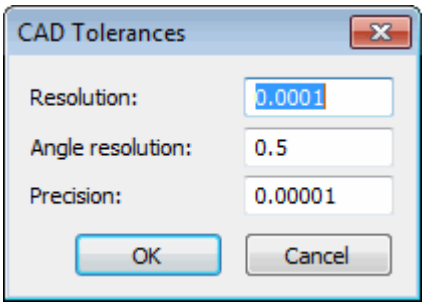


Increased Diameter

The **Arrows** check mark shows an arrow on the path lines:



Changing CAD Tolerances



CAD Tolerances Dialog Box

The **Edit | Graphic Display Window | CAD Tolerances** menu item displays the **CAD Tolerances** dialog box. This dialog box allows you to view and modify the following CAD tolerances that are stored in the .cad file:

- **Resolution** tolerance - Determines the distances at which two XYZ points are considered coincident.

- **Angle Resolution** tolerance - Determines the angle (in degrees) at which two angles are considered equal. It also determines if two vectors are considered equal by checking the angle between the two vectors.
- **Precision** tolerance - Specifies the accuracy of iterated solutions on the geometry.

The **Resolution**, **Angle Resolution** and **Precision** boxes allow you to view and modify these tolerances.

CAD Resolution Tolerance Information

The resolution tolerance is the distance at which two XYZ points are considered to be coincident.

This tolerance determines whether or not a freeform geometry defines an analytic shape. For example, a freeform curve, depending on the tolerance, may or may not be defined as a circle. If the curve defines a circle within the resolution tolerance, PC-DMIS identifies it as a circle, and any functions that depend on this information work properly. For example, the Single-Click Auto feature functionality depends on this information.

In addition, this tolerance determines whether or not two adjacent geometries are connected. For example, if you have PC-DMIS perform a Section Cut scan operation on the CAD model, PC-DMIS compares the gap between adjacent surfaces against the resolution tolerance. If the gap is within this tolerance, PC-DMIS considers the surfaces to be connected and there is not a break in the section cut.

The default resolution tolerance is 0.01 mm. The minimum resolution tolerance is 0.0001 mm and the maximum is 2.0 mm. When you import a new CAD model, PC-DMIS sets the resolution tolerance to the default value, except in cases where the imported CAD file itself specifies a resolution tolerance. For example, if an imported IGES file specifies a resolution tolerance in the header, PC-DMIS uses that value instead of the default value.

CAD Angle Resolution Tolerance Information

The CAD angle resolution tolerance determines the angle (in degrees) at which two angles are considered equal. It also determines if two vectors are considered equal by checking the angle between the two vectors.

This tolerance is mainly used to check if geometry forms a feature when angles are involved. For example, a round slot has two circular arcs at its ends. The angle between the two circle normals must be within the angle resolution for the feature to be recognized as a round slot.

Another example is a square slot where adjacent sides must form 90 degree angles. If this angle is off more than the angle resolution, then the feature is not recognized as a square slot.

The default angle resolution tolerance is 0.5 degrees. The minimum angle resolution tolerance is 0.01 degrees and the maximum is 5.0 degrees. When you import a new CAD model, PC-DMIS sets the angle resolution tolerance to the default value.

CAD Precision Tolerance Information

The precision tolerance specifies the accuracy of iterated solutions on the geometry. For example, during some find nominals operations, an iteration process is used to compute the solution on the CAD geometry. Once the solution is within the precision tolerance of the actual solution, the iteration process stops.

The smaller the precision tolerance, the slower the algorithms that use this tolerance for computing a solution.

The default precision tolerance is 0.00001 mm and this is the recommended tolerance to use. The minimum precision tolerance is 0.0000000001 mm and the maximum is 0.001 mm. When you import a new CAD model, the precision tolerance is set to the default value.

Centering the Probe on the Screen

By default, the part remains stationary on the Graphic Display window and the animated probe moves around the part as its physical counterpart moves in 3D space; to see a different section of a larger part on the screen, you have to translate (or move) the part image inside the Graphic Display window.

The **Operation | Graphic Display window | Center Probe** menu item changes this default panning functionality so that as the probe physically moves, the part on the screen moves instead thereby keeping the animated probe image always centered on the screen.

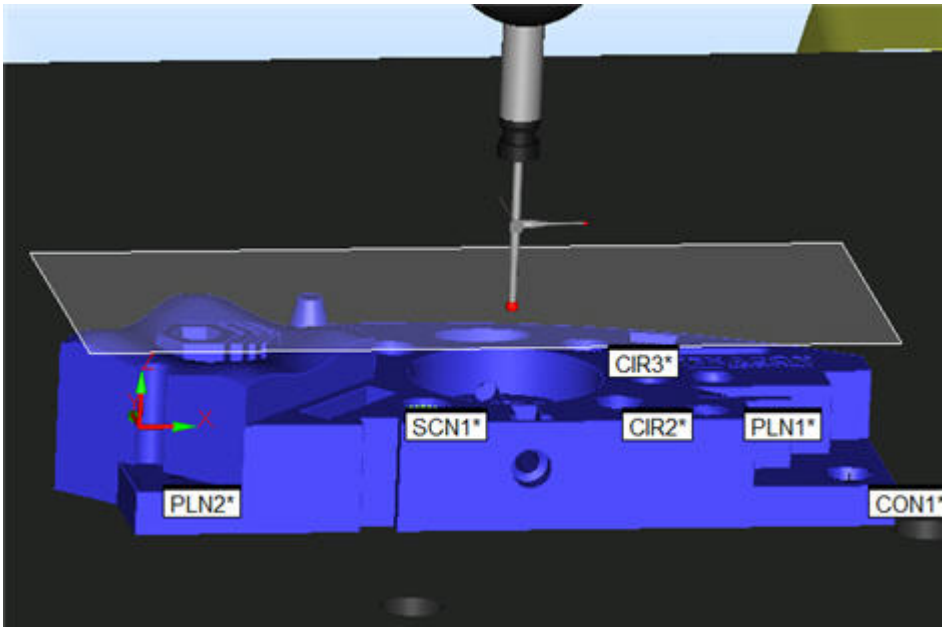
You can also access this from the **Graphic Modes** toolbar, and clicking the **Center Probe** icon .

You may find this centering functionality helpful if you are using portable devices to measure a large part. It allows you to walk around a large part, and even though you aren't near the computer, the Graphic Display window automatically updates so that the probe remains visible in the window along with the section of the CAD model you are inspecting.

Viewing Clearance Planes

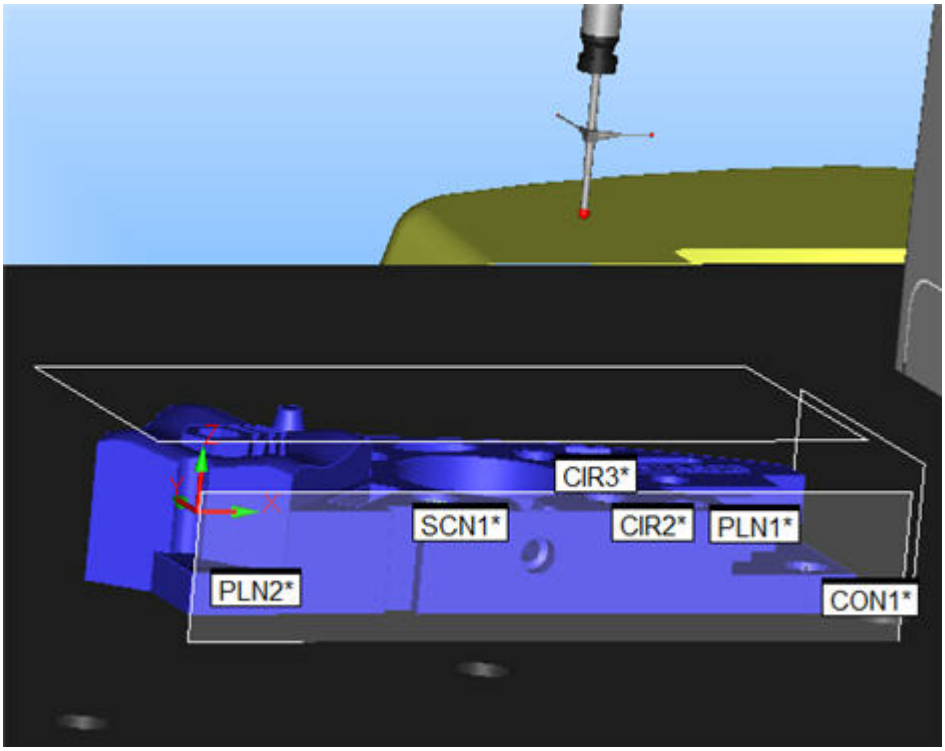
You can display the active clearance plane as a translucent image in the Graphic Display window. To do this, from the Graphic Items toolbar, select the **Toggle Clearance Plane Items** icon .

By default, the active clearance planes are displayed as white translucent planes; while all non-active clearance planes are displayed as white polylines.



A sample clearance plane displayed as a translucent image.

PC-DMIS displays up to one clearance plane along each axis, for a maximum of three clearance planes at a time (one along Z, one along Y, and one along X). If you have more than one clearance plane defined along the same axis and it isn't the currently displayed clearance plane, it displays the most recently displayed clearance plane used on that axis.



Example showing active and non-active clearance planes.

You can further control the display of both the active and non-active clearance planes by modifying these entries in the **OpenGLSettingsClearancePlanes** section in the PC-DMIS Settings Editor:

- `ActiveSymbol` - Displays the active clearance plane as either a polyline or transparent plane (0=Polyline; 1=Transparent Plane; the default is 1).
- `ActiveColor` - Determines the color of the active clearance plane.
- `ActiveLineWidth` - Determines the line width of the active clearance plane when drawn as a polyline.
- `ActivePercentTransparency` - Determines the amount of transparency for the active clearance plane.
- `Symbol` - Displays the non-active clearance planes as either polylines or transparent planes (0=Polyline; 1=Transparent Plane; the default is 1).
- `Color` - Determines the color of the non-active clearance planes.
- `LineWidth` - Determines the line width of the non-active clearance planes when drawn as a polyline.
- `PercentTransparency` - Determines the amount of transparency for the non-active clearance planes.

You can find details on these settings in your PC-DMIS Settings Editor documentation. For information on how to use the Settings Editor, see "Modifying Setting Entries".

Editing a Measurement Routine

Editing a Measurement Routine: Introduction

The main purposes of PC-DMIS are to allow you to create, edit, and execute measurement routines with ease. This chapter discusses using the **Edit** menu (with other menu options) to edit your measurement routines. While the **Edit** menu works with the commands that appear in the Edit window, a discussion of the Edit window itself is beyond the scope of this chapter. For an in-depth look at the Edit window, see the "Using the Edit Window" chapter.

This chapter covers these topics:

- Using Standard Edit Commands
- Editing Patterns of Features
- Finding and Replacing Text
- Editing Data Fields
- Jumping to Specified Line Numbers
- Jumping to and from Referenced Commands
- Overriding Guessed Features
- Overriding Found Nominals
- Marking Commands for Execution
- Creating and Executing Marked Sets
- Using Bookmarks
- Using Breakpoints
- Changing Fonts and Colors
- Editing External Objects
- Protecting Measurement Routines from Edits
- Updating Nominals from CAD

- Resetting Measured Values to Nominals

Using Standard Edit Commands

PC-DMIS, like most Windows applications, allows you to use standard edit commands in your measurement routine. The following standard menu options are available:

- Undo
- Redo
- Cut
- Copy
- Paste
- Delete
- Select All

Undo

The **Edit | Undo** menu option removes the last change you made to the Edit window. You can continue to select the **Undo** option to remove multiple changes to the Edit window.

Be aware that switching to a different Edit window mode, completely removes all changes from memory.

Redo

The **Edit | Redo** menu option reverses the last changes that took place when you used the **Undo** menu option. Like the **Undo** option, you can use the **Redo** option multiple times to replace multiple changes.

Be aware that switching to a different Edit window mode, completely removes all changes from memory.

Cut

The **Edit | Cut** menu option allows you to "cut" or move commands (or text) from one area to another using the clipboard.

To move commands using **Cut**:

1. Highlight the commands you want to move.
2. Select the **Cut** option. The commands are removed from the Edit window and stored on the Clipboard.
3. Select the **Paste** command to restore the cut commands. (For information, see "Paste".)

When you select the **Cut** command, the Clipboard contents are replaced with the cut selection.

Copy

The **Edit | Copy** menu option also allows you to copy and move commands (or text) from one area to another using the clipboard. The only difference between this option and the **Cut** option is that the commands are not removed from the Edit window when it is copied.

To copy and paste commands:

1. Highlight the desired commands.
2. Select the **Copy** command. The text remains in its current location but is stored in the Clipboard as well.
3. Select the **Paste** command to restore the cut text. (See "Paste".)

When you select the **Copy** command, the Clipboard contents are replaced with the copied selection.

Paste

The **Edit | Paste** menu option pastes the copied commands (or text) from the Clipboard into the Edit window at the current insertion point (or cursor location).

When you paste a command, PC-DMIS keeps the original command's ID, so two commands then have the same ID. Give the pasted command a new ID that the measurement routine does not already use. If you type an ID that another command already uses, PC-DMIS does not accept it.

Delete

The **Edit | Delete | Selection** menu option deletes the currently highlighted selection from the Edit window. This does not place the contents of the deleted selection in the Clipboard.

Select All

The **Edit | Select All** menu option allows you to select all the contents of the Edit window for editing purposes.

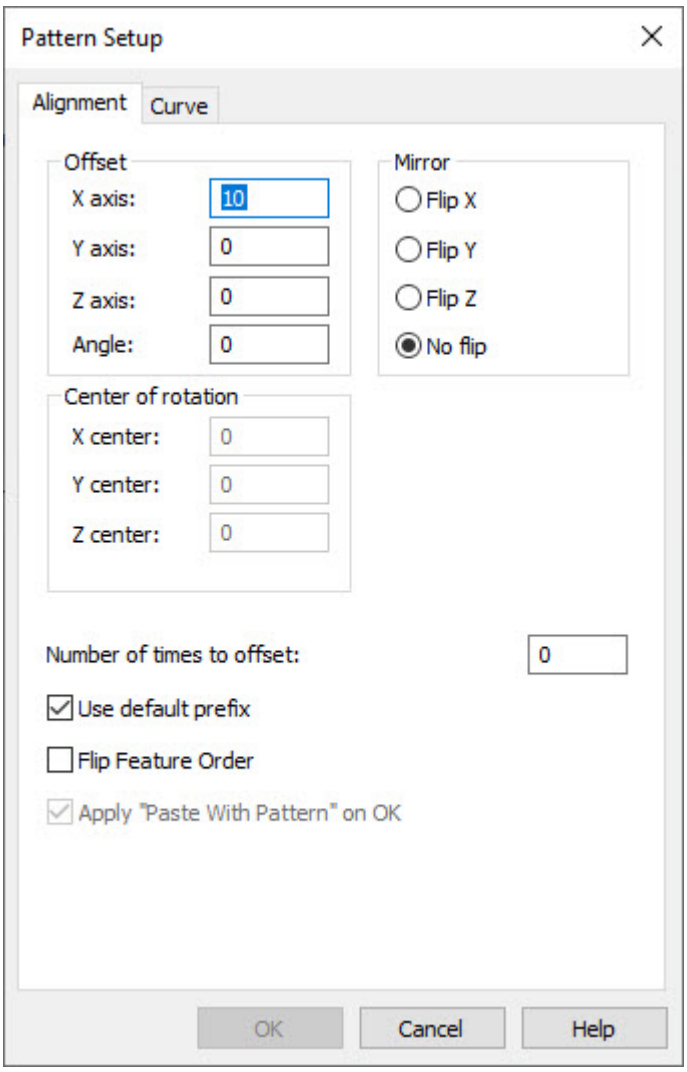
Defining and Pasting Patterns of Features

Patterns of features often occur in parts. With PC-DMIS, you can create patterned features.

You can use **Edit | Pattern** to open the **Pattern Setup** dialog box. This dialog box contains two tabs, the **Alignment** tab and the **Curve** tab. These tabs define the offsets and other options to use when you select the **Edit | Paste With Pattern** menu item.

Pattern Setup - Alignment Tab

The **Alignment** tab on the **Pattern Setup** dialog box provides the basic options of pattern setup for non-curve patterns. It can also establish a temporary alignment for an angle offset pattern.



Offset

The **X axis**, **Y axis**, and **Z axis** boxes allow you to set the X, Y, and Z Offsets between pattern occurrences. PC-DMIS offsets the nominal X, Y, and Z data of the pasted feature (or set of features) by these offset values.

The **Angle** box allows you to set the angular offset between pattern occurrences.

An angular offset may be useful when you measure the position location of several holes in a bolt hole pattern where the datum is a hole in the center of the pattern. PC-DMIS rotates the offset around the origin defined with the **Center of Rotation** area.

You can use angular offsets with X, Y, and Z offsets and the flips in the **Mirror** area. PC-DMIS applies these offsets in this order: flips, rotations, translations.

Mirror

This allows you to mirror an axis. The **Flip X**, **Flip Y**, or **Flip Z** option flips the selected X, Y, or Z axis for the pasted pattern. **No Flip** means the axis is not flipped.

Center of Rotation

The **Center of Rotation** area contains boxes for you to define a rotation center for an angle offset pattern (for example, a bolt hole pattern around a central hole). Prior to version 2021.1, if you wanted to do an angle pattern around a central hole, you had to create an alignment at that feature. Now, you don't have to create that alignment. Instead, you can click on the central circle feature, and PC-DMIS extracts the XYZ center location from the CAD and puts those values into **X center**, **Y center**, and **Z center** boxes. PC-DMIS applies the rotation around the center of rotation and within the currently active workplane.

This box becomes available to edit, if you type a value in the **Angle** box under **Offset**.

Number of times to offset

This box lets you set the number of times that PC-DMIS offsets a pattern. The default value is 1.

Use default prefix

The **Use default prefix** check box specifies whether PC-DMIS uses a default ID prefix when you use the **Paste With Pattern** menu item to paste features.

- If you select this check box, the **Paste With Pattern** menu item uses the default ID prefix when you paste new features.
- If you clear this check box, the **Paste With Pattern** menu item uses each feature ID as the base feature name and adds an incremental and numerical suffix.

If you don't use a default prefix when you paste many lines, the processing time is longer because each feature ID represents a new pattern.

Flip Feature Order

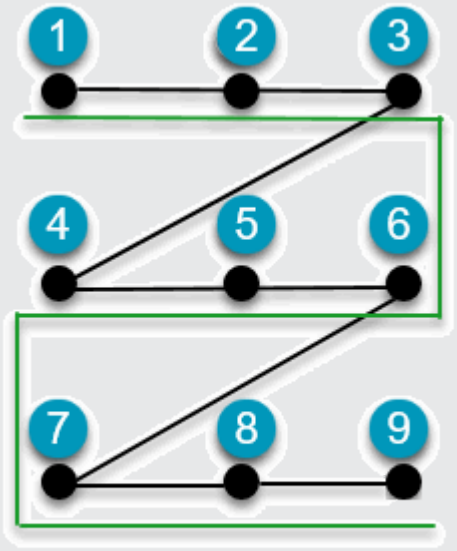
The **Flip Feature Order** check box reverses the order of the pasted features.

This check box works only with Auto features and measured features. Also, this works with only these move commands:

`MOVE/POINT,MOVE/INCREMENT,MOVE/CLEARPLANE,MOVE/CIRCULAR,MOVE/ALL,and MOVE/CLEARPOINT`

Suppose you have three Auto features: 1, 2, and 3. If you don’t select this check box, PC-DMIS pastes the new features as 4, 5, 6.

If you select this check box and change the **Number of times to offset** value from 1 to 2, you have nine features in this order: 1, 2, 3, 6, 5, 4, 7, 8, 9. Each new set of features (6, 5, 4 and 7, 8, and 9) reverses its order from the previous set. PC-DMIS follows that order during execution. In the diagram below, you can see this with the green lines. If you don't select this check box, the black lines show the original execution order:



Apply "Paste With Pattern" on OK

You can manually select the **Paste With Pattern** menu option if you like, or you can use this check box. This check box applies the **Paste With Pattern** operation behind the scenes automatically when you click **OK**.

You can use Paste with Pattern to pattern a TIP command for star probe configurations. PC-DMIS searches for a TIP on the star probe with a vector that matches the vector of the patterned feature. It handles the TIP as follows:

- If a matching TIP is available within the tolerance defined by the **Wrist warning delta** value on the **Part/Machine** tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**), PC-DMIS assigns it to the patterned feature.
- If no matching TIP is found, PC-DMIS inserts an operator comment in the Edit window instead of a TIP command. The comment indicates that the required TIP was not found. You must create or select the required TIP and modify the measurement routine as needed.

Paste With Pattern - Non Curve Procedure

To create a non-curve pattern, follow this procedure:

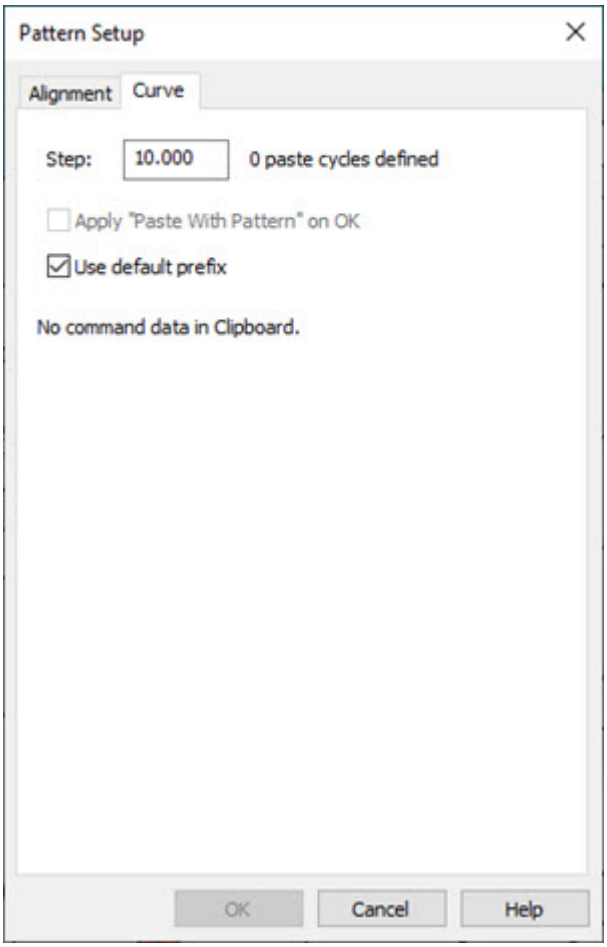
1. Define the Auto feature, features, and other commands that you want to paste, and then copy them to the Clipboard. If you want to copy and paste one or more Auto features and want to use a predefined clearance plane, make sure that you have set `CLEARPLANE=ON` inside the Auto features you are copying.
2. Choose **Edit | Pattern** to open the **Pattern Setup** dialog box.
3. Access the **Alignment** tab and type the desired offset values in the **Offset** area. If you're doing an angle pattern, type an angle offset, and then click on the center hole to get the values for the **Center of Rotation** area.
4. If you want to mirror the axis, select the desired option from the **Mirror** area.
5. Type the number of times to offset in the **Number of times to offset** box.
6. Mark **Apply "Paste With Pattern" on OK**.
7. Click **OK** to store the definition and to paste the defined pattern.

Pattern Setup - Curve Tab

The **Curve** tab on the **Pattern Setup** dialog box allows you to set up a pattern for a part with one or more edge segments around a part surface. These segments can be straight edges or curved edges. With this tab open, you can click on your CAD model to select an edge. To select multiple edges, press Ctrl and click on the part to add a new edge. You may find this tab helpful to measure a profile comprised of several points pasted around a part's surface.

To remove a selected edge, hover over it and click on it again. To remove the last selected edge, click the blue ball.

When you paste the pattern, the copied commands are pasted at the defined offset value along the selected edges.



Step

This defines the offset distance between patterned features. The default is 10. The units are based on the measurement routine units which get converted accordingly. The **Step** value must be greater than 0 (zero).

When you type a value in the **Step** box, you need to tab out of the box or click outside the box to set the value. PC-DMIS updates the text to the right of the **Step** box based on the value you typed.

Apply "Paste With Pattern" on OK

You can manually select the **Paste With Pattern** menu option if you like, or you can use this check box. This check box applies the **Paste With Pattern** operation behind the scenes automatically when you click **OK**.

Use default prefix

The **Use default prefix** check box specifies whether PC-DMIS uses a default ID prefix when you use the **Paste With Pattern** menu item to paste features.

- If you select this check box, the **Paste With Pattern** menu item uses the default ID prefix when you paste new features.
- If you clear this check box, the **Paste With Pattern** menu item uses each feature ID as the base feature name and adds an incremental and numerical suffix.

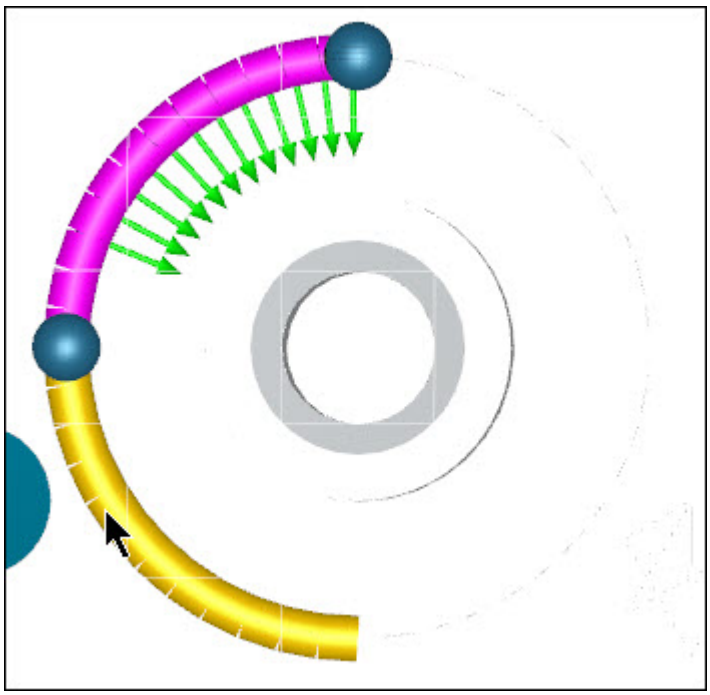
If you don't use a default prefix when you paste many lines, the processing time is longer because each feature ID represents a new pattern.

Once you click the **OK** button, you can press the Esc key to stop the Paste With Pattern process. Features that have already been pasted remain, but PC-DMIS does not paste any new features.

Paste With Pattern - Curve Procedure

To create a curve pattern with one or more edge segments, follow this procedure:

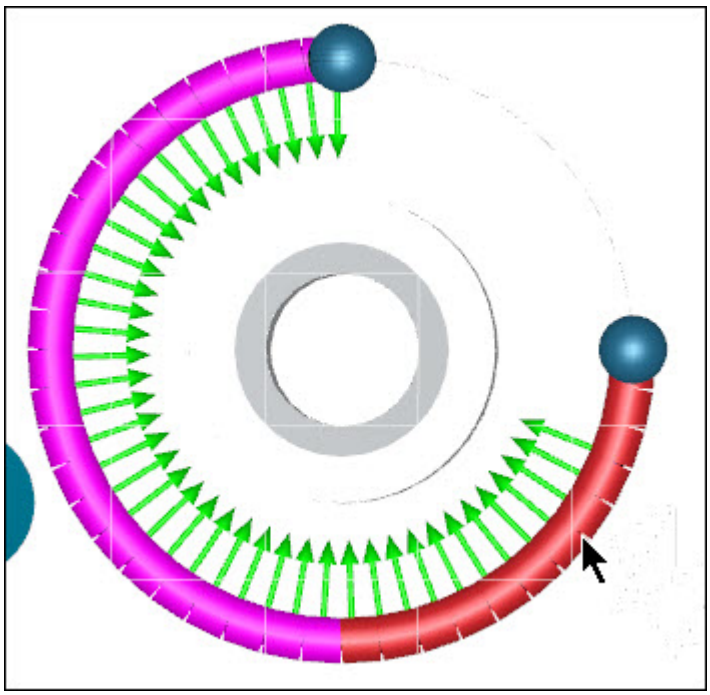
1. Define the Auto feature, features, and other commands that you want to paste, and then copy them to the Clipboard. If you want to copy and paste one or more Auto features and want to use a predefined clearance plane, make sure that you have set `CLEARPLANE=ON` inside the Auto features you are copying.
2. Choose **Edit | Pattern** to open the **Pattern Setup** dialog box.
3. Access the **Curve** tab and type the desired **Step** value in the current measurement routine units (mm or inch).
4. Keep the dialog box open and then hover your pointer over the first segment. It turns yellow.
5. Click on that segment to select it. The selected segment turns pink.



Example of an added segment (pink) and a new segment to add (yellow).

6. If you want to select multiple segments, hold down Ctrl before each additional click on segments that you want to add.

7. If you make a mistake and want to remove the last segment (or if PC-DMIS interprets the vectors incorrectly), press Ctrl and hover your pointer over the last-selected segment. When it turns red, click on that segment again to remove it. You can then re-select the segment and select a different segment.



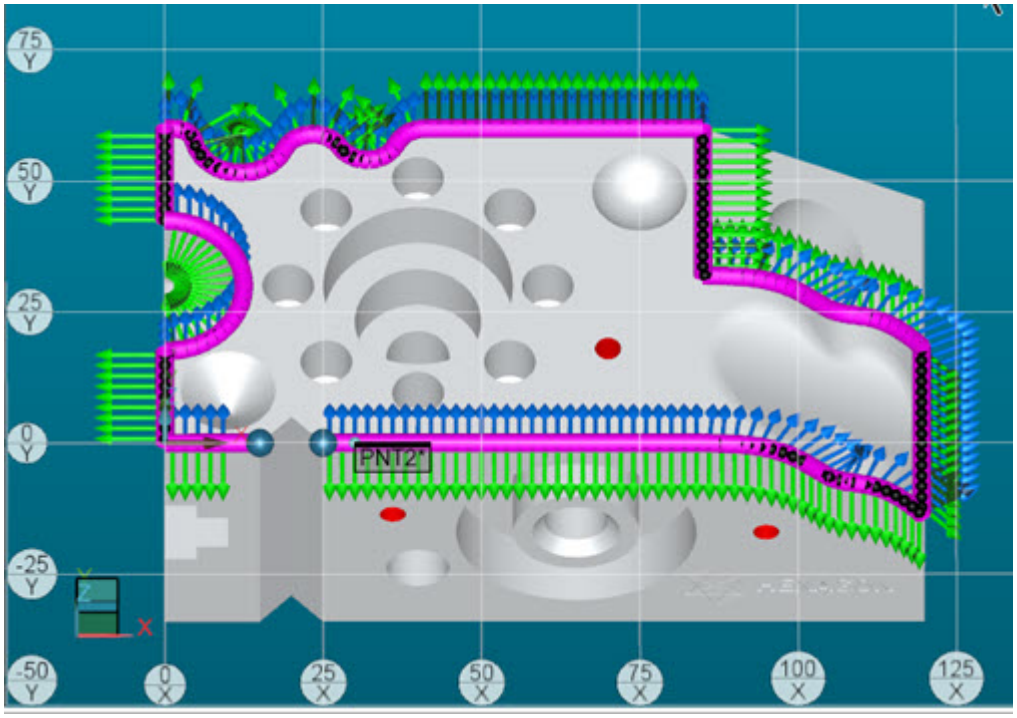
Example of a segment to delete (red).

8. Mark **Apply "Paste With Pattern" on OK**.

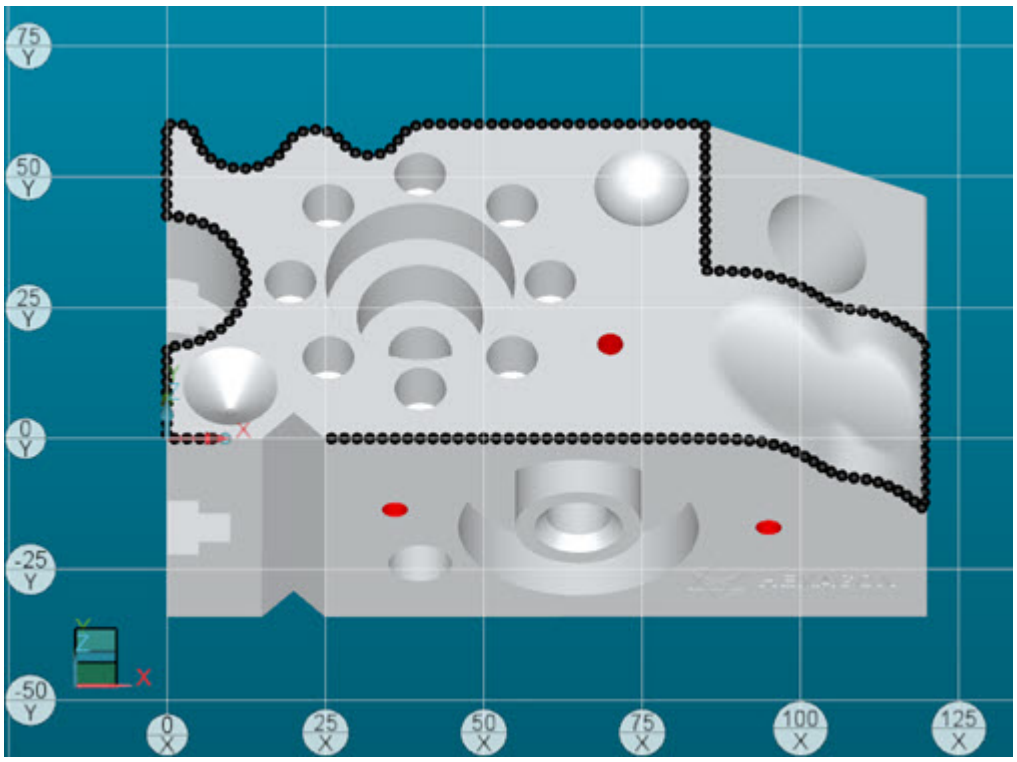
9. Click **OK** to store the definition and to paste the defined pattern.

Example

This first image shows a paste with pattern of a single auto edge point feature pasted around the top surface of the Hexagon demo block at a step value of 2 mm. With the dialog box open, PC-DMIS shows blue and green arrows for the surface and edge vectors of each point. The pink lines and curves indicate the selected edges:



When you click **OK** to accept the pasted pattern and hide the feature labels, the above example results in hundreds of generated point commands equally spaced along the selected edges:



Paste With Pattern

The **Edit | Paste With Pattern** menu item pastes a feature or group of features from the Clipboard into the Edit window using the offsets and other parameters defined in the **Pattern Setup** dialog box.

You don't need to select this menu item if you marked the mark the **Apply "Paste With Pattern" on OK** check box on the **Alignment** or **Curve** tabs of the **Pattern Setup** dialog box.

PC-DMIS creates these new features based on those that were copied to the Clipboard.

PC-DMIS draws the new features in the Graphic Display window.

PC-DMIS assigns a new ID to each feature that it creates, so the new features do not use the same IDs as the copied features.

For Non-Curve Patterns

PC-DMIS applies features with the pattern offsets defined in the **Alignment** tab of the **Pattern Setup** dialog box.

PC-DMIS pastes the contents of the Clipboard into the Edit window by the number of times shown in the **Number of times to offset** box in the **Alignment** tab of the **Part Setup** dialog box.

Each time PC-DMIS pastes the Clipboard's contents, the new features are offset with respect to the previously inserted features by the defined pattern offsets.

PC-DMIS generates feature IDs based on how the **Use default prefix** check box in the **Pattern Setup** dialog box is set.

For Curve Patterns

PC-DMIS pastes the contents of the Clipboard into the Edit window equally spaced by the **Step** value among all the selected edges.

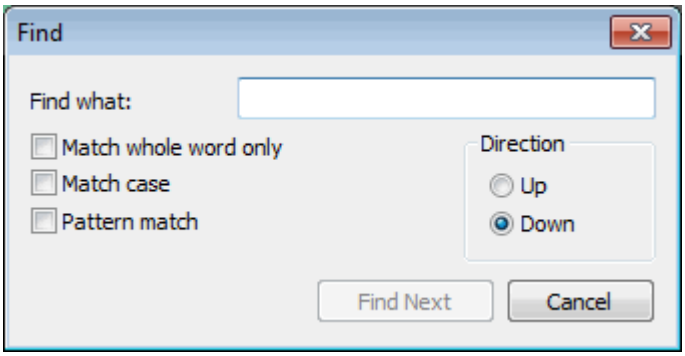
Finding and Replacing Text

You can find and replace text in Edit window fields by using standard regular expressions described in these menu options:

- Find
- Replace

Find

The **Edit | Find and Replace | Find** menu option opens the **Find** dialog box which allows you to find a specified keyword within the Edit window.



Find Dialog Box

Using Wildcard Characters

Select the **Pattern match** check box in the **Replace** dialog (**Edit | Find and Replace | Replace**) box to use wildcard characters to perform pattern matching.

This option also allows you to find text matching a variety of different search criteria. Consider the following table:

Text To Find	Wildcard to Use	Some Examples
Any one character	.	D.M matches "DIM" or "D4M".
Character set	[ ]	D[MI]S finds "DIS" and "DMS" but not "DMIS" or "DUS".
Any one character in a range	[-]	LINE[2-6] finds "LINE2" and "LINE3" but not "LINE1" or "LINE7". Ranges must be in ascending order.
Any one character except character(s) inside brackets	[^]	POINT[^32] finds "POINT1", "POINT5", and "POINT12", but not "POINT3", "POINT2", "POINT21", or "POINT30".
Any one character except range of characters inside brackets	[^x-z]	LINE[^2-5] finds "LINE6" and "LINEH", but not "LINE3"
Character sets that include the "-" character should have the "-" as the first or last character of the range. If the range excludes the "-" then the "-" should be the second character.	[-]	LINE[0-9-] matches "LINE4" and "LINE-". LINE[^-0-9] matches "LINEH" but not "LINE-".
0 or more instances of the preceding character, unless the following: "*" starts a string "*" follows a "^" that starts a string "*" starts a parenthesized sub-expression	*	lo*p matches "lp" and "looooop". ^* matches a "*" if it starts a line.

Line beginning with a specified phrase or character. The "^" is special only at the beginning of a string.	^	^CIRCLE finds all lines that begin with the word "CIRCLE". Note that indented lines in the software's Edit window begin with spaces.
Line ending with a specified phrase or character. The "$" is special only at the end of a string.	$	ENDMEAS/$ finds lines ending in "ENDMEAS/" but not "MEAS/"
Parentheses in the **Find What** box store what is within them to be recalled later in the **Replace With** box. In the **Replace With** box a backslash "\" character, followed by a number would bring that defined pattern into the replace text.	() and \	Find What: BO(BB)Y(RAY) Replace With: DO1YP2 Would Give: DOBBYPRAY \1 uses the first set of characters offset by parentheses, \2 the second set and so on.

For pattern matches, you no longer need to precede parentheses with a backslash (\) character as you had to do in some earlier versions of PC-DMIS.

Using Predefined Character Sets

To match a predefined character set, select the **Pattern match** check box. You can then search the text by using these special predefined character sets:

Character set	Characters in set
[[:alnum:]]	ABCDEFGHIJKLMNOPQRSTUVWXYZ abcdefghijklmnopqrstuvwxyz 0123456789
[[:alpha:]]	ABCDEFGHIJKLMNOPQRSTUVWXYZ abcdefghijklmnopqrstuvwxyz
[[:blank:]]	(The space character and the tab character)
[[:digit:]]	0123456789
[[:graph:]]	ABCDEFGHIJKLMNOPQRSTUVWXYZ abcdefghijklmnopqrstuvwxyz 0123456789 !"#$%&'()*+,-./:;<=>?@[]^_`{ }~
[[:lower:]]	Abcdefghijklmnopqrstuvwxyz
[[:print:]]	ABCDEFGHIJKLMNOPQRSTUVWXYZ abcdefghijklmnopqrstuvwxyz 0123456789 !"#$%&'()*+,-./:;<=>?@[]^_`{ }~
[[:punct:]]	!"#$%&'()*+,-./:;<=>?@[]^_`{ }~
[[:upper:]]	ABCDEFGHIJKLMNOPQRSTUVWXYZ
[[:xdigit:]]	0123456789ABCDEF abcdef

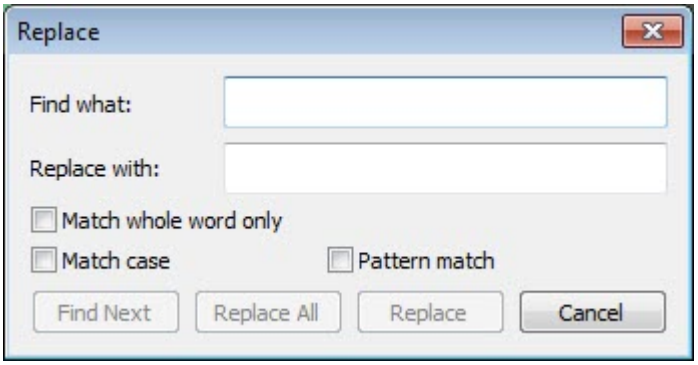
To search for a string which consists of a letter, followed by some letters or numbers, followed by that same first letter, you would use a back reference, as shown here: ([[:alpha:]])[[:alnum:]]\{1,\}\1.

To Search for a Specific Word or Phrase:

1. Select **Edit | Find and Replace | Find** from the menu bar.
2. Type in a keyword or phrase to search.
3. Indicate the direction to search (**Up** or **Down**).
4. Select the **Match whole word only** check box if you want PC-DMIS to match the entire word. For example, if you type "CIR", PC-DMIS will find "CIR" but not "CIRCLE".
5. Select the **Match Case** check box if you want PC-DMIS to search based on upper or lower case.
6. Press the **Find** button (or press the Enter key).

Replace

The **Edit | Find and Replace | Replace** option works much the same way as the **Find** option (see "Find"). Once the text is found, however, you can replace that text by using the **Replace** dialog box.



Replace Dialog Box

You can search and replace with any matching string as long as the last part of the string corresponds to an editable field, and as long as it is the only editable field in the string that will be changing.

A Valid Find and Replace Example:

Find string:	`=AUTO/CIRCLE,SHOWALLPARAMS= NO`
Replace string:	**`=AUTO/CIRCLE,SHOWALLPARAMS= YES`**

Notice that the end of the string corresponds to an editable field. You can only change the last editable field of the search string.

Find and Replace Examples That Are Not Valid:

You *cannot* replace two editable fields in one replace as in this example:

Find string:	`=AUTO/CIRCLE,SHOWALLPARAMS= NO`
Replace string:	**`=AUTO/LINE,SHOWALLPARAMS = YES`**

This is not valid because CIRCLE to LINE is one editable field, and NO to YES is another editable field.

You *cannot* replace an editable field with a non-editable field as in this example:

Find string:	`=AUTO/CIRCLE,SHOWALLPARAMS`
Replace string:	**`=AUTO/CIRCLE,MYSHOWALL`**

This is not valid because `MYSHOWALL` is a constant and not an editable field.

Find What

You can use this box to type the text for PC-DMIS to locate. You can use any of the various wild cards and search patterns discussed in the "Find" section. See "Find".

Replace With

You can use this box to type the text that you want to replace the found text.

Match Whole Word Only

If you select this check box, PC-DMIS only looks for an entire word containing that text. For example, if you type in "CIR" in the **Find what** box, and select this check box, PC-DMIS finds only "CIR". It does not find "CIRCLE" or "CIRCULAR".

Match Case

This check box tells PC-DMIS to search for text matching the case (upper or lower) used in the Find what box. For example, if you type "Point" in the **Find what** box and selected the **Match case** check box, PC-DMIS finds "Point" and "Points", but not "POINT".

Pattern Matching

This check box tells PC-DMIS to look for specified patterns. You should select this check box when searching for pattern matches using wildcard characters or other special character matching.

Find Next Button

The **Find Next** button tells PC-DMIS to find the next instance of the text for which you're searching.

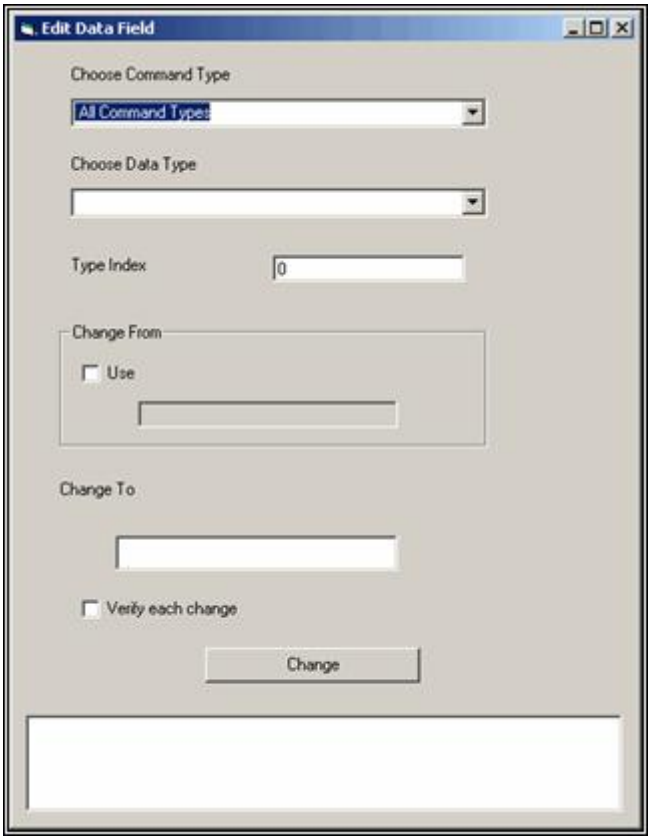
Replace Button

The **Replace** button replaces the found text with the text string in the **Replace with** box. This allows you to replace instances of found text one at a time.

Replace All Button

The **Replace all** button tells PC-DMIS to instantly find all occurrences of text in the **Find what** box and replaces them with the text in the **Replace with** box.

Editing Data Fields



Edit Data Field Wizard

The Edit Data Field wizard is an external program that works with PC-DMIS to let you change data inside specified data fields of certain command types inside the Edit window. To access this wizard, select the **DataFieldEdit** icon from the **Wizards** toolbar.

This wizard differs from the **Replace** dialog box. It allows you to change data items globally inside any mode of the Edit window, whereas the **Replace** dialog box only works inside of Command Mode. Additionally, this will allow you to replace certain values that you cannot change using the **Replace** dialog box.

The **Edit Data Field** dialog box contains these items:

Choose Command Type – This list displays the available command types.

Choose Data Type – This list displays the data types for the selected command type. If you want to see all data types in this list, select **All Command Types**, from the **Choose Command Type** list.

Type Index – This box lets you specify an exact field you want to change by its numerical index. You will find this useful when you have more than one field of the same data type and you want to change only one of the fields. Typing an index value lets you determine which one to change. For example, the `CLEARP` command has two distance fields, one for the clearance distance and one for the pass distance. Typing an index of 1 would target the clearance distance while a value of 2 would target the pass distance.

Change From – This area contains the **Use** check box and a box that holds a value. This check box lets you specify a value you want to change from. This means that PC-DMIS will only target those fields that have the given value.

Change To – This box lets you determine the new value for the data field you want to update.

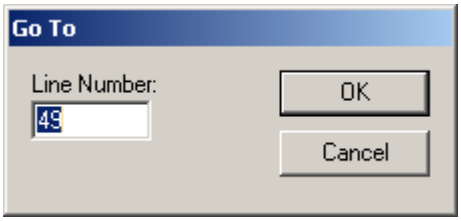
Verify Each Change – If you select this check box, PC-DMIS will display a message box showing the ID of the item to change, its current value, and whether or not you want to change that data field to the new value.

Change – This button begins the process of finding the data field and changing it to the new value.

Status – The box at the bottom of the dialog box displays any status or diagnostic messages during the change process.

Jumping to Specified Line Numbers

PC-DMIS can easily jump to specified line numbers. Use the **Edit | Find and Replace | Go To** menu option to jump to a specified line within the Edit window.



Go To Dialog Box

To move the cursor to a specific line number in *Command* or *DMIS Mode*, follow these steps:

1. To open the **Go To** dialog box, choose the **Edit | Go To** menu option.
2. The **Go To** dialog box initially shows the line that the cursor is currently on in the **Line Number** box.
3. Type the desired line number to jump to.
4. Click the **OK** button (or press Enter). PC-DMIS locates and places your cursor on the specified line.

Jumping to and from Referenced Commands

In the Edit window's Command Mode, if one command in the Edit window references another command, you can jump to the referenced command, by highlighting the label to the referenced command and selecting the **Edit | Find and Replace | Jump To** menu option.

When you arrive at the referenced command, you can quickly jump back to the previous feature by selecting the **Edit | Find and Replace | Jump Back** menu option.

Suppose in an alignment block you have the following commands and you want to jump to the LIN2 feature referenced in the block:

```
A1= ALIGNMENT/START,RECALL:STARTUP, LIST= YES
    ALIGNMENT/LEVEL,ZPLUS,PLN1
    ALIGNMENT/ROTATE,XPLUS,TO,LIN1,ABOUT,ZPLUS
    ALIGNMENT/TRANS,XAXIS,LIN2
    ALIGNMENT/TRANS,YAXIS,LIN1
    ALIGNMENT/TRANS,ZAXIS,PLN1
    ALIGNMENT/END
```

You would highlight LIN2 and select the **Jump To** menu option from the menu bar or right-click and select it from the shortcut menu. You can then jump back to the command you were just at by selecting **Jump Back**.

You can also select these menu options from a shortcut menu that appears when you right-click on the features in the Edit window's Command Mode.

Editing Nominal and Target Values

Most of the time you can measure your features just fine, but sometimes, due to manufacturing errors, a feature won't be close to its theoretical (nominal) location, but rather shifted somehow. For Measured features, you need to adjust your theoretical values to handle this situation. However, using the more advanced Auto features, you can modify the target instead. This will adjust the path accordingly, yet will allow dimensioning to take place relative to the original theoretical values.

Modifying Nominal Values (for both Measured and Auto Features)

PC-DMIS provides you with simple ways to modify the nominal value. To modify the nominal value field in Command Mode, place the cursor over the feature then press the F9 key. A dialog box will appear displaying the nominal information which can be updated as necessary.

Modify the nominal information and click **OK** or **Create**. The dialog box closes.

- If you are modifying a measured feature, PC-DMIS asks if you want to update measured values as well. If you click **Yes**, the measured values are updated to match the newly entered nominal values. If you click **No**, the measured values remain what they were.
- If you are modifying an Auto feature, PC-DMIS asks if you want to update the target values to match the new theoretical values. If you click **Yes**, the target values are updated to match the newly entered nominal values. If you click **No**, the target values remain what they were.

When you have an associated dimension, if you then change the associated nominal values in the feature, a message box appears. If you choose **Yes** to update the dimension nominals, PC-DMIS updates the nominal information in the associated legacy dimension command. Be aware that Geometric Tolerance commands always use the feature nominals. For information on FCF dimensions, see the "Using Geometric Tolerances" chapter.

Modifying Target Values (for Auto features only)

If you have an Auto feature, you can choose to modify target values instead of the theoretical values. The target values determine the location where PC-DMIS will try to measure the Auto feature. This lets you keep the theoretical values for dimensioning purposes, but still changes the location at which the software attempts measurement. To modify the target values, use the Edit window:

Modifying Target Values in Command Mode: Press the Tab key to move your cursor to the field to change, enter the new value, and press the Tab key again to store the change.

You cannot modify the target values in Summary Mode.

Overriding Guessed Features

The **Edit | Override Guess** submenu allows you to change the type of feature last measured.

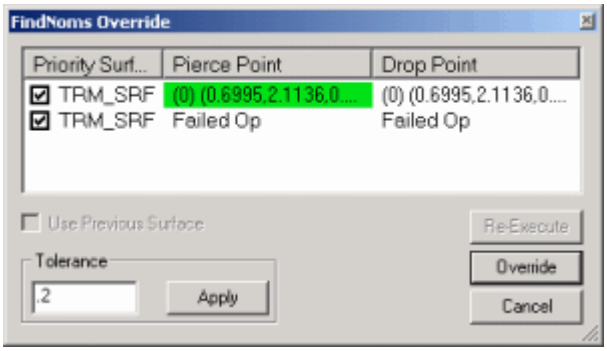
For example, if a circle was the last feature measured and PC-DMIS guessed that it was a plane, you can use this option to convert the feature to the proper type. You must use this option before any other features are measured or constructed.

To use the Override feature:

1. Access the Edit window.
2. Place your cursor on the incorrect feature type in the Edit window.
3. From the **Override Guess** submenu, select the correct feature type.

PC-DMIS updates the feature type in the Edit window.

Overriding Found Nominals



FindNoms Override Dialog Box

The **FindNoms Override** dialog box (**Edit | Override Find Noms**) allows you to choose the appropriate nominal point from CAD surfaces for Auto Vector Points, Auto Surface Points, and individual hits inside other features (such as scans). This dialog box overrides the default FindNoms behavior of PC-DMIS during Learn mode and Execute mode.

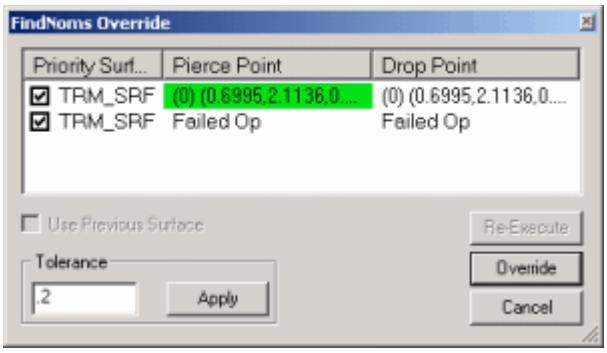
When attempting to find a valid nominal point (within the FindNoms tolerance) by taking a manual hit, PC-DMIS will, most of the time, choose the correct point. However, there are exceptional circumstances when PC-DMIS cannot find an appropriate point and instead chooses an inaccurate point on the CAD model. In these situations, you can use the **FindNoms Override** dialog box to help PC-DMIS find the appropriate nominal point from the CAD surfaces.

To enable the **Override Find Noms** menu option, do the following:

1. Ensure that you have imported a valid CAD model that supports surfaces.
2. Select the Surface Mode icon.
3. Select the Program Mode icon.
4. From the **Setup Options** dialog box, from the **General** tab (**Edit | Preferences | Setup**), select both the Find Nominals and Point Only Mode check boxes.

The following topics describe the **FindNoms Override** dialog box itself and how to use the dialog box in the different modes:

Understanding the FindNoms Override Dialog Box



FindNoms Override Dialog Box

The following topics describe the **FindNoms Override** dialog box (**Edit | Override FindNoms**).

The Priority Surface, Pierce Point, and Drop Point Columns

This area of the dialog box contains these three columns that display the relevant nominal point values and their T-values (the value displayed to the left of the X, Y, and Z values in parentheses):

A "T-value" is the distance of the measured hit from the nominal point along the nominal CAD surface vector.

- **Priority Surface** - This column lists the surfaces that you have stored as priority surfaces in the **Edit CAD Elements** dialog box (**Edit | Graphic Display Window | CAD Elements**). It displays the type of surface and a check box. The check box allows you to add or remove the surface from the list of priority surfaces maintained by PC-DMIS. If you select the check box, PC-DMIS adds the surface to the priority list. Deselecting the check box removes the surface from the list.
- **Pierce Point** - This column lists the nominal point values found using PC-DMIS's Pierce Point operation. If you see the text "Failed OP" in this column, it means that the pierce point operation failed to find the nominal point on that surface. If PC-DMIS highlights a point in green then that point is the best nominal point found by the selection algorithm. You can, of course, override this selected point.
- **Drop Point** - This column lists the nominal point values found using PC-DMIS's Drop Point operation.

The Tolerance Box

The **Tolerance** box allows you to specify a new tolerance value to use when finding the nominal points using this dialog box.

The Use Previous Surface Check Box

The **Use Previous Surface** check box tells PC-DMIS to use the most recent surface to look for the nominal points. This check box becomes available for selection only after you take a hit on a surface with the dialog box open. After you take a hit, PC-DMIS then has a surface to work with for future hits.

The Override Button

The **Override** button overrides an incorrect nominal point found by PC-DMIS with the nominal point data selected from the list containing the **Priority Surface**, **Pierce Point**, and **Drop Point** columns.

Using the FindNoms Override Dialog Box in Learn mode:

To access this dialog box in Learn mode:

1. Select the **Point Only Mode** and **Find Nominals** check boxes from the **General** tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**).
2. Ensure that you have imported a CAD's solid model.
3. Select the **Surface Mode** icon from the **Graphics Modes** toolbar.
4. Select the **Override FindNoms** menu option. The **FindNoms Override** dialog box appears.

With the **FindNoms Override** dialog box open, when you take a manual hit, PC-DMIS follows its normal logic to choose as accurate a nominal point as possible by using the most recently measured hit coordinates and approach vector.

You can then use the **FindNoms Override** dialog box to perform additional procedures allowing you to override the found nominal point.

Procedure 1: Finding Nominal Points on the Previous Surface

If you select the **Use Previous Surface** check box, the FindNoms Override dialog box attempts to find a nominal point from the most recent surface used. If the dialog box can find a point within FindNoms tolerance on the most recent surface it will select that nominal point and create an Auto Vector Point based on the nominal values.

Procedure 2: Finding Nominal Points on Priority Surfaces

If the **FindNoms Override** dialog box cannot find a nominal point on the recent surface (see "Procedure 1: Finding Nominal Points on the Previous Surface"), it tries to find a nominal point from the *priority surfaces*. Priority surfaces are surfaces that the user has selected as a subset of CAD surfaces to find nominal points. Priority surfaces can be selected or deselected using the **Set as Priority** check box in the **Edit CAD Elements** dialog box (see the "Editing CAD" topic in the "Editing the CAD Display" section). If PC-DMIS finds an appropriate point among the priority surfaces, it selects the point and creates an Auto Vector Point based on the nominal values. It also displays the valid nominal points within the FindNoms tolerance of all the priority surfaces in the **FindNoms Override** dialog box.

Procedure 3: Finding Nominal Points on All CAD Surfaces

If PC-DMIS still cannot find a valid nominal point by using the procedures discussed in procedures 1 and 2, (see the "Procedure 1: Finding Nominal Points on the Previous Surface" and "Procedure 2: Finding Nominal Points on Priority Surfaces" topics), it does the following:

- Looks for the best nominal point on all the CAD surfaces within the FindNoms tolerance
- Creates an Auto Vector Point based on the best available nominal point.
- Displays all the CAD surfaces that had nominal points in the **FindNoms Override** dialog box.

Procedure 4: Choosing a Nominal Point Later

If PC-DMIS still cannot find an appropriate point on all the CAD surfaces, it asks if it can create the Auto Vector Point and you can choose a nominal point later. If you accept, then PC-DMIS creates an Auto Vector Point in the Edit window and you can select from these options:

Option 1 - You can take a new hit and PC-DMIS will try to find a new nominal point. Essentially you're starting over if you do this.

Option 2 - You can choose a different nominal point from the dialog box and click the **Override** button. PC-DMIS will then override its earlier chosen nominal point with the new selected point for the recently created Auto Vector Point.

You will usually want to do this if you don't like the nominal point that PC-DMIS attempted to find in the procedures discussed in these topics:

- "Procedure 1: Finding Nominal Points on the Previous Surface"
- "Procedure 2: Finding Nominal Points on Priority Surfaces"

- "Procedure 3: Finding Nominal Points on All CAD Surfaces"

Options 3 - You can select a CAD surface on the screen. PC-DMIS would then attempt to find nominal points on the selected surface and display those points in the **FindNoms Override** dialog box.

You can then override the previous found nominal, by selecting a point from this new surface and clicking **Override**.

PC-DMIS ignores the FindNoms tolerance with this option. So, even if the selected CAD surface is out of FindNoms tolerance, the dialog box still displays the points.

Option 4 - You can increase the FindNoms tolerance by changing the value in the **Tolerance** box and clicking the **Apply** button. PC-DMIS will then apply these procedures again, using the higher tolerance value and display any appropriate points:

- "Procedure 1: Finding Nominal Points on the Previous Surface"
- "Procedure 2: Finding Nominal Points on Priority Surfaces"
- "Procedure 3: Finding Nominal Points on All CAD Surfaces"

You can then choose a valid point and click **Override** to accept a nominal point for the recently created Auto Vector Point.

Increasing the FindNoms tolerance in the **Tolerance** box has the same effect as changing the FindNoms tolerance from the **General** tab of the **Setup Options** dialog box.

After Choosing the Best Nominal Point

After you choose the best nominal point, PC-DMIS remembers the selected surface for that feature.

During execution in Manual Mode, PC-DMIS:

1. Uses the tolerance value in the **FindNoms During Execution** box on the **General** tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**). For this to work, you must select the **Find Nominals During Execution** check box on the **General** tab.
2. Attempts to use the same surface and CAD operation (Pierce Point or Drop Point operation) to find the new nominals for the recently executed point.

If PC-DMIS cannot find a nominal point on that CAD surface, it opens the **FindNoms Override** dialog box again. For information on the execution time behavior, see the "Using FindNoms Override in Execute Mode:" topic in the PC-DMIS Core documentation.

Using FindNoms Override in Execute Mode:

As mentioned in the "After Choosing the Best Nominal Point" topic, PC-DMIS displays the **FindNoms Override** dialog box in execute mode upon meeting the following conditions:

- You must import a solid model with surfaces and select the **Surface Mode** icon from the **Graphic Modes** toolbar.
- You must select the **Find Nominals During Execution** check box from the **General** tab of the **Setup Options** dialog box.
- The Auto Vector Point or Auto Surface Point must have a valid nominal point found in Learn mode (see "Using the FindNoms Override Dialog Box in Learn mode:").
- Execution must take place in Manual Mode.
- PC-DMIS must execute the Auto Vector Point or Auto Surface Point feature.
- PC-DMIS must fail to find a nominal point for executed Auto Vector Point or Auto Surface Point.

Once the dialog box appears, execution stops and you can interact with the dialog box in ways already discussed in the "Using the FindNoms Override Dialog Box in Learn mode:" topic.

You can also choose to re-execute the recently measured point feature. In that case, PC-DMIS re-executes and attempts to find nominal values again. If it still can't find any nominal values for the point, PC-DMIS again displays the **FindNoms Override** dialog box.

You can then do one of the following:

- Re-execute again.
- Use the **Override** button as discussed in the "Procedure 4: Choosing a Nominal Point Later" topic
- Close the dialog box by clicking the **Cancel** button. If you close without choosing an appropriate nominal, PC-DMIS replaces the measured data with the previous nominal values.

Using the FindNoms Override Dialog Box from the Edit Window

To access the **FindNoms Override** dialog box, right-click on one of these features and select **Override FindNoms** from the shortcut menu:

- Vector point

- Surface point
- Individual Hit

The dialog box then uses the feature's measured data (point and vector) to find an appropriate nominal point as discussed in the "Using the FindNoms Override Dialog Box in Learn mode" topic.

Marking Commands for Execution

In order to execute PC-DMIS commands, you must first mark them for execution. The following menu options and commands control marking:

Mark

From the **Edit | Markings | Mark** menu option, you can mark a specified feature or command for execution. By default, whenever you create a new measurement routine, newly added features and commands are already marked for execution. If you select **Mark** on an already marked item, the marking is cleared.

Subroutines are an exception to unmarked commands. PC-DMIS executes unmarked commands in subroutines whenever subroutines are called. For information on calling subroutines, see "Calling a Subroutine" in the "Branching by Using Flow Control" chapter.

PC-DMIS indicates a marked item using the current Marked Text Color in the Edit window. PC-DMIS also displays an asterisk (*) next to the feature ID in the Graphic Display window. For information on the Marked Text Color, see "Defining Edit Window Colors" in the "Setting your Preferences" chapter.

You can mark features or commands in any of these ways:

- *Mark the desired feature or command in the Edit window.* Position the cursor over the feature to be marked, and select **Mark**. PC-DMIS highlights the marked command.
- *Mark multiple commands in the Edit window.* Select multiple commands to be marked in the Edit window, and select **Mark**. PC-DMIS highlights the marked command.
- *Mark the desired feature in the Graphic Display window.* Make sure PC-DMIS is in Translate Mode. Hold down the Alt key and click the desired feature.
- *Mark Multiple features in the Graphic Display window.* Make sure PC-DMIS is in Translate or Text Box Mode. Hold down the Alt key and drag a box around the desired features.

If you select **Edit | Markings | Parent Mode**, and you mark a constructed feature or a dimension, PC-DMIS also marks any related features used in the construction or dimension process. For details on Parent Mode, see the "Parent Mode" topic in the PC-DMIS Core documentation.

If you select **Edit | Markings | Child Mode**, and mark a feature that is used to construct a feature or create a dimension, PC-DMIS also marks any related child features. For details on Child Mode, see the "Child Mode" topic in the PC-DMIS Core documentation.

Features and commands can be unmarked by repeating one of the above procedures on marked features. To unmark all features, you can select the **Clear Marked** menu item.

Once an item is marked, specific lines within some items can be unmarked. For example, you can unmark a `HIT/BASIC` line in a feature. When you unmark such a line, PC-DMIS does not execute that line.

If dimensions are marked after they are executed, PC-DMIS sends the results to the Report window or statistics file based on the dimension output and the report output configuration. For more information, see "Output To" in the "Using Legacy Dimensions" chapter.

To Unmark Specific Lines Within a Feature:

1. Move the cursor to the desired line within the marked feature (such as the `HIT / BASIC` line).
2. Re-select the **Edit | Markings | Mark** option to unmark the indicated line.

Mark All

The **Edit | Markings | Mark All** menu option marks all of the features or commands in the Edit window. PC-DMIS marks the selected items in the Edit window, displaying them in green colored text. PC-DMIS also displays an asterisk (*) next to each feature ID in the Graphic Display window that is marked for execution.

When you select **Mark All**, PC-DMIS asks if you also want to mark manual alignment features.

- If you select the **Yes** button, then PC-DMIS marks the entire measurement routine for execution, including the alignment features.
- If you select the **No** button, PC-DMIS marks the entire measurement routine for execution, but does not mark the alignment feature. Additionally, since move commands don't function in Manual Mode, they remain unmarked as well.

Clear All

The **Edit | Markings | Clear All** menu option clears (or unmarks) all the items in the Edit window that were earlier marked for execution.

Parent Mode

The **Edit | Markings | Parent Mode** menu option places PC-DMIS in a mode where it marks associated parent commands whenever you mark a child command. Whenever PC-DMIS is in this mode, the check mark next to the **Parent Mode** menu option changes from gray to black.

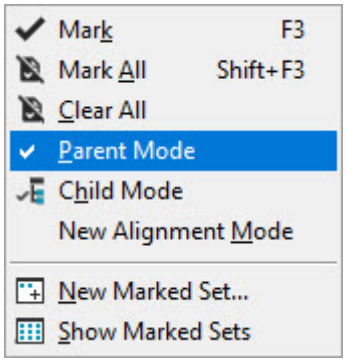
- A "parent" is a command (or information from a command) that is used in another command.
- A "child" is a command that uses information from a parent command.

For example, if you enable **Parent Mode** and then you mark a constructed feature, PC-DMIS marks the constructed feature (a child command), PC-DMIS marks the constructed feature as well as any features used to create the constructed feature (parent command).

The **Parent Mode** and **Child Mode** functions only work when you are in **Command** Mode in the Edit window.

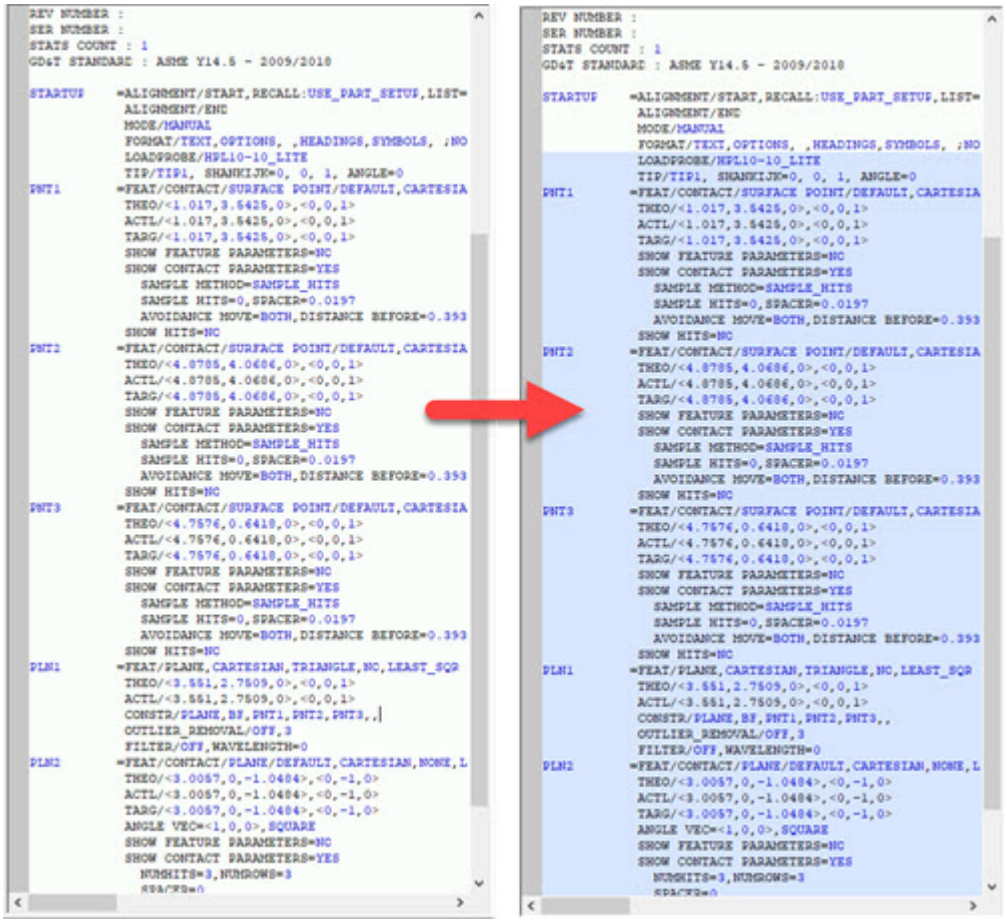
To better understand this:

1. Select and enable the **Parent Mode** option from the menu (**Edit | Markings | Parent Mode**).



2. From the Edit window toolbar (**View | Toolbars | Edit Window**), click the **Mark All** button and then click the **Clear Marked** button .

   You can see in the image below that on the left is what the Edit window looks like after you click the **Mark All** button and on the right is what the same measurement routine looks like after you click the **Clear Marked** button.



In the above image on the right, `PLN1` is constructed from `PNT1`, `PNT2`, and `PNT3`. Those three points are all shown as unmarked.

3. In the Edit window, click anywhere in the `PLN1` command and then from the **Edit Window** toolbar, click the **Mark** button .

   The constructed plane and all of the features that are used to define it are also marked as shown on the right in the image below.

If you unmark a marked child command, the parent command stays marked.

Child Mode

The **Edit | Markings | Child Mode** menu option places PC-DMIS in a mode where it marks associated children commands whenever you mark a parent command. Whenever PC-DMIS is in this mode, the check mark next to the **Child Mode** menu option changes from gray to black.

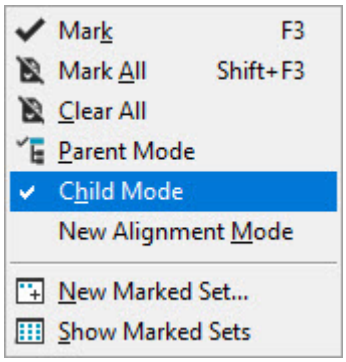
- A "parent" is a command (or information from a command) that is used in another command.
- A "child" is a command that uses information from a parent command.

For example, if you select this option and you unmark a constructed feature and any features used to create it, when you then mark one of the features used to create it (parent feature), PC-DMIS also marks the associated constructed feature (child feature).

The **Parent Mode** and **Child Mode** functions only work when you are in **Command** Mode in the Edit window.

To better understand this:

1. Select and enable the **Child Mode** option from the menu (**Edit | Markings | Child Mode**).



2. From the **Edit Window** toolbar (**View | Toolbars | Edit Window**), click the **Mark All** button and then click the **Clear Marked** button .

   You can see in the image below that on the left is what the Edit window looks like after you click the **Mark All** button and on the right is what the same measurement routine looks like after you click the **Clear Marked** button.

In the image above on the right, `PLN1` is constructed from the unmarked `PNT1`, `PNT2`, and `PNT3` Point features. `PLN2` is constructed from the unmarked `PNT3`, `PNT4`, and `PNT5` Point features. Constructed Planes `PLN1` and `PLN2` share the same `PNT3` child feature.

3. In the Edit window, click anywhere in the `PNT3` command and then from the **Edit Window** toolbar, click the **Mark** button .

   Since the constructed planes, `PLN1` and `PLN2,` share the same parent feature `PNT3`, they are also marked as shown on the right in the image below.

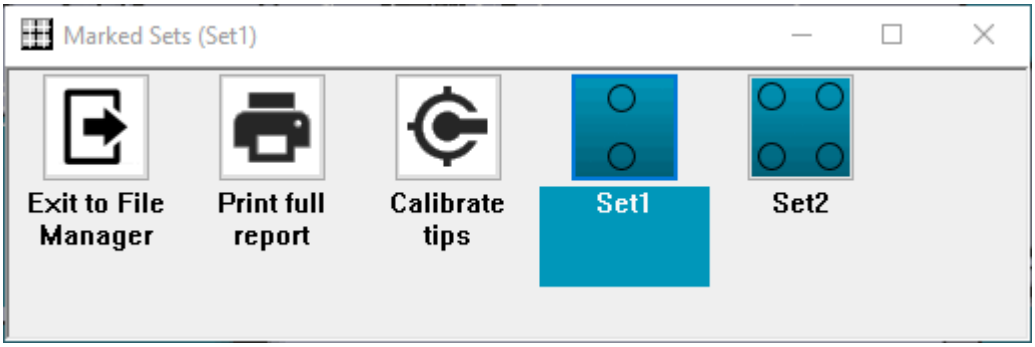
If you unmark a marked parent command, the child command stays marked.

New Alignment Mode

The **Edit | Markings | New Alignment Mode** (indicated with a check mark next to the menu option) marks corresponding alignment data every time a feature/dimension is marked for execution.

Creating and Executing Marked Sets

You can organize marked features into groups called "sets". You can then execute your stored sets of features with the Marked Sets window (**Edit| Markings | Show Marked Sets**).



A Sample Marked Sets window with two created marked sets (Set1 and Set2)

- You can define up to thirty (30) marked sets for a measurement routine.
- When you execute a marked set, PC-DMIS executes only those features within the active marked set.
- PC-DMIS displays every marked set as an icon in the Marked Set window. Each icon graphically indicates all of the features that are associated with that marked set.

When the Marked Sets window is hidden, all marked sets are disabled and the standard mode for executing a measurement routine is followed.

Available Buttons

Exit to File Manager - This button closes any open measurement routines and returns you to the **Open** dialog box. For information on the **Open** dialog box, see "Opening Existing Measurement Routines" in the "Using Basic File Options" chapter.

Print full report - This button sends the current report to the selected output. (For information on printing options, see "Printing the Report Window" in the "Using Basic File Options" chapter.)

Calibrate tips - This button accesses the **Probe Utilities** dialog box so you can calibrate your probe tips. PC-DMIS disables this button for the Romer and Garda interfaces. (For information on probe definition and tip calibration, see "Defining Probes" in the "Defining Hardware" chapter.)

If you click a button for a marked set, PC-DMIS executes the features associated with that marked set.

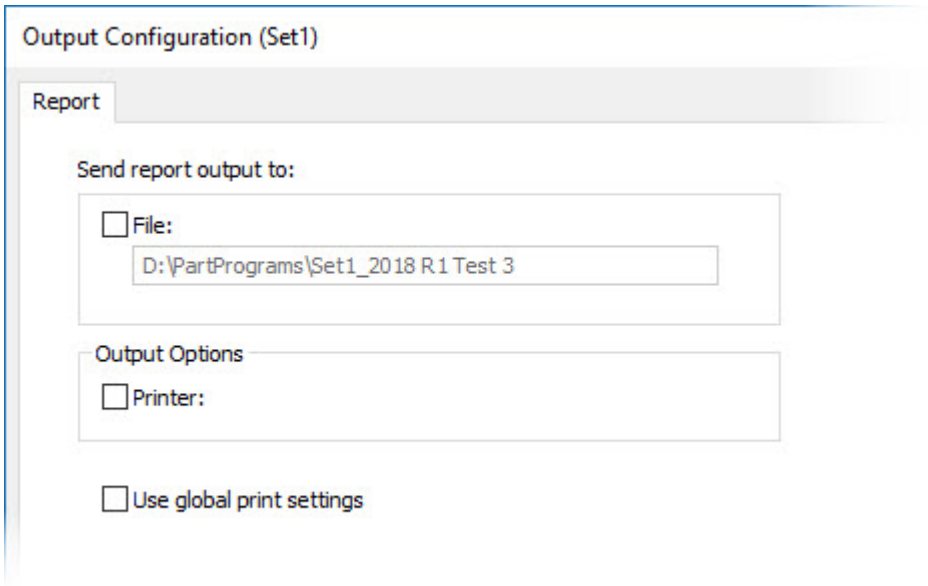
To Create New Marked Sets

1. Select the **Edit | Markings | New Marked Set** option, or double-click anywhere in the Marked Sets window. The **New Mark Set** dialog box appears requesting a name for the new marked set.

New Mark Set Dialog Box

2. In **Enter mark set label**, type a name to identify the marked set. While there's no limit to the length of the name, short descriptive keywords improve readability.

3. Click **OK**. Your new marked set is stored in the Marked Sets window. At this point, PC-DMIS also displays an **Output Configuration** dialog box. You can use this dialog box to define printing options specific to this marked set. (For information on the options in this dialog box, see "Setting Output and Printer Options for the Report Window" in the "Using Basic File Options" chapter.)



Output Configuration Dialog Box

4. Define specific printing options for this set. If you want to use existing print options that are defined for your entire measurement routine, select the **Use Global Print Settings** check box.

5. Click **OK** to close the dialog box.

6. Now, you need to select this Marked Set and add features to it. To do this, follow the procedure in the "To Add or Remove Features on Existing Marked Sets" topic.

To Add or Remove Features on Marked Sets

1. Select the **Edit | Markings | Show Marked Sets** option to open the Marked Sets window.
2. With the Marked Sets window active, select the marked set to modify. You can press Tab to cycle through the sets, or you can click on the set once to select it.
3. To add features, from the Edit window, mark the features you want to add.

You can choose **Edit | Markings | Mark** (or press F3) to toggle the marking state on selected features.

The icon for the set in the Marked Sets window changes dynamically to reflect your changes.

To Customize the Marked Set Icons

Marked sets can have user defined bitmap images, if desired, in place of the default graphics. To apply a user bitmap,

1. Create a color bitmap using the Paint application that comes with Windows or some other image editor program of your choice. The bitmap should not be larger than 48 x 48 pixels in size.
2. Save the bitmap file in the same directory as the measurement routine. The bitmap filenames must use the following naming convention in order to be recognized by PC-DMIS:

   MARKST00.BMP for the first marked set

   MARKST01.BMP for the second marked set

   MARKST02.BMP for the third marked set

   …

   MARKST30.BMP for the thirty-first marked set

If you place the bitmap file MARKST00.BMP in the measurement routine directory when you create the first marked set, PC-DMIS shows the bitmap image contained in MARKST00.BMP. If a marked set does not have a bitmap file, PC-DMIS shows the default image. Also, it is not necessary to use consecutive bitmaps. In other words, you can use a bitmap for marked set 1 and marked set 5, but use the default graphics for marked sets 2, 3, and 4.

To Reposition Marked Sets

To reposition a marked set:

1. Select the **Edit | Markings | Show Marked Sets** option to open the Marked Sets window.
2. Hold down the Shift key and click the desired marked set.
3. Drag the marked set to the new location.
4. PC-DMIS updates the Marked Set window with the change.

To Execute Marked Sets

1. Select the **Edit | Markings | Show Marked Sets** option to open the Marked Sets window.
2. Double-click on the set you want to execute. PC-DMIS executes the marked set.
3. Close the Marked Sets window when finished.

To Lock Marked Sets

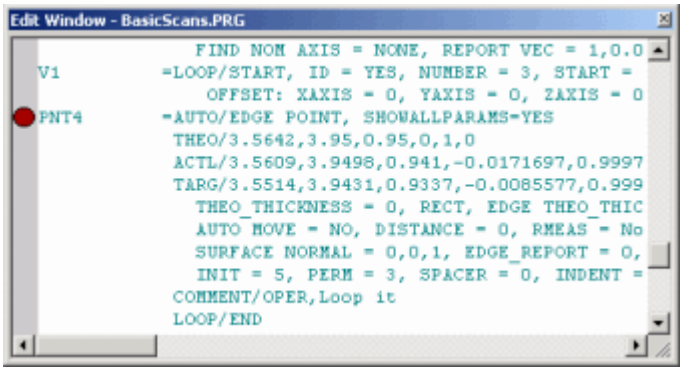
Once a marked set has been defined for a measurement routine, a lock can be established to prevent anyone from accidentally deleting or otherwise modifying the current configuration. For more information on this option see the "Lock Marked Sets" topic in the "Setting your Preferences" chapter.

To Delete Marked Sets

You can easily delete any previously created marked sets. To do this:

1. Select the **Edit | Markings | Show Marked Sets** option. The Marked Sets window appears.
2. Ensure the marked set you want to delete is active (press the Tab key to cycle through the sets, or simply click on the set once to select it).
3. Press the Delete key to open a confirmation box that you can use to confirm the deletion of the marked set.
4. Click the **Yes** button to delete the marked set. This also deletes the icon from the Marked Sets window.
5. When done, close the Marked Sets window.

Using Breakpoints



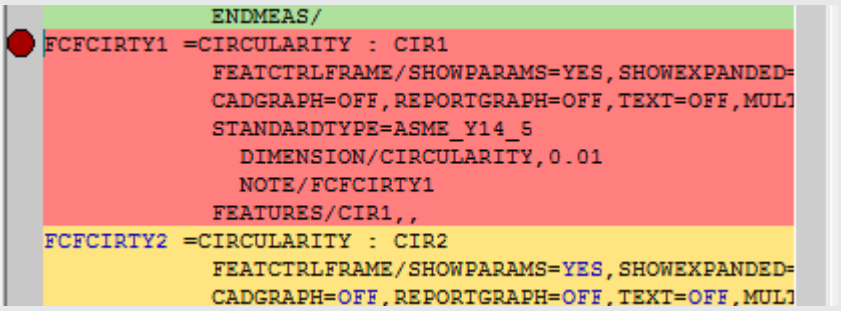
Example of the Edit window with a breakpoint (red icon).

The **Edit | Breakpoints** menu option provides a useful debugging tool to create, test, and run a measurement routine. Generally, measurement routines are executed sequentially, line by line. By placing a breakpoint at a particular line in the measurement routine, the execution pauses when it reaches the breakpoint. If the measurement routine makes use of variable expressions and flow control, you can examine these variables to help ensure that the measurement routine functions as desired.

Once PC-DMIS pauses for the breakpoint, you can use the **Step Next** button on the **Execution** dialog box to continue the measurement process one step at a time. This pauses the CMM after executing each step of any command that tells the CMM to move. While in Step Mode, you can insert additional hits into features, or you can insert new features between existing features or commands. Step Mode can also be simulated offline.

When you are ready to continue with the measurement routine's execution, click **Continue** on the **Execution** dialog box. You can use menu and keyboard commands to speed up the placement and removal of breakpoints. Breakpoints are saved with the measurement routine; they remain available the next time you open the measurement routine.

If your measurement routine uses breakpoints and the Edit window is in Command Mode, PC-DMIS continues to display the Edit window during execution but highlights the current command to execute in red.



Example showing the colors used in Command mode during execution with a breakpoint.

Breakpoint

The **Edit | Breakpoints | Breakpoint** menu option allows you to set or remove a breakpoint. The software sets or removes the breakpoint on the line in the Edit window at the current cursor position.

When you set a breakpoint, PC-DMIS displays a small circular red icon in the left margin on the line in the Edit window to indicate that a breakpoint is set. The icon disappears when you remove a breakpoint.

Insert Defaults

The **Edit | Breakpoints | Insert Defaults** menu option allows you to set breakpoints throughout the measurement routine at default locations. Default locations are defined as lines in the Edit window that contain commands which generate motion of the CMM or cause branching to occur as a result of a flow control command (such as IF THEN statements). See the "Branching by Using Flow Control" chapter for more information.

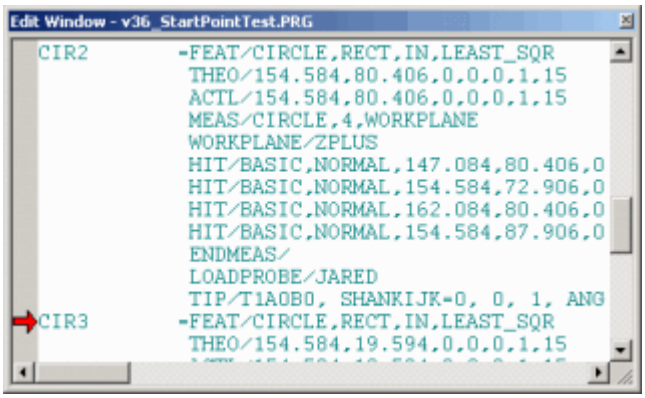
Remove Defaults

The **Edit | Breakpoints | Remove Defaults** menu option allows you to remove breakpoints throughout the measurement routine from default locations. PC-DMIS only removes those breakpoints that are set on default locations. Any breakpoints that are set in non-default locations remain in place. For details, see "Insert Defaults".

Remove All

The **Edit | Breakpoints | Remove All** menu option allows you to remove *all* breakpoints from a measurement routine.

Setting Start Points



Edit window with start point (red arrow)

You can only set start points when the Edit window is in Command Mode (see "Working in Command Mode" in the "Using the Edit Window" chapter).

When you insert a start point into the measurement routine and then select **File | Partial Execution | Execute From Start Points**, PC-DMIS begins the measurement routine execution from the first start point instead of starting the execution flow at the beginning of the measurement routine.

> Be aware that if the current tip for that location in the measurement routine does not match the current orientation of the probe head, PC-DMIS does not try to and go back to execute the tip command above it in order to change the tip orientation.

Start points are especially useful if you are working in Multiple Arm Mode and you need to set a different start point for each arm (see the "Using Multiple Arm Mode" chapter).

To insert a start point into your measurement routine:

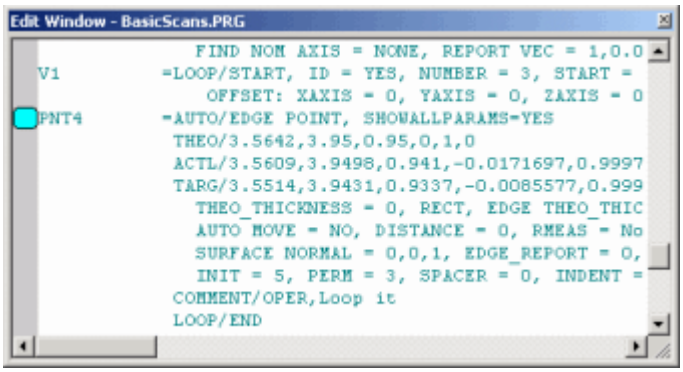
1. Click the location in the Edit window where you want the start point to appear
2. Then select the **Set Start Point** button from the **Edit window** toolbar. You can also right-click in the Command Mode and select the **Set Start Point** option from the shortcut menu.

For more information on the **Set Start Point** icon, see "Edit Window Toolbar" in the "Using Toolbars" chapter.

For information, on how to enable start points to always track the execution of a measurement routine, see "Start Points Always Track Execution" in the "Check Boxes for the General tab" chapter.

For information on start points for multiple-arm machines, see "Setting Start Points for Multiple Arms" in the "Using Multiple Arm Mode" chapter.

Using Bookmarks



Example of the Edit window with a bookmark (blue icon).

You can set bookmarks when the Edit window is in Command Mode (see "Working in Command Mode" in the "Using the Edit Window" chapter) or, if enabled, in DMIS Mode. Bookmarks mark frequently-accessed lines in a measurement routine. Once a bookmark is set, you can use menu or keyboard commands to move to it. You can remove a bookmark when you no longer need it. Bookmarks are saved between editing sessions and are therefore available the next time you open the measurement routine.

Be aware that bookmarks are assigned to line numbers, not commands. Thus, setting bookmarks in one mode and then switching to another mode may cause the bookmarks to show up on different commands even though they're on the same line numbers.

Bookmark

The **Edit | Bookmarks | Bookmark** menu option allows you to set or remove a bookmark. The software sets or removes a bookmark on the line in the Edit window at the current cursor position.

When you set a bookmark, PC-DMIS displays a small blue icon in the left margin on the line in the Edit window to indicate that a bookmark is set. The icon disappears when you remove a bookmark.

Next Bookmark

The **Edit | Bookmarks | Next Bookmark** menu option allows you to move to the next bookmark in the Edit window. If the search finds that no bookmarks exist below the current cursor position, the search resumes at the top of the Edit window.

Clear All Bookmarks

The **Edit | Bookmarks | Clear All Bookmarks** menu option allows you to remove all bookmarks from the Edit window.

Changing Fonts and Colors

You can edit the fonts and colors used in the Edit window by following instructions described in:

- "Customizing User Interface Fonts" topic of the "Navigating the User Interface" chapter.
- "Setting up the Edit Window" topic of the "Setting your Preferences" chapter.

Editing External Objects

PC-DMIS allows you to edit embedded external objects in Command Mode only. To do this, select the object in Command Mode, and double-click on the selected object.

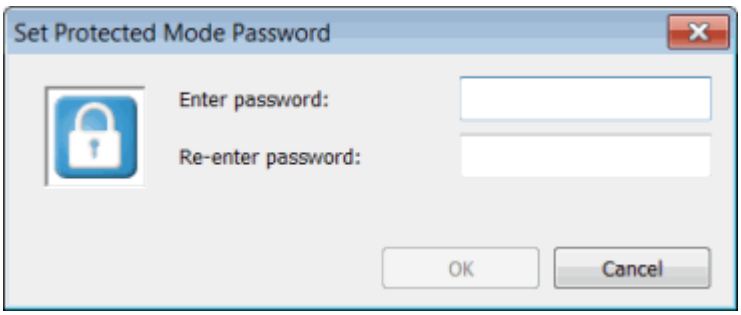
For information on creating and inserting external objects, see "Inserting External Objects" in the "Adding External Elements" chapter.

Using Protected Mode to Protect Measurement Routines from Edits

Enabling Protected Mode

To protect a measurement routine from unwanted edits, before you open a measurement routine, from the PC-DMIS Home screen, select the **Edit | Protected Mode** menu option to enable Protected Mode. This menu option is only available if no measurement routine is currently open.

When you select this option, PC-DMIS displays the **Set Protected Mode Password** dialog box where you can define a password to enable Protected Mode:



To define the password, type the exact string of characters into the two boxes and click **OK**. When you enable Protected Mode, a check mark appears next to the **Protected Mode** option in the **Edit** menu.

The Protected Mode password supersedes and overwrites any other password you have defined. For instance, if you have enabled password protection for the **Setup Options** dialog box (**Edit | Preferences |Setup**) or a .ipd (Inspection Plan Default) file, you must use the Protected Mode password instead.

As a PC-DMIS administrator, you can create marked sets to allow the execution of a partial measurement routine. Operators can execute marked sets while in Protected Mode.

Effects of Protected Mode

To protect your measurement routine, when you are in Protected Mode, you cannot do the following:

- Modify commands
- Add commands
- Modify some settings
- Calibrate probes

After you enable Protected Mode on a computer, you cannot modify any measurement routines for that version of PC-DMIS until Protected Mode is disabled.

With Protected Mode enabled, you can still do the following:

- View the Edit window and Report window
- Load and view different report templates
- Change the marking state of commands
- Execute the measurement routine

You cannot modify the measurement routine or reporting templates in any way.

Visual Indicators

When PC-DMIS is in Protected Mode, you will notice these visual indicators:

- Only a few menus are available, and most options within those menus are not editable. For example:

  
- Only the **Edit Window** toolbar, **Probe Mode** toolbar, and **Graphic View** toolbar are available.
- PC-DMIS displays the Edit window only in Summary Mode and disables both Command Mode and DMIS Mode.

How to Disable Protected Mode

To disable Protected Mode, follow these steps:

1. Close all open measurement routines.
2. Select the **Edit | Protected Mode** menu option to open the **Protected Mode Password** dialog box.
3. Type your password.
4. Click **OK**.

PC-DMIS then removes all editing restrictions.

If you are a member of the **PC-DMIS-User** or **PC-DMIS-Programmer** group, see the "Certify" section and "Edit Certified Measurement Routines" topic in the PC-DMIS Core documentation.

Updating Nominals from CAD

You can update the nominals of features in the Edit window based on an imported CAD file. This makes it possible to easily update your features' nominal (or theoretical) values to match the nominals of the CAD model. This is useful in these situations:

- You have already measured features without any CAD, but you now have CAD, and want to update your features' nominals.
- You want to update your features' nominals to match an updated CAD model.

To update your features' nominals from the CAD:

1. Select **File | Import** to import the CAD model you want to use. For more information on how to import a model, see "Importing a CAD file" in the "Using Advanced File Options" chapter.

2. Select **Operation | Features | Update Nominals from CAD** and choose one of these submenu items:

   All - Updates all the features' nominals in the measurement routine.

   Current - Updates only the selected feature's nominals.

The Status bar shows the operation results as it runs.

How it Works

This operation uses the **Find Noms** tolerance located on the **General** tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**). For information on the **Find Noms** tolerance, see "Other Edit Boxes for the General tab" topic.

This list provides information about how this operation updates the nominals for specific features:

- **Point** - PC-DMIS uses the XYZ and IJK of the point feature to draw an imaginary line that pierces the CAD model. It updates the nominal values to match the closest intersection to the original XYZ with the CAD model.

- **Edge Point, Angle Point, Corner Point** - PC-DMIS looks on the CAD model for the nearest feature of that type. The XYZ value must lie within the **Find Noms** tolerance of the original feature. It then updates the nominal values to match the CAD model.

- **Plane** - PC-DMIS projects the plane's XYZ onto the CAD model's closest planar surface. The XYZ must lie within the **Find Noms** tolerance of the original feature. It then updates the nominal values to match the CAD model.

- **Circle, Ellipse, Cylinder, Cone, Sphere** - PC-DMIS looks on the CAD model for the nearest feature of that type. The XYZ and diameter must each lie within the **Find Noms** tolerance of the original feature. Cylinder and Cone also have a length value that must also lie within the **Find Noms** tolerance. It then updates the nominal values to match the CAD model.

- **Square Slot, Notch Slot, Round Slot**, **Flush & Gap** - PC-DMIS looks on the CAD model for the nearest feature of that type. The XYZ as well as the length and width of the sides must each lie within the **Find Noms** tolerance of the original feature. It then updates the nominal values to match the CAD model.

- **Polygon** - PC-DMIS looks on the CAD model for the nearest feature of that type. The XYZ and the diameter must each lie within the **Find Noms** tolerance of the original feature. The feature on the CAD must have the same number of sides as the original feature. It then updates the nominal values to match the CAD model.

- **Line** - PC-DMIS projects the line's start and end points of the original feature onto the CAD model. Both points must lie within the **Find Noms** tolerance. It then updates the nominal values to match the CAD model.
- **All other feature types** - PC-DMIS locates all the features' hits, and projects each hit onto the CAD model to find the nearest XYZ point on the model. The XYZ of each projected point must lie within the **Find Noms** tolerance of the original hit.

Resetting Measured Values to Nominals

You can reset the measured values of features to match their respective nominal values. This is probably most useful when using portable devices. Measured features before the alignment are shown in relation to the device at the measured locations in the Graphic Display window. If those locations are from a previous run, and the part has moved, then those features will be drawn in an unexpected location on the screen. Resetting those measured values to the nominals will redraw the features so they rest appropriately atop the CAD model.

To reset features' measured values to match the nominal values:

1. Click **Operations | Features | Reset Measured Values to Nominals**.
2. You can update all nominals by clicking the **All** menu item. To update just the currently selected nominal feature, click the **Current** menu item.

Estimate Execution Time

The topics in this chapter include:

About Estimate Execution Time

Workflow

Calibrating Execution Time Parameters

Calibrating Execution Time Parameters on Your Machine

    Performing Execution Time Calibration

Estimating Execution Time

About Estimate Execution Time

This function estimates the execution time of a measurement routine in Offline Mode. You can use a computer connected to a CMM or an offline computer used to create measurement routines to estimate the execution time.

Execution time is an estimation; actual execution time may vary. Several factors affect the actual execution time. Among these are:

- Execution time depends on the jog box speed setting. It should be set to full speed and should not be reduced.
- Execution time depends on the type of commands used in the measurement routine. Some commands, like unknown contour scans, do not have a stored path. In such cases, the machine navigates the shape of the part, making the time for such scans incalculable.
- Execution time depends on the communication time with the controller, which varies depending on the computer's available RAM.

To estimate execution time accurately on an offline computer, ensure that global parameters like move speed, touch speed, and scan speed match those set on the machine for which the execution time is being calculated or define these parameters in the measurement routine.

The Estimate Execution Time function does not support horizontal arm machines or machines with rotary tables.

Workflow

To estimate execution time:

1. Calibrate the Execution Time parameters for your machine or use a parameter file from another machine to estimate the execution time on that machine.
2. Create a measurement routine.
3. Use the Estimate Execution Time command to estimate the execution time.

Calibrating Execution Time Parameters

Every machine is different. The machine’s kinematics, controller parameters, and hardware determine the execution time of a measurement routine. These parameters contribute the most to the execution time:

- **TIP command** - This command rotates the wrist mounted on a machine.
- **Time for measuring HIT points** - The time required to measure HIT points depends on the type of probe used. Scanning probes take longer to record a hit point than touch-type probes.

- **Tool Change time** - This depends on the complexity of the tool change. It can be as simple as changing the probe-holding disk or as complex as changing both the module and the probe-holding disk.
- **Machine Acceleration** - Modern machines, such as Hexagon's, move with very high acceleration. This allows them to achieve the defined move speed over a short duration.

During calibration, these parameters are measured and recorded. They are used to estimate execution time. You can get the parameters for calculating execution time by:

1. Calibrating your machine
2. Using a packaged generic parameters file that best matches your measurement machine.

Calibrating Execution Time Parameters on Your Machine

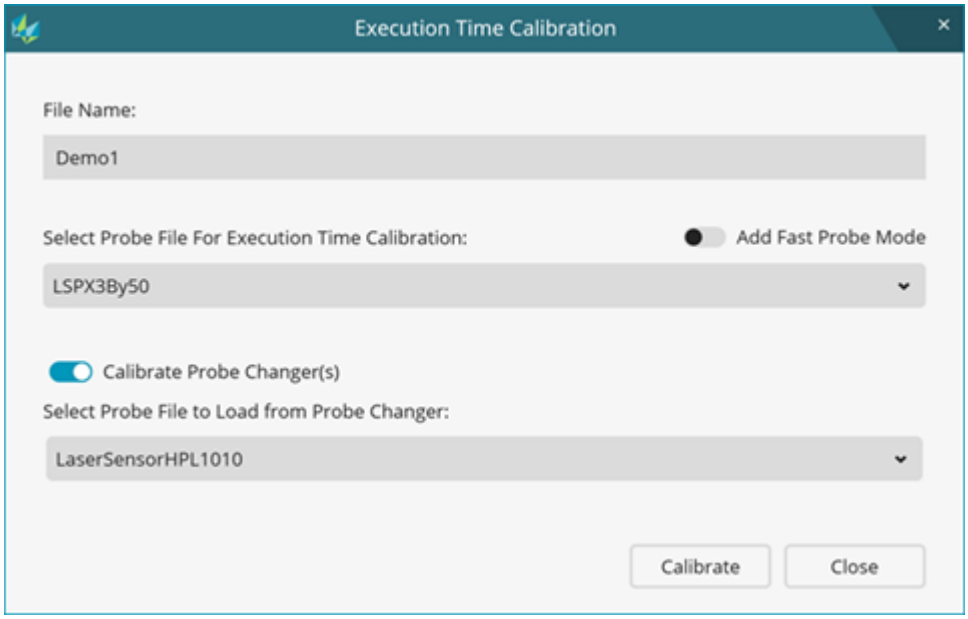
To calibrate execution time parameters on your machine, follow these steps:

1. Create and calibrate the probe files. Ensure to add these angles to the probe file:
    - TIP/T1A0B0
    - TIP/T1A90B0
    - TIP/T1A90B90
    - TIP/T1A90B-90
    - TIP/T1A90B-180
2. The probe file used to exchange probes from the tool changer must have at least one calibrated probe tip.
3. Calibrate probe tips.
4. For a fixed-head machine, create a star probe and calibrate it.
5. Mount the calibration sphere on your measuring machine. Ensure that there is enough space around it to measure points in the Z, X, and -Y directions. If you select tool changer calibration, ensure the path to the probe changer is collision free.
6. If your measuring machine is equipped with a tool changer, ensure that the probe file for calibration and at least one additional probe file is assigned to the appropriate slot on the tool changer. The calibration process exchanges tips from the tool changer multiple times.

Performing Execution Time Calibration

To perform execution time calibration, follow these steps:

1. From the Home page, select the menu option **Operation | Execution Time Calibration**. PC-DMIS displays the **Execution Time Calibration** dialog box.



2. Complete the options:

    - **File Name**: Type a name for the file. The name should help you identify the machine, wrist, and probe.
    - **Select Probe File For Execution Time Calibration**: Select the probe file for calibration. We recommend using a 3 to 5 mm diameter probe tip. Ensure that you create and calibrate the tip angles required for calibration.
    - **Add Fast Probe Mode**: Turn this on if your machine's controller supports fast probes with scanning sensors and you use them in your measurement routines.
    - **Calibrate Probe Changer(s)**: If you turn this on, you must define the second probe.
    - **Select Probe File to Load from Probe Changer**: Select a probe file other than the one selected above for calibration. This option is enabled only if you turn on the **Calibrate Probe Changer(s)** option.

3. Do one of the following:

    - To start the calibration, click **Calibrate**.
    - To cancel the calibration and return to the Home page, click **Close**.

Once you click the **Calibrate** button, PC-DMIS generates a new measurement routine. Its execution starts immediately after generation. It is important to generate and start execution this way; otherwise, the required parameters are not created, and time estimation is not possible.

Follow the prompts provided by the calibration routine. Complete the menu to enter the nominal diameter of the calibration sphere used. The calibration routine asks you to take one point on top of the calibration sphere. After that, it determines the sphere position and measures points multiple times. At the end of the time calibration process, PC-DMIS generates a CSV file and saves it in this folder:

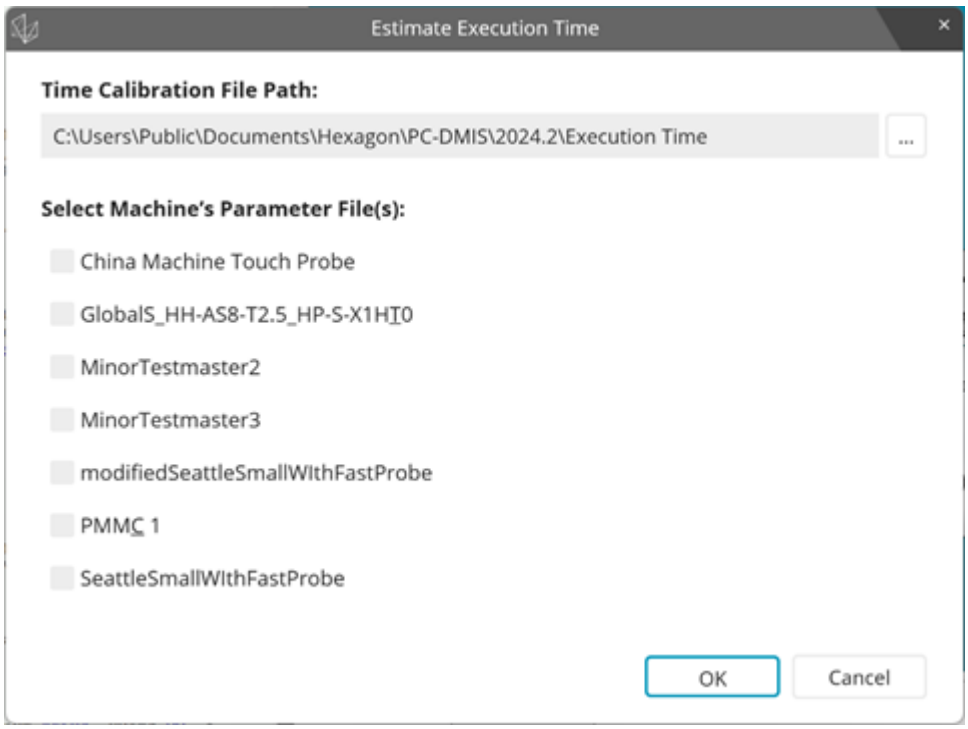
C:\Users\Public\Documents\Hexagon\PC-DMIS\Variable "currentversion" is not defined\Execution Time

You can copy and store the calibration file in any desired location. If your organization owns multiple machines, you can copy it into a folder on a network drive, making it accessible to multiple users.

Estimating Execution Time

You can use the Estimate Execution Time functionality to approximate the time PC-DMIS takes to execute your measurement routine. To do this, follow these steps:

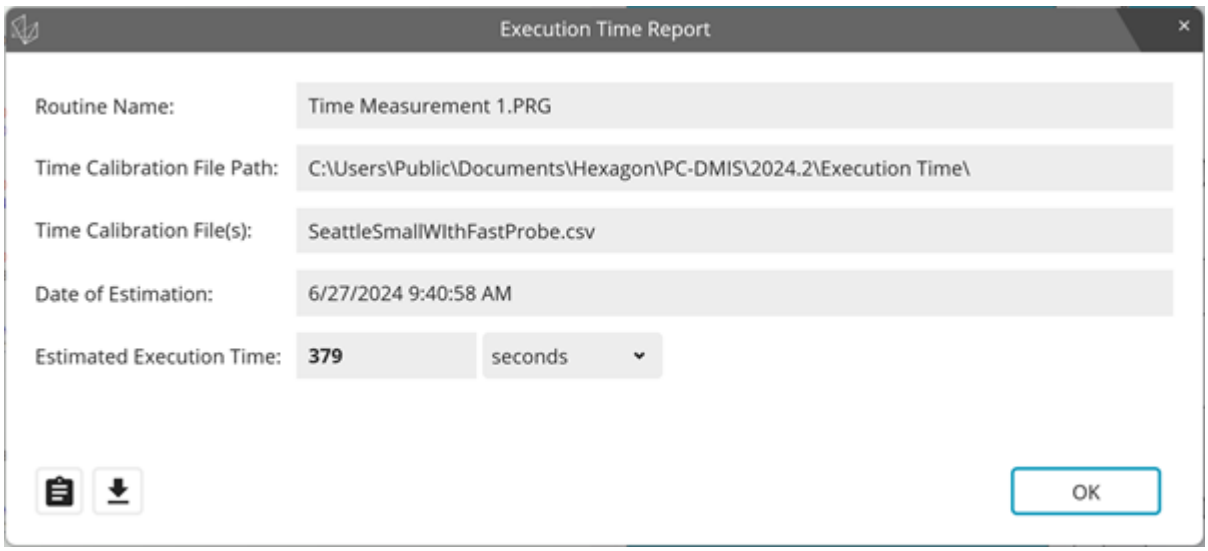
1. Open the measurement routine.
2. Select the menu option **Operation | Estimate Execution Time** to open the **Estimate Execution Time** dialog box.



Complete the options:

- **Time Calibration File Path** - Use this box to type the path for the calibration file or click the **Browser** (...) button and navigate to the location of the calibration file.
- **Select Machine's Parameter File(s)** - Select the calibration file(s) for your machine.

3. To start the calculation, click **OK**.
4. At the end of the execution time estimation, PC-DMIS displays the **Execution Time Report** dialog box.

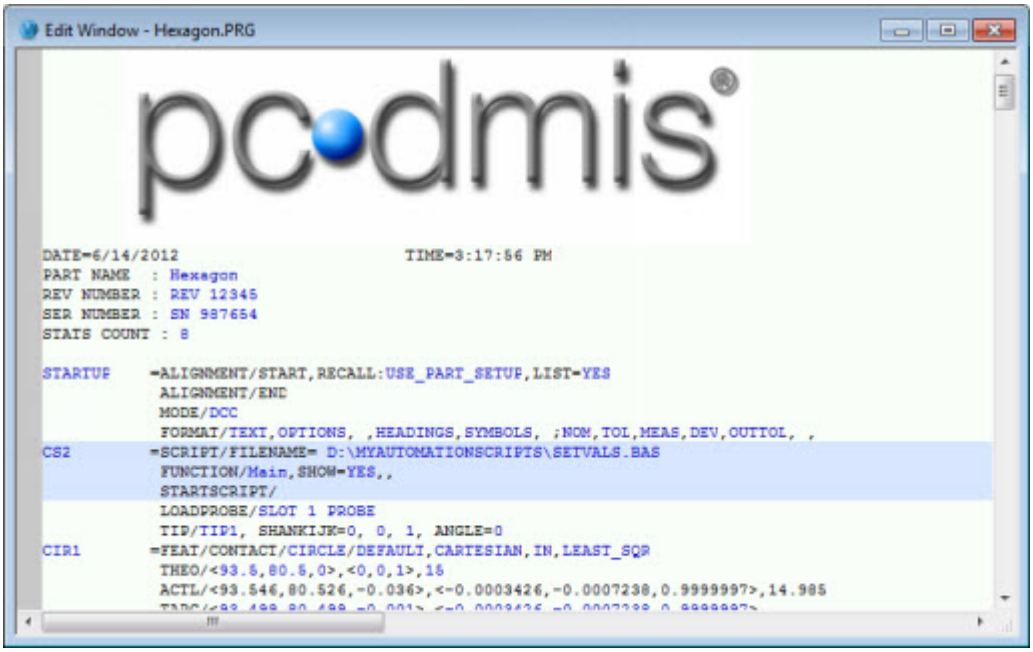


The dialog box displays the routine name, time calibration file path, time calibration file(s) used, date of calculation, and estimated execution time. You can select the estimated execution time in seconds, mm:ss, or hh:mm:ss.

- **Copy** - Copies the report to the clipboard.
- **Download** - Downloads the report in PDF format.
- **OK** - Closes the **Execution Time Report** dialog box.

Using the Edit Window

Using the Edit Window: Introduction



Example of the Edit window in Command mode.

One of the main tools that you can use to edit a measurement routine is the Edit window. The Edit window houses all of the commands for the measurement routine. You can perform editing operations such as cutting, copying, pasting, and modifying existing text and commands. You can also use the Edit window to add new commands, execute existing commands, display a command's information, and debug code.

To access the Edit window, select the **View | Edit Window** menu option.

This chapter covers the Edit window and how to edit measurement routines in general in these topics:

- Understanding Core Concepts
- Working in Summary Mode
- Working in Command Mode
- Working in DMIS Mode
- Working with User-Defined Groups

Understanding Core Concepts

The Edit window allows you to easily access the current measurement routine. Changes can be made to the measurement routine using only the Edit window, the dialog boxes, or a combination of the Edit window with the applicable dialog boxes. The sections below provide core concepts that can aid you in learning to use the Edit window.

Navigating the Edit Window

The Edit window houses all the commands that make up your measurement routine.

To change the display of the Edit window, you can switch between different modes. PC-DMIS enables the two most common modes by default. These are Command Mode and Summary Mode. You can enable a third mode, called DMIS Mode, from the **Setup Options** dialog box (**Edit | Preferences | Setup**). To do this, select the **Use DMIS button in Edit Window** check box.

- Summary Mode - This mode provides a visual summary of your measurement routine.
- Command Mode - This mode shows a detailed code view of each command.
- DMIS Mode - This mode shows a view similar to Command Mode, but the code language is written in the DMIS programming language. Also, you don't have all the editing functionality that you have in Command Mode.

You can click the appropriate icon on the **Edit Window** toolbar to switch between these different modes. The **Edit Window** toolbar also lets you perform other operations on your measurement routine. For information on this toolbar, see the "Edit Window Toolbar" topic in the "Using Toolbars" chapter.

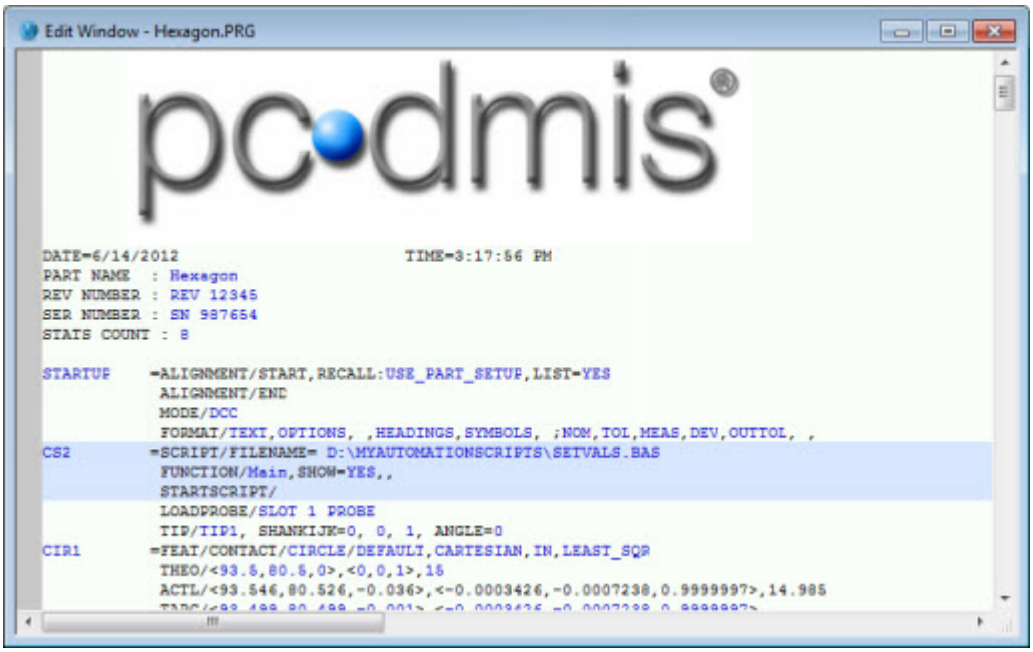
In each mode, you can work with existing commands and add new commands, although the capabilities of each mode and the methods of working with commands differ. Commands can have both editable and non-editable fields. Editable fields are fields that take a value. Some editable fields are called *toggle fields* and allow you to switch between a predefined set of acceptable values.

- *If you're in Command Mode or DMIS Mode*, press Tab to move the cursor to the next editable field. You know that you're on an editable field when the value is highlighted in the highlight color (the default is blue).
- *If you're in Summary Mode*, PC-DMIS provides you with the **Select**, **Add**, **Remove**, **Copy**, **Cut**, **Paste**, **Mark**, **Unmark**, and **Edit** commands. For more information, see "Editing a Measurement Routine from Summary Mode".

Moving to a Feature Using the Graphic Display Window

To move the cursor to a specific feature's location in the Edit window, click on that feature in the Graphic Display window while you hold down the Ctrl key. PC-DMIS displays a message for your confirmation to move the insertion point.

Understanding the Default Edit Window Colors and Formatting



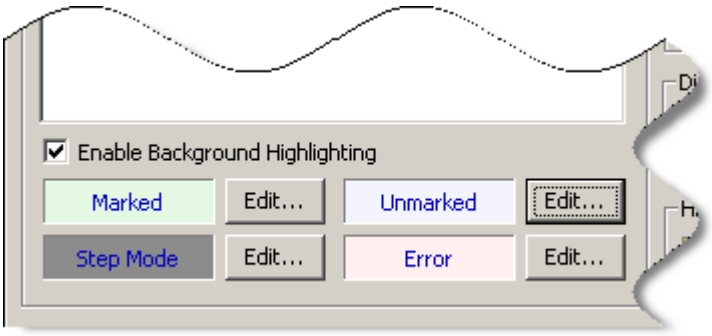
Edit window in Command Mode

PC-DMIS uses different background colors, command text colors, and text characters to offset information in Command Mode and DMIS Modes. This coloring and text formatting may seem somewhat confusing at first, especially if you are used to very old versions of PC-DMIS that only used a single color. If you don't like the default color scheme, you can configure your coloring scheme similar to that of old versions or come up with your own. For information on how to do this, see "Defining Edit Window Colors" in the "Setting Your Preferences" chapter.

The colors and formatting are valuable tools that can help increase your productivity. The following describes these tools.

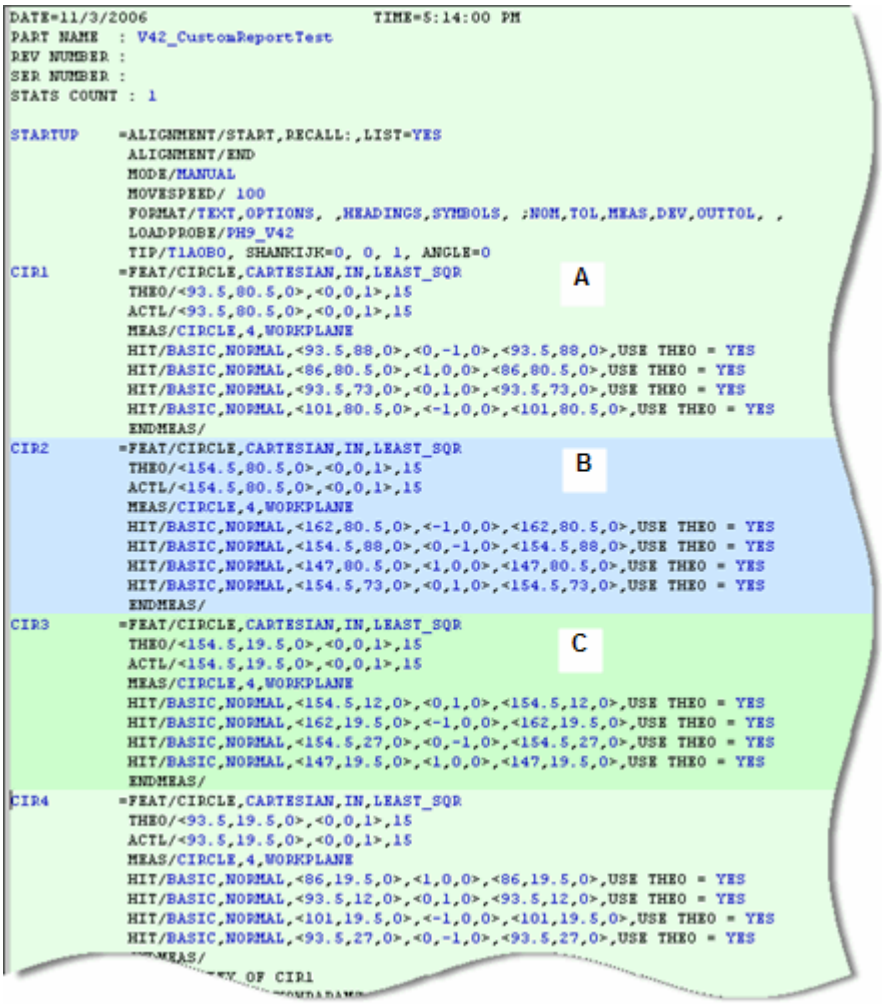
Background Colors

Different background colors help you know what commands are marked, unmarked, have errors, are active, or are being stepped through. You can find the definitions for these background colors in the **Color Editor** dialog box (**Edit | Preferences | Edit Window Colors**) for the Edit window.



Edit window background color information in the Edit window's Color Editor

Consider this example screenshot:



Edit window example showing the coloring scheme
***A** - A light-green background means the command has been marked for execution.*
***B** - The light-blue background means the command has not yet been marked for execution.*
***C** - A slightly darker background color (either darker green for marked commands or darker blue for unmarked commands) shows the current active command.*

Command Text Colors

Black text - Any non-editable command text. You cannot change this text.

Blue text - Any editable command text.

Red text - For non-dimension commands, this indicates an error in the command text. The command is skipped during measurement routine execution. Errors come from unsupported commands, unsupported probe types, and syntax errors (usually while working with expression or scripting commands). For dimension commands, red text indicates that the dimension is out of tolerance.

For details on how PC-DMIS reports dimensions that use skipped features during execution, see the "Reporting a Dimension Using a Feature Skipped During Execution" topic in this documentation.

If your measurement routine contains unsupported commands (commands in red text), check it thoroughly before you execute it in Online Mode. Since unsupported commands are skipped during measurement routine execution, in some cases this could cause a probe collision if you aren't careful.

Highlighted Text Shows the Active Command or Group

When you move your mouse over a command block, or command blocks that are grouped together, the entire command block, or the entire group, is highlighted with a slightly darker background color (see item C in the example above). This helps you immediately see the extents of an entire command block. Doing this also makes the command "active". This means you don't need to click on the command to operate on it. For example, you can hover your mouse over a command and press F9. The associated dialog box appears if one exists. To delete the command, you don't need to select the entire command, just hover your mouse over it until it becomes active, and press Delete. When editing large measurement routines, shaving off a mouse click here and there can increase your productivity.

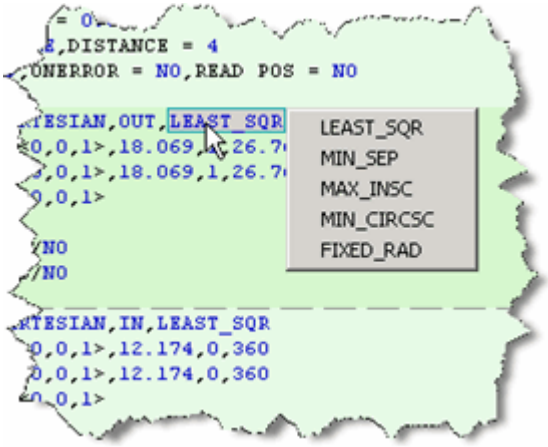
"<" and ">" Characters Provide Enhanced Readability

The "<" and ">" characters group like values together, thereby more easily delineating the different fields for various X, Y, Z and I, J, K values. These characters show where these pairs begin and end. This enhances readability and makes it much easier to locate needed values.

```
PLN2        =FEAT/CONTACT/PLANE,CARTESIAN,
              THEO/<186.865,30.085,-1.705>,
              ACTL/<186.865,30.085,-1.705>,
              TARG/<186.865,30.085,-1.705>,
```

Popup Menu Provides an Additional Toggle Field Selection

While you can cycle through a list of available commands on a toggle field, you can also hover your mouse over the darker blue text for a moment, and the background color takes on a button-like quality. Click on the button to show a drop-down list from which you can select the desired value for that toggle field.



Easier Filename Fields

Certain fields take filename values. If the file moves to a new location, there's an easier way to update it than arduously retyping a long directory pathway. Instead, hover your mouse over the field; the filename turns into a button. Click the button to display a **File Open** dialog box, which allows you to locate and update the file's location.

Inserting Commands

In many cases, commands are automatically inserted when you take measurements or when you use dialog boxes to enter information. However, you can also add commands directly from within the Edit window. Depending on what mode you're in, PC-DMIS gives you different options:

- *If you're in Command Mode*, you can type the first few letters of the command and press Tab or Enter to insert new commands.
- *If you're in Summary Mode*, you can right-click and select **Add Command** from the shortcut menu to insert new commands. PC-DMIS displays a list of the commands that you can add.
- *If you're in DMIS Mode*, you can press Enter on a line to insert new commands. A list appears from which you can select the appropriate DMIS command to add.

Indenting Commands

To improve the Edit window's readability, PC-DMIS automatically performs an indent inside of supported code blocks, loops, and flow control pairs. This occurs whenever you insert these types of commands into the Edit window.

Summary Mode uses a fixed indent value. Command Mode and DMIS Mode use a two-character default for the indent. You can modify the number of spaces with the `EWGroupIndent` entry in the PC-DMIS Settings Editor.

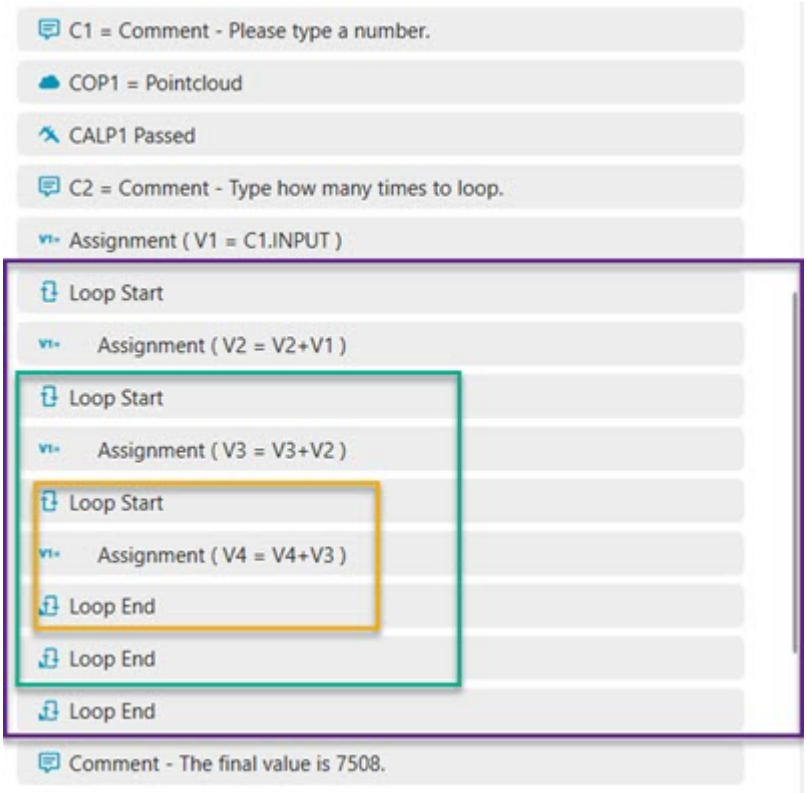
This shows a list of commands that support indenting:

Supported Commands

- Alignment (ALIGNMENT/START and ALIGNMENT/END)
- Measure (MEAS/<FEATURE> and ENDMEAS for all measured features)
- GROUP and ENDGROUP
- LOOP/START and LOOP/END
- IF and END_IF
- ELSE_IF and END_ELSEIF
- ELSE and END_ELSE
- While and END_WHILE
- DO and UNTIL
- SELECT and END_Select
- CASE and END_CASE
- DEFAULT_CASE and END_DEFAULT_CASE

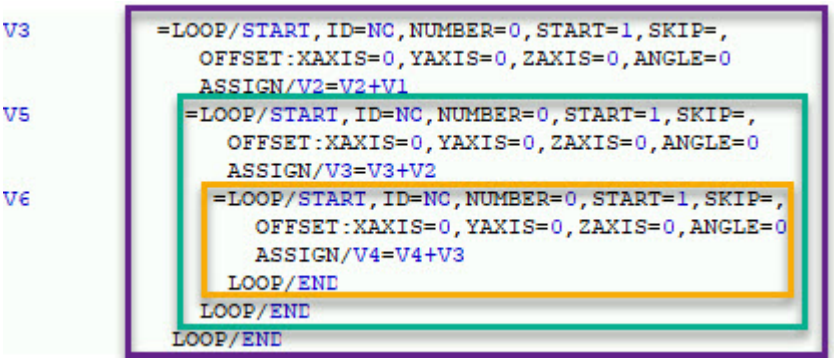
The following examples show how nested indents appear in each Edit window mode (Summary Mode, Command Mode, and DMIS Mode):

Summary Mode Example



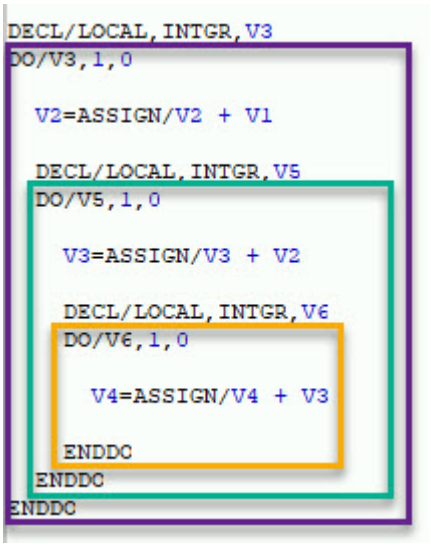
Example of nested loops in Summary mode.

Command Mode Example



Example of nested loops in Command mode.

Dmis Mode Example



Example of nested loops in DMIS mode.

> The Edit window can display a maximum of 256 characters on a single line, including white space. This means many levels of nested commands can push the innermost commands so far to the right that the Edit window cannot display their text.

Editing Values and IDs

You can use the Edit window to change a command's settings.

If you're in Command Mode or DMIS Mode, press the Tab key to go to the editable field you want to change. Either type in a new value or press F7 or F8 to cycle forward or backward through a list of available values. You can also move your pointer over a toggle field and after a moment it changes to a gray background. You can then click on that to select from a menu of available values.

If you edit a feature or dimension's ID using the Edit window, PC-DMIS asks if you want to make this ID the default for that same feature or dimension type. If you click **Yes**, features

or dimensions of that same type, when created later, will use the new ID as the default. If you click **No**, then future IDs continue to use the current default value.

Selecting Commands

You can select most commands in any mode in PC-DMIS.

- In Summary Mode, click on a collapsed group command to select the entire command block. PC-DMIS also selects all of the data items associated with the commands present in the group. For details see "Selecting Commands in Summary Mode".
- In Command Mode or DMIS Mode, click the start of the command, hold down the mouse, and then drag it until you highlight the entire command.

The **Edit | Select All** menu option selects the entire window's contents for editing purposes.

As you select feature commands, PC-DMIS highlights those features in the Graphic Display window in a light blue color. Also, in Command Mode, this happens if you click anywhere in a feature command. To change the highlight color, see "Highlight" under "Changing Screen Colors" in the "Editing the CAD Display" chapter. Auto Plane features also highlight the entire surface.

Repositioning Commands

You can reposition many commands in PC-DMIS*. If you're in Summary Mode, Command Mode, or DMIS Mode*, do the following to reposition a command:

1. Select the entire command block.
2. Select the **Edit | Cut** menu option to remove the command from its current location.
3. Move the cursor in the Edit window to the new location and select the **Edit | Paste** menu option to place the command in its new location.

You can also use the **Edit | Copy** menu option to make a copy of a command and store it in the Clipboard until you decide to paste the copy into another location.

For information on these and other standard edit commands, see "Using Standard Edit Commands" in the "Editing a Measurement Routine" chapter.

Deleting Commands

To delete a command from the Edit window, select the command and press **Delete**.

You can restore any deleted command if you immediately click the **Undo** icon on the **Edit Window** toolbar or if you press Alt + Backspace.

Accessing Dialog Boxes

When you edit features or commands, you may want to access dialog boxes associated with a particular feature or command. To do this, when you are in one of the editing modes, place the cursor on the feature or command block and then press F9. The software opens the dialog box associated with the feature. You can then make any changes in the dialog box itself. After you click **OK** or **Apply**, the software automatically updates the Edit window with your changes.

On some commands, you can press F9 to access the dialog box only if PC-DMIS is in Command Mode.

Modifying the Edit Window's Headers and Footers

There are three data files that are used to format the header / footer text in the Edit window. These files are LOGO.DAT, HEADER.DAT, and ELOGO.DAT. These files are located in your PC-DMIS installation directory.

You can edit the Edit window's header or footer by making and saving changes to these text files using a standard text editor (such as Notepad).

To modify the header or footer of a generated report, not the Edit window's header, you have these options that the "Reporting Measurement Results" chapter covers:

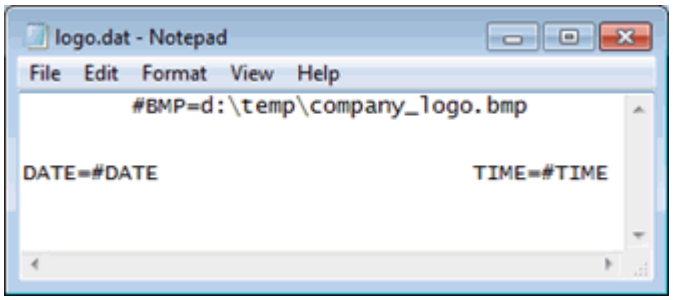
1. Modify templates to control what gets displayed in the Report window. (See "Modifying the Report's Header".)
2. Use LOGO.DAT, HEADER.DAT, and ELOGO.DAT files to a limited extent. (See "Using .DAT Files in Generated Reports".)

The Edit Window's Header

To define the header layout in your Edit window, you can edit the LOGO.DAT and HEADER.DAT files.

LOGO.DAT – This file defines the header for the very first page of the Edit window. You can define a bitmap with your company's logo, specific date, and time formats.

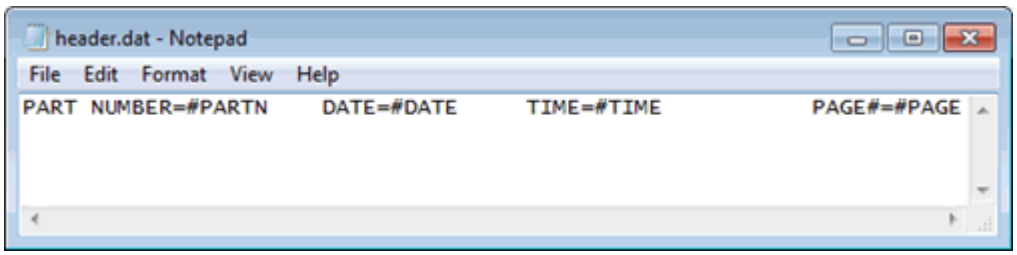
Example of the Edit window's header formatting.



Example of a Logo.dat file in Notepad.

That PART NAME, REV NUMBER, SER NUMBER, and STATS COUNT are static fields and cannot be changed in the LOGO.DAT file.

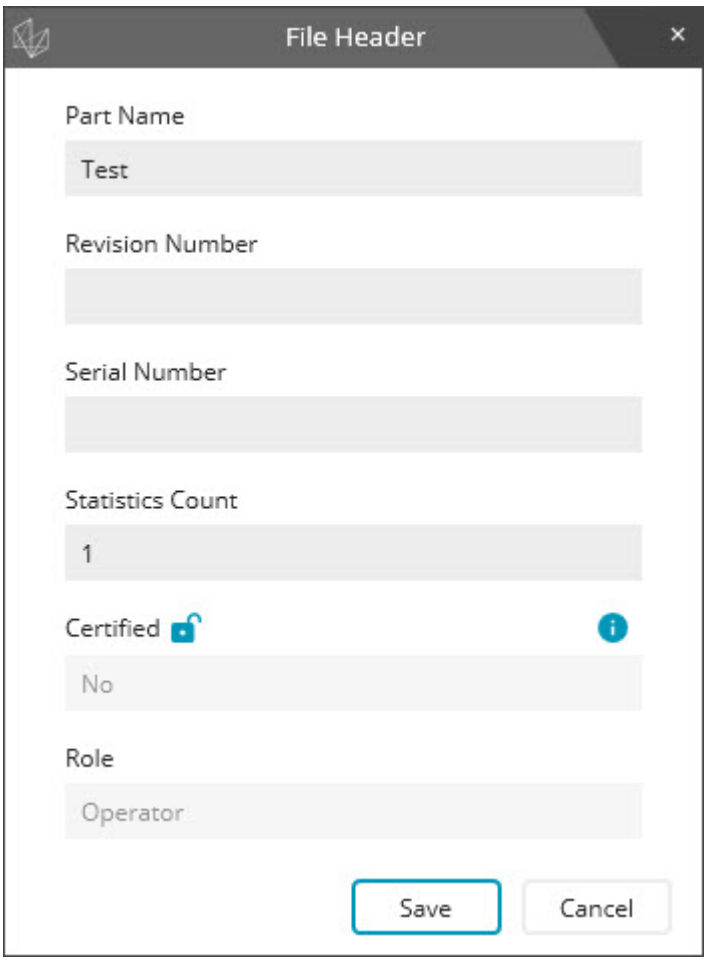
HEADER.DAT – This file is used to format page headers for all other pages.



Example of a Header.dat file in Notepad.

File Header dialog box

To edit header file values, you can change them in the Edit window or press F9 to open the **File Header** dialog box.



File Header Dialog Box

Part Name - This box displays the part name.

Revision Number - This box displays the revision number.

Serial Number - This box displays the revision number.

Statistics Count - This box displays the number of transactions or runs.

Certified - This box informs you if the measurement routine is certified or not. You cannot edit this value. For information on how to certify a measurement routine, see "Certify".

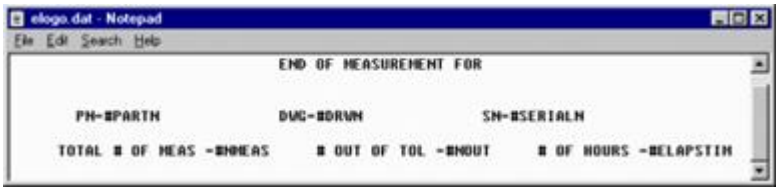
Role - This box displays the role of the author who opened the measurement routine. You cannot edit this value.

The Edit Window's Footer

ELOGO.DAT is used to format a footer for the last page only of your Edit window.

Example of the Edit window's footer formatting.

The corresponding ELOGO.DAT file is displayed below:



Example of an Elogo.dat file in Notepad.

Edit Window Header and Footer Formatting Keywords

Following is a list of the available formatting keywords and their functions. You can insert these keywords into the .dat files to have them displayed in a header or footer in the Edit window.

The keywords *are* case sensitive.

#DATE
Inserts the current date.

#TIME
Inserts the current time.

#PAGE
Inserts the current page number. This is ideal for use in the HEADER.DAT file.

#TRn
Inserts both the name and the value of tracefield n, where n is the tracefield number.

#PARTN
Inserts the measurement routine name.

#DRWN
Inserts the revision number.

#SERIALN
Inserts the serial number.

#SEQUENCE
Inserts the sequence number.

#SHRINK
Inserts the scale factor.

#NMEAS
Inserts the total number of dimensions.

#NOUT
Inserts the total number of dimensions that are out of tolerance.

#ELAPSTIM
Inserts the time elapsed between start and end of execution. This is ideal for use in the FOOTER.DAT file.

#BMP=<path>
Inserts a bitmap where <path> represents the full path pointing to the bitmap file (for example, D:\Files\Bmp\Pcdhead.bmp).

Using Expressions and Tracefields to Customize Edit Window Headers and Footers

You'll notice that the keywords themselves aren't customizable. For example the `#DATE` keyword in the logo.dat file only gives you one way to display the date, in the mm-dd-yyyy format. For example, in this format, May 5, 2018 is written as 5-5-2018 in your Edit window's header or footer.

For more information on the elogo.dat, logo.dat, and header.dat files, and where to find them, see the "Understanding Data Files" topic in this chapter.

The following example shows how you can use expressions and tracefields to change the format of your date on the Edit window.

1. Type the following commands somewhere into your measurement routine:

   ```
   ASSIGN/V1=SYSTEMDATE("MMM dd, yyyy")
   ```

   This gives V1 the string value of your current date (for example, "May 05, 2018").

   ```
   TRACEFIELD/DISPLAY,LIMIT=15;DATE:V1
   ```

   This assigns V1 to the TRACEFIELD.

2. Assuming this is the first tracefield in your measurement routine, open up your logo.dat file inside a text editor and modify the DATE= field so that it looks like this:

   ```
   DATE=#TR1
   ```

   Notice that the DATE field now references the first tracefield by using #TR1.

3. Save and close your logo.dat file.

4. Access the Edit window. Assuming your Edit window is enabled to show headers and footers, the header now uses the formatted system date that was stored in the V1 variable and subsequently in the first tracefield.

You can use tracefields and expressions to give you greater control over what you see in the Edit window.

For information on tracefields, see the "Using Tracefields" topic in the "Tracking Statistical Data" chapter.

For information on expressions, see the "Using Expressions and Variables" chapter.

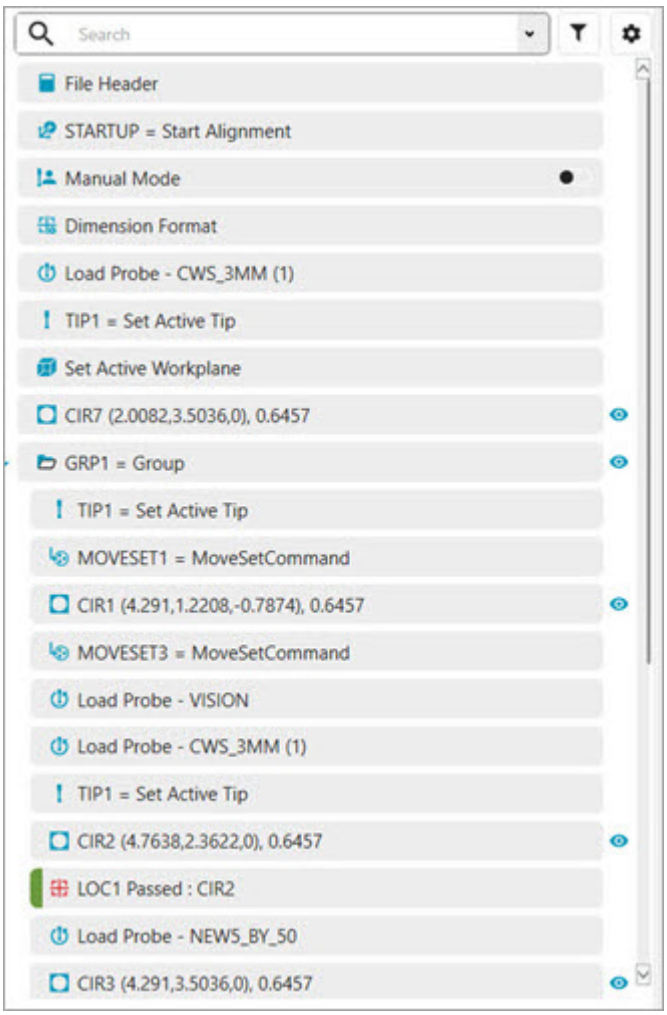
For information on how to modify your report's headers or footers with .DAT files, see "Using .DAT Files in Generated Reports".

For information on how to use templates and rules to modify your report, see "Modifying the Report's Header".

Working in Summary Mode

Summary Mode displays a summary of the measurement routine, as well as measurement routine commands in different levels of detail. Through the interface, you can also re-order and edit commands. You can use the **Search and Filter** toolbar to find specific features, dimensions, commands, or any other data.

To place the Edit window in Summary Mode, select **View | Summary Mode** from the menu, or from the **Edit Window** toolbar, click the **Summary Mode** icon .

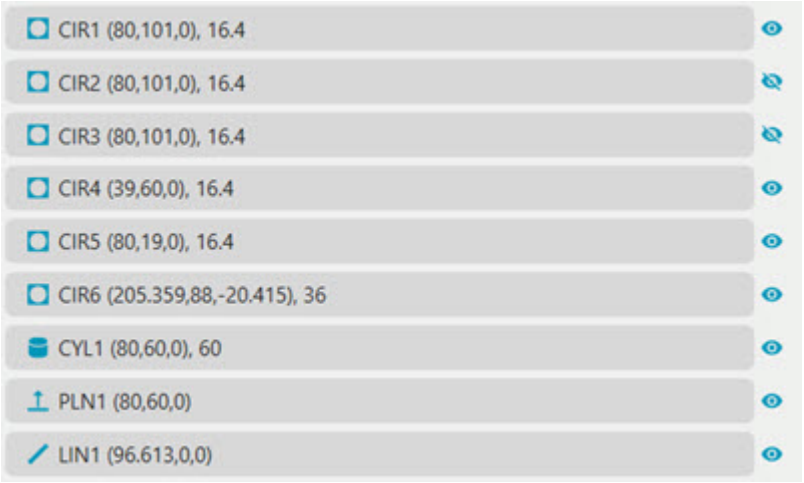


Example showing PC-DMIS Summary mode.

Summary Mode also appears when you create or edit a custom report. For more information on custom reports, see "Creating Custom Reports" in the "Reporting Measurement Results" chapter.

Customizing the Main Display to Show XYZ Information

You can customize the main display of the Summary Mode to show your features' XYZ information in the header line. To do this, access the PC-DMIS Settings Editor, expand the **USER_Option** section, and set the `ShowAdvancedSummaryText` entry to 1. PC-DMIS then displays the commands similar to the following:



Example showing PC-DMIS in Summary mode with advanced summary text.

For information on the Settings Editor, see the "Modifying Setting Entries" topic.

Layout

PC-DMIS's Summary Mode layout is in the form of pieces of data. At the top level, PC-DMIS displays command objects.

- To expand a group to view its data items, click the expand button ( ) to the left of the group command.
- To collapse a group, click the collapse button ( ).

You can also press the Right Arrow and Left Arrow keys to expand and collapse a group, respectively.

Summary Mode Commands

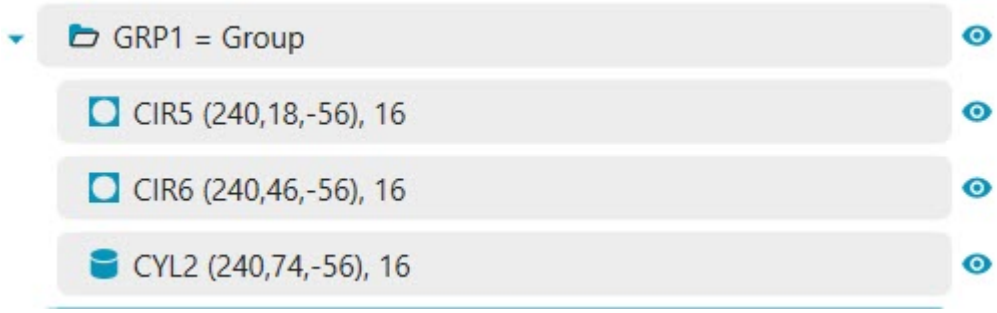
Summary Mode with commands

PC-DMIS displays the measurement routine commands at the top level. Also:

- The search and filter toolbar to find specific features, dimensions, commands, or any other data. For more information, see "Search and Filter Toolbar".
- Each command has a unique icon associated with it to help you quickly identify needed commands.

- If the command has an ID, PC-DMIS displays the ID before the command's description.
- The Peek window displays a command's complete information.
- The switch lets you change between DCC Mode and Manual Mode.
- The icon shows or hides a single feature. If you choose to hide a feature, the feature still exists in the measurement routine but is merely hidden from view in the Graphic Display window. For items that you can show or hide, see "Showing and Hiding Graphics".
- The **Settings** icon ( ) lets you show or hide the Peek window and access the **File Header** dialog box.

Summary Mode Groups



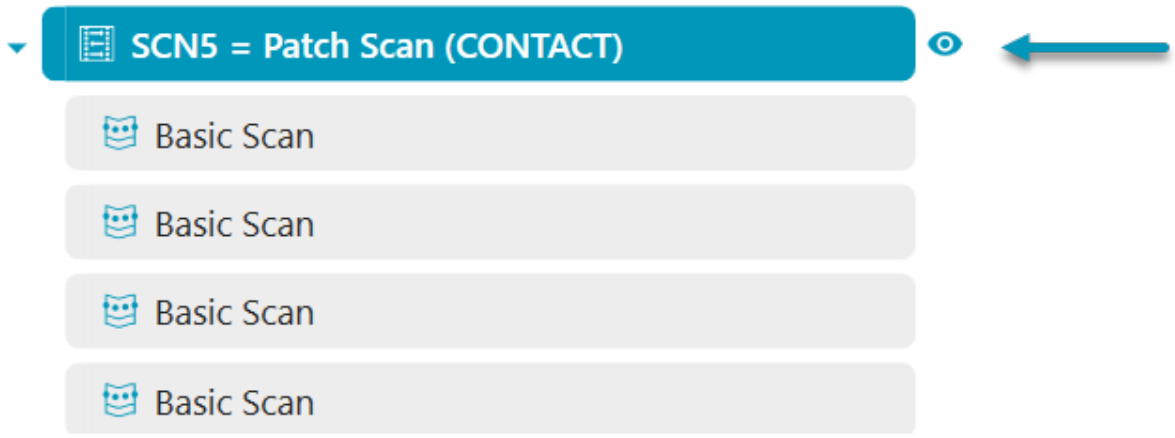
Summary Mode with groups (folder icons)

Groups appear with a folder icon in the Edit window. They are composed of a command's similar data items. If a group contains features that are shown and hidden, PC-DMIS displays this icon .

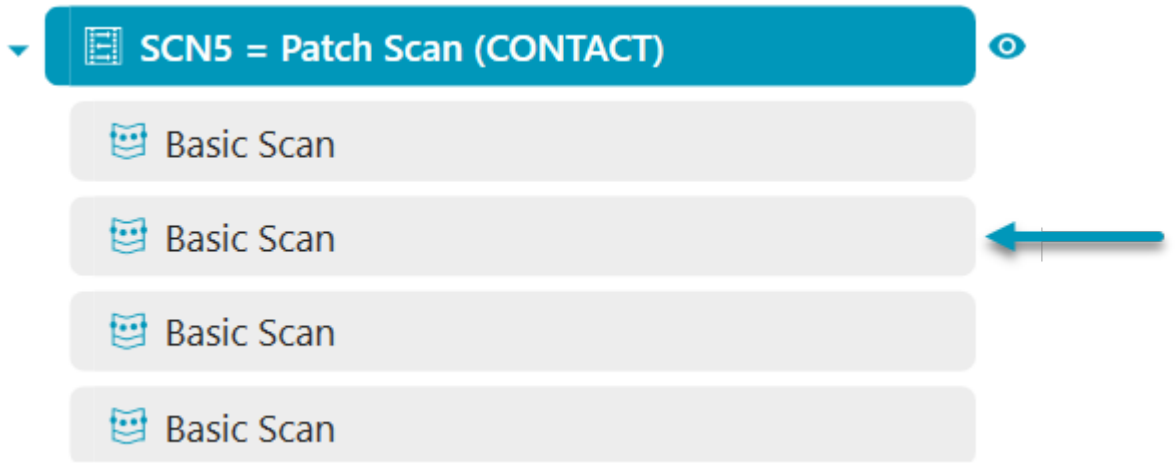
Scan Command

A scan command is composed of one or more Basic scans.

- To set the ClearanceCube motion for the start and end of the main scan, in the Edit window, place your cursor on the main scan's header line. For example, at this location:



- To set the ClearanceCube motion for a Basic scan, in the Edit window, place your cursor at the location of the desired Basic scan. For example, at this location:



From the Feature Shortcut Menu:

- If you select **Hide All Features**, **Hide Feature**, and **Show All Features**, the icon also turns on or off in the Summary Mode Edit window.
- If you select **Hide ID** and **Show ID**, the icon turns on or off only for the Point Infos, Dimension Infos, Datums, Pointclouds, Mesh, and Basic scan commands but not for the features.

Editing a Measurement Routine from Summary Mode

PC-DMIS gives you the ability to edit the measurement routine while in Summary Mode. With the provided interface, you can perform select, add, remove, copy, cut, paste, mark,

unmark, and edit commands. You can also show and hide features in the Graphic Display window.

Selecting Commands in Summary Mode

To select a command, either left-click with the mouse or use the Up and Down Arrow keys to navigate to it.

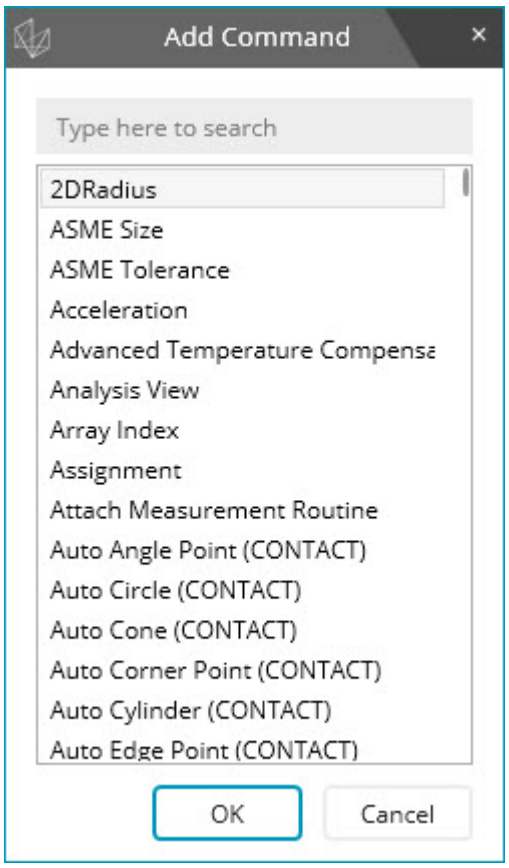
- To select multiple commands, hold down the Ctrl key while you left-click.
- To select a group of items at once, select the first item in the block of objects, hold down the Shift key, and select the last item in the block.

PC-DMIS highlights all of the selected items.

Adding Commands

In Summary Mode, you can use PC-DMIS's standard menu options or a special shortcut menu to add commands to the measurement routine.

1. To access the shortcut menu, right-click on a command item. For more information on the items that are available, see "Summary Mode Command Shortcut Menu" in the "Using Shortcut Keys and Shortcut Menus" appendix.
2. From the shortcut menu, select **Add Command** to open the **Add Command** dialog box.



Add Command Dialog Box

3. To add a command, select the command and click **OK**. PC-DMIS inserts the command into the Edit window. If you want to close the **Add Command** dialog box, click **Cancel** or press Esc on your keyboard.

PC-DMIS generally inserts the new command after the currently-selected item in the expandable/collapsible list.

Renaming Feature IDs

The **Rename Feature IDs** option is only available when you select multiple features in Summary Mode.

In Summary Mode, you can use PC-DMIS's standard menu options or a special shortcut menu to rename feature IDs in measurement routines. This option lets you rename multiple feature IDs at the same time with a Prefix, Suffix, and Index number.

1. To access the shortcut menu, select multiple feature IDs and then right-click them.

   For more information on the available items, see "Summary Mode Command Shortcut Menu" in the "Using Shortcut Keys and Shortcut Menus" chapter of the PC-DMIS Core documentation.

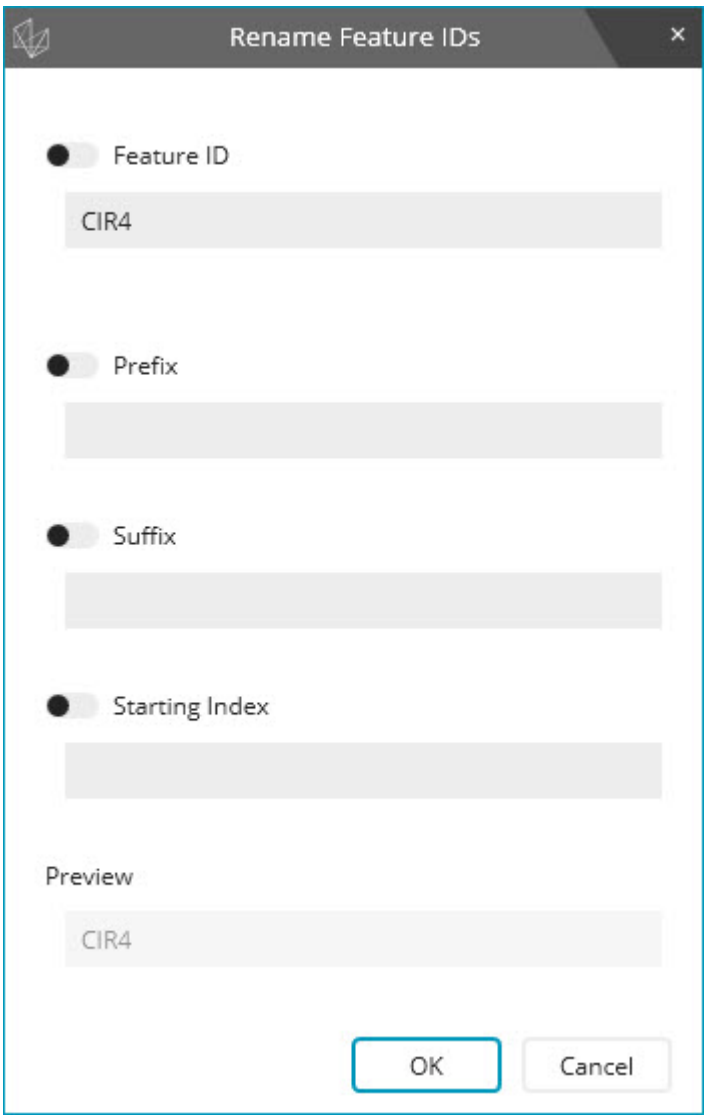
2. From the shortcut menu, select **Rename Feature IDs** to open the **Rename Feature IDs** dialog box. For information about the dialog box, see "Rename Feature IDs dialog box".
3. From the **Rename Feature IDs** dialog box, define a new unique ID.
4. Click **OK**.

PC-DMIS replaces the names of all the selected IDs with the new names in the Edit window.

Rename Feature IDs dialog box

This dialog box allows you to:

- Rename multiple feature IDs in a measurement routine
- Add a prefix to multiple feature IDs in a measurement routine
- Add a suffix to multiple feature IDs in a measurement routine
- Add an index number to multiple feature IDs in a measurement routine



Rename Feature IDs Dialog Box

Feature ID - This option enables you to define multiple feature IDs. PC-DMIS displays the first feature that you selected. To modify a feature ID, use the slider switch to enable the **Feature ID** option for editing. You can then type a new ID name.

Feature IDs must always start with a letter.

Prefix - This option enables you to define a prefix for multiple feature IDs.

Suffix - This option enables you to define a suffix for multiple feature IDs.

Starting Index - This option enables you to define a starting index number for multiple feature IDs. PC-DMIS increments the number by 1 after the first feature.

You must type an index number when you turn on the **Feature ID** option in the **Rename Feature IDs** dialog box.

Preview - This box shows you the preview of the first item of the selected multiple features.

Removing Commands

To remove a command from a measurement routine, select an object and press the Delete key.

If a group command contains any sub-commands, those commands are also deleted.

Copying, Cutting, and Pasting Commands

To copy or cut a command, follow these steps:

1. Select the desired command.
2. Choose the copy or cut command from any of these locations:
    - The Edit window's **Edit** menu
    - The keyboard (Ctrl + C for copy, and Ctrl + X for cut)
    - The shortcut menu's **Cut** or **Copy** option that appears when you right-click on the command

If the command contains any sub-commands, PC-DMIS also cuts or copies those commands.

To paste a command that you have cut or copied, follow these steps:

1. Select the command that precedes the command that you want to paste.
2. Choose the paste command from any of these locations:
    - The Edit window's **Edit** menu
    - The keyboard (Ctrl + V)
    - The shortcut menu's **Paste** option that appears when you right-click on the command.

When you paste a command, PC-DMIS keeps the original command's ID, so two commands then have the same ID. Give the pasted command a new ID that the measurement routine does not already use. If you type an ID that another command already uses, PC-DMIS does not accept it.

Dragging and Dropping Commands

To rearrange commands, you can cut and paste commands in Summary Mode. You can also drag and drop one or more contiguous commands to a new location.

To drag and drop a command, follow these steps:

1. Select one or more contiguous commands in the Edit window.
2. Use the left mouse button, and drag the selected commands to a new location in the Edit window.
3. Release the mouse button to move the selected command below the command that was under the mouse pointer when you released the mouse button.

Marking and Unmarking Commands for Execution in Summary Mode

To mark or unmark a command for execution in Summary Mode, follow these steps:

1. Select the command in the Edit window.
2. Press F3.

Editing from a Dialog Box

To edit a command via the dialog box specific to that command, follow these steps:

1. Select the command in the Edit window.
2. Double-click, press F9, or select **Edit | Command** (or right-click on the command and choose **Edit** from the pop-up menu) to open the appropriate dialog box for the command. Be aware that in some cases, you can only edit a command if PC-DMIS is in Command Mode.

For commands that do not use a dialog box, F9 does nothing, and **Edit | Command** is unavailable for selection.

Showing and Hiding Features

In the Summary Mode, you can show and hide features in the Graphic Display window. The **Show / Hide** button shows the current visibility state of the feature.

- This button means the feature is already visible. Click it to hide the feature.

- This button means the feature is already hidden. Click it to show the feature.

You can also use this with multiple features:

This option toggles the display of selected feature commands and their IDs in the Graphic Display window. You can also use this on a GROUP command to toggle the display of features within the group.

From the Feature Shortcut menu in the Graphic Display window:

- If you select **Hide Feature** for a feature, PC-DMIS hides the feature and its ID in the Graphic Display window and Summary Mode turns off the **Show / Hide** button.
- If you select **Hide ID** for a feature, PC-DMIS hides the ID of a feature in the Graphic Display window but Summary Mode does not turn off the **Show / Hide** button.

Search and Filter Toolbar

You can use the **Search and Filter** toolbar to find specific features, dimensions, commands, or any other data in your measurement routine.

The **Search and Filter** toolbar is available only in the Summary Mode.

Search and Filter Toolbar

Filter by Text (Search)

You can type characters in the **Search** box to dynamically filter items in the Edit window according to the typed text. To clear the filter, click the **Remove** button. PC-DMIS displays the number of search results in the Edit window below the Search bar.

Filter by Text (Search)

To clear the Search box, click the **Clear Search** button.

Filter by Advanced Search

For more complex searches, you can use the **Advanced Search** option. This option allows you to type a string or expression into the **Search** box and, along with various filter options, display the resulting matches in the Edit window.

The available filtering options are:

- **Pattern match** - This option allows you to use special notations and characters in the **Search** box to define patterns of text to match items defined in your measurement routine. For more information, see "Pattern Match".

- **Match case** - This option defines whether to perform a case-sensitive search or not.
- **Match whole word only** - This option defines whether the search returns whole-word matches.

When you select the check box for any of the above advanced search options, PC-DMIS changes the search icon to show this icon .

> You cannot use the **Pattern match** option with the **Match whole word only** option.

Filter by Dimension

You can use the **Filter** button ( ) to filter according to dimension type. You can select multiple dimensions for your filter.

Filter by Dimension

For information on the available dimension types, see "Dimension Toolbar".

When you filter by dimension type, a small **Clear Filter** icon ( ) appears on top of the **Filter** button.

You can click the **Clear Filter** icon ( ) to clear all the dimension filters.

You can use a combination of filters to filter by text and by dimension at the same time. Suppose you want to search for all circle features that have a Position dimension in your measurement routine. To do this, follow these steps:

1. In the **Search** box, type "CIR". PC-DMIS filters the commands to show all the circles that start with a feature ID "CIR".
2. Click the **Filter** button ( ) to see the list of dimension types.
3. Select **Position Dimension** .

PC-DMIS displays all the circles with the Position dimension.

Pattern Match

With the **Pattern Match** option, you can search and filter your Summary Mode text using regular expressions.

Regular expressions provide a powerful, flexible, and efficient method to find text that matches a pattern that you define.

Pattern matches are case insensitive unless you choose **Match case** from the advanced options.

Common Operators for Expressions

The table below has a few common operators that you can use to build your search expression.

- You can combine multiple operators together in your search expression.
- The highlighted text in the Examples column below indicates matched text.

Operators	Description	Examples
.	Use this operator to match any single character, except a newline character.	c.r matches "**CIR**1", "**CIR**2", "**Car**", and "**Cor**osive" but not "Cody".
*	Use this operator to match zero or more instances of the preceding token or character. This matches as many characters as possible (greedy). • Precede this character with . to match one or more instances of any character. • Follow this character with ? to match as few characters as possible (lazy).	C*r matches “CI**R**1” and “SPHE**R**E1” In the phrase “CIR1 CIR2”, c.*r matches “**CIR1 CIR**2” (greedy) But c.*?r matches “**CIR**1 CIR2” (lazy)
+	Use this operator to match one or more instances of the preceding token or character. As discussed in the row above, you can follow this with ? to make the search lazy and match as few characters as possible.	L+1 matches "E**LL1**" and "CY**L1**" but not "CYL2"
^	Use this operator to match the beginning of a line followed by the text that begins the line.	^cir matches “**CIR**1 = CIRCLE(CONTACT)” but not “FCFCIRTY1 Passed : CIR1”.

$	Use this operator to match text that is at the end of a line. You must place the text that you want to search before this operator.	And$ matches “MOVESET1 = MovesetComm**and**”.
[a-f]	Use square brackets to match any single character from a range of characters within the brackets.	S[i-t] matches “**St**art”, “**So**rt”, and “**Si**ze” but not “Sam”.
|	Use this operator to match either of the strings on either side of the operator. This works similarly to an “or” function.	Active (Workplane|Tip) matches "**Active Workplane**" and "**Active Tip**" but not "Active Role".
\	Use this operator to suppress special meaning in any character or token after the operator.	\+ matches the text “ASSIGNMENT(V1 = 10**+**5)” rather than treating the + character as a regular expression operator.
\w	Use this operator to match any single character in a whole word.	Mo\we matches “Mode” and “Move” but not “Motor”.
\s	Use this operator to match any whitespace character.	Manual\sMode matches “**Manual Mode**” but not “Manual-Mode”.
\d	Use this operator to search any decimal digit character.	t\d matches “**T1**A0B0” but not “tip” or “top”

?	Use this operator to match the preceding token zero or once. (In essence, this makes the preceding token optional.) You can also use this token to make a search lazy (non-greedy). See * and + above.	m\w+? matches “co**mm**and” and “Align**me**nt”. \+?2 matches “3 **+ 2**” and “3**2**”.
(lar)	Use parentheses to group the characters within them together as a single token.	c.rc.(lar)? matches “**circ**le” and “**circular**” and “**circu**mference”.

Regular expressions can be difficult to understand and the information here provides some basics. For additional information and examples on regular expressions, we invite you to consult trusted resources on the Internet.

- This site provides examples and additional information: Microsoft | Learn : Use regular expressions in Visual Studio
- This site may be useful to help you test and create your own regular expressions: Regular Expressions 101

Using the Peek Window

The Peek window displays a command's information when you hover over the command in the Edit window. This feature enables you to quickly identify a command's properties and become accustomed to the command's language.

The Peek window automatically updates with the properties of the command that you point to. You do not need to click on the command to update the information in the Peek window.

Hits do not appear for features in the Peek window. For a group, only the first line of the commands in that particular group appears in the Peek window.

To use the Peek window, follow these steps:

1. Access the Edit window. For help, see "Using the Edit Window: Introduction".
2. Place the Edit window in Summary Mode. For help, see "Working in Summary Mode".

3. To enable the Peek window, mark the **Show Peek Window** check box on the **General** tab in the **Setup Options** dialog box. (The Peek window is enabled by default.) For help, see "Show Peek Window".

   In Summary Mode, you can also select the **Peek Window** icon ( ) from the **Settings** icon ( ) in the Edit window to enable the Peek window.

4. To use the Peek window, position your mouse pointer over a command. The Peek window aligns to the center of the command.

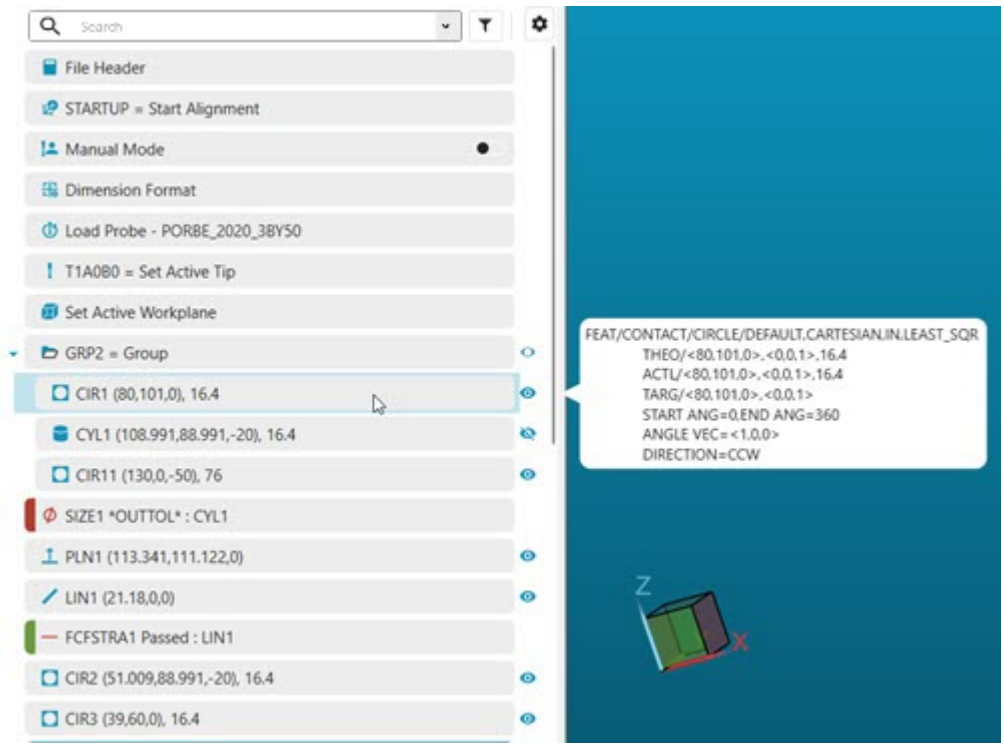
   If you move the mouse pointer, the Peek window becomes transparent with no text in it. The transparent Peek window enables you to see the application through it. The transparent window follows the mouse up and down the commands in the Edit window until you stop and hover over a command. At this point, the Peek window becomes active again and displays the command's information.

5. Execute your measurement routine.

   In Summary Mode, PC-DMIS displays an icon that indicates the execution status. For more information, see "Marking and Unmarking Commands in Summary Mode".

6. To close the Peek window, do one of the following:

   - Select a command.
   - Close the Edit window.
   - Move your mouse pointer to another area in PC-DMIS.
   - Press any sequence of keys.
   - In Summary Mode, select the **Peek Window** icon ( ) from the **Settings** icon ( ).



Example of an active Peek window.

Summary Mode Shortcut Keys

The following list shows the available keyboard functions:

- Shift + Tab - Moves the insertion point up one line.
- Ctrl + Click on feature in Graphic Display window - Moves the insertion point to the corresponding command item in the Edit window.
- Ctrl + A - Selects all of the commands in the Edit window.
- Ctrl + C - Copies text or objects to the Clipboard.
- Ctrl + End - Moves the cursor to the end of the measurement routine.
- Ctrl + Home - Moves the cursor to the beginning of the measurement routine.
- Ctrl + Q - Displays the **Execution** dialog box and automatically executes the measurement routine.
- Ctrl + V - Pastes the Clipboard contents. If you selected a field that can take a value, it pastes the text in that field. If a command has been cut or copied, it pastes the command after the current selected command.
- Ctrl + X - Cuts any selected text from a field that can take a value and stores it in the Clipboard. If you've selected a command, it cuts that command and stores it in the Clipboard.

- Ctrl + Y - Displays the **Execution** dialog box after you cancelled the execution and allows you to continue execution of the measurement routine from that specified location.
- Delete - Deletes any selected characters from a field that can take a value. If a command or command block is selected, and you can normally delete it, this function deletes it.
- Double-click - Opens a dialog box for the currently selected command if a corresponding dialog box exists for the command. If it's a group item, PC-DMIS expands and collapses a group item. You can also double-click on the `MODE` command in the Edit window to switch between the DCC Mode and Manual Mode.
- Down Arrow - Moves the insertion point down one line.
- F3 - Marks a single feature for execution. It also marks and unmarks multiple selected commands.
- F9 - Opens a dialog box for the currently selected command if a corresponding dialog box exists for the command. (For the `MODE` command in the Edit window, this key switches between the DCC Mode and Manual Mode. You can also double-click on a `MODE` command to switch between the two modes.)
- Page Down - Moves the insertion point down one page.
- Page Up - Moves the insertion point up one page.
- Shift - Facilitates selecting a block of objects. Select an object, hold Shift, and then click again to select a range of objects.
- Tab - Moves the insertion point down one line.
- Up Arrow - Moves the insertion point up one line.
- Left Arrow - Collapses an expanded command or group.
- Right Arrow - Expands a collapsed command or group.
- Alt + Backspace - Undo. Undoes the last edit made.
- Shift + Backspace - Redo. Redoes the last undone edit.

Related Topics

Using Shortcut Keys and Shortcut Menus

Working in Command Mode

Command Mode allows you to insert or edit a wide variety of PC-DMIS commands into the Edit window and to work with the Edit window in a pure textual format. To place the Edit window in Command Mode, select **View | Command Mode**, or from the **Edit Window** toolbar, click the **Command Mode** icon .

The main features or commands that you can add to the Edit window include:

- Constructed Features
- Dimensions
- Statistical Data
- Alignment
- Measured Features
- Hits
- Motion Commands
- Move Commands
- Sheet Metal Measurements
- Probe
- Comments
- Tracefields
- Expressions
- Screen Captures
- Global Commands
- Command Mode Shortcut Keys

You can also determine which commands get displayed in Command Mode. For additional information, see "Command Mode Display Options" in the "Setting Your Preferences" chapter.

Constructed Features

PC-DMIS allows you to create specified features from existing features. Additional information including specific rules for constructing features can be found in the "Constructing New Features from Existing Features" chapter.

PC-DMIS supports the construction of the following features:

- POINT
- CIRCLE
- ELLIPSE
- SPHERE
- LINE
- CONE
- CYLINDER
- PLANE
- SLOT
- CURVE
- SURFACE
- FEATURE SET
- GAUSSIAN FILTER SET

Dimensions

Dimension commands allow you to dimension features or the relationship between features. You can find additional information regarding the calculation of dimensions in the "Using Legacy Dimensions" chapter.

Dimension Format

Only if you mark a dimension for printing does the data appear on the inspection report. The `FORMAT` command allows you to create more than one dimensional format within a measurement routine. This allows you to show or hide the information stored in any dimension that follows the `FORMAT` command.

For example, for some dimensions, you may not want the nominals printed, such as with certain types of zone tolerances that always have a nominal of zero. In these cases, you can hide the `NOM` field. Later in the measurement routine you might want to display the nominals for a different type of dimension, such as Location or Position. The `FORMAT` command lets you control these manipulations.

The default `FORMAT` command prints out all of the columns and column headings. It also creates the statistics XSTATS11.TMP file.

For details on the locations of PC-DMIS files, see "Understanding File Locations".

- To hide an item, move your pointer over a field, once it turns into region you can click, select the empty item at the bottom of the list of options.
- To show an item, type it in the field and press Tab.

You can also press F8 or F7 to toggle the field values.

Command line in the Edit window:

```
FORMAT/
TEXT,OPTIONS, ,HEADINGS,SYMBOLS, ;NOM,TOL,MEAS,DEV,OUTTOL, ,
```

TEXT = This field controls whether or not additional text appears in the dimension's command block.

HEADINGS = This field controls whether the dimensions that follow the `FORMAT` command will have column headings above the numbers.

OPTIONS = This field controls whether or not option fields are displayed. These options include the following:

GRAPH = This shows or hides graphical analysis of the dimension.

TEXT = This shows or hides textual analysis of the dimension

MULT = This sets the multiplier for deviation arrows and tolerance zone used in the Graphic Display window. This is only used if GRAPH = YES.

OUTPUT = This determines where to send dimensional output. Options are statistics, report, both statistics and report, or none.

ID = This shows or hides the dimension's ID in the header.

SYMBOL = This field controls whether the deviation symbols will be printed. This field can be toggled on or off. A blank field indicates that this command is off.

SD = This shows or hides the dimension's standard deviation value.

NOM,TOL,MEAS,MAXMIN,DEV,OUTTOL,DEVANG = These fields appear after the semi-colon character (;). They control which columns get printed for dimensions following the `FORMAT` command. You can toggle any combination of these columns on or off. They can also be displayed in any order. Simply type the desired command in the order needed. (The order is displayed numerically in the **Parameters Dimension** dialog box.)

For more information consult the "Using Legacy Dimensions" chapter.

Available Dimensions

To edit these dimensions, view their individual sections in the "Using Legacy Dimensions" chapter.

Analysis

To edit the Analysis information, see the "Inserting Report Commands" chapter.

Statistical Data

To include and edit statistical data, see the "Tracking Statistical Data" chapter.

Alignment

The **Alignment** option allows you to recall or create a new coordinate system.

Alignment Commands

For more information on how to use these alignment commands in the Edit window, see the individual topics in the "Creating and Using Alignments" chapter.

CAD Equals Part

For more information on how to use the **CAD Equals Part** command in the Edit window, see "Equating CAD to Measured Part Data" in the "Creating and Using Alignments" chapter.

Equate Alignment

For more information on how to use Equate Alignment command in the Edit window, see "Equating an Alignment" in the "Creating and Using Alignments" chapter.

Measured Features

You can insert commands that create the following measured features:

- Measured Point
- Measured Line
- Measured Plane
- Measured Sphere
- Measured Cylinder
- Measured Cone
- Measured Circle

These features, along with information about measured features in general, are discussed in the "Creating Measured Features" chapter.

Hits

This command targets the location for actual touches by the probe.

Basic Hit

```
HIT/BASIC,x,y,z,i,j,k,x,y,z,USE_THEO=YES/NO
```

This is the simplest hit format. See "Understanding the Command Format" in the "Creating Measured Features" chapter for more information.

Sheet Metal Hits

```
HIT/type,x,y,z,i,j,k,x,y,z
```

type = VECTOR, SURFACE, EDGE, CORNER, ANGLE

There are five available types of sheet metal hits. The Sheet Metal package must be installed for this option to be available. (See "Sheet Metal Measurements".)

Adding Hit Lines

To add a hit line, place the cursor in the desired location and press the Enter key. Begin by typing the command **HIT**. Press the Tab key. PC-DMIS adds the new line depending on where the cursor is located. If the cursor is in the middle of a command, a new line is

created below the current line. If the cursor is placed anywhere within the first four lines PC-DMIS creates the new line immediately after the measured line.

Deleting Blank Lines

To delete a blank line press the Down Arrow or Enter key. The line may also be highlighted and deleted. (See "Command Mode Keyboard Functions".)

Motion Commands

The various Motion commands control the movement of the machine. All but the FASTPROBEMODE command are discussed in greater detail in the "Parameter Settings: Motion tab" and the "Parameter Settings: Optional Motion tab" topics of the "Setting Your Preferences" chapter.

Mode = MANUAL / DCC

```
MODE/MANUAL (or DCC )
```

This command allows you to select between Manual Mode and DCC Mode.

Prehit Distance

```
PREHIT/nnn.nnnn
```

This command determines the distance away from the theoretical hit location on the surface where PC-DMIS begins to search for the part. The machine travels at touch speed while traversing this distance to search for the part.

`nnn.nnnn` represents a number value for the machine prehit distance.

For additional information, see the "Prehit Distance" topic in the "Setting your Preferences" chapter.

```
MOVESPEED/nnn.nnnn
```

`nnn.nnnn` represents a number value for the speed. This command changes the point to point positioning speed of the CMM. Depending on the state of the **Display absolute speeds** check box in the **Part/Machine** tab of the **Setup Options** dialog box (**Edit |**

Preferences | Setup), this is either an absolute speed (mm/sec) or a percentage of the machine's total speed capability.

Touch Speed

```
TOUCHSPEED/nnn.nnnn
```

`nnn.nnnn` represents a number value for the speed. This command changes the speed at which the CMM takes hits. Depending on the state of the **Display absolute speeds** check box in the Part/Machine tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**), this is either an absolute speed (mm/sec) or a percentage of the machine's total speed capability.

Scan Speed

```
SCANSPEED/nnn.nnnn
```

`nnn.nnnn` represents a number value for the speed. This command changes the speed at which the CMM scans the part. Depending on the state of the **Display absolute speeds** check box in the Part/Machine tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**), this is either an absolute speed (mm/sec) or a percentage of the machine's total speed capability.

Retract Distance

```
RETRACT/nnn.nnnn
```

`nnn.nnnn` represents a number value for the distance. This command determines the distance the machine will move away from the actual hit location before going from "Touch Speed" to "Move Speed".

How the probe retracts depends on the CMM controller:

- **Some controllers handle the retract internally.** After a hit, the controller automatically retracts the probe, but it may only know the prehit distance, not the retract distance. In these cases, the controller retracts the probe to the prehit standoff, and PC-DMIS then issues an additional move to reposition the probe at the retract distance. If the retract distance is less than or equal to the prehit distance, the probe remains at the prehit standoff; PC-DMIS does not move the probe back toward the part after the controller's retract. *The retract value takes effect only when it is greater than the prehit.*
- **Some controllers do not retract on their own.** In these cases, PC-DMIS issues the move to perform the retract, and the distance is based on the probe tip's ball surface to the part's theoretical hit location.

When the controller does perform its own retract, the distance may be calculated from either the ball surface or the ball center to either the theoretical or measured hit location, depending on the particular controller.

Check Distance

```
CHECK/nnn.nnnn,p.pp
```

This command determines the distance in inches or millimeters (depending on the system of measurement that was initially set up for the particular measurement routine) past the theoretical hit location that the machine will continue to search for the surface of the part until it determines the surface is not there.

nnn.nnnn:

This represents the check distance.

p.pp:

This represents the percentage of the total check distance that PC-DMIS moves when performing a Find Hole operation. The default value is 1 which means 100% of the check distance. Thus .1=10%, .2=20%, .3=30% etc. This only functions with Find Hole operations.

- If PC-DMIS finds a surface within the specified check distance, it takes a hit.
- If no surface is found, PC-DMIS displays an error message that it has encountered an unexpected end of move.

If you enter .3 inches as the check distance, PC-DMIS moves 0.3 inches past the theoretical surface, searching for a surface on which to take the hit.

For additional information, see the example in the "Check Distance" topic in the "Setting your Preferences" chapter.

Using Fast Probe Mode

Use the **Insert | Parameter Change | Probe | Fast Probe Mode** menu item to insert a `FASTPROBEMODE/OFF` command into the Edit window. To enable Fast Probe Mode, after you insert this command, highlight OFF and press F8 to change it to ON.

This probing mode applies to analog scanning probes when taking individual hits rather than scanning. When it is ON, it provides a significant reduction in the time required to take individual hits. The biggest reduction in time occurs when the probe retracts from the part.

Some probe types (such as the SP25) do not support Fast Probe Mode. Some machines do not support Fast Probe Mode regardless of the probe type. If you have a measurement routine with the `FASTPROBEMODE/ON` command in it, but your probe type or machine does not support it, the command does nothing.

Move Commands

The commands listed below provide you with the ability to alter the movement of the probe between hits.

```
MOVE/POINT
MOVE/INCREMENT
MOVE/CLEARPLANE
MOVE/CIRCULAR
MOVE/SYNC
MOVE/SWEEP
MOVE/ROTAB
MOVE/EXCLUSIVE_ZONE
```

These are described in the "Inserting Move Commands" chapter.

Sheet Metal Measurements

Sheet metal measurements, also known as "Auto Features", are available only as an additional option to the basic PC-DMIS geometric software package. For more information, see the "Creating Auto Features" chapter in the PC-DMIS Core documentation. This option provides several alternative methods for taking hits. The available sheet metal features are listed below. When applicable, you can update the **Number of Hits**, **Number of Rows**, **Spacer**, and **Indent** values. The required minimum value appears as the default.

The following sheet metal measurements are available:

- Auto Vector Point
- Auto Line
- Auto Plane
- Auto Circle
- Auto Ellipse
- Auto Notch Slot
- Auto Round Slot
- Auto Angle Point
- Auto Corner Point
- Auto Edge Point
- Auto High Point
- Auto Surface Point
- Auto Square Slot
- Auto Cylinder
- Auto Cone
- Auto Sphere

Probe

The following commands allow you to access options that affect the probe. These commands allow you to change the active tip in a probe cluster or change the position of the rotating probe head. Probe compensation can also be turned on or off as needed.

Load Probe

```
LOADPROBE/<probe name>
```

In the Load Probe command, <probe name> represents a user editable field that allows you to load a file of qualified probe tips to be used within the measurement routine. For example, `LOADPROBE/TESASTAR` loads a probe named TESASTAR.

The **File | New** and **File | Open** menu options are unavailable while a probe change is in progress. This protects your hardware by preventing you from opening or creating a measurement routine that could power on a laser sensor and damage the probe mounted on the head.

You can only load probe files made in valid versions of PC-DMIS. For this version of PC-DMIS, if you attempt to load a probe file created before PC-DMIS version 2021.1, PC-DMIS shows an error message.

Example error message when you try to load an invalid probe file:

PC-DMIS Message

PC-DMIS cannot read this probe file <probe file>. This happens because of these reasons: It may be corrupt. It may come from a newer version. It may come from an unsupported earlier version. The earliest supported version is 2021.1.

Where <probe file> is the name and location of the file you are trying to open.

Probe Comp

```
PROBECOM/ON (or OFF)
```

The Probe Comp command allows you to turn probe compensation on or off. It is considered ON if the command is displayed in the Edit window.

Read Point

For information, see "Creating a ReadPoint from the Probe's Position" in the "Creating Generic Features" chapter.

Tip

The tip command tells PC-DMIS to use the specified probe tip.

```
TIP/T1A0B0, SHANKIJK=0, 0, 1, ANGLE=0
```

The `SHANKIJK` is just another vector form of specifying the A and B angles for the tip.

The `ANGLE` specifies the angle that the tip transformation matrix is rotated about the shank vector.

Comments

This option allows you to display comments during the execution of the measurement routine, or to send the comments to the inspection report. These comments are created using the **Insert | Report Command | Comment** menu option. The **Show Comments** option also allows you to add, edit, or delete operator notes and inspection report comments within the Edit window. The `COMMENT` command switches between the options `OPER`, `REPORT`, `YESNO`, `$$`, `INPUT`, and `READOUTS`.

After you insert a PC-DMIS comment, to type additional PC-DMIS commands in Command Mode, you must first press Enter *twice* after the `COMMENT` command. This tells PC-DMIS that you no longer want to add text to the comment but are ready to add a new command.

When you open a measurement routine that was saved from a later version, any commands that are not supported in the current version will show up as DOC comments.

For more information on comments, see the "Inserting Programmer Comments" topic in the "Inserting Report Commands" chapter.

Operator

This option displays a message to the operator when the measurement routine is executed.

You can type directly into the Edit window:

1. Type the command `COMMENT/OPER` in the desired location of the Edit window.
2. Type in the desired text you want to display to the operator, and press Enter.

You can also access this option through a dialog box:

1. Select **Insert | Report Command | Comment** from the menu bar to show the **Comment** dialog box.
2. Then select **Operator**.
3. In **Comment Text**, type your text to display.
4. Click **OK**.

When the operator executes the measurement routine with this command, a message displays the comment to the operator.

You can press F9 while the cursor is in a `COMMENT/OPER` command line to display the **Comments** dialog box, allowing you to alter the displayed message.

Command line in the Edit window:

```
COMMENT/OPER,NO,Full Screen=YES,

comment text
```

For more information on comments, see the "Inserting Programmer Comments" topic in the "Inserting Report Commands" chapter.

Report

This option sends text to the inspection report when the measurement routine is executed. Type the command `COMMENT/REPT` in the desired location of the Edit window. Type in the desired text, and press Enter. You can also access this option by selecting **Insert | Report Command | Comment** from the menu bar to show the **Comment** dialog box. Then select **Report**.

When the operator executes the measurement routine, PC-DMIS does not display these messages during execution. However, it does send them to the inspection report.

If you press the F9 key while the cursor is in a `COMMENT/REPT` command line, PC-DMIS displays the **Comments** dialog box, allowing you to alter the displayed message.

Command line in the Edit window:

```
COMMENT/REPT,
```

```
comment text
```

For more information on comments, see the "Inserting Programmer Comments" topic in the "Inserting Report Commands" chapter.

Input

This option is similar to Operator in that it allows you to display text when you execute a measurement routine. In addition to displaying a message, a comment box appears so the operator can type information that is then written to the inspection report.

Type the command `COMMENT/INPUT` in the desired location of the Edit window. Type in the desired text. The input from the operator is assigned to the Comment ID and is accessible via an expression reference (such as `C1.INPUT` for example).

You can also access this option by selecting **Insert | Report Command | Comment** from the menu bar to open the **Comment** dialog box. Then select **Report**.

Pressing the F9 key while the cursor is in a `COMMENT/INPUT` command line displays display the **Comments** dialog box, allowing you to alter the displayed message.

Command line in the Edit window:

```
comment ID=COMMENT/INPUT,NO,Full Screen=NO,
            comment text
```

For more information on comments, see the "Inserting Programmer Comments" topic in the "Inserting Report Commands" chapter.

$$ (Document)

This option provides you with the ability to document (add programmer comments to) the internal measurement routine. It will not display any text when executing the measurement routine. Visually, this command does not have the usual COMMENT prefix to the command in the Edit window. This is done to help the comment stand out inside the Edit window.

Command line in the Edit window:

```
$$ NO,
          comment text
```

To type a document comment directly into the Edit window:

1. Type COMMENT and press Tab. PC-DMIS highlights the OPER field.

2. Type $$ and press Tab or Enter.

You select **Insert | Report Command | Comment** from the menu bar to show the **Comment** dialog box. Then, from the **Comment type** area, select **Document**.

When you open a measurement routine that was saved from a later version into the current version, any commands that are not supported in the current version show up as DOC comments. See "Save As" in the "Using Basic File Options" chapter.

For more information on comments, see the "Inserting Programmer Comments" topic in the "Inserting Report Commands" chapter.

Yes / No

This option displays a message box with a question and **YES / NO** buttons when the measurement routine is executed.

1. Type the command `COMMENT/YESNO` in the desired location of the Edit window.
2. Type in the desired question that you want to display to the operator, and press Enter.

You can also access this option by selecting **Insert | Report Command | Comment** from the menu bar to show the **Comment** dialog box. Then select **Yes / No**.

The response to the YES / NO question appears in the measurement routine. The text 'YES' or 'NO' is associated with the comment identification and is available in any expression via a reference to the Comment ID (such as C1.INPUT for example).

Command line in the Edit window:

```
comment ID = COMMENT/YESNO,NO,Full Screen=NO,
             comment text
```

For more information on comments, see the "Inserting Programmer Comments" topic in the "Inserting Report Commands" chapter.

Readouts

This option allows you to display text inside the Probe Readouts window when you execute the measurement routine. Type the comment `/READOUTS` in the desired location of the Edit window. Type in the desired text you want to display in the Probe Readouts window, and press Enter. You can also access this option by selecting **Insert | Report**

Command | Comment from the menu bar to show the **Comment** dialog box. Then select **Readouts**.

If you press the F9 key while the cursor is in a `COMMENT/READOUTS` command line, PC-DMIS displays the **Comments** dialog box, allowing you to alter the displayed message.

The Edit window command line for this option reads:

```
COMMENT/READOUTS,
                comment text
```

For more information on comments, see the "Inserting Programmer Comments" topic in the "Inserting Report Commands" chapter.

Tracefields

PC-DMIS uses tracefields to send additional information into your statistical database along with your measurement results. The **Insert | Statistics Command | Trace Field** menu option opens the **Trace Field** dialog box.

For more information about tracefields, see "Using Tracefields".

Expressions

You can insert expressions into most of PC-DMIS's editable fields. See the "Using Expressions and Variables" chapter.

Screen Captures

You can insert a `DISPLAY/METAFILE` command to insert screen captures of the Graphic Display window into your report. See the "Inserting Screen Captures" topic in the "Inserting Report Commands" chapter.

Global Commands

The table below defines the list of global commands available in the Edit window. While you cannot alter these commands, the Edit window does allow you to select the minor commands following these major commands.

To select the minor commands, do the following:

1. Press the Tab key to select the minor command in the Edit window.
2. Press F7 or F8. This toggles through the available choices.

This list serves as a comprehensive summary of the commands that can be added to a measurement routine. See each specific section for more information as necessary.

The maximum number of characters that PC-DMIS can manage within any line of the Edit window is 280.

MAJOR COMMAND	MINOR COMMAND
2DANGLE (see "Dimensioning Angle")	A
2DDISTANCE (see "Dimensioning Distance")	M
3DANGLE (see "Dimensioning Angle")	A
3DDISTANCE (see "Dimensioning Distance")	M
ALIGNMENT (see the "Creating and Using Alignments")	BF2D, BF3D, ITERATE, LEVEL, ROTATE, TRANS, ROTATE_OFFSET, TRANS_OFFSET, RECALL, RECALL_EXTERNAL
ANGULARITY (see "Dimensioning Angularity")	M
ANALYSISVIEW (see "Analysis area")	
ARRAY INDICES (see "Arrays")	
ASSIGN (see "Using Variables with Expressions")	
ATTACH (see "IDs for features within subroutines, basic scripts, or external routines")	

AUTO (see "Sheet Metal Measurements")	VECTOR POINT, SURFACE POINT, EDGE POINT, CORNER POINT, ANGLE POINT, HIGH POINT, SPHERE, CIRCLE, CYLINDER, SQUARE SLOT, ROUND SLOT, CONE, ELLIPSE, NOTCH, CONE
AUTOTRIGGER (see "Parameter Settings: Probe Trigger Options tab")	
CAD EQUALS PART (see "CAD Equals Part")	
CALCULATION	
CALLSUB (see "Calling a Subroutine")	
CASE (see "Case / End Case")	
CHECK (see "Check Distance")	
CLEARP (see "Parameter Settings: Clearance Plane tab")	"WORK PLANE VALUE"
CLAMP (see "Clamping Value")	
COLUMN132 (see "Dimensions")	

COMMENT (see "Comments")	OPER, REPT, INPUT, $$, YESNO, READOUTS After you insert a PC-DMIS comment, to type additional PC-DMIS commands in Command Mode, you must first press Enter *twice* after the `COMMENT` command. This tells PC-DMIS that you no longer want to add text to the comment but are ready to add a new command.
CONCENTRICITY (see "Dimensioning Concentricity")	M
CONST (see "Constructed Features")	CIRCLE, CONE, CURVE, CYLINDER, ELLIPSE, LINE, PLANE, POINT, SET, SURFACE, SPHERE
CIRCULARITY (see "Dimensioning Circularity")	
CYLINDRICITY (see "Dimensioning Cylindricity")	
DEFAULT_CASE (See "Default Case / End Default Case")	
DISPLAY (see "Screen Captures")	METAFILE
DO (see "Do / Until")	
ELSE (see "Else / End Else")	
END_ELSEIF (See "Else If / End Else If")	

ELSE_IF (see "Else If / End Else If")	
END_CASE (see "Case / End Case")	
END_DEFAULTCASE (see "Default Case / End Default Case")	
END_ELSE (see "Else / End Else")	
END_IF (see "If / End If")	
END_SELECT (see "Select / End Select")	
END WHILE (see "While / End While")	
ENDSUB (see "Branching with Subroutines")	
EQUATE (see "Equate Alignment")	
EXTERNALCOMMAND (see "Inserting External Objects")	
FILE (see "Using File Input / Output")	OPEN, MOVE, EXISTS, DIALOG, DELETE, COPY, CLOSE, WRITE_CHARACTER, WRITE_BLOCK, WRITELINE, SAVE_POSITION, REWIND, RECALL_POSITION, READ_UPTO, READ_CHARACTER, READ_BLOCK, READLINE
FLATNESS (see "Dimensioning Flatness")	M

FLY (see "Machine area")	
FORMFEED (see "Inserting a Form Feed Command")	
FORMAT (see "Dimension Format")	HEADINGS,STATS
GAPONLY (see "Dimensioning Location")	ON
GENERIC (see "Creating a Generic Feature")	POINT, PLANE, NONE, LINE, CYLINDER, CONE, CIRCLE, SQUARE_SLOT, SPHERE, ROUNDSLOT
GO TO (see "Jumping to a Label Using GoTo")	
HIT (see "Hits")	BASIC, ANGLE, VECTOR, SURFACE, EDGE, CORNER
IF (see "If / End If")	
KEYIN (see "Dimensioning through Keyboard Input")	M
LABEL (see "Using Labels")	
LEITZPROBE	
LOADPROBE (see "Load Probe")	"FILE NAME"
LOCATION (see "Dimensioning Location")	A, D, M, PA, PR, R, T, X, Y, Z
LOOP (see "Creating a Loop")	START, END

MEAS (see "Measured Features")	CIRCLE, CONE, CURVE, CYLINDER, LINE, PLANE, POINT, SET, SLOT, SPHERE
MODE (see "Probe Mode Toolbar")	DCC, MANUAL
MOVE (see "Move Commands")	POINT, ROTAB, CIRCULAR, CLEARPLANE, INCREMENT, PH9 (X,Y,Z)
MOVESPEED (see "Move Speed")	% of overall machine speed
ONERROR (see "Branching on an Error")	Unexpected_hit, probe_miss
OPTIONMOTION (see "Parameter Settings: Probe Options tab")	
PARALLELISM (see "Dimensioning Parallelism")	M
PD	
PERPENDICULARITY (see "Dimensioning Perpendicularity")	M
POSITION (see "Dimensioning Position")	A, D, M, PA, PR, R, T, V, X, Y, Z
PREHIT (see "Prehit Distance")	"distance"
PROBECOMP (see "Probe Comp")	"ON, OFF"
PROFILE (see "Dimensioning Profile - Line or Surface")	

ROUTINE	END "ends the measurement routine at the command's location"
READPOINT (see "Read Point")	"xyz value of probe location"
RECALL (see "Recalling an Existing Alignment")	VIEWSET, ALIGNMENT (INTERNAL/ EXTERNAL)
RETRACT (see "Retract Distance")	"distance"
RETROLINEARONLY (see "Location Options")	ON, OFF
RMEAS (see "Setting Up Relative Measure (RMEAS)")	
RS	
RT	
RUNOUT (see "Dimensioning Runout - Circular or Total")	M
S	
SAVE (see "Saving an Alignment")	ALIGNMENT
SCANSPEED (see "Scan Speed %")	% of overall machine speed
SCRIPT (see "Inserting BASIC Scripts")	
SELECT (see "Select / End Select")	

STATS (see the "Tracking Statistical Data")	ON, OFF
STRAIGHTNESS (see "Dimensioning Straightness")	M
SUBROUTINE (see "Branching with Subroutines")	
TIP (see "Tip")	"file name"
TEMPCOMP (see "Compensating for Temperature")	
TOUCHSPEED (see "Touch Speed %")	"% of overall machine speed"
TRACEFIELD (see "Tracefields")	(field name : value)
UNTIL (see "Do / Until")	
WHILE (see "While / End While")	
WORKPLANE (see "Settings Toolbar")	TOP, BACK, BOTTOM, FRONT, LEFT, RIGHT

Command Mode Shortcut Keys

The following list shows the various keyboard functions available within the Edit window's Command Mode.

- Alt + F3
  Displays the **Search** dialog box.
- Shift + Tab or Ctrl + Left Arrow
  Moves the cursor backward to the last editable field.

- Ctrl
  Hold Ctrl and click on a feature in the Graphic Display window to move the cursor to the corresponding feature line in the Edit window. Hold Ctrl and double-click on a feature to select the entire feature.
- Ctrl + A
  Selects and highlights all the text in the Edit window.
- Ctrl + C
  Copies text or objects to the Clipboard. If you highlight text from a single field, that text is copied to the Clipboard. If more than one field is highlighted, then the entire object is copied to the Clipboard.
- Ctrl + E
  Executes selected features or the feature or operator comment command on which the cursor rests.
- Ctrl + End
  Moves the cursor to the end of the measurement routine.
- Ctrl + Tab
  Minimizes or restores the Edit window.
- Ctrl + Home
  Moves the cursor to the beginning of the measurement routine.
- Ctrl + Page Down
  Moves the cursor to the end of the file.
- Ctrl + Page Up
  Moves the cursor to the beginning of the file.
- Ctrl + Q
  Displays the **Execution** dialog box so you can execute the measurement routine.
- Ctrl + T
  Assigns the current command to the selected active arm.
- Ctrl + V
  Pastes the Clipboard's contents at the insertion point. If you only copied text, this attempts to paste the text. If you copied an entire object to the Clipboard, this attempts to paste the entire object. In the latter case, if the insertion point is in the first column of the Edit window on the first line of a command, the Clipboard object is placed before this object. In all other cases, the insertion is after the object.
- Ctrl + X
  Cuts any highlighted characters.
- Ctrl + Y
  Displays the **Execution** dialog box and resumes a paused execution.

- Ctrl + Shift + F

  This option toggles the display of selected feature commands and their IDs in the Graphic Display window. You can also use this on a GROUP command to toggle the display of features within the group.

- Delete or Backspace
  Deletes any highlighted characters. If nothing is highlighted, then both keystrokes function as in a normal editor.

- Double-click
  Highlights the editable field that the cursor is on.

- Down Arrow
  Moves the cursor down one line.

- F1
  Displays the Help topic for the command.

- F2
  Inserts an expression.

- F3
  Marks a single feature for execution. Multiple features can be marked simultaneously by highlighting them before selecting this command.

- F4
  Prints the entire contents of the Edit window.

- F5
  Displays the **Setup Options** dialog box.

- F6
  Displays the **Change all the fonts** dialog box.

- F7
  If the cursor is placed in a toggle field, this key switches the entry in the field forward to the next entry in the alphabetical list of allowed entries. If the end of allowed entries is reached, it cycles to the beginning of the list.

- F8
  If the cursor is placed in a toggle field, this key switches the entry in the field backward to the previous entry in the alphabetical list of allowed entries. If the beginning of allowed entries is reached, it cycles to the end of the list.

- F9
  Opens the dialog box for the command on which the cursor is residing when you press this key.

- F10
  Displays the **Parameter Settings** dialog box.
- F12
  Displays the **Fixture Setup** dialog box.
- Left Arrow
  Moves the cursor left one character.
- Page Down
  Moves the cursor down one page.
- Page Up
  Moves the cursor up one page.
- Right Arrow
  Moves the cursor right one character.
- Shift
  If you hold Shift and an arrow key is pressed, the text is highlighted as the cursor moves. Holding Shift and double-clicking on a start block or end block selects the entire command block.
- Shift + F10
  Displays the **Jump To** dialog box.
- Tab + Ctrl + Right Arrow
  Moves the cursor forward to the next editable field.
- Up Arrow
  Moves the cursor up one line.
- - (minus key) or Alt + -
  Removes the last hit from the hit buffer.
- End
  Inserts the measured feature into the measurement routine.

Related Topics

Using Shortcut Keys and Shortcut Menus

Working in DMIS Mode

DMIS Mode displays the Edit window commands in DMIS format. This means you can use the DMIS syntax to edit your measurement routines. To place the Edit window in DMIS Mode, select **View | DMIS Mode** or from the **Edit Window** toolbar, click the **DMIS Mode** icon ( ).

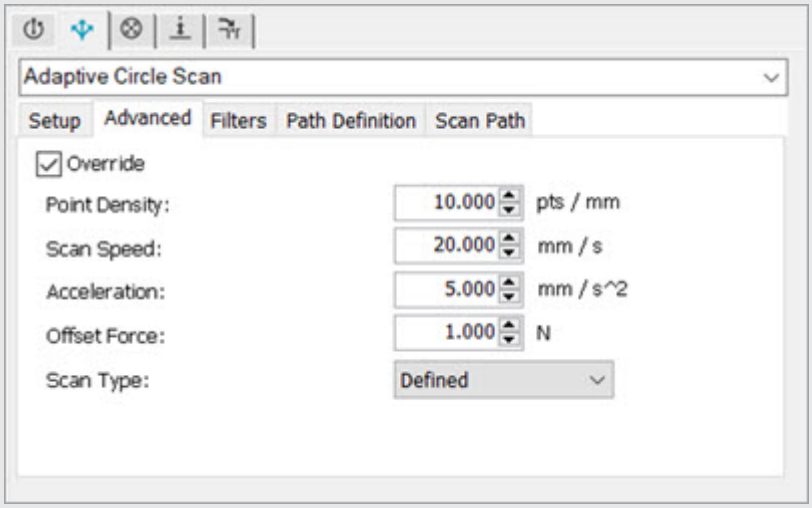
Most of the commands and features that you can add to your measurement routine from Command Mode you can also add from DMIS Mode. For information on how to insert or edit commands in DMIS Mode, see "Understanding Core Concepts".

For information on DMIS, see https://qifstandards.org/.

Copying and Pasting Parameters

The Copy Parameters and Paste Parameters functions help you copy parameters from one feature or dimension and paste them to another feature(s) or dimension(s) in the Edit window. For example, you can copy and paste the following:

- Feature parameters, such as NUMHITS and DEPTH
- Dimension parameters, such as OUTPUT, TEXT, and tolerances



Probe Toolbox Adaptive Scan Strategies tab for Adaptive Circle scan

For Auto features using Adaptive Scanning strategies, you can also use these scanning parameters for Copy and Paste:

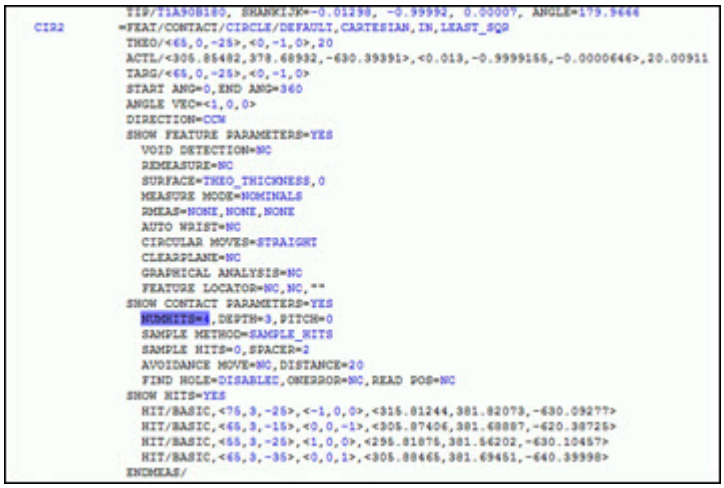
- Point Density
- Scan Speed
- Acceleration
- Offset Force

Nominal values, basic hit values, and vector component values are not parameters; therefore, you cannot copy and paste them.

Copying a Parameter

1. Use one of the following methods to select the parameter(s) that you want to copy:

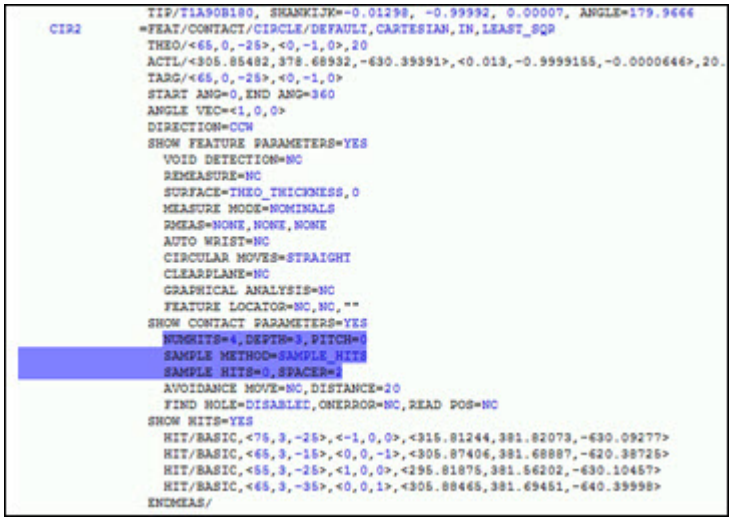
   - To select a single parameter, click anywhere on it or highlight it. For example:



Command Mode

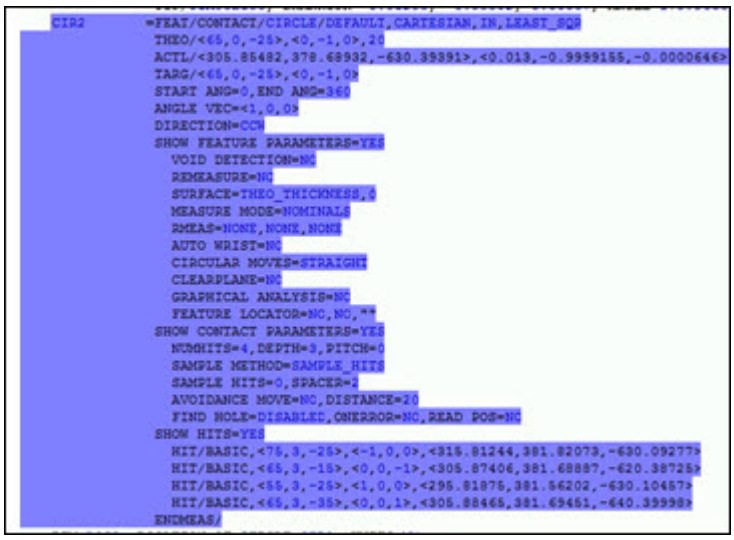
Summary Mode

   - To select multiple, continuous parameters for a single feature, click on the first parameter and then drag your mouse while holding the mouse button. For example:

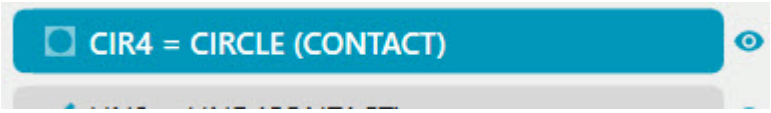


Command Mode

   - To select a complete feature to copy all of its parameters, hold down the Ctrl key and then drag your mouse. For example:



Command Mode



Summary Mode

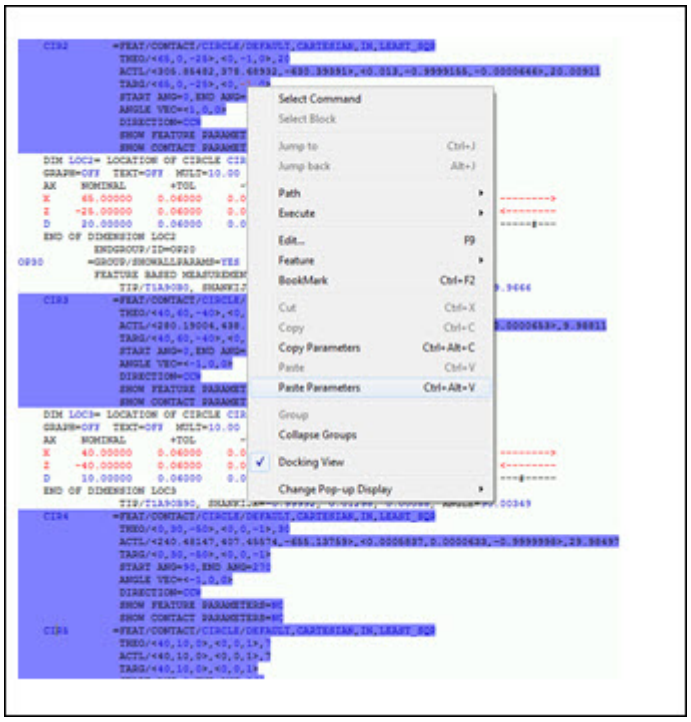
2. Use one of the following methods to copy the selected parameter(s):
    - Press Ctrl + Alt + C.
    - Right-click and select **Copy Parameters** on the shortcut menu.
    - Select **Edit | Copy Parameters**.

Pasting a Parameter

1. Use one of the following methods to select the feature to paste the copied parameter(s) to:
    - To select a single feature, click anywhere on the feature or dimension.
    - To select multiple, continuous features, click on the first feature and then drag your mouse while holding the mouse button. For example:

Command Mode

- To select multiple, non-continuous features, click anywhere on the feature, and then hold down the Ctrl key while clicking each non-continuous feature. For example:



Command Mode

2. Use one of the following methods to paste the selected parameter(s):

   - Press Ctrl + Alt + V.
   - Right-click and select **Paste Parameters** on the shortcut menu.
   - Select **Edit | Paste Parameters**.

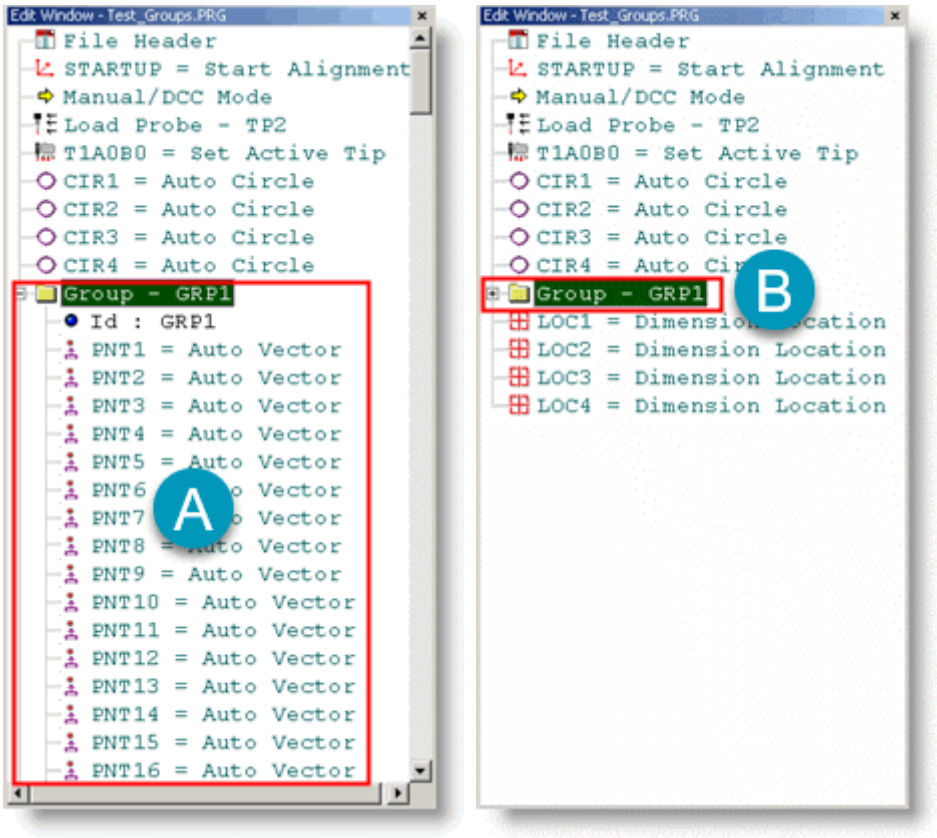
Working with User-Defined Groups

PC-DMIS lets you group contiguous Edit window commands together and place them inside of a user-defined `GROUP` / `ENDGROUP` command pair (in DMIS Mode, groups appear as DMISEW commands).

Grouped commands help simplify user interaction with a measurement routine by enabling you to apply operations on all commands inside the group, by applying them to the group itself. In addition, the measurement routine is visually less busy, enabling you to better visualize the overall structure of the measurement routine.

For example, suppose you have several hundred points in your measurement routine from a scan that you want to hide to make the overall structure of the measurement routine more visible and easier to work with. You can select all of the point commands as long as they are all in one list, and then select the **Insert | Group** menu item to group those commands together. In any mode of the Edit window, you can then show or hide the commands inside of the group as needed.

For example, in the images below, the left Edit window shows a group with the points expanded (A). The right Edit window shows a group with the points collapsed (B).



Groups appear in this format inside the Edit window in Command Mode:

```
GRP1 = GROUP/SHOWALLPARAMS = YES

    ... commands inside the group are listed
```

```
    ... between the two commands

ENDGROUP/
```

SHOWALLPARAMS = This toggle field let you show or hide commands inside of the group in Command Mode or DMIS Mode. By default, this command is set to YES, which shows all of the commands within the group. If you set it to NO, commands inside the group still exist, but are hidden.

Inserting Groups

When you insert your first group command into a measurement routine, PC-DMIS gives the command a default name of "GRP1" in Command Mode and DMIS Mode, and "GRP1 = GROUP" in Summary Mode. PC-DMIS then increments the number in the ID for each additional group. To easily modify the name of the group to something more descriptive, type a new ID in Command Mode or DMIS Mode, or press F9 and edit the GROUP command that way.

There are several different ways to insert groups into a measurement routine:

- **Insert | Group** menu item - This menu item inserts the `GROUP` and `ENDGROUP` commands. If you selected multiple commands before you selected this menu item, they would be placed inside of the group. In Command Mode and DMIS Mode, this means that the `GROUP` command would precede the very first selected command, and the `ENDGROUP` command would follow the last selected command. If you don't have any commands selected, PC-DMIS displays a dialog box that asks if you want to insert the command pair without any features inside it. This menu item works in any mode of the Edit window.
- Right-click shortcut menu -
  - Command Mode - Right-click inside Command Mode or DMIS Mode, and select **Group** from the shortcut menu. If you selected multiple commands before you selected this menu item, they would be placed inside of the group. In Command Mode and DMIS Mode, this means that the `GROUP` command precedes the very first selected command, and the `ENDGROUP` command follows the last selected command.
  - Summary Mode - Right-click inside Summary Mode, and select **Add Command**. From the list of commands that appears, select **Group**. This option inserts an empty `GROUP` / `ENDGROUP` command pair. Groups appear as folders inside Summary Mode. Commands appear indented inside those folders. To expand or collapse these groups, click the plus (+) or minus (-) buttons, respectively. The `ENDGROUP` is hidden in Summary Mode.
- Type the command - In Command Mode or DMIS Mode, type `GROUP` , and press Enter or Tab. PC-DMIS inserts an empty `GROUP` / `ENDGROUP` command pair.

PC-DMIS makes the **Group** menu item unavailable for selection if you try to group something that is not allowed, such as attempting to only group a portion of a command's block.

Feature Based Measurement

If your PC-DMIS license is programmed with the Feature Based Measurement (FBM) module, you will see an extended group command. For example:

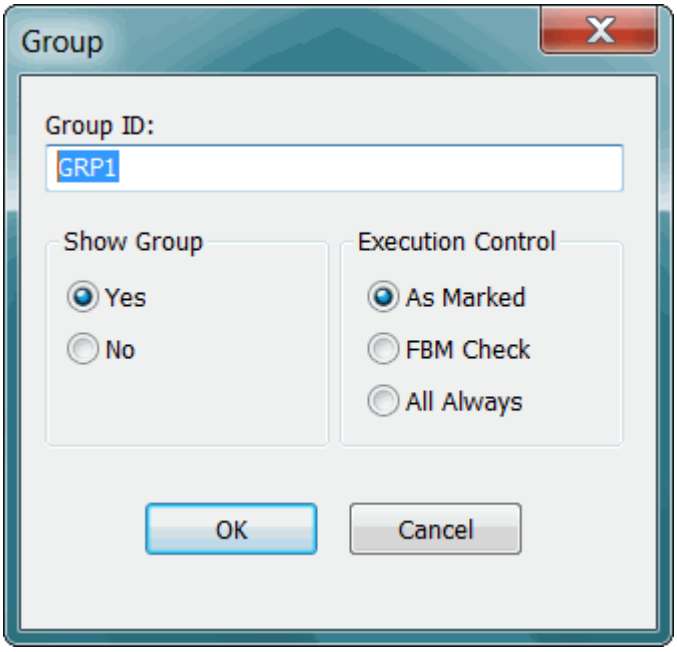
```
OP10          =GROUP/SHOWALLPARAMS=NO
               EXECUTION CONTROL=FBM CHECK
               ENDGROUP/ID=OP10
```

Example of the FBM extended group command.

PC-DMIS extends the `GROUP` command when you use the command with FBM. The group header displays an additional choice for execution control. For complete information, see "Mini Routines" in the PC-DMIS Core documentation.

Editing Groups

To edit a group, modify it directly in the Edit window. You can also press F9 on the `GROUP` command, or double-click on the command, and use the **Group** dialog box:



Group Dialog Box

- **Group ID** - Use this box to change the group's ID.
- **Show Group** area - If you select **Yes**, it sets the `SHOWALLPARAMS` entry to **TRUE** in the PC-DMIS Settings Editor. If you select **No**, it sets the `SHOWALLPARAMS` entry to **FALSE**.

- **Execution Control** area - This area of the dialog box is available only when the Feature Based Measurement (FBM) option is enabled on your PC-DMIS license. This area determines how PC-DMIS will execute the commands in a group. For more information, see "Mini Routines" in the PC-DMIS Core documentation.
    - **As Marked** - If you select **As Marked**, PC-DMIS executes all of the marked features. PC-DMIS skips all of the non-marked commands.
    - **FBM Check** - At the time of execution, PC-DMIS determines if a feature or dimension is marked in the group. If it finds a marked feature or dimension, it executes the entire group according to its marking status. If PC-DMIS determines that no feature or dimension is marked, it skips the entire group.
    - **All Always** - PC-DMIS always marks and executes the entire group and its nested subgroups. There may be several situations where the PC-DMIS application programmer would like to always measure certain features.

Removing Groups

Removing Only Group Commands

To remove the `GROUP` / `ENDGROUP` commands, *but retain the group's contents*, do one of the following:

- In the Edit window in Command Mode, ensure that all the items in the group are visible, select either the `GROUP` or `ENDGROUP` command (but not the entire group), and press Delete on your keyboard.
- In the Edit window in Summary Mode, expand the group, right-click on the `GROUP` command, and either select **Delete** from the shortcut menu or press Delete on your keyboard.

Removing both Group Commands and Contents

To remove the `GROUP` / `ENDGROUP` command *and its contents*, do one of the following:

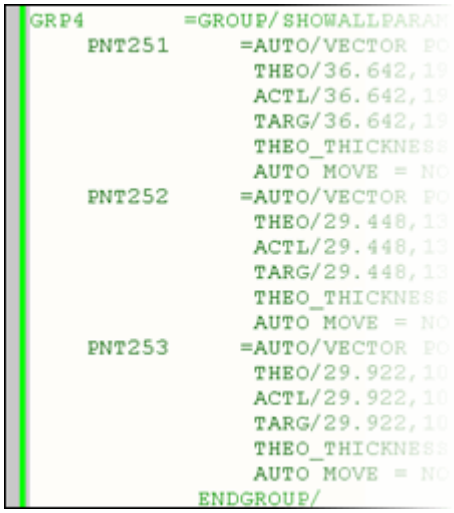
- In the Edit window in Command Mode, hide all of the features in the group, select the `GROUP` and `ENDGROUP` commands (ensure that you select both commands), and press Delete on your keyboard.
- In the Edit window in Summary Mode, collapse the group, right-click on the `GROUP` command, and either select **Delete** from the shortcut menu or press Delete on your keyboard.

If the items in the group are visible, you need to select the entire `GROUP` / `ENDGROUP` command block before you remove it.

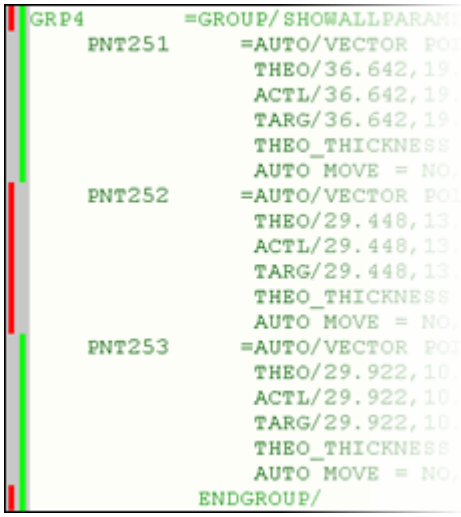
Using Multiple Arm Mode with Groups

In Command Mode or DMIS Mode, groups that contain commands set for execution by a specific arm will have the same red and/or green Multiple Arm Mode margin markings as those commands.

If all the commands in a group are tied to one arm, the `GROUP` command also has the same margin color markings. If you then change the arm mode of the `GROUP` command, all commands inside switch their margin color markings to the other arm.



If one or more commands are tied to both arms, the `GROUP` command also has the same margin color markings as both arms.



For information on Multiple Arm Mode, see the "Using Multiple Arm Mode" chapter.

Performing Operations on Groups

In general, all operations that can be performed on a single command in the Edit window, when performed on a group, are performed on every item contained within the group.

The various operations you can perform on a group are described in detail below. Most are taken from the Command Mode's shortcut menu. Right-click in the Command Mode to see this shortcut menu. This shortcut menu is discussed in the "Command Mode Shortcut Menu" topic in the "Using Shortcut Keys and Shortcut Menus" chapter. The information below only applies to how this menu works with `GROUP` commands or features inside of groups.

Shortcut Menu Operations on Groups

- **Select Command** - When the group is collapsed and you choose **Select Command**, PC-DMIS selects every command contained in the group as a block. When the group is expanded, **Select Command** selects only the `GROUP` command itself.
- **Select Block** - This menu item selects every command contained in the group as a block, regardless of the expanded/collapsed state of the group.
- **Execute From Cursor (Ctrl + U)** - This doesn't change from the usual operation.
- **Execute Block (Ctrl + L**) - If you select a block, PC-DMIS only executes the block. If you selected a group as the block, then PC-DMIS executes the group.
- **Jump To (Ctrl + J)** - This doesn't change from the usual operation.
- **Jump Back (Alt + J)** - This doesn't change from the usual operation.
- **Edit (F9)** - When the cursor is positioned on the GROUP command, a **Group** dialog box appears. You can modify the group's ID and display state. If you select **Edit** on the ENDGROUP command, nothing happens.
- **Mark (F3)** - If you place the cursor on the GROUP command and select this menu item, all items contained within the group are Marked or Unmarked as a whole. If you have any unmarked commands within the group when you select this menu item, those commands become marked, and all other commands remain marked. If all commands within the group are already marked when you select **Mark (F3)**, all commands become unmarked. The color of the GROUP command reflects the marked state of the commands contained within the group. If at least one command within the group is marked for execution, then the group displays as marked for execution. If no command is marked, then the group displays as unmarked.
- **Delete** - *This menu item only appears on the Summary Mode shortcut menu*. If you select a GROUP command and then select **Delete**, PC-DMIS deletes the GROUP and ENDGROUP commands and everything in between. You cannot undo a GROUP deletion.
- **Group** - If you select an existing GROUP command and then select the **Group** menu item, PC-DMIS creates a new GROUP command and nests the selected group inside it.
- **Collapse Groups** - This doesn't change from the usual operation.
- **Expand Groups** - This doesn't change from the usual operation.

- **Set as Start Point** - This doesn't change from the usual operation.
- **Cut** - Removes the GROUP command and ENDGROUP command. All items stored inside the group remain in the measurement routine.
- **Copy** and **Paste** - This copies and pastes a GROUP / ENDGROUP pair and everything inside the group.

Other Group Operations

- **File | Partial Execution | Execute Feature (Ctrl + E)** - Selecting this menu item while selecting the GROUP command executes all features inside the group.
- **Flow Control Statements** - The ID can be used to control the flow of measurement routine execution, similar to how you can send execution flow to a LABEL command. You can use GOTO or IF_GOTO flow control commands to send the execution flow to a group based on defined conditions. For example:

```
IF_GOTO/VAR > 0, GOTO = GRP1
```

or

```
GOTO/GRP1
```

Executing a Mini Routine or Sub Mini Routine

Examples of Creating Mini Routines and Sub Mini Routines

Important Notes

About Mini Routines

Mini routines enable you to measure a selected dimension or group of dimensions from a lengthy measurement routine.

With a mini routine, you can create a single measurement routine and measure the dimensions manufactured after every operation or only the dimensions that are affected by one or more tools or the critical dimensions. Mini routines also allow you to remeasure out-of-tolerance dimensions.

A mini routine provides you with the ability to create the structure to measure tool-based, cell-based, and operation-based features from your measurement routine.

Since mini routines can execute partial measurements in a measurement routine, it’s crucial to ensure there are no collisions when you execute a partial measurement routine. You can achieve this by using either of the following methods:

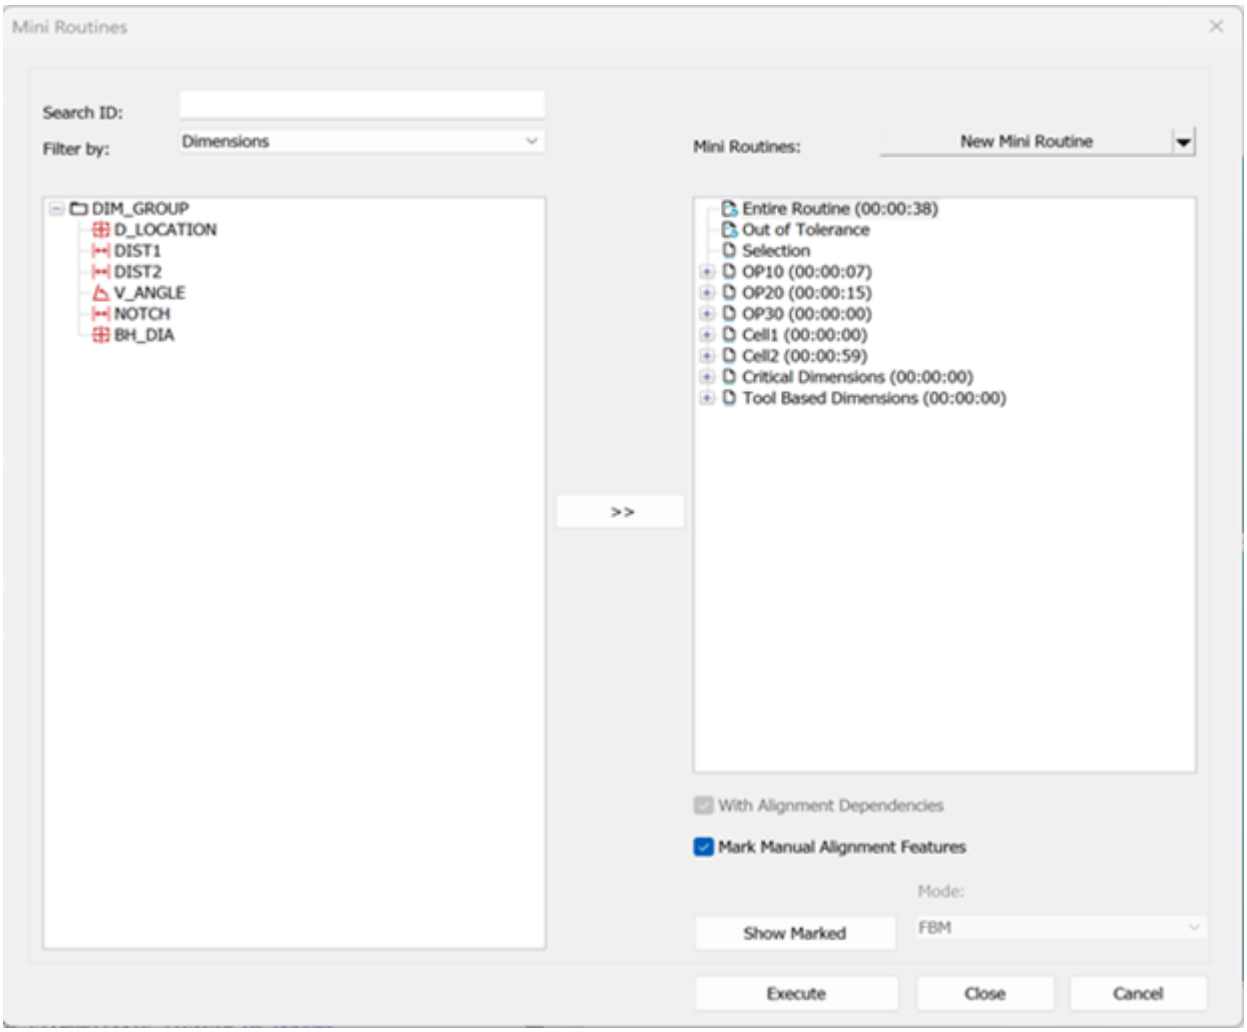
- Using ClearanceCube
- Using an FBM license

> The FBM license is an optional feature in PC-DMIS. FBM functionality is only available if your PC-DMIS license is programmed with the Feature Based Measurement module.

Both methods require you to use the `GROUP` command to create your measurement routine. For details, see "Creating a Measurement Routine Capable of Executing a Mini Routine" in the PC-DMIS Core documentation.

Using Mini Routines

To use mini routines, select the menu option **File | Partial Execution | Mini Routines** to open the **Mini Routines** dialog box.



Mini Routines Dialog Box

The left pane displays the dimensions available in the measurement routine, while the right pane displays the mini routines.

PC-DMIS automatically creates these mini routines:

- **Entire Routine** - Measures all the dimensions in the measurement routine.
- **Out of Tolerance** - Measures only the dimensions that are out of tolerance in the measurement routine.
- **Selection** - A "one-time" mini routine that measures items during the current session only. This mini routine will be empty when you re-open the **Mini Routines** dialog box.

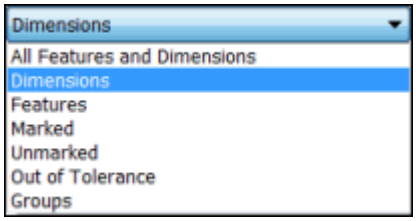
Using Search ID box and Filter by List

You can use filters to find the items you want to measure in your measurement routine. The filtered items are displayed in the Dimension pane.

1. To filter, do one of the following:

   - In the **Search ID** box, type the ID of the item that you want to find and then press Enter. You can also use meta characters in this box. For help, see "Selecting Features Using Meta-Character Matching" in the PC-DMIS Core documentation.

   - In the **Filter by** list, select a filtering option:



Filter by List

All Features and Dimensions - Displays the IDs of the features and dimensions.

Dimensions - Displays the IDs of the dimensions. This is the default.

Features - Displays the IDs of the features.

Marked - Displays the IDs of the features that are marked in the measurement routine.

Unmarked - Displays the IDs of the features that are not marked in the measurement routine.

Out of Tolerance - Displays the IDs of the features that are out of tolerance.

Groups - Displays the names of the groups. All dimensions that belong to a group are included in a mini routine.

2. Tooltips in the Dimension pane provide detailed information about dimensions. To display a tooltip, hover your mouse pointer over an item. The tooltip remains visible until you move the pointer off the item.

If you change the name of an item in the Edit window, PC-DMIS automatically changes its name in the filtered list as well as in the mini routine.

Creating a Mini Routine

To create your own mini routine:

1. In the **Mini Routines** list, click **New Mini Routine**. You can also right-click in the Mini Routine pane and select **New Mini Routine** on the shortcut menu. Click on the default name that appears and type the name of your choice.

2. To create another mini routine, click on the icon of any existing mini routine to select it and then select **New Mini Routine**. This places the mini routine at the root level of the tree structure.

Creating a Sub Mini Routine

You can create a sub mini routine for a mini routine that has no items.

1. Select the desired mini routine.

2. In the **Mini Routines** list, click **New Sub Mini Routine**. You can also right-click in the Mini Routine pane and select **New Sub Mini Routine** on the shortcut menu.

3. Click on the default name that appears and type a name of your choice.

Adding Dimensions to Mini Routines

1. In the filtered list in the Dimension pane, select each item that you want to add to a mini routine or sub mini routine.

   To display additional selection options, right-click in the pane. A shortcut menu appears:

   Filtering Shortcut Menu

   Select All - Selects all of the items in the filtered list.

   Unselect All - Deselects all of the items in the filtered list.

   Expand All - Displays all features and dimensions in all groups.

   Collapse All - Hides all features and dimensions in all groups.

2. With **Filter by** set to **Groups**, select **Expand All** and then click on each item in a group that you want to add to a mini routine or sub mini routine.

3. In the Mini Routine pane, click on the icon for the desired mini routine or sub mini routine to select it.
4. Click **>>** to move the selected items from the Dimension pane to the selected mini routine.
5. To save your changes to mini routines at any time, click **Close**. To discard your changes to mini routines, click **Cancel**. The **Mini Routines** dialog box closes.

When you select the **Close** button to close the dialog box, PC-DMIS automatically saves the mini routines as an .xml file with this naming convention:

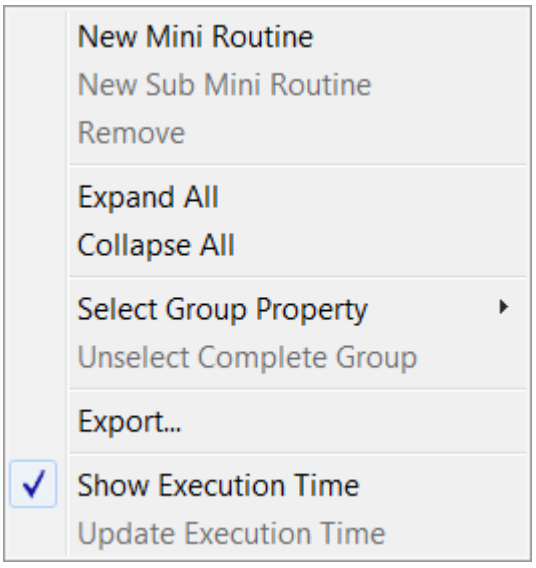
<name of measurement routine>.MiniRoutines.xml

This file is saved in the folder in which the measurement routine resides. When you open the measurement routine, the data in the .xml file displays in the **Mini Routines** dialog box.

If you send the measurement routine to another machine, you must include the *<name of measurement routine>*.MiniRoutines.xml file to see the mini routines on the other machine.

Shortcut Menu in the Mini Routine Dialog Box

If you right-click in the right pane of the Mini Routine dialog box, PC-DMIS displays a shortcut menu. The menu has these options:



Mini Routine Shortcut Menu

New Mini Routine - Creates a new mini routine.

New Sub Mini Routine - Creates a new sub mini routine.

Remove - Deletes the selected mini routine or sub mini routine.

Expand All - Displays all items in all mini routines and sub mini routines.

Collapse All - Hides all items in all mini routines and sub mini routines.

Select Group Property - Displays additional options:

- **Features and Dimensions Group** - This group property indicates that all features and dimensions in the group will be marked. The parents of all dimensions will also be marked.
- **Whole Group** - Marks all of the commands in the group regardless of the type of command. This includes commands that are not features and dimensions, or commands that do not get marked by dependency relations. This property is similar to the marked `GROUP` command header in PC-DMIS. For more information, see "Performing Operations on Groups".

Unselect Complete Group - Deselects the complete group and displays all of the dimensions in the group.

Export - Saves the tree structure for each mini routine in an .xml file, which you can use with automation. A dialog box appears and prompts you for the name and location of the file.

Show Execution Time - Displays the execution time in <hours>:<minutes>:<seconds> to the right of the **Entire Routine** option, the mini routine name, and the sub mini routine name.

Update Execution Time - This option is selected by default. If this option is selected, the execution time will be updated every time it is executed. This update function is available for the entire routine as well as for each separate mini routine. If you do not want the time to be updated after every execution, clear this option.

The **Update Execution Time** option is available when:

- The **Record and display execution time** check box on the **General** tab in the **Setup Options** dialog box is selected (for more information about the **Record and display execution time** check box, see "Execution Area").
- The **Entire Routine** option is selected.
- A mini routine or sub mini routine is selected.

Creating a Measurement Routine Capable of Executing a Mini Routine

PC-DMIS offers the following methods for collision-free measurement of any dimension in a measurement routine:

- Using ClearanceCube

- Using FBM License (Optional License)

> The FBM license is an optional feature in PC-DMIS. FBM functionality is available only if your PC-DMIS license includes the Feature Based Measurement module.

Creating a Measurement Routine Capable of Measuring any Dimension Collision Free with ClearanceCube

You can use the ClearanceCube and mini routine concepts to create measurement routines to provide a collision-free path for measuring any selected dimensions.

For information on how to use ClearanceCube, see the "Using the ClearanceCube" topic in the PC-DMIS Core documentation.

Creating a Mini Routine Using ClearanceCube: Key Concepts

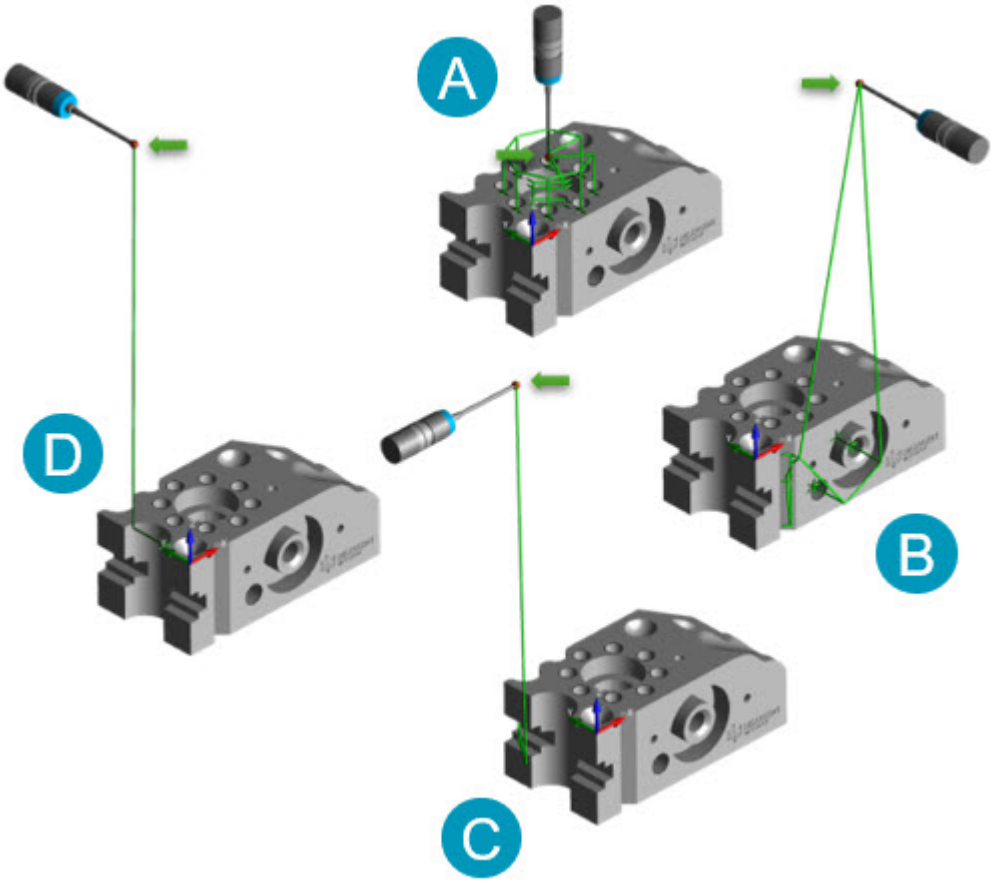
Organization of a Measurement Routine

- **Features and commands are measured always** - As a PC-DMIS application programmer, if you would like to always (with every execution) measure certain features then you must create them outside of a group.
- **Features and commands are measured only if required for selected dimensions** - As a PC-DMIS application programmer, if you would like to measure a feature only if the selected dimension requires it, you must create that feature inside a group.

Use Groups

Typically, CMM measures all features possible with one tip unless some features are required explicitly for alignment purposes. Features are measured logically based on the use of the tip or face of the part. Continue to create routines in your usual style, and, as an additional step, group the features measured in this logical manner.

The following image explains the concept.



A. *ZPLUS Group*

B. *YMINUS Group*

C. *XMINUS Group*

D. *YPLUS Group*

For information about how to insert groups into a measurement routine, see "Inserting Groups" in the PC-DMIS Core documentation.

Using a MOVESET Command

Each group can measure features on one side of a part. You can use a `MOVESET` command at the group's beginning and end.

When you insert the `MOVESET` command at the beginning and end of a group, it is like how a car enters and exits a freeway. After entering the freeway, a car can move at high speed but needs to avoid accidents. Similarly, after executing the beginning Moveset, the tip can move freely and avoid collisions by using avoidance moves.

For the Moveset at the beginning of the group, assign the ClearanceCube motion to the starting face and turn off the ClearanceCube motion at the ending face.

Similarly, for the Moveset at the end of the group, turn off the ClearanceCube motion at the starting face and assign the ClearanceCube motion to the ending face.

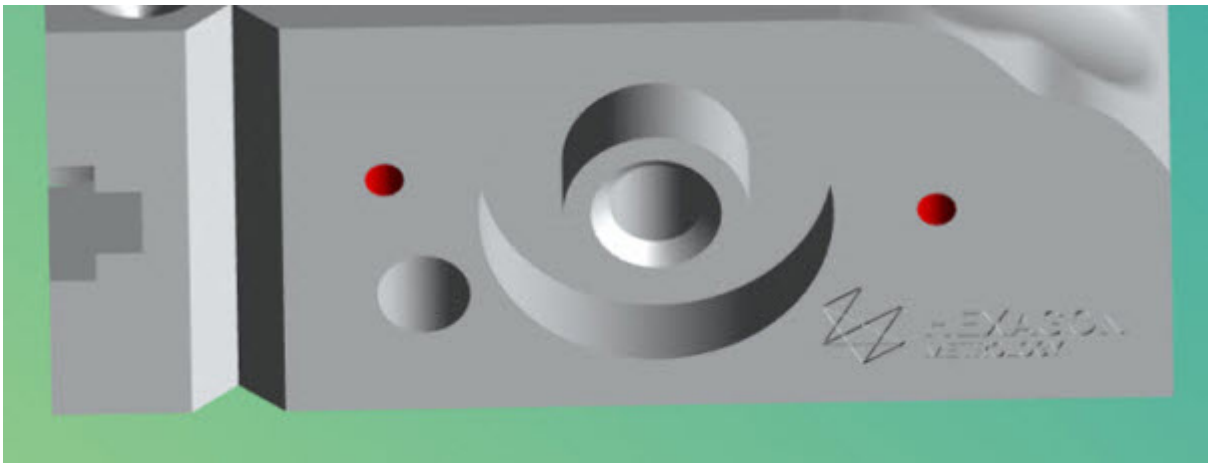
Now, you can use any method in PC-DMIS to measure features on this side (face) of the part. Use the Avoidance Move to navigate between features. You do not need to activate the ClearanceCube motion for these features unless required for a specific reason.

Alternatively, you can activate ClearanceCube for all features in a group for parts with simple geometry instead of using `MOVESET` commands.

Using Nested Groups

You can use nested groups where additional move commands are required to safely measure features without collision.

For example, you can create a nested group to measure the planes on the V groove. This nested group includes entry and exit `MOVESET` commands. Use the `MOVESET` command inside the nested group to position the tip in front of the V groove and ensure collision-free measurement of the planes within the groove.



Example showing nested groups.

Datum Assignments

If you assign datum feature reference letters to the datum features, that assignment should be within the group that measures the features.

Dimensions

You can create dimensions in the group where they are measured or you create them in a separate group. You can also group the dimensions into operation, cell, or manufacturing tool categories. This helps you select a whole group of dimensions property in a mini routine.

Create Alignment to Constrain 6 Degrees of Freedom

In PC-DMIS, you can base alignments on the recall of a previous alignment. If you create alignment in this way, the mini routine looks at recalled alignment dependencies and marks everything required to create the recalled alignment.

If an alignment constrains all 6 Degrees of Freedom (DOF), we recommend you recall the STARTUP alignment rather than the previous one. This breaks the dependency chain, and PC-DMIS only measures those features.

Using LOADPROBE and TIP Commands

If your measurement routine requires a tool or tip change, define this within the group where it is needed. Ensure that you select the necessary probe and tip in each group.

Using Variables

Create variables outside of the group if you need input from the user. Create other variables within the group if you want to use that variable for measuring a feature or dimension.

Commands Outside of Groups

When used with ClearanceCube mode, a mini routine always marks and executes every command that is not part of any group. You must place anything that must be executed (tracefields, operator responses, and generating strings for output file names) outside of a group.

Creating a Measurement Routine Capable of Measuring any Dimension Collision Free with FBM License

You can use FBM license and mini-routine concepts to create measurement routines to provide a collision-free path for measuring any selected dimension.

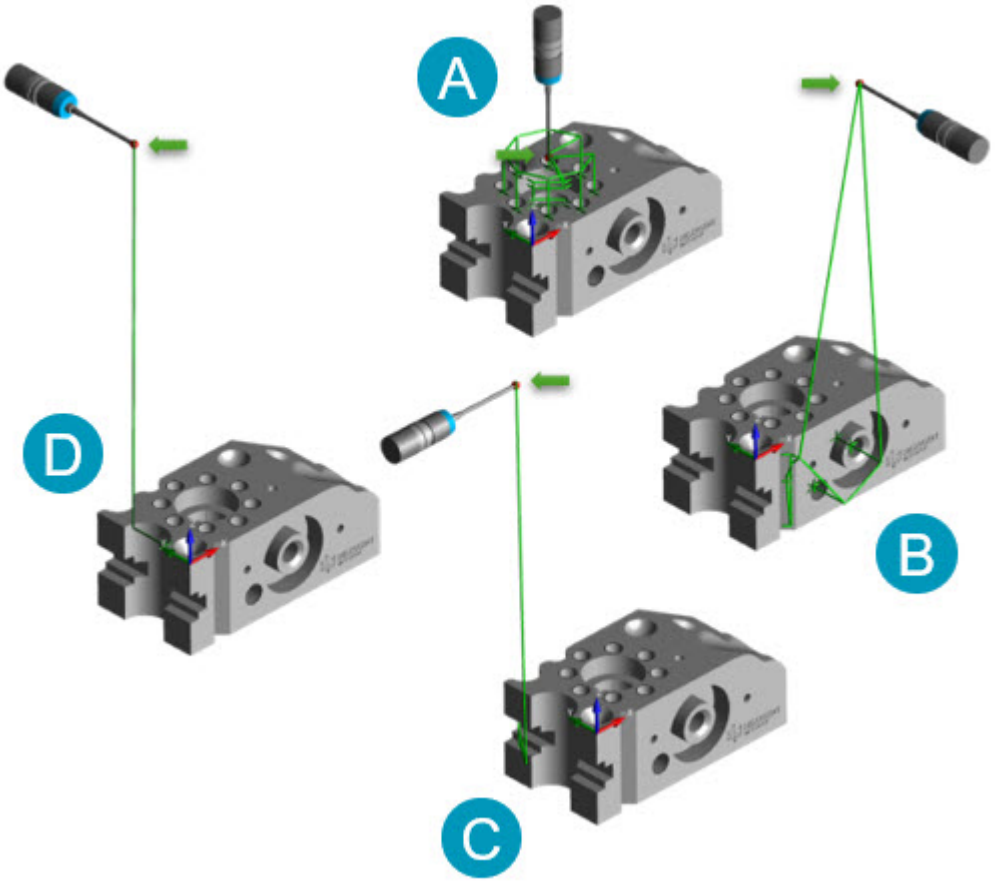
Use the FBM license when the ClearanceCube method does not support the complexity of your requirement or the part’s geometry.

Creating a Mini Routine using FBM License: Key Concepts

Use Groups

Typically, CMM measures all features possible with one tip unless some features are required explicitly for alignment purposes. Features are measured logically based on the use of the tip or face of the part. Continue to create routines in your usual style, and, as an additional step, group the features measured in this logical manner.

The following image explains the concept.



A. *ZPLUS Group*

B. *YMINUS Group*

C. *XMINUS Group*

D. *YPLUS Group*

A mini routine with an FBM license is tightly coupled with the `GROUP` command. The following is an example of a measurement routine where all measured features and dimensions are organized into groups.

```
STARTUP    =ALIGNMENT/START,RECALL:USE_PART_SETUP,LIST
            ALIGNMENT/END
            MODE/MANUAL
            PREHIT/3
            RETRACT/3
            MOVESPEED/ 150
            TOUCHSPEED/ 5
            FORMAT/TEXT,OPTIONS, ,HEADINGS,SYMBOLS, ;M
            LOADPROBE/LSPX3BY50
            TIP/T1A0B0, SHANKIJK=0, 0, 1, ANGLE=0
            RECALL/ALIGNMENT,EXTERNAL,MANUAL FIXTURE
            MODE/DCC
START_GROUP=GROUP/SHOWALLPARAMS=NO
            EXECUTION CONTROL=ALL ALWAYS
            ENDGROUP/ID=START_GROUP
ALIGN_GROUP=GROUP/SHOWALLPARAMS=NO
            EXECUTION CONTROL=FBM CHECK
            ENDGROUP/ID=ALIGN_GROUP
ZPLUS_GROUP=GROUP/SHOWALLPARAMS=NO
            EXECUTION CONTROL=FBM CHECK
            ENDGROUP/ID=ZPLUS_GROUP
YMINUS_GROUP=GROUP/SHOWALLPARAMS=NO
            EXECUTION CONTROL=FBM CHECK
            ENDGROUP/ID=YMINUS_GROUP
XMINUS_GROUP=GROUP/SHOWALLPARAMS=NO
            EXECUTION CONTROL=FBM CHECK
            ENDGROUP/ID=XMINUS_GROUP
YPLUS_GROUP=GROUP/SHOWALLPARAMS=NO
            EXECUTION CONTROL=FBM CHECK
            ENDGROUP/ID=YPLUS_GROUP
CONST_GROUP=GROUP/SHOWALLPARAMS=NO
            EXECUTION CONTROL=AS MARKED
            ENDGROUP/ID=CONST_GROUP
DIM_GROUP  =GROUP/SHOWALLPARAMS=NO
            EXECUTION CONTROL=AS MARKED
            ENDGROUP/ID=DIM_GROUP
VIEWSET1   =VIEWSET/
                              END OF MEASUREMENT FOR
```

Example of a measurement routine with groups

Group Command Concepts

PC-DMIS extends the `GROUP` command when you use the command with FBM enabled in the license.

```
START_GROUP=GROUP/SHOWALLPARAMS=NO
            EXECUTION CONTROL=ALL ALWAYS
            ENDGROUP/ID=START_GROUP
ALIGN_GROUP=GROUP/SHOWALLPARAMS=NO
            EXECUTION CONTROL=AS MARKED
            ENDGROUP/ID=ALIGN_GROUP
ZPLUS_GROUP=GROUP/SHOWALLPARAMS=NO
            EXECUTION CONTROL=FBM CHECK
            ENDGROUP/ID=ZPLUS_GROUP
```

Example of group commands with FBM

The group header displays an additional choice for execution control. Three options are available in the group control:

- **ALL ALWAYS** – The mini routine always marks and executes the entire group and its nested subgroups. There may be several situations where the PC-DMIS application programmer wants to always measure certain features.

- **AS MARKED** - The mini routine marking method with the FBM license marks the commands in the measurement routine to measure the selected dimensions. All parent features of every dimension are selected, and any required alignment is marked. If you select **AS MARKED**, the mini routine executes all marked features. Mini routine skips all the non-marked commands.
- **FBM CHECK** - At the time of execution, PC-DMIS determines if a feature or dimension is marked in the group. If it finds a marked feature or dimension, it executes the entire group according to its marking status. If PC-DMIS determines that no feature or dimension is marked, it skips the whole group.

For information about how to insert groups into a PC-DMIS measurement routine, see "Inserting Groups" in the PC-DMIS Core documentation.

Using a Move Point Command

Each group can measure features on a given face of a part. There may be move point(s) commands at the beginning of the group. These move points position the tip on top of the face of interest. You can use any method in PC-DMIS to measure all features on this face.

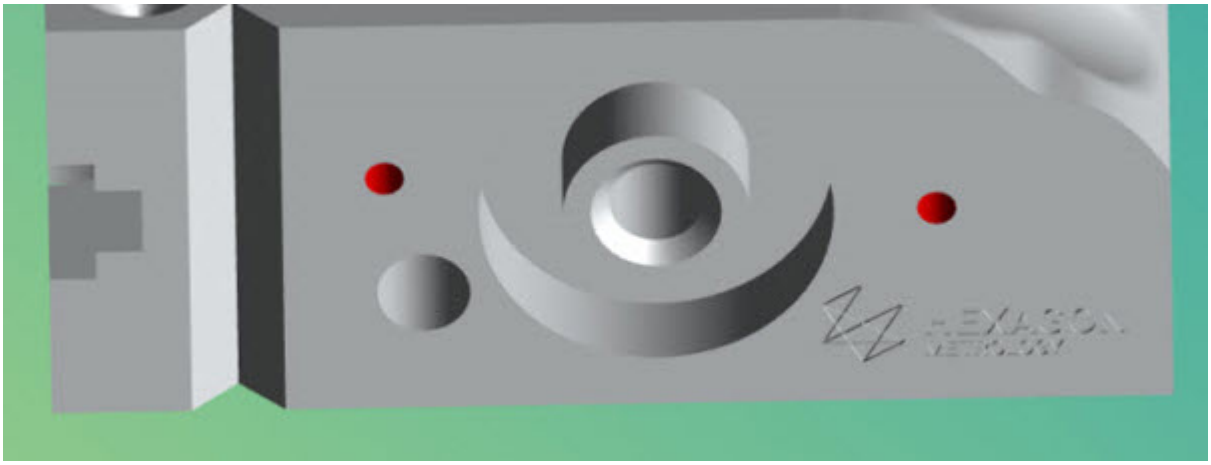
When all measurements are complete, the probe safely moves back to a position using move point(s). It can then safely move to any other group.

When you insert the `MOVE/POINT` command at the beginning and end of a group, it is like how a car enters and exits a freeway. After entering the freeway, a car moves at high speed but needs to avoid accidents. Similarly, after entering the move point, the tip uses avoidance moves so it can move freely and avoid collisions.

Using Nested Groups

You can use nested groups where additional move points are required to measure features without collision.

For example, you can create a nested group to measure the planes on the V groove. This nested group includes entry and exit move commands in front of the V groove. This ensures collision-free measurement of the planes within the groove.



Example of nested groups

Datum Assignments

If you assign datum feature reference letters to the datum features, that assignment should be within the group that measures the features.

Dimensions

You can create dimensions in the group where they are measured or you create them in a separate group. You can also group the dimensions into operation, cell, or manufacturing tool categories. This helps you select a whole group of dimensions property in a mini routine.

Create Alignment to Constrain 6 Degrees of Freedom

In PC-DMIS, you can base alignments on the recall of a previous alignment. If you create alignment in this way, the mini routine looks at recalled alignment dependencies and marks everything required to create the recalled alignment.

If an alignment constrains all 6 Degrees of Freedom (DOF), we recommend you recall the STARTUP alignment rather than the previous one. This breaks the dependency chain, and PC-DMIS only measures those features.

Using LOADPROBE and TIP Commands

If your measurement routine requires a tool or tip change, define this within the group where it is needed. Ensure that you select the necessary probe and tip in each group.

Using Variables

Create variables in a group with execution control set as “All Always” if you need to get input from the user.

Create other types of variables in the group in which you want to use that variable for measuring a feature or a dimension.

Commands Required to be Executed Always

A mini routine always marks and executes every command that is in a group with execution control set to ALL ALWAYS. You must place anything that must be executed (tracefields, operator responses, and generating strings for output file names) inside of a group.

Commands Outside of Groups

Any command that exists outside of groups has a global scope. PC-DMIS always executes these commands according to their marked status.

Executing a Mini Routine or Sub Mini Routine

1. Select **File | Partial Execution | Mini Routines** to open the **Mini Routines** dialog box.

2. Click the icon for the mini routine or sub-mini routine to select it.

3. If you want to measure the mini routine with alignment dependencies, select the **With Alignment Dependencies** check box. To measure it without alignment dependencies, clear the check box.

   The availability of the **With Alignment Dependencies** check box depends on the `MiniRoutineWithAlignDependencyEnabled` setting in the Settings Editor application.

   - If the entry is enabled, the **With Alignment Dependencies** check box is available.
   - If the entry is disabled, the check box is dimmed and unavailable to prevent unauthorized or unintentional use.

   "Alignment dependencies" means that the features required to create an alignment for the selected items will be marked and measured. For example:

   - Suppose that PC-DMIS has measured the part. The part has not moved yet, and you want to remeasure certain features. You can measure the mini routines and sub mini routines without measuring the alignment features again.
   - Suppose that PC-DMIS has measured the part. You then notice that one hole is dirty, and you need to measure only the dimensions associated with that hole. You can measure the dimensions with alignment dependency because the part has moved and needs to be realigned.

4. To mark manual alignment features for measurement, click **Mark Manual Alignment Features**.
5. To mark the features and dimensions to be measured, select the desired mini routine or sub mini routine and click **Show Marked**. PC-DMIS marks the features and dimensions in the Edit window.
6. In the **Mode** list, select **ClearanceCube** or **FBM**, depending on whether you created the measurement routine with ClearanceCube or FBM license concept. If your license does not include the FBM option, ClearanceCube is the only available choice.
7. Click **Execute**. PC-DMIS closes the **Mini Routines** dialog box and displays the **Execution** dialog box.

Marking Method for Routines using ClearanceCube

When using ClearanceCube, a mini routine marks the selected dimensions and dependent commands through the following steps:

1. The mini routine marks the complete measurement routine.

2. The mini routine unmarks all groups or all commands in each group.
3. The mini routine marks the selected dimensions with parent mode dependency. This includes marking all features on which they depend.
4. The mini routine identifies each group where one or more features are marked. It then marks all the commands in that group that are not features or dimensions. For example, load probe, tip, recall of alignment, prehit, retract, comments, move, moveset, move speed, display precision, format, mode, etc.

Marking Method for Routines using FBM License

When you use the FBM license, a mini routine marks the selected dimensions and dependent commands through the following steps:

1. The mini routine marks the complete measurement routine.
2. The mini routine unmarks all features and dimensions.
3. The mini routine marks the selected dimensions with parent mode dependency. This includes marking all features on which they depend.
4. The mini routine marks all commands of groups that have the execution control set to **ALL ALWAYS**.
5. When PC-DMIS executes a measurement routine with one or more groups with the execution control set to **FBM CHECK**, PC-DMIS determines if any features or dimensions in the group need to be measured.
    - PC-DMIS does not execute the entire group if a group has no marked features. It does not execute any other commands in the group (such as move points and tip change commands), whether they are marked or not.
    - If a group has marked features, PC-DMIS executes the group, as marked by the mini routine.
6. For groups with the execution control set to **AS MARKED**, PC-DMIS fully executes the group according to the normal marking rule.

Example of Creating Mini Routines and Sub Mini Routines

This example creates mini routines and sub mini routines for a part. The part is manufactured in two operations: Operation 10 and Operation 20. Operation 10 manufactures the part in Station 1 and Station 2. This example assumes that a measurement routine has been created to measure the entire part.

1. In the Mini Routine pane, find the items to measure in the measurement routine.
2. Create the mini routines and sub mini routines:

a. Click **New Mini Routine**. **MiniRoutine1** appears.

b. Click **New Mini Routine** again. **MiniRoutine2** appears.

c. Rename **MiniRoutine1** to **Op10**, and **MiniRoutine2** to **Op20**.

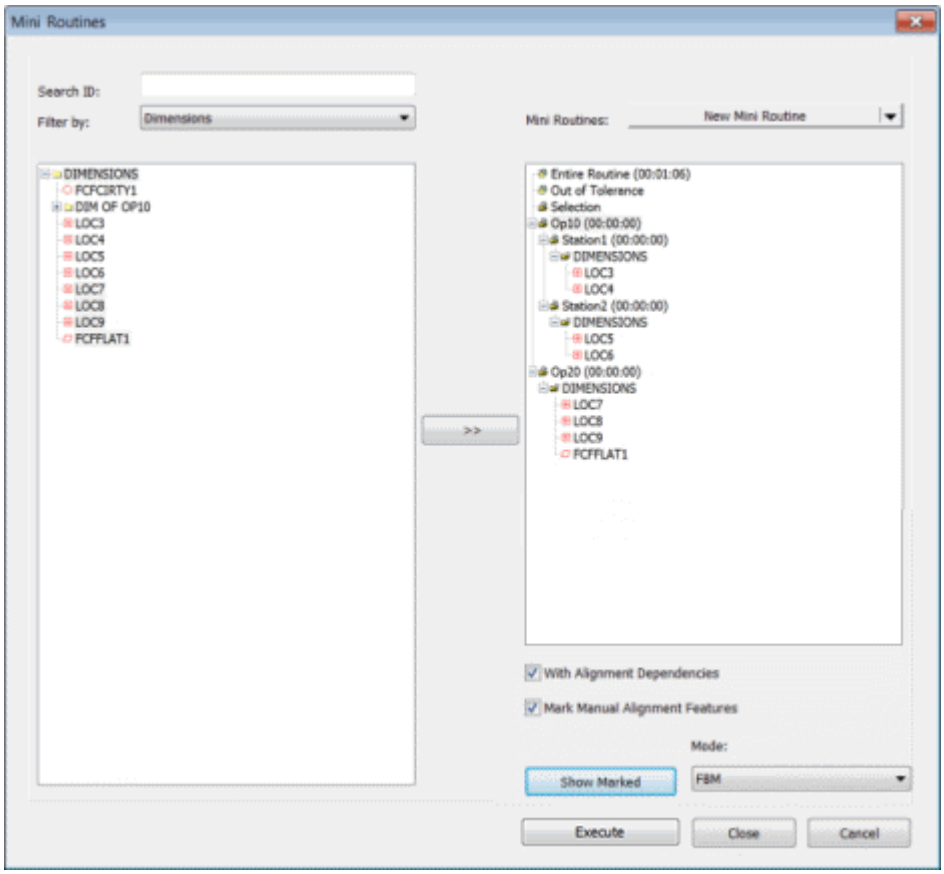
d. Select **Op10** and then click **New Sub Mini Routine**. **Op101** appears.

e. Select **Op10** again and then click **New Sub Mini Routine**. **Op102** appears.

f. Rename **Op101** to **Station 1**, and **Op102** to **Station 2**.

3. In the Dimension pane, select the items to measure.

4. Move the selected items to the **Station 1** and **Station 2** sub mini routines, and the **Op20** mini routine.



Example of mini routines and sub mini routines

Station 1 has the dimensions of the features manufactured by Station 1. **Station 2** has the dimensions of the features manufactured by Station 2.

Click **Close**. PC-DMIS saves the data as a .xml file in the measurement routine's folder.

5. To execute the **Op10** mini routine, select it and then click **Execute**. PC-DMIS measures the dimensions of the features manufactured in Operation 10.

6. To execute the **Op20** mini routine, select it and then click **Execute**. PC-DMIS measures the dimensions of the features manufactured in Operation 20.

Important Notes

- Mini routines provide a way to measure selected dimensions and features with or without alignment dependency.
- Recall the necessary alignment at the beginning of every group to ensure that PC-DMIS uses the correct alignment to measure all features. This functionality is provided for specific industries that may want to quickly re-measure certain dimensions after measuring the complete part without moving it from its fixture.
- Any command outside of all groups (that is, it does not belong to a group) has a global scope. PC-DMIS always executes these commands according to their marked status.
- Nested groups follow the same execution rules. If an inner group contains a measurement command, PC-DMIS also executes its outer group.

  For example, suppose you have GROUP A and GROUP B. GROUP B is nested inside GROUP A. If execution control is set to **FBM CHECK** for both GROUP commands, but only GROUP B has features or a marked dimension, GROUP A also executes its marked commands.
- If you delete a dimension and recreate it, remember to edit the mini routine to include it.
- If you change the ID of a dimension, PC-DMIS automatically updates it in the mini routine.

Using Other Windows, Editors, and Tools

Using Other Windows, Editors, and Tools: Overview

PC-DMIS provides you with an assortment of windows, editors, and other aids that can help make your measurement routine more productive.

These include:

- The Edit window, which has already been discussed in the "Using the Edit Window" chapter
- A Report window to display measurement results (see "Using the Report Window")
- The PC-DMIS FUSION application brings all your measurement data in one place (see "Using PC-DMIS FUSION")
- A script editor that creates scripts in the BASIC programming language (see "Using the Basic Script Editor")
- An editor that creates and displays interactive forms and dialog boxes (see "Using the Form Editor")
- An inspection report editor that enables you to quickly view and make small editing changes to your automatically-generated inspection reports (see "Viewing an Inspection Report")
- An interface for quick generation of simple measurement routines (see "Using the Quick Start Interface")
- A Settings window that you can use to make quick edits to frequently-used values (see "Using the Settings Window")
- A Preview window that previews your measurements before you accept them (see "Using the Preview Window")
- A window that creates and stores marked sets of features for future execution (see "Using the Marked Sets Window")
- A Probe Readouts window that shows the current probe's location and other information (see "Using the Probe Readouts Window")

- A Status window that displays the current status of an operation or feature information (see "Using the Status Window")
- A Probe Toolbox that performs probe manipulations (see "Using the Probe Toolbox")
- A dockable color bar that shows the different tolerance zones and dimension colors (see "Using the Dimension Colors Window")
- A dockable Q-DAS Data Editor window that modifies K-field data for their Q-DAS statistical results (see "Using the Q-DAS Data Editor Window")
- A dialog box that you can use to select an active tip (see "Selecting a Tip")
- A path viewer that shows the path your probe takes during measurement routine execution (see "Viewing Path Lines")
- A **CAD Information** dialog box that displays information about a CAD element in the Graphic Display window (see "Viewing CAD Information" in the "Editing the CAD Display" chapter)
- A **CAD Import History** dialog box that displays a history of CAD models imported into the current measurement routine (see "Viewing CAD Import History")

Using the Report Window

Select the **View | Report Window** menu option to display the Report Window. This window, after measurement routine execution, displays your measurement results and automatically configures the output according to a default report template. For detailed information, see the "About the Report Window" topic in the "Reporting Measurement Results" chapter.

Using PC-DMIS FUSION

PC-DMIS FUSION brings all your metrology data together so you can:

- Review PC-DMIS results and reports
- See sample-level details over time
- Explore SPC trends
- View part information in a central dashboard

If you have PC-DMIS FUSION installed, you can choose **View | PC-DMIS FUSION Reporting** to open the latest report data from your current measurement routine in the PC-DMIS FUSION application. This starts PC-DMIS FUSION if it's not already running.

For more information about PC-DMIS FUSION, see the **Welcome** tab of the FUSION view in the PC-DMIS Home page.

Using the Basic Script Editor

The Basic Script Editor can be used to create and edit BASIC scripts that can be used in Basic Script objects during execution or from the **Basic Script Editor** toolbar.

The **View | Basic Script Editor** menu option opens the Basic Script Editor and replaces PC-DMIS's main menu bar with these menus: **File**, **Edit**, **Run**, and **Help**. You can restore PC-DMIS's normal menu bar by minimizing or closing the Basic Script Editor.

The Basic Script Editor consists of the following:

- **Basic Script Editor** toolbar
- **File** menu
- **Edit** menu
- **Run** menu
- **Help** menu

These topics are discussed below.

Basic Script Editor Toolbar

The **Basic Script Editor** toolbar supports the following functions:

New

This button allows you to create a new basic script in the editor.

Open

This button displays the **Open File** dialog box used to open an existing basic script into the editor.

Save

This button saves the current basic script. If you have not already named the current script, a **Save As** dialog box asking for the name of the script will appear.

Print

This button prints the current basic script.

Print Preview

This button allows you to see the current basic script in the Print Preview window as it appears when printed.

Find

This button allows you to search for text in the current basic script.

Cut

This button cuts currently selected text and put text on the clipboard.

Copy

This button copies currently selected text and put text on the clipboard.

Paste

This button pastes text from the clipboard into the editor at the current insertion point.

Undo

This button allows you to undo the last editing change.

Compile

The **Compile** icon compiles (makes the script understandable and ready to run on the computer system) the current BASIC script. You must compile a script before running it.

Start

This button compiles and runs the current basic script.

Scripts run from the editor using the PC-DMIS basic commands can insert objects into the current measurement routine.

File Menu

The Basic Script Editor's **File** menu gives you the following commands and options:

New

The **File | New** menu option opens a new Basic Script Editor in which you can write a new script.

Open

The **File | Open** menu option allows you to navigate to and open an existing script. In order for files to appear in the Basic Script Editor, files must be of file type *.bas.

Save

The **File | Save** menu option is used to save a script. With a new script, the first time you select this option, the **Save As** dialog box appears, and you can use it to choose what to name your script and where you want to save it.

Save As

The **File | Save As** menu option saves a new script, or an already existing script with a new file name. When you choose it, the **Save As** dialog box appears for you to enter the file name and select the folder where you want to save the script.

Print

The **File | Print** menu option allows you to print the script in the Basic Script Editor from your system's printer.

Print Preview

The **File | Print Preview** menu option allows you to preview what PC-DMIS sends to the printer when you choose **Print** from the Basic Script Editor's **File** menu.

Exit

The **File | Exit** menu option allows you to exit out of the Basic Script Editor without saving any changes you have made to any open scripts. Choosing **File | Exit** will return you the main user interface. The menu bar will return to normal PC-DMIS functions.

Unicode

The **File | Unicode** menu item specifies whether your basic script is a Unicode script or not. If it isn't a Unicode script, then the Basic Script Editor interprets the script as ASCII text.

The Basic Script Editor needs to know the format of your script in order to correctly display and interpret it. Unicode formatting allows the editor to handle more complex characters (such as those displayed in Chinese or Japanese).

Unless you're working in a language that uses multi-byte characters, you generally won't need to select this menu item.

Edit Menu

The **Edit** menu of the Basic Script Editor allows you to use basic Edit functions to manipulate the text displayed in the Basic Script Editor.

Undo

The **Edit | Undo** menu option allows you to undo the most recent action taken in the Basic Script Editor.

Cut

The **Edit | Cut** menu option allows you to cut selected text from the Basic Script Editor. Cut text is stored in the Windows clipboard to later be pasted elsewhere.

Copy

The **Edit | Copy** menu option allows you to copy selected text. Copied text is stored in the Windows clipboard to later be pasted elsewhere.

Paste

The **Edit | Paste** command allows you to paste text that is stored in the Windows clipboard.

Delete

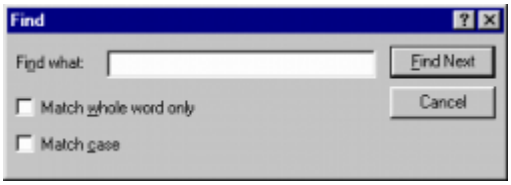
The **Edit | Delete** command allows you to delete highlighted text.

Select All

The **Edit | Select All** menu option automatically selects all the text within the Basic Script Editor. You can then **Cut**, **Copy**, or **Delete** the selected text.

Find

The **Edit | Find** menu option brings up the **Find** dialog box.



Find Dialog Box

This dialog box allows you to search for a specific word, or term within the Basic Script Editor.

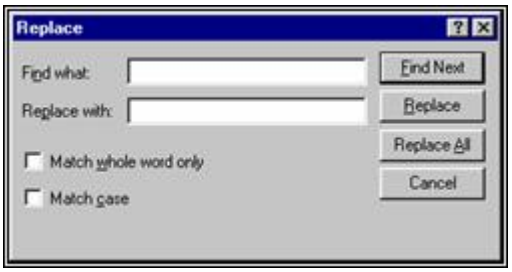
- If you choose the **Match Whole Word Only** check box, the dialog displays only those words that match the entire word.
- If you choose the **Match Case** check box, the dialog displays only those terms that match the case (Uppercase or Lowercase) that you used in the **Find what** box.

Find Next

The **Edit | Find Next** searches in the Basic Script Editor for the next term that meets the qualifications specified in the **Find** dialog box (See **Edit | Find** topic for details.)

Replace

The **Edit | Replace** menu option displays the **Replace** dialog box.



Replace Dialog Box

The **Replace** dialog box is an extension of the **Edit | Find** command. It is used to search for a specific term and then replace it with the term entered in the **Replace with** box.

The **Match whole word only** check box only matches whole words, not partial matches. For example, if you are looking for "point" and you do not have this check box selected, it may find the sequence of characters inside the words "points" or "pointer".

The **Match case check box** only finds instances that match the exact case typed into the **Find what** box. If you typed "point", it would not find "Point" or "POINT" because of their case differences.

The **Find Next** button searches through the Basic Script Editor and displays the first instance that meets the qualifications entered in the dialog box.

The **Replace** button is used to replace what has been found (using the **Find Next** button) with what is in the **Replace with** box.

The **Replace All** button is used to replace all instances in the Basic Script Editor that meet the search qualifications with what is in the **Replace with** box.

The **Cancel** button closes the **Replace** dialog box.

Dialog Editor

The **Edit | Dialog Editor** option opens a window with a grid named **Dialog One** and also the **MasQ Enable Dialog Designer** toolbar. This toolbar and the **Dialog One** grid provide the necessary tools to design dialog boxes that can later be programmed for your scripts.

Clicking the "X" in the upper right-hand corner of the **MasQ Enable Dialog Designer** toolbar closes these tools.

View Menu

The **View** menu allows you to choose if the **Basic Script Editor** toolbar and Status Bar are being displayed.

- Select **View | Toolbars** to display or hide the various toolbars.
- Select **View | Status Bar** to display or hide the Status bar.

With this menu, you can also determine where to set tab stops. This option allows you to indent BASIC language program statements a set number of characters, to help to improve the script's readability. To do this, select **View | Set Tab Stops** and type a number. PC-DMIS then indents by the indicated number of characters whenever you press the Tab key.

For example, if you want a tab stop at every five characters, type "5" in the **Set Tab Stops** dialog box.

You can use the `TabStops` entry in the PC-DMIS Settings Editor to set the number of characters that appear in the **Set Tab Stops** dialog box.

Run Menu

The **Run** menu allows you to select the **Compile** or **Start** command. The compile command compiles the script—checking it for syntax errors—while the start command executes the script.

Help Menu

The **Help** menu provides a **Basic Help** menu option. This option shows commands from the BASIC language that you can use with the Basic Script Editor.

Using the Form Editor

You can select **File | Reporting | New | Form Report** to open the Form Editor. This editor provides you with powerful tools to aid you in building interactive forms and dialog boxes that get activated during execution. For detailed information, see the "Creating Forms" topic in the "Reporting Measurement Results" chapter.

Viewing an Inspection Report

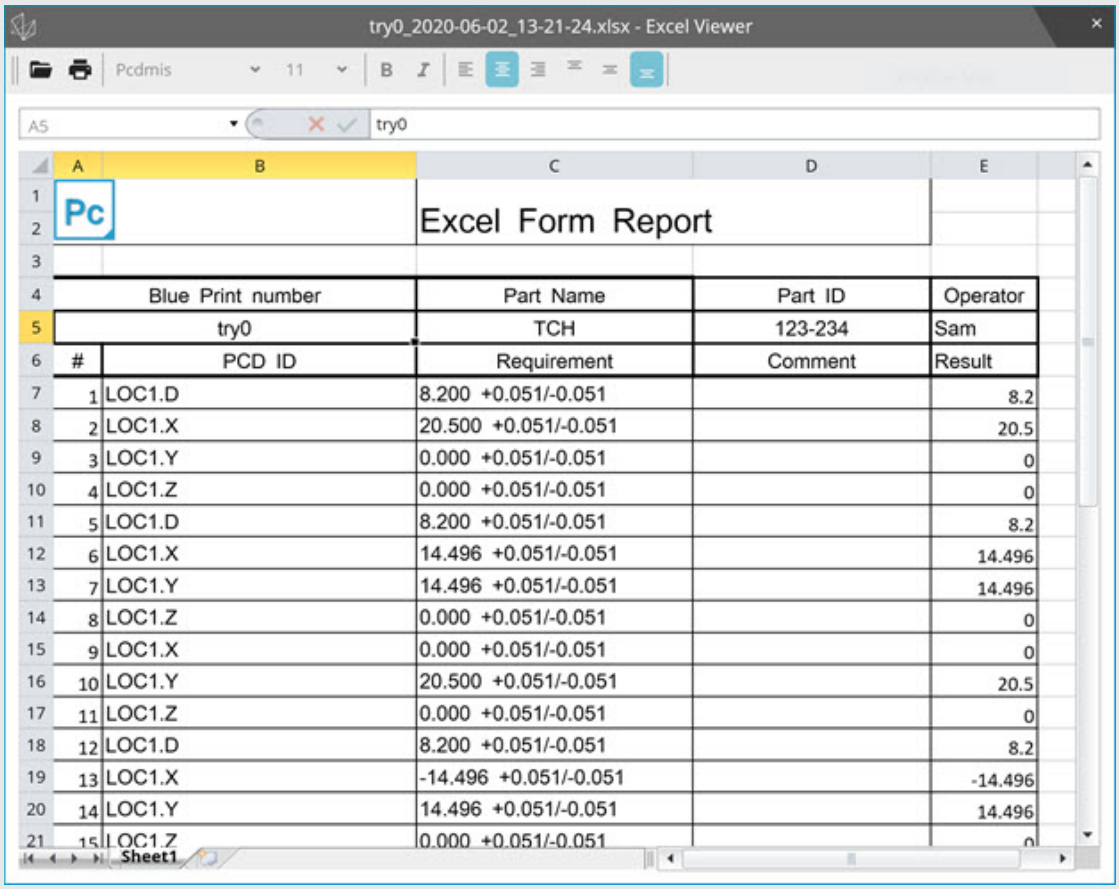
You can select **View | Inspection Report** to open an inspection report that was previously saved in one of these file types:

- .rtf
- .pdf
- .xls
- .xlsx
- .csv

To open an inspection report:

1. Select **View | Inspection Report** to display the **Open** dialog box.
2. From the **Files of type** list, select the file type that filters the current folder.
3. From the **Open** dialog box, navigate to the folder that contains the report file. Then select the file.
4. Click **Open**. PC-DMIS uses the default software installed on your computer to open the selected file.

If you select **Excel Files (*.XLS;*.XLSX;*.CSV;)**, and you want to use the internal Excel viewer that comes with PC-DMIS, select the **Use internal Excel viewer** check box. PC-DMIS shows the report in an internal Excel viewer.



Excel Viewer

Open ( ) - This icon displays the **Open** dialog box that enables you to open an Excel report.

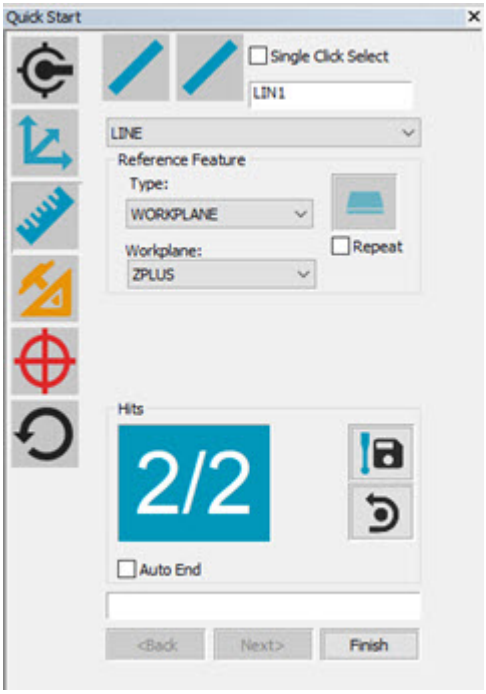
Print ( ) - This icon opens a standard **Print Setup** dialog box that enables you to send the print job to the printer.

Exit ( ) - This icon closes the **Excel Viewer**.

To maximize the window, double-click the title bar. To return the window to its previous size, double-click the title bar again.

Using the Quick Start Interface

The **Quick Start** interface (**View | Other Windows | Quick Start**) is a dialog box with a connected toolbar down the side.



Quick Start Dialog Box

This interface helps you create a measurement routine. It does this by providing dialog boxes or procedures that help you define or calibrate a probe, align your part, measure features, construct additional features, and dimension existing features.

To access an item, click on the desired toolbar icon. If the icon contains additional procedures, another toolbar appears to the right of the selected icon. You can select a specific procedure from the new toolbar.

Quick Start Toolbar Icons

The **Quick Start** toolbar contains these icons:

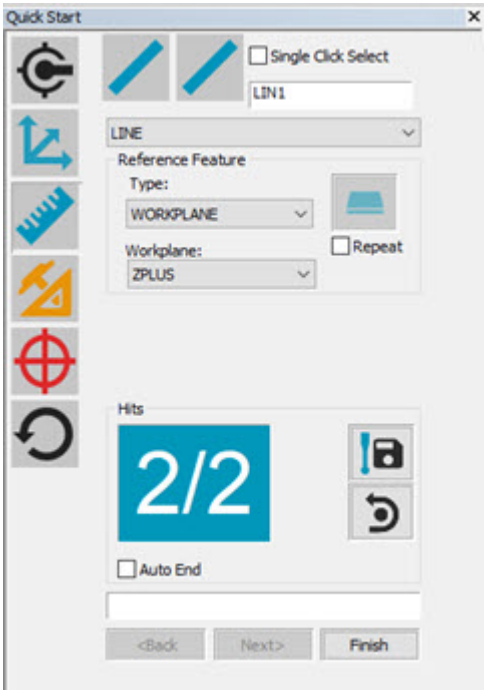
Icon	Description
	Calibrate Probes - This icon does not have a toolbar. It opens the **Probe Utilities** dialog box. You can use this dialog box to define a probe and calibrate probe tips.
	Alignments - Displays the **Quick Start Align** toolbar. You can select an alignment procedure from this toolbar.
	Measure - Displays the **Quick Start Measure** toolbar. You can select a measurement procedure from this toolbar.
	Construct - Displays the **Quick Start Construct** toolbar. You can select a construction procedure from this toolbar.
	Dimension - Displays the **Quick Start Dimension** toolbar. You can select a desired dimension procedure from this toolbar.
	Reset - This icon does not have a toolbar. It resets the **Quick Start** dialog box to Guess Mode.

Understanding the Quick Start Interface

When you enable the **Quick Start** interface, PC-DMIS disables the QuickFeature functionality. Also, if you are in the process of creating a Quick Start feature, you cannot perform any editing in the Edit window.

For example, you cannot use QuickFeatures if you enable the **Quick Start** interface. Also, you cannot delete, copy, or mark features in the Edit window; neither can you execute your measurement routine. To perform these and other actions, you need to first close the **Quick Start** interface.

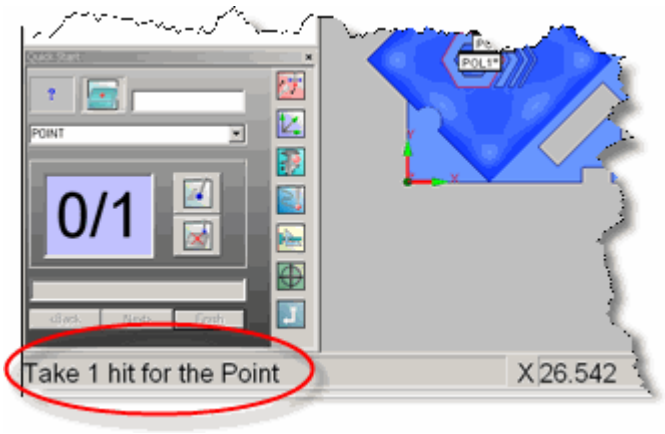
The **Quick Start** toolbar is tied to the **Quick Start** dialog box. This means that whenever you select the **Quick Start** interface, both the toolbar down the left side and the dialog box automatically appear and are inseparable.



Quick Start Dialog Box

In addition:

- Hover your mouse over a particular item on the dialog box or toolbar to display a tooltip with information on what that item does.
- To dock or undock the **Quick Start** dialog box to or from the left side of the screen, click the title bar and then drag and drop it. For details on docking and undocking user interface elements, see "Docking and Undocking User Interface Elements".
- Instructions for the various Quick Start procedures appear on the status bar at the bottom of your screen. If the instructions are too long for the Status bar area, PC-DMIS scrolls the instructions from right to left. To reset the scrolling of the current instructions to the beginning, move your mouse over the **Quick Start** dialog box.



Example showing the Quick Start instruction on the left side of the Status bar.

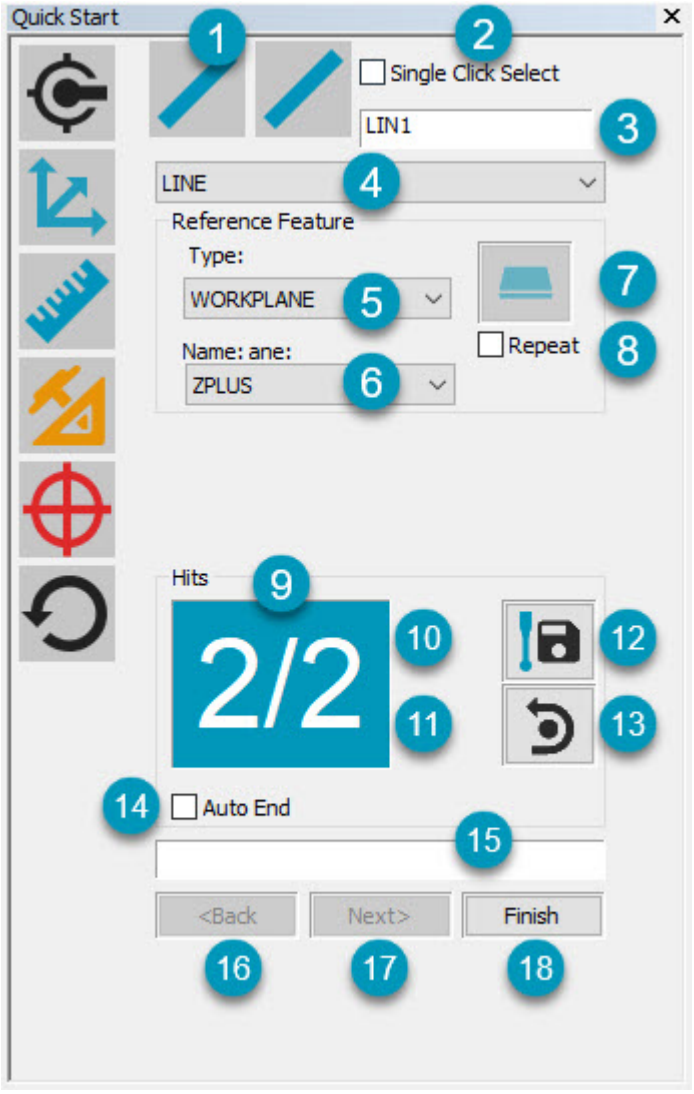
- To select input features used in the different procedures, click the feature from the Edit window or Graphic Display window.

- PC-DMIS includes a Status window that you can use to preview a dimension. If the dialog box is in Guess Mode, the preview is useful for reviewing a measured feature before you click the **Finish** button to insert the dimension or feature into the measurement routine. See "Using the Status Window" in the "Using Other Windows, Editors, and Tools" chapter.

Using the Quick Start Dialog Box

The **Quick Start** interface contains a toolbar attached to the **Quick Start** dialog box (**View | Other Windows | Quick Start**). Many of the procedures on this toolbar use the **Quick Start** dialog box to perform their operations. The toolbar icons are discussed in the "Using the Quick Start Interface" topic.

This topic focuses on describing the items on the dialog box portion of the interface and how to use the dialog box to perform various operations.



Quick Start Dialog Box

1 - **Graphical Description**

For all operations that use the **Quick Start** dialog box, PC-DMIS displays two icons at the top of the dialog box. A current procedure on the left and the current step in that procedure, or the current guessed feature, on the right.

If you see an asterisk icon, that means PC-DMIS is in a Guess Mode operation.

For example, in the above image, the Point icon on the right shows that with a single hit, a point feature gets created. The icon on the right changes to a line if you take another hit. PC-DMIS returns to this mode whenever you finish creating a Constructed feature or Alignment using the **Quick Start** dialog box. Click the **Guess Mode** button from the **Quick Start: Measure** toolbar to place PC-DMIS in Guess Mode.

Depending on the number of points taken, this mode guesses the feature type you're attempting to measure and dynamically updates the **Quick Start** dialog box to reflect this. For example:

- If you are in **Guess Mode** and you take two points, the **Quick Start** dialog box updates to a Line feature.
- If you take four points, it updates to a Circle feature.
- If you take eight points, it updates to a Cylinder, and so on.

See "Guessing a Measured Feature Type" in the "Creating Measured Features" chapter.

2 - **Single Click Select**

You can use this check box to create a measured feature with a single click of the mouse on the CAD model.

See "Creating Quick Start Measured Features" below for information.

3 - **ID**

The unique ID for the feature. An ID appears in the box once you select an appropriate procedure.

See "ID" in the "Navigating the User Interface" chapter.

See "Editing Values and IDs" in the "Using the Edit Window" chapter.

4 - **Feature Override**

This list is used to override the guessed feature measurement to the selected feature type. For example, if you take four hits and PC-DMIS guesses a plane, you can select **Circle** from this list to force it to create a measured circle instead.

See "Overriding a Guessed Measured Feature" in the "Creating Measured Features" chapter.

5, 6, 7, 8 - **Reference Feature**

You can project some measured features (circles, ellipses, lines, polygons, and slots) relative to a reference plane. The **Reference Feature** area appears in the **Quick Start** dialog box for these feature types where you can determine whether or not the measured feature is 3D, projected relative to the current workplane, or another user-defined plane.

You can select one of these types of reference features from the **Type** list (5):

- **3D** - The measured feature is created in 3D space directly from the hits probed on the part. It is not constrained to fit relative to a plane.

  For measured lines, the **3D** item is not available because there is no way for PC-DMIS to know which way to compensate them.

- **Workplane** - The measured feature is created as a 2D feature that is snapped onto a plane parallel to the referenced workplane and located at the average distance between the points.

- **Feature** - The measured feature is created as a 2D feature that is snapped onto a referenced user-defined plane.

  If you want the feature created at the average distance between the points on a plane parallel to the referenced user-defined plane, you must clear the **Move Feature to Reference Plane** check box in the list of check boxes on the **General tab** of the **Setup Options** dialog box. See "Setup Options: General Tab" for more information.

  If you need a reference plane feature that doesn't exist in the **Name** list (6), click the plane icon (7). The **Quick Start** dialog box walks you through the process of measuring the plane feature and then returns to the current line, circle, or slot measurement.

Repeat - This functionality ties into the plane icon discussed in the previous paragraph. In some instances, you may want to create a new reference plane for each feature. Rather than clicking the plane icon before each feature measurement, you can mark this check box to have PC-DMIS repeat the plane creation sequence before measuring each feature. PC-DMIS prompts you to take three hits to create the reference plane first. When you click **Finish**, it then prompts you to take the hits for the actual feature.

You can use the **Move Feature to Reference Plane** check box on the **General** tab of the **Set Up Options** dialog box to have 2D features snapped directly onto the reference plane instead of onto a parallel plane.

9 - **Number of Hits Taken / Required Hits**

This display shows two numbers.

- The number on the left of the slash indicates the number of hits you have currently taken.
- The number on the right of the slash indicates the minimum hits you need to measure the feature. You can take more than the minimum number of hits, in which case, the number to the left of the slash will be greater than the number on the right. You can also increase the number to a user-defined minimum.

10 - **Increase Hits**

The up arrow increases the feature's defined minimum number of hits (the number on the right of the slash) by one.

11 - **Decrease Hits**

The down arrow decreases the feature's defined minimum number of hits (the number on the right of the slash) by one.

12 - **Store a Move**

The **Store a Move** icon is used to easily store move points into the measurement routine. When you click this icon, PC-DMIS reads the current location of the probe and inserts a `MOVE/POINT` command into the Edit window.

See "Inserting a Move Point Command" in the "Inserting Move Commands" chapter.

13 - **Remove a Hit**

The **Remove a Hit** icon removes the last hit from the hit buffer.

14 - **Auto End**

You can use the **Auto End** check box to have the software automatically finish or end a feature in learn mode once it detects that you have taken the required number of hits. This means you don't need to press a key or click a button to learn the feature. You can use the **Increase Hits** or **Decrease Hits** arrow buttons to set the required number of hits.

Notes on laser Trackers

- If you mark **Auto End**, and from the **Compensation** area, you mark **Predefined**, the software finishes the feature when you measure the defined number of hits.

- If you clear **Auto End**, and from the **Compensation** area, you mark **Predefined**, the feature may finish early. Suppose you defined the required hits above the internal minimum needed for a feature (such as seven hits for a circle feature which internally only requires three), you can press END to learn the feature early as long as the number of hits you take meets or exceeds the internal required minimum.

- If you clear both **Auto End** and **Predefined**, you must always press **END** or click **Finish** to complete the feature.

For more information on the **Compensation** area, see "Predefined Compensation" in the Portable documentation.

15 - **Results**

The **Results** box shows the results of all steps in a measurement procedure taken thus far. For example, if you want to do a Plane - Line - Line alignment, the results box shows the following when you select or measure the second line:

Step 1:PLN1=Measured Plane

Step 2:LIN1=Measured Line

Step 3:LIN2=Measured Line

The **Results** box is tied to the buttons at the bottom of the dialog box. The buttons become enabled whenever you fulfill the requirements for a certain step in a procedure.

16, 17 - **<Back and Next>**

The **<Back** and **Next>** buttons cycle between lists of the required features or inputs. These buttons become available when procedures used on the toolbars require the selection or creation of multiple features (such as the **Dimension** and **Align** toolbars) or user input (such as upper and lower tolerance values for dimensions).

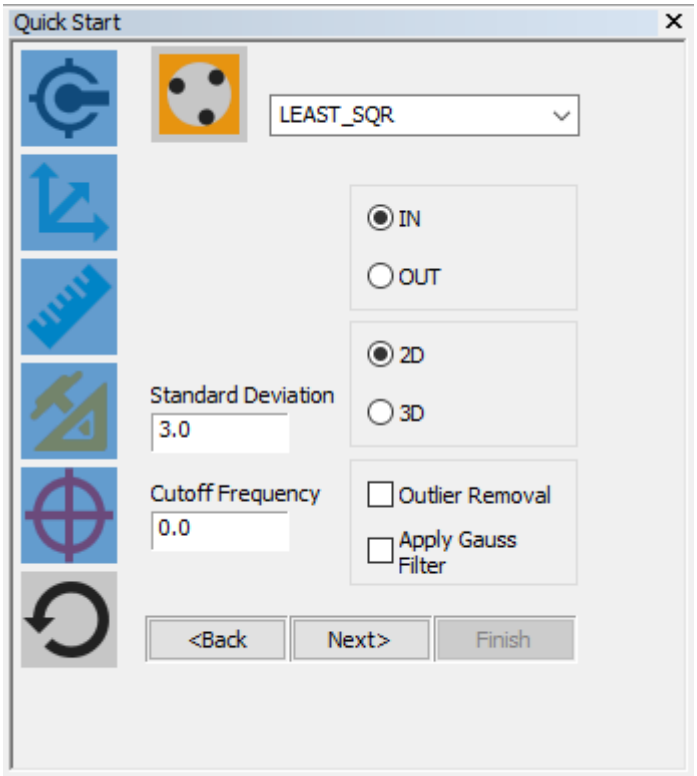
Clicking the **Done** button on your jog box acts the same as clicking the **Next>** button when using the **Quick Start** dialog box.

18 - **Finish**

The **Finish** button completes the procedure, inserts the appropriate command into the Edit window, and then, in most cases, PC-DMIS returns to the initial step of the current procedure. For alignments or constructed features, however, after you click **Finish**, PC-DMIS returns to the default Guess Mode.

Constructed Features Interface

For some constructed features, when working through the steps to create the features, the Quick Start interface displays additional options with a green background, similar to this:



These options are not described in this chapter. For information on these options, consult the appropriate topic in the "Constructing New Features from Existing Features" chapter.

Quick Start: Measure Toolbar

Quick Start Measure Toolbar

This toolbar contains the icons relative to the following measuring functions:

Point	Line	Plane
Circle	Cylinder	Cone
Sphere	Torus	Round Slot
Square Slot	Guess Mode	

For more information on creating measured features, see the "Creating Measured Features" chapter.

Scanning

The **Scan** icon lets you quickly perform a Fixed Time / Distance Manual Scan (Variable Delta). PC-DMIS prompts you with instructions in the Status bar. For more information on this type of scan, see one of the following:

- For a CMM, see "Performing a Fixed Time / Distance Manual Scan" in the "Scanning" chapter of the PC-DMIS CMM help.
- For a portable device, see "Performing a Fixed Time / Distance Manual Scan" in the "Portable Hard Probe Scanning" chapter of the PC-DMIS Portable help.

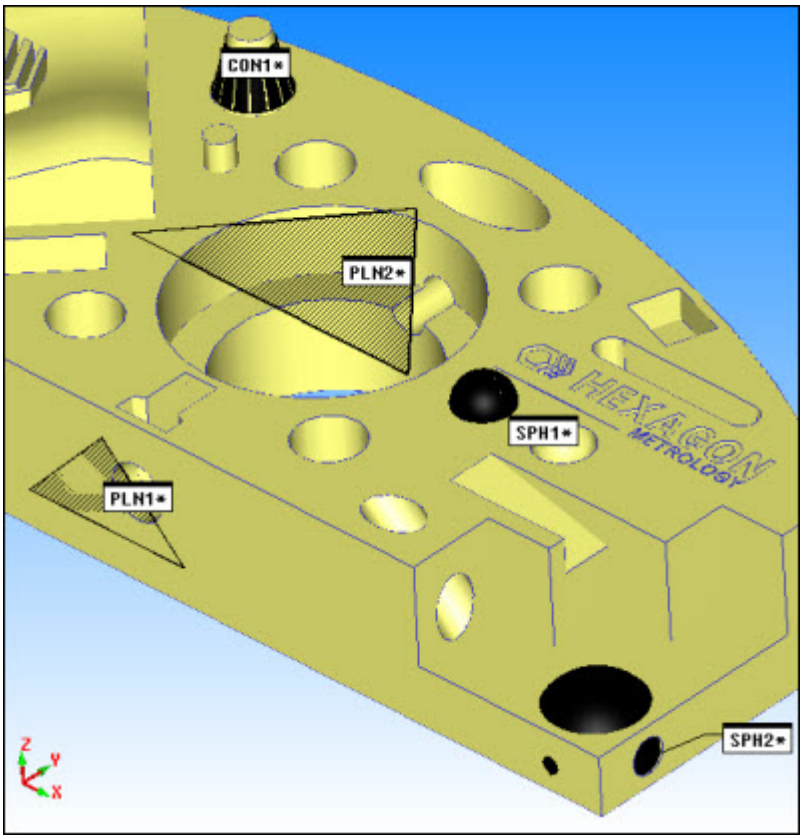
Creating Quick Start Measured Features

1. From the **Quick Start** toolbar, select the **Measure** toolbar. For details, see the "Using the Quick Start Interface" chapter.

2. Click the icon of the feature to measure. The top-left icon in the dialog box changes to display the features that PC-DMIS measures in this procedure. Instructions appear on the status bar.
3. With PC-DMIS in Offline mode, click the **Program Mode** icon on the **Graphic Modes** toolbar (for details, see "Graphic Modes Toolbar"). PC-DMIS draws a simulated depiction of the probe near the part in the Graphic Display window.
4. With PC-DMIS in Offline mode, right-click to set the depth for the probe. With PC-DMIS in Online mode, move the probe to the desired depth.
5. Take the minimum number of hits on the part to measure the feature.
6. Click **Finish** or press **Done** on your jog box when the measurement is complete. The **Quick Start** dialog box remains open. PC-DMIS automatically compensates for the probe radius and places the measured feature on the part in the Graphic Display window.
7. Follow steps four through six until you create all of the measured features you need.

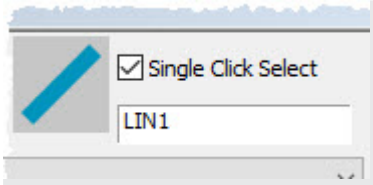
8. Click **Close** when finished. The **Quick Start** dialog box closes.

As PC-DMIS takes hits and creates the feature, it draws the measured feature on the screen. For 3D measured features (Torus, Cylinder, Sphere, Cone, and Plane), PC-DMIS draws the feature with a shaded surface.



Example showing measured features with shaded surfaces.

Creating Measured Features from CAD Using Single Click Select Option



The **Single Click Select** option works with all measured features except Torus and scans. PC-DMIS disables this option internally during Guess Mode. See the note below.

The **Single Click Select** check box controls how PC-DMIS creates features when you use CAD. If you select the check box, you can now learn a measured feature with a single mouse-click on the CAD model. To do this:

1. Select the type of feature that you want to create from the **Quick Start** dialog box's **Measure** toolbar.

2. Mark the **Single Click Select** check box.

3. Click, with your mouse, on the CAD model near the feature that you want to create. PC-DMIS locates the feature in the CAD model and automatically generates the necessary hits to create the feature. The hit count increases and displays the predefined number of hits for the feature type you chose.

Feature Type	Number of Hits
Point	1
Line	2
Plane	4
Circle	4
Cylinder	8
Cone	8
Sphere	5
Round Slot	6
Square Slot	5

4. Once PC-DMIS generates the hits, click **Finish** to insert the feature into the measurement routine.

Single Click Select and Guess Mode

This icon places PC-DMIS into Guess mode. Single Click Select does not work in Guess mode even though the check box remains selected. For Guess mode to function, PC-DMIS attempts to detect the feature type at each successive hit. To maintain consistency with existing functionality, PC-DMIS disables Single Click Select internally if you use Guess mode. If the Quick Start window is closed, PC-DMIS automatically reverts to the legacy Guess mode even if Single Click Select was selected when the Quick Start window was closed. Single Click Select requires you to identify, ahead of time, what feature is being measured. This capability is unique to the Quick Start window.

An asterisk icon appears in the top-left corner of the **Quick Start** dialog box to show that the software is in Guess mode.

Measuring a Point

	You can use the **Point** icon to measure the position of a point belonging to a plane aligned with a reference plane (shoulder) or a point in space.
To create a measured point you must take one hit on the part.	
For information on the associated Edit window command, see the "Basic Measurement Format for a Point" topic in the "Creating Measured Features" chapter.	

Measuring a Line

	You can use the **Line** icon to measure the orientation and linearity of a line belonging to a plane aligned with a reference plane, or a line in space.

To create a measured line, you must take two hits on the part.

Measured Lines and Workplanes

When creating a measured line, PC-DMIS expects the hits for the line to be taken at a vector perpendicular to the current workplane.

For example, if your current workplane is ZPLUS (with a vector 0,0,1), and you have a block-like part, the hits for the measured line must be on a vertical wall of that part, such as the front or side.

If you then wanted to measure a line feature on the top surface of the part, you would need to switch the workplane to XPLUS, XMINUS, YPLUS, or YMINUS, depending on the direction of the line.

For information on the associated Edit window command, see the "Basic Measurement Format for a Line" topic in the "Creating Measured Features" chapter.

Measuring a Plane

	You can use the **Plane** icon to measure any flat or planar surface.
To create a measured plane, you must take a minimum of three hits on any flat surface. If you only use the minimum of three hits, it's best to select the points in a large triangular pattern that cover the widest area of the surface.	
Example Plane with 4 Points	Example Plane with 8 Points
	When you create a plane feature, PC-DMIS shows the outline of the plane from the plane's hits in the Graphic Display window:  *Sample plane from four hits taken on the Y-face* For information on the associated Edit window command, see the "Basic Measurement Format for a Plane" topic in the "Creating Measured Features" chapter.	

Measuring a Circle

<table>
<tr><td> then </td><td>You can use these Circle icons to measure the diameter, roundness, and position of the center of a hole or stud parallel to a reference plane, i.e. the perpendicular section of a cylinder aligned with a reference axis.</td></tr>
<tr><td colspan="2">To create a measured hole or stud, you must take a minimum of three hits. The plane is automatically recognized and set by the system during measurement. You must distribute the points to be picked uniformly around the circumference of the circle.</td></tr>
<tr><td>Example Circle with 4 Points</td><td>Example Circle with 8 Points</td></tr>
<tr><td> </td><td> </td></tr>
<tr><td colspan="2">For information on the associated Edit window command, see the "Basic Measurement Format for a Circle" topic in the "Creating Measured Features" chapter.

 You can also create circles from a single point by using the Measure Single Point Circle toolbar item. This is useful when you attempt to measure a hole with a probe whose sphere size is larger than the hole's diameter and therefore cannot fit entirely into the hole to take the usual minimum three hits required. For more information, see the PC-DMIS Portable documentation.

For details on how to create single-point circle features with PC-DMIS Portable, see "Creating Single-Point Circle Features" topic in the PC-DMIS Portable documentation.</td></tr>
</table>

Measuring a Cylinder

	You can use the **Cylinder** icon to measure the diameter, cylindricity, and orientation of the axis of a cylinder oriented in space. PC-DMIS also calculates the position of the baricenter of the points picked.
To create a measured cylinder, you must take a minimum of six hits on the cylinder. You must distribute the points to be picked uniformly over the surface of the cylinder. The first three points picked must lie on a plane perpendicular to the main axis.	
 *Example showing a cylinder feature with eight points.*	
For information on the associated Edit window command, see the "Basic Measurement Format for a Cylinder" topic in the "Creating Measured Features" chapter.	

Measuring a Cone

	You can use the **Cone** icon to measure conicity, angle at the tip, and orientation in space of the axis of a cone. The position of the baricenter of the points picked is also calculated.
To create a measured cone, you must take a minimum of six hits. The points to be picked must be uniformly distributed on the surface. The first three points picked must lie on a plane perpendicular to the main axis.	
 *Example showing a cone feature with eight points.*	
For information on the associated Edit window command, see the "Basic Measurement Format for a Cone" topic in the "Creating Measured Features" chapter.	

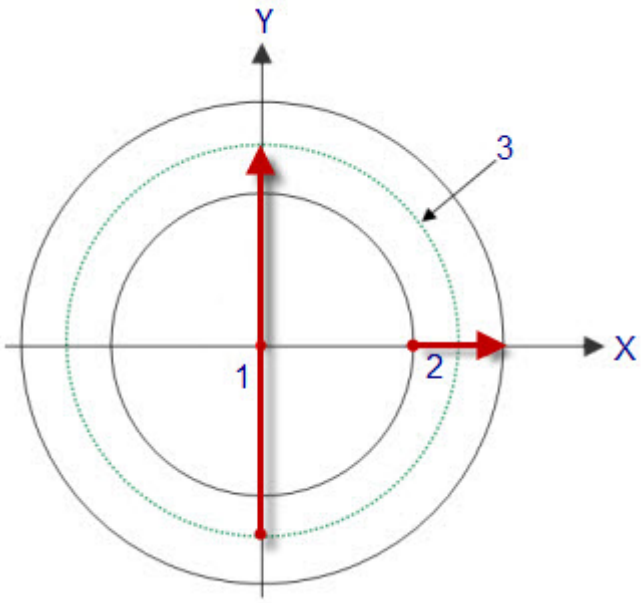
Measuring a Sphere

	You can use the **Sphere** icon to measure the diameter, sphericity, and position of the center of a sphere.
To create a measured sphere, you must take a minimum of four hits. You must distribute the points to be picked uniformly over the surface of the sphere. The first four points picked must not lie on the same circumference. The first point should be taken on the pole of the sphere's cup. The other three points are taken on a circumference.	
Example Sphere with 5 Points	Example Sphere with 9 Points
	For information on the associated Edit window command, see the "Basic Measurement Format for a Sphere" topic in the "Creating Measured Features" chapter.	

Measuring a Torus

	You can use the **Torus** icon to measure the center diameter and ring diameter of the torus feature. The position of the barycenter of the points picked is also calculated.

To create a measured torus, you must take a minimum of seven hits. Take the first three hits on one level of the torus's center line circle (see the diagrams below). These hits must represent the orientation of the torus so that an imaginary circle generated through these three hits would have roughly the same vector as the torus.

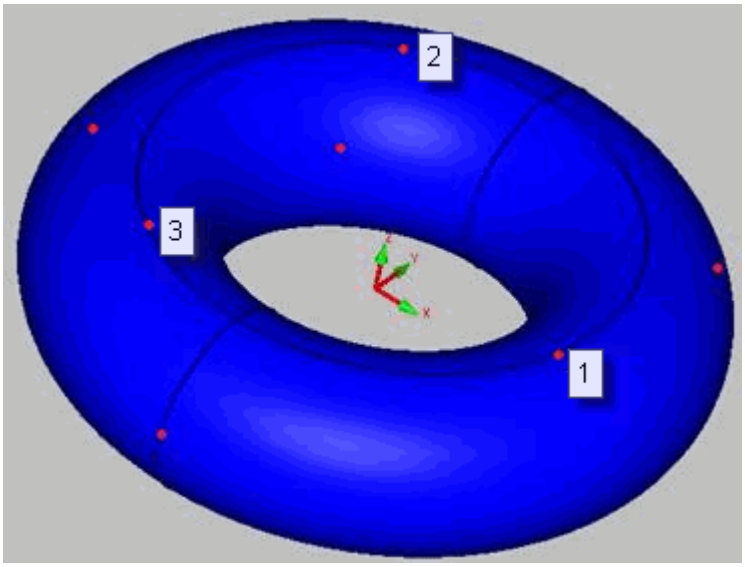


Top-down view of a torus. Note the major diameter (1), the minor diameter (2), and the center line circle (3).

If you orient the torus and are looking down on it from a bird's eye view, with Z+ pointing up towards you, take the first three hits in a counter-clockwise direction to give the torus a vector of 0,0,1. If you take the hits in a clockwise direction, the torus will have a vector of (0,0,-1).

You can probe the remaining 4 hits in any random location as long as they all don't lie in the same plane.

Example Torus with 7 Points



Example Torus created from 7 points, with the first three taken in a counter clockwise direction

For information on the associated Edit window command, see the "Basic Measurement Format for a Torus" topic in the "Creating Measured Features" chapter.

Measuring a Round Slot

then	You can use these **Round Slot** icons to create a measured round slot.

To create a measured round slot, you must take at least six hits on the slot, usually two points on each straight side and one point on each curve. Alternately, you could take three points on each curve.

Example showing a round slot feature with six points.

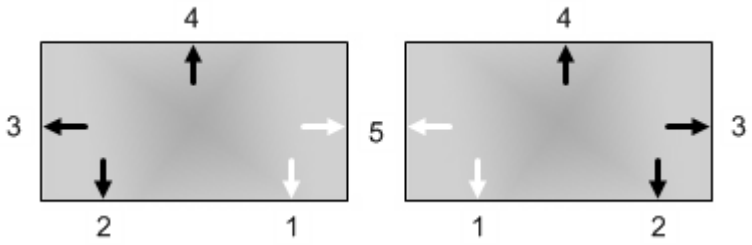
You can also create measured slots from two points. This is useful when the probe sphere is larger than the slot's diameter, and you're not able to take the required hits. For more information, see the PC-DMIS Portable documentation.

For information on the associated Edit window command, see the "Basic Measurement Format for a Round Slot" topic in the "Creating Measured Features" chapter.

Measuring a Square Slot

then	You can use these **Square Slot** icons to create a measured square slot.

To create a measured square slot, you must take five hits on the slot, two on one of the long sides of the slot and then one hit on each of the three remaining sides. The hits must be taken in a strictly Clockwise (CW) or Counterclockwise (CCW) direction.



Example showing a square slot feature with five points in CW (left) and CCW (right) directions.

With this icon, you can also create measured slots from two points. This is useful when the probe sphere is larger than the slot's diameter, and you're not able to take the required hits. For more information, see the PC-DMIS Portable documentation.

For information on the associated Edit window command, see the "Basic Measurement Format for a Square Slot" topic in the "Creating Measured Features" chapter.

Using Guess Mode

	Use the **Guess Mode** icon to have PC-DMIS guess the type of measured feature to create based on the hits taken.

The following table shows the minimum number of hits PC-DMIS needs to guess a particular Measured Feature and that feature's dimension type.

Minimum # of Hits	Feature	Dimension
1	Point	1D
2	Line	2D
3	Plane	2D
3	Circle	2D
6	Cylinder	3D
6	Cone	3D
4	Sphere	3D
7	Torus	3D
6	Round Slot	2D
5	Square Slot	2D

See the "Guessing a Measured Feature Type" topic in the "Creating Measured Features" chapter for rules and additional information on using guess mode.

Quick Start: Construct Toolbar

Quick Start Construct Toolbar

When you construct elements, instead of processing picked points, PC-DMIS processes the characteristic points of already measured elements or elements you will measure.

The range of elements that you can construct is identical to the range of the elements that you can measure using the **Quick Start Measure** toolbar. The most frequent application is the construction of the circle passing through the centers of a circular pattern of holes or bosses.

Typically, the elements used to construct other elements are points and circles (or spheres) which you may or may not have measured and stored already. If you have not already measured a needed feature, you can measure it during the construction procedure.

The features you can construct are:

Point Features		Line Features	
	• Intersect Point • Mid Point • Projected Point		• Best Fit Line • Intersect Line • Mid Line
Plane Features		**Circle Features**	
	• Best Fit Plane • Mid Plane • Alignment Plane		• Best Fit Circle • Intersect Circle • Height Circle • Diameter Circle
Slot Features		**Cylinder Features**	
	• Slot Feature		• Cylinder Feature
Cone Feature			
	• Cone Feature		

See the topics in the "Constructing New Features from Existing Features" chapter of the PC-DMIS Core documentation for in-depth information on these feature constructions.

Creating Constructed Features

This procedure below contains very basic information on constructing features. For in-depth information, see the "Constructing New Features from Existing Features" chapter.

1. From the **Quick Start** toolbar, select the **Construct** toolbar. See "Using the Quick Start Interface" chapter for details.
2. Click the icon of the feature to be measured. The **Quick Start** dialog box shows an icon of the procedure and a second icon for the first needed feature type.
3. Follow the instructions at the bottom of the toolbar or on the Status bar. You can either fill in the data in the dialog or select (or measure) the needed features to use in the construction.
4. Continue following the instructions until the **Finish** button becomes available. If you find items that appear in the Quick Start user interface that are not covered in the "Using the Quick Start Dialog Box" topic, consult the "Constructing New Features from Existing Features" chapter.
5. Click **Finish** when ready. PC-DMIS places the newly constructed feature on the part in the Graphic Display window and also in the Edit window.

Quick Start: Dimension Toolbar

Quick Start Dimension Toolbar

The **Dimension** toolbar lets you perform geometric measurements and geometric tolerance checks. With the exception of the **Key-In** dimension, this toolbar contains all the dimensions from the normal PC-DMIS **Dimension** toolbar. See "Dimension Toolbar" in this chapter.

> The **Quick Start Dimension** toolbar only creates legacy dimensions. It does not create the new Geometric Tolerance dimension commands covered in the "Using Geometric Tolerances" chapter.

About Geometric Measurements	About Geometric Tolerance Checks
You can use geometric measurements in the following circumstances: • When dimensions involve two elements (such as distances and angles). • When dimension elements are not measurable (such as corners). • When you can obtain dimension measurements from geometric calculation procedures (intersections, projections, and / or middle elements). In each geometric relationship between two elements, PC-DMIS creates a third element (point, circle, line, or plane). The default output format of the calculated element includes the most meaningful dimensions. Do not confuse *Geometric relationships* with *geometric tolerances*. • *Geometric tolerances* are used to check the *functional requirements* of a feature. *Functional requirements* are feature characteristics that ensure sufficient assembly, safety, appearance, performance etc. • *Geometric relationships*, as used in PC-DMIS, are not sufficient to ensure functional requirements because they do not utilize the full extent of datum theory.	Geometric tolerance checks test the location, orientation, profile, runout, or form error of a feature (checked feature) relative to a datum reference frame (as applicable). The following checks are available: • **Orientation checks:** test for errors of parallelism, perpendicularity, and angularity. • **Location checks:** test for errors of coaxiality, and concentricity, location, and position. • **Profile checks:** test for errors of profile form or profile, relative to the current alignment. • **Runout checks:** test for errors of total runout of a circle, cylinder, or plane. PC-DMIS inserts a dimension of the resulting geometric tolerance check between two elements into the Edit window.

Icon	Description	Quick Start Procedure
	Creates a legacy Location dimension.	Select or measure the feature and click **Next**. Specify the plus and minus tolerances and then click **Finish** to insert the Location dimension.
	Creates a legacy Position dimension.	Select or measure the feature and click **Next**. Specify the plus and minus tolerances and then click **Finish** to insert the Position dimension.
	Creates a legacy Distance dimension.	Select or measure the first feature and click **Next**. Select or measure the second feature and click **Next**. Specify the plus and minus tolerances, type a nominal value, select either 2D or 3D, and then click **Finish** to insert the Distance dimension.
	Creates a legacy Angle dimension.	Select or measure the first feature and click **Next**. Select or measure the second feature and click **Next**. Specify the plus and minus tolerances, type a nominal value, select either 2D or 3D, and then click **Finish** to insert the Angle dimension.
	Creates a legacy Concentricity dimension.	Select or measure the first circular feature and click **Next**. Select or measure the second circular feature and click **Next**. Specify the plus tolerance and click **Next**. Click **Finish** to insert the Concentricity dimension.
	Creates a legacy Coaxiality dimension.	Select or measure the first feature (cylinder, cone, or line) and click **Next**. Select or measure the second feature (cylinder, cone, or line) and click **Next**. Specify the plus tolerance and click **Next**. Click **Finish** to insert the Coaxiality dimension.
	Creates a legacy Circularity dimension.	Select or measure the first circular feature and click **Next**. Select or measure the second circular feature and click **Next**. Specify the plus tolerance and click **Next**. Click **Finish** to insert the Roundness dimension.

	Creates a legacy Cylindricity dimension.	Select or measure a Cylinder and click **Next**. Select or measure the second feature and click **Next**. Specify the plus tolerance and click **Next**. Click **Finish** to insert the Cylindricity dimension.
	Creates a legacy Straightness dimension.	Select or measure a Cone, Line, or Cylinder and click **Next**. Specify a plus tolerance and click **Next**. Click **Finish** to insert the Straightness dimension.
	Creates a legacy Flatness dimension.	Select or measure a Plane and click **Next**. Specify a plus tolerance and click **Next**. Click **Finish** to insert the Flatness dimension.
	Creates a legacy Perpendicularity dimension.	Select or measure the first feature and click **Next**. Select or measure the second feature. Specify a plus tolerance and a projection distance and click **Next**. Click **Finish** to insert the Perpendicularity dimension.
	Creates a legacy Parallelism dimension.	Select or measure a non-point feature and click **Next**. Select or measure the second non-point feature. Specify a plus tolerance and a projection distance and click **Next**. Click **Finish** to insert the Parallelism dimension.
	Creates a legacy Total Runout dimension.	Select or measure a Cone, Cylinder, Line, or Plane and click **Next**. Specify a plus and minus tolerance and click **Next**. Click **Finish** to insert the Total Runout dimension.
	Creates a legacy Circular Runout dimension.	Select or measure a Circle, Cone, Cylinder, Line, or Sphere and click **Next**. Specify a plus and minus tolerance and click **Next**. Click **Finish** to insert the Circular Runout dimension.
	Creates a legacy Surface Profile dimension.	Select or measure a feature and click **Next**. Specify a plus and minus tolerance. Choose whether the profile is Form Only or Form and Location and click **Next**. Click **Finish** to insert the Surface Profile dimension.

	Creates a legacy Line Profile dimension.	Select or measure a feature, and click **Next**. Specify a plus and minus tolerance and click **Next**. Click **Finish** to insert the Line Profile dimension.
	Creates a legacy Angularity dimension.	Select or measure any non-point or non-sphere feature and click **Next**. Select a Cone, Cylinder, Line, or Plane and click **Next**. Specify a plus tolerance, a distance, and angle and click **Next**. Click **Finish** to insert the Angularity dimension.
	Creates a legacy Symmetry dimension.	Select or measure a line or set for the first feature and click **Next**. Select the second feature and click **Next**. Select the third (or datum) feature and click **Next**. Type a plus tolerance and click **Next**. Click **Finish** to insert the Symmetry dimension.

Dimensioning Features Using the Quick Start Interface

The procedure below provides basic instructions on how to use the Quick Start interface to create dimensions:

1. From the **Quick Start** toolbar, select the **Dimension** toolbar. See "Using the Quick Start Interface" chapter for details.
2. Select the desired dimension from the toolbar. The icon for the selected dimension procedure appears in the **Quick Start** dialog box and instructions appear in the Status Bar at the bottom of your screen.
3. Follow the instructions on the Status Bar by selecting features from the Edit window or Graphic Display window (or by measuring them if they don't exist).
4. Follow the instructions on the Status Bar to type values into the **Quick Start** dialog box.
5. Continue following instructions and clicking **Next** until the **Finish** button becomes available.
6. Click **Finish**. PC-DMIS inserts the dimension into the measurement routine.

Quick Start: Align Toolbar

Quick Start Align Toolbar

The **Align** toolbar is used to create alignments from specific feature types by using these procedures.

Icon	Description	Quick Start Procedure
	Plane, Line, Line alignment	Select or measure a Plane to level to, and click **Next**. Select or measure a Line to rotate to, and click **Next**. Select or measure a second Line. The origin is created by translating the part to the two lines. Click **Finish** to insert the alignment.
	Plane, Line, Circle alignment	Select or measure a Plane to level to, and click **Next**. Select or measure a Line to rotate to, and click **Next**. Select or measure a Circle. The circle's center, projected onto the line, is where PC-DMIS sets the alignment's origin. Click **Finish** to insert the alignment.
	Plane, Circle, Circle alignment	Select or measure a Plane to level to, and click **Next**. Select or measure the first Circle feature, and click **Next**. Select or measure the second Circle feature. PC-DMIS rotates the alignment to the line created from the centers of the two circles. It then uses the first circle's center to set the alignment's origin. Click **Finish** to insert the alignment.
	Plane, Line, Point alignment	Select or measure a Plane to level to, and click **Next**. Select or measure a Line to rotate to, and click **Next**. Select or measure a Point for the alignment's origin. Click **Finish** to insert the alignment.
	Cylinder, Line, Point alignment	Select or measure a Cylinder, and click **Next**. Select or measure a Line, and click **Next**. Select or measure a Point. PC-DMIS levels the alignment to the surface where you clicked the point, rotates the alignment to the line, and sets its XY origin in the center of the cylinder. Click **Finish** to insert the alignment.
	Align Free alignment	This opens up the **Alignment Utilities** dialog box. See "Description of the Alignment Utilities Dialog Box" in the "Creating and Using Alignments" chapter for information on using this dialog box to create an alignment.

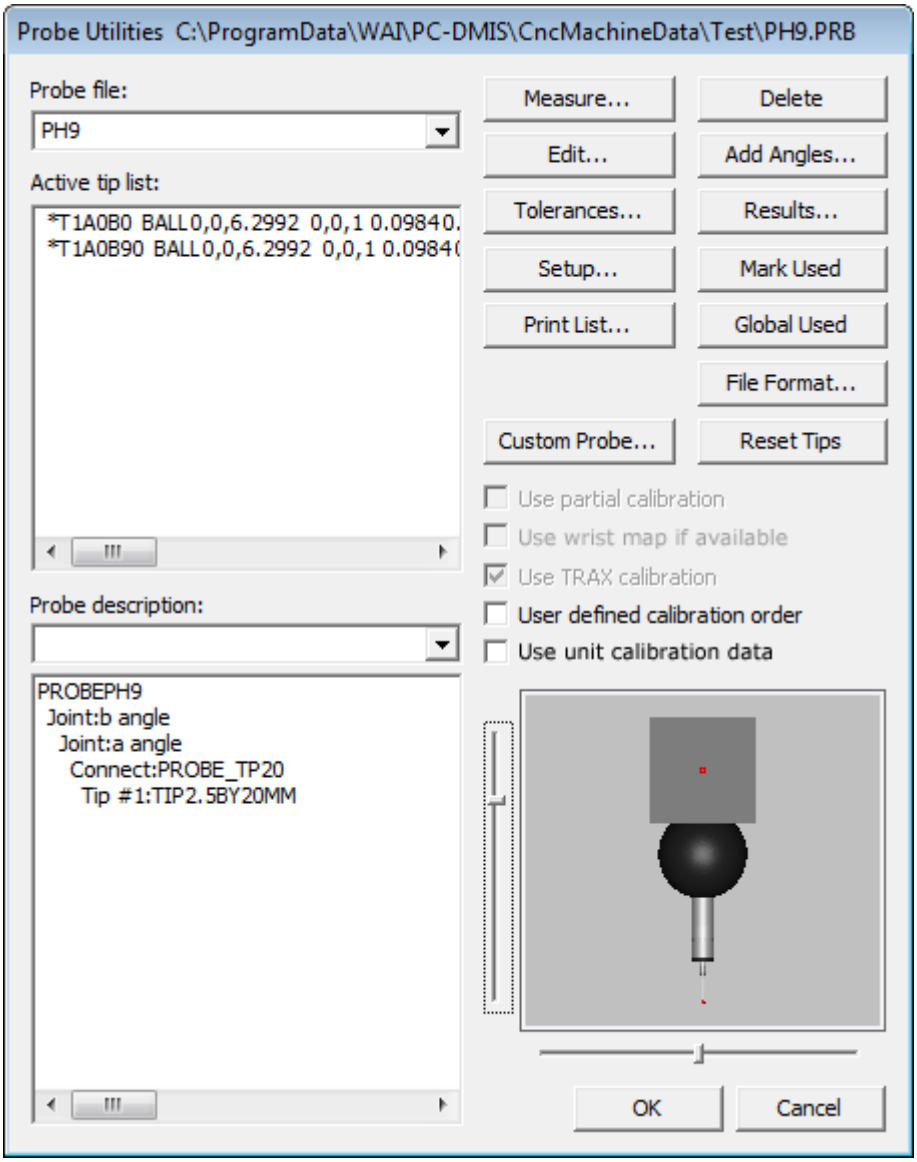
	Six Points Best Fit alignment	Follow the on-screen prompts to select or measure six points. A typical procedure is to measure three points on the top surface to level to the Z Axis. Measure two points on the front surface to rotate to the X Axis. Then measure one point to define the origin for the Y axis. Click **Finish**. This establishes the correct origin for the alignment. PC-DMIS inserts the Best Fit 3D Alignment. Following execution, PC-DMIS displays a 3D Alignment Best Fit Graphical Analysis in the Report window.  *Example showing the graphical analysis of a Best Fit alignment.* This graphical analysis of the 3D Best Fit alignment displays this information in the Report window: • **Header** - This contains various values used in the Best Fit alignment: Method, Standard Deviation, Mean, Translation offsets, Rotation offsets, Max iterations, Iterations. • **Vertical Axis** - This shows the amount of deviation after the alignment. • **Horizontal Axis** - This displays the IDs of the points used in the alignment.

For additional ways of creating alignments see the "Creating and Using Alignments" chapter.

Quick Start: CALIBRATE PROBES

CALIBRATE PROBES Button

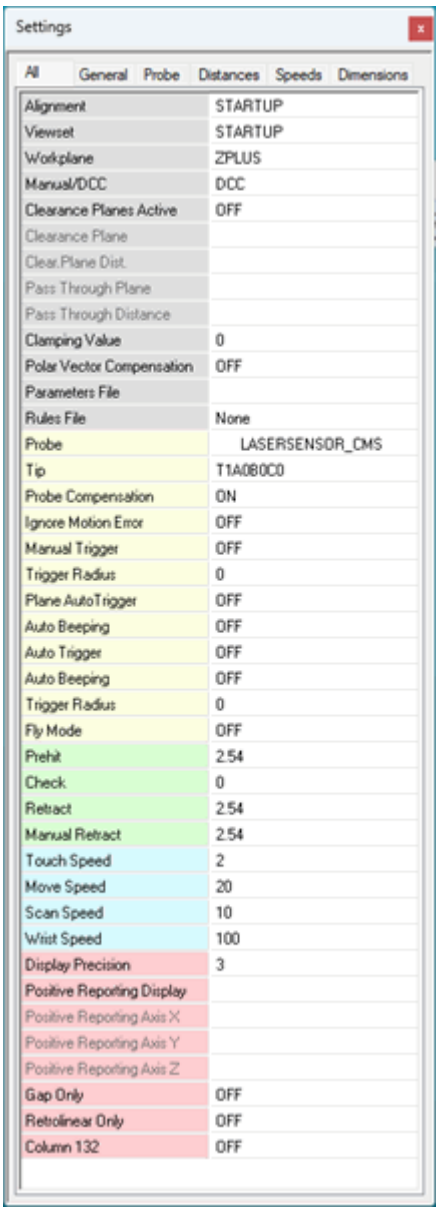
Click the **CALIBRATE PROBES** button to open the **Probe Utilities** dialog box. You can use this dialog box to create probes and calibrate their angles. For information on how to use this dialog box, see the "Defining Probes" topic in the "Defining Hardware" chapter of the PC-DMIS Core documentation.



Probe Utilities Dialog Box

Using the Settings Window

Select **View | Other Windows | Settings Window** to open the Settings window.



Settings Window

This dockable window contains several tabs of frequently modified settings. Each tab contains color-coded, editable settings, specific to that tab. The settings are linked to your cursor's current location in the measurement routine and updates their display to match the setting in the measurement routine at the cursor's location. For example, if you have multiple `LOADPROBE` commands, and you select each `LOADPROBE` command in the Edit window, PC-DMIS updates the Settings window to display the selected `LOADPROBE` command.

Editing a Setting

To edit a setting, simply click on the field to the right of the setting, and select a different option, or type a new value. When you change a setting, PC-DMIS inserts the appropriate parameter change into the measurement routine at the cursor's location.

Available Settings

The following tabs and settings are available. The shaded background on the cells in the table below indicates the default color associated with those settings:

All tab

This tab contains all the settings from all the tabs

General tab

Alignment - This inserts a `RECALL/ALIGNMENT` command, to recall the alignment you select from the list.

Viewset - This inserts a `RECALL/VIEWSET` command for the saved view you selected from the list.

Manual/DCC* - This inserts a `MODE/DCC` or `MODE/MANUAL` to place the measuring machine into either DCC or Manual mode respectively.

Workplane - This changes your current workplane by inserting a new `WORKPLANE` command into the measurement routine.

Clearance Plane Active - This activates a clearance plane by inserting a `CLEARP` command. Pressing F9 on the inserted command allows you to change the affected plane.

Clearance Plane - Allows you to define what plane has the clearance plane. This remains unavailable for selection until you activate the Clearance Plane Active setting or until a cursor rests on a `CLEARP` command.

Clear Plane Dist. - Lets you set the distance for the defined Clearance Plane.

Pass Through Plane - This indicates the plane that the probe passes through to get to the next feature plane.

Pass Through Distance - This defines the distance for the pass through plane.

Clamping Value - This value tells the controller how firmly to hold the probe on a Leitz CMM. It only works with the Leitz controller and the Leitz brand TTP.

Polar Vector Compensation - This allows the measurement of Vector and Surface points to always be compensated along a Polar vector by inserting a `POLARVECTORCOMP` command.

Probe tab

Probe - This inserts a `LOADPROBE` command for the selected probe into the measurement routine.

Tip - This defines the AB angle to use for the `LOADPROBE` command by inserting the selected `TIP` command into the measurement routine.

Probe Compensation - This turns probe compensation on or off by inserting the appropriate `PROBECOM` command.

Ignore Motion Error - This inserts an `IGNOREMOTIONERROR/ON` or `IGNOREMOTIONERROR/OFF` command into the measurement routine. If you turn this setting on, PC-DMIS will not stop when the probe encounters a collision.

Manual Trigger - This setting inserts a `POINT MANUAL TRIGGER` command into your measurement routine. For details, see the "Point Manual Trigger area" topic in the "Setting Your Preferences" chapter of the PC-DMIS Core documentation. This option is disabled in DCC mode.

Trigger Tolerance - This setting inserts a `TRIGGERTOLERANCE` command. This command tells PC-DMIS to only accept a hit if the hit is within the defined tolerance zone. You can use this with manual machines to take accurate hits.

Trigger Tol. Zone - This value determines the tolerance radius for the Trigger Tolerance setting.

Trigger Plane - This setting inserts a `TRIGGERPLANE` command. This tells PC-DMIS to automatically take a hit when the probe passes the plane defined by the surface normal of an Auto feature at the level of the defined depth. You can use this command with manual machines; instead of pressing a button to take a hit, you can place `TRIGGERPLANE` commands at any standard location within the Edit window.

Auto Trigger - This setting inserts an `AUTOTRIGGER` command into your measurement routine. When PC-DMIS detects that the probe has moved into the defined tolerance zone, it automatically takes a hit. For details, see the "Point AutoTrigger area" topic in the "Setting Your Preferences" chapter of the PC-DMIS Core documentation.

Auto Beeping - This setting determines whether or not PC-DMIS uses a beeping with your `AUTOTRIGGER` command. If this is ON, the closer the probe gets to the target, the more frequent the beeps.

Auto Tolerance Zone - This setting defines the radius for the Auto Trigger tolerance zone.

Fly Mode* - This inserts a `FLY` command and sets it to either ON or OFF. The `FLY` command works with a `MOVEPOINT` command and moves the probe around the part in a smooth, non-stopping motion.

Distances tab

Prehit* - This inserts a `LOADPROBE` command for the selected probe into the measurement routine.

Check* - This setting inserts a `CHECK` command that sets the distance past the theoretical hit location that the machine will continue to search for the surface of the part.

Retract* - This setting inserts a `RETRACT` command that sets the distance that the machine will move away from the actual hit location before going from Touch Speed to Move Speed.

Manual Retract* - This setting inserts a `MANRETRACT` command that sets the retract distance your CMM will automatically travel whenever you take a manual hit.

Speeds tab

Touch Speed* - This setting inserts a `TOUCHSPEED` command that changes the speed at which the CMM takes hits. Values include 1 - 20 percent.

Move Speed* - This inserts a `MOVESPEED` command that determines how fast the CMM moves in between taking hits. Values include 1 - 100 percent.

Scan Speed* - This setting inserts a `SCANSPEED` command that determines how fast your machine scans your part. Possible values include 1 - 100 percent.

Dimensions tab

Display Precision - This setting inserts a `DISPLAYPRECISION` command with a value equal to the value in the setting. Any features following this command shows decimal places to the specified value.

Display Positive Reporting - This setting inserts a `POSITIVEREPORTING` command into the measurement routine. This command displays features on the negative side of the origin with positive values. You can choose this reporting on all data or only on deviations.

Positive Reporting Axis X - This setting determines whether or not PC-DMIS displays the positive reporting on the X axis.

Positive Reporting Axis Y - This setting determines whether or not PC-DMIS displays the positive reporting on the Y axis.

Positive Reporting Axis Z - This setting determines whether or not PC-DMIS displays the positive reporting on the Z axis.

Gap Only - This setting inserts a `GAPONLY` command into the measurement routine. When set to ON, and dimensioning an edge point location, PC-DMIS calculates the location axes by projecting the measured point to the theoretical surface and then projecting this new point onto the theoretical approach vector. PC-DMIS then calculates any location axes from this new point.

Retrolinear Only - This setting inserts a `RETROLINEARONLY` command into the measurement routine. When set to ON, and dimensioning surface or vector point locations, the location axes are calculated in this manner:

- First, finding the largest component of the theoretical surface normal vector (largest in the X, Y, or Z direction).

- Second, projecting the measured point to this largest component vector in a manner that the projection is perpendicular to the original theoretical surface normal vector.
- The location axes are then calculated from this new projected point.

*These items are not available when using a portable device.

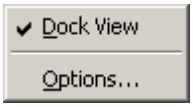
For in-depth documentation, find the specific options in one of these topics:

- Settings Toolbar
- Probe Mode Toolbar
- Selecting Setup Options
- Modifying Report and Motion Parameters

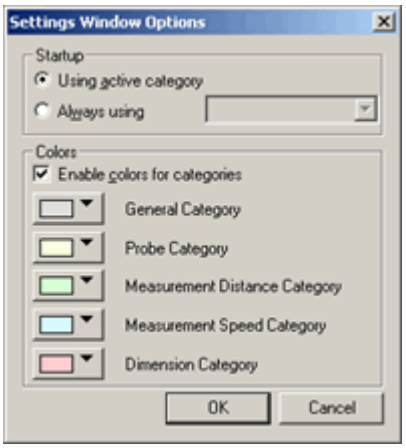
You can also insert many of these settings from the **Insert | Parameter Change** submenu.

Changing Settings Window Options

You can change your Settings window options by right-clicking in the window and selecting **Options** from the shortcut menu.



The **Settings Window Options** dialog box appears.



Settings Window Options Dialog Box

You can use the **Settings Window Options** dialog box to modify the colors for the different categories. It is also used to control the categories that appear when the Settings window is started.

Startup Area

This area contains two startup options for the Settings window:

Using active category - The Settings window displays the last used category when it starts.

Always using - The Settings window displays the category selected from the drop-down list when it starts.

Colors Area

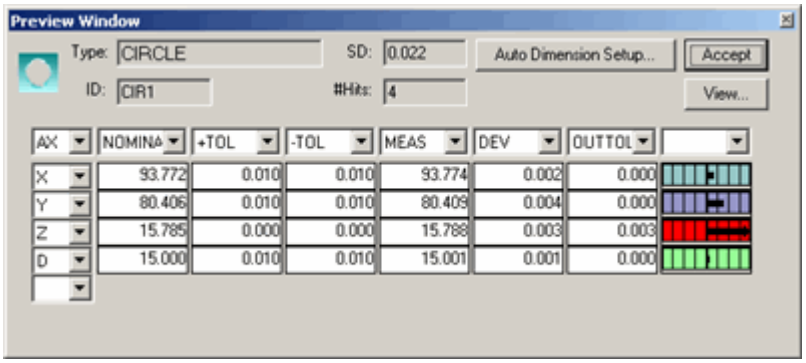
You can use the **Enable colors for categories** check box to disable or enable the color-coded display for the categories of settings.

The drop down arrows on the colored boxes are used to modify the default color-coded display for the available categories.

Using the Preview Window

> The Preview window functionality is deprecated and is no longer developed. While it remains in the software for any who still use it, the Status window functionality and elements of the Using the Probe Readouts window ultimately replace it. Please consider using those tools instead.

Selecting the **View | Other Windows | Preview Window** menu option opens a window that allows you to preview the results of a feature measurement before actually accepting the measurement. After taking probe hits and pressing the End key on your keyboard (or DONE on the jog box) PC-DMIS displays the feature in the Graphic Display window and dimension information for the feature in the Preview window.



Preview Window dialog box showing the X, Y, Z, and diameter values of a measured circle feature.

The Preview window uses the same color scheme used for dimensions to show the deviations from acceptable tolerances; these colors allow you to quickly determine whether or not a particular measurement falls within acceptable tolerances or not (see

"Editing Dimension Colors" in the "Editing the CAD Display" chapter for information on how to change the tolerance colors used for dimensions).

To determine which feature information is displayed in the Preview window, simply place your Edit window cursor on the command line for any feature in the Edit window. Generally the cursor rests on the last feature in the Edit window.

Below are the available options for the Preview window.

Preview Window Options

The Preview window displays general information about a feature as well as more specific dimensional information. It contains these options:

ID - This box determines the name label for the measured feature or dimension.

SD - This box determines the Standard Deviation for the measured feature.

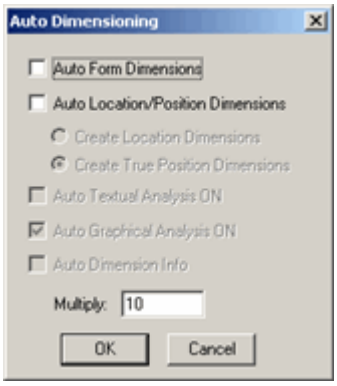
#Hits - This box determines the number of probe hits taken to measure the feature.

Hide - The **Hide** button closes the Preview window. You can open the Preview window by selecting **View | Preview Window**.

Accept - The **Accept** button accepts the measurement and creates an automatic dimension for the feature. You can only select this functionality using the **Auto Dimension Setup** button (see "Auto Dimension Setup" for details).

View - The **View** button displays the Analysis window for the appropriate dimension for the measured feature. See "Inserting Commands Related to the Analysis Window" for a discussion on the Analysis window.

Auto Dimension Setup - Selecting the **Auto Dimension Setup** button displays the **Auto Dimensioning** dialog box:



For information on this dialog box, see "Auto Dimension Setup" under "Setup Options: Dimension tab" in the "Setting Your Preferences" chapter.

AX - This list displays the selected axes in the Preview window. You can select these axes: **X, Y, Z, D, R, A, T, PR, PA, M, V, L, PD, RS, RT, S, H.** You can view information on up to six axes at one time by selecting them from the various **AX** lists.

For information on these axes, see "Default Axes" and "Sheet Metal Axes" in the "Using Legacy Dimensions" chapter.

NOMINAL - This box determines the nominal (or ideal) values for each axis.

+ TOL - This box determines a tolerance value above the nominal value for which the measurement is still acceptable.

- TOL - This box determines a tolerance value below the nominal value for which the measurement is still acceptable.

MEAS - This box determines the actual measured values.

MAX - This box determines the maximum value you can have before your measurement goes out of tolerance.

MIN - This box determines the minimum value you can have before your measurement goes out of tolerance.

DEV - This box determines the measurement's deviation from the nominal value.

OUTTOL - This box determines the value by which the measured value is out of tolerance.

If a sound file is associated with the **Preview Window Feature In Tolerance** event, a sound plays when a dimension is within tolerance. If a sound file is associated with the **Preview Window Feature Out Of Tolerance** event, a sound plays when a dimension is out of tolerance. For help with associating sound files with events, see "Setup Options: Sound Events tab".

Sizing the Preview Window

Like most windows, the Preview window can be sized to fit your current needs. If you need it larger or smaller, simply drag the edge of the window with the mouse and make it the desired size.

The Preview window in Learn mode differs from the Preview window in Execute mode, and you can change the sizes for each.

Using the Marked Sets Window

Selecting the **View | Other Windows | Marked Sets Window** menu option accesses the Marked Sets window. You can use this window to store a group of marked features that you want to execute. See the "Creating and Executing Marked Sets" topic in the "Editing a Measurement Routine" chapter.

Using the Probe Readouts Window

The **View | Other Windows | Probe Readouts** menu option displays a readout of the current CMM position and other useful information.

Sample Probe Readouts Window	Explanation
 Probe Readouts Window	A. Feature ID (CIR1) and Feature type (CIRCLE) B. Current XYZ probe position C. Form error D. XYZ position of the last hit E. Total deviation value F. Distance to next location shown in out-of-tolerance dimension colors G. Error of last measured feature H. Rotary table angle I. Screen counters that show the mouse location by using the CAD model's coordinate system J. Screen counters that show the mouse location by using the current part coordinate system K. Number of hits taken AB axis angles appear below the number of hits taken if you have an active wrist probe (such as a PHS or the CW43 light). L. Probe Readouts comments. This comes from the Probe Readouts comment type. See the "Inserting Programmer Comments" in the "Inserting Report Commands" chapter.

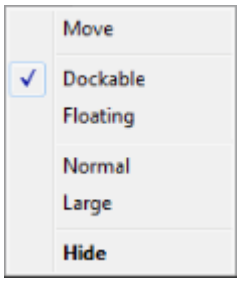
The Probe Readouts window changes depending on the options that you selected from the **Probe Readouts Setup** dialog box (see "Setting Up the Probe Readouts Window" in the "Setting your Preferences" chapter).

To access the **Probe Readouts Setup** dialog box, right-click in the Probe Readouts window and click Setup.

Sizing the Probe Readouts Window

You can alter the size of this window in two ways. If the window is docked, first float the readouts window (see below):

- **Method 1:** With the mouse, drag any of the window borders until you reach the desired size.
- **Method 2:** Right-click on the window's title bar to display the Probe Readouts menu. Select the **Large** option to display the Probe Readouts window centered on the screen and maximized to 95% of the screen's size. Select the **Normal** option to display the Probe Readouts window in the previous size prior to maximizing. Click anywhere outside the menu to close it.



Probe Readouts Menu

To close the Probe Readouts window, click on the **X** button in the upper right-hand corner.

Each time you change the location or size of the Probe Readouts window, PC-DMIS updates the proper entry. The next time you select the option, the window displays precisely as it did in the previous viewing.

On machines with an external DRO, this option is not available.

Docking or Floating the Probe Readouts Window

You can dock the Probe Readouts window to the sides of the screen or against other windows by right-clicking on the title bar. From the Probe Readouts menu (shown above), select the **Docking** option. To make the window float on top of other windows again, choose the **Floating** option from the same menu. You may need to drag the window on top of the Graphic Display window if the title bar is not visible.

You can also hold down the Ctrl key while you drag the window to prevent it from docking.

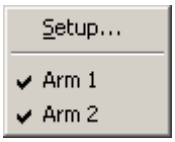
For details on docking and undocking user interface elements, see "Docking and Undocking User Interface Elements".

Multiple Arm Mode and the Probe Readouts Window

If you have more than one arm measuring your part, PC-DMIS displays the probe readout information for each additional arm in a new column.

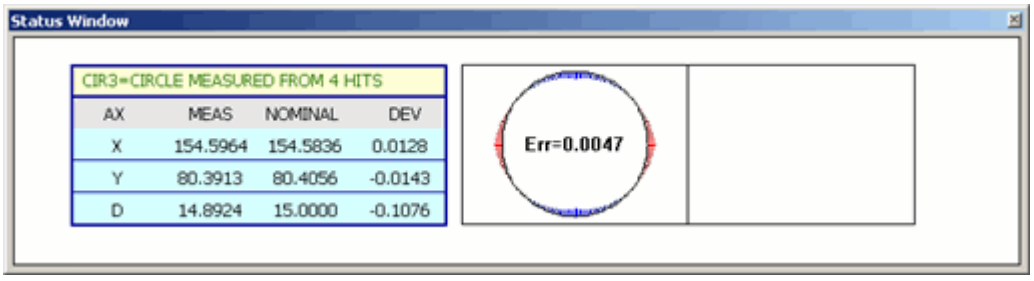
Example of the Probe Readouts window showing multiple arms in two columns.

You can right-click on this window to display a shortcut menu that you can use to show or hide information about a particular probe.



If a check mark appears next to a menu item, its information appears in the Probe Readouts window.

Using the Status Window



Status Window

The **View | Other Windows | Status Window** menu option displays the Status window. You can use this window to preview commands and features while you create them from the **Quick Start** toolbar, during feature execution, when you create or edit dimensions, and when you click the item in the Edit window with the Status window open. See "Using the Quick Start Interface" chapter for details.

While similar in some ways to the Preview window, the Status window differs in these ways:

- You don't specify tolerances or nominal values in this window. The window is for display only.
- It provides a flexible way to display commands by tying into the template-based Reporting functionality.
- It displays a dynamic preview for any command or dimension type, not just Location dimensions, as long as those commands are properly assigned inside your report and label templates.

This window functions the same as other dockable and scrollable windows. It displays scroll bars if the content within the window exceeds the window's size. Additionally, you can dock and undock this window at the bottom or top of the Graphic Display window when you double-click the window's title bar. You can also drag the window and then release it at the desired location. For details on docking and undocking user interface elements, see "Docking and Undocking User Interface Elements".

You can also hold down the Ctrl key while you drag the window to prevent it from docking.

The Status Window with the Quick Start Toolbar

The Status window displays the current status of any Guess Mode measurements, feature selections, and dimensions when you use the **Quick Start** toolbar. In the case of the screen shot shown above, this dimension has not yet been created, yet PC-DMIS provides a preview of the dimension in this window before you click **Finish** from the **Quick Start** toolbar.

The Status Window during Feature Creation or Execution

The Status window displays preview information of features not yet displayed in the Report window. This window utilizes the reporting template functionality to generate dynamic previews of commands during execution and creation. During feature creation, it only previews the feature if PC-DMIS is in Guess Mode.

The Status Window during Dimensioning

When you have one of the dimension dialog boxes open (either for legacy dimensions or for Geometric Tolerance dimensions), the Status window provides you with a preview of what the dimension will look like based on the items currently selected in the dialog box. For example, if you are creating a Distance dimension and want to preview the distances as you select different items, that information appears in the Status window as you click on the items in the dialog box. If a dialog box isn't active, it reverts to its default functionality of displaying information for the last item that you clicked on in the Edit window.

Changing the Status Window Template

Since the Status window uses reporting templates to display its information, you can change what template it uses if you would like it to display different information. You can display any command in the Status window as long as a label template is assigned to that command in the report template (.rtp) file. You assign what report template this uses from

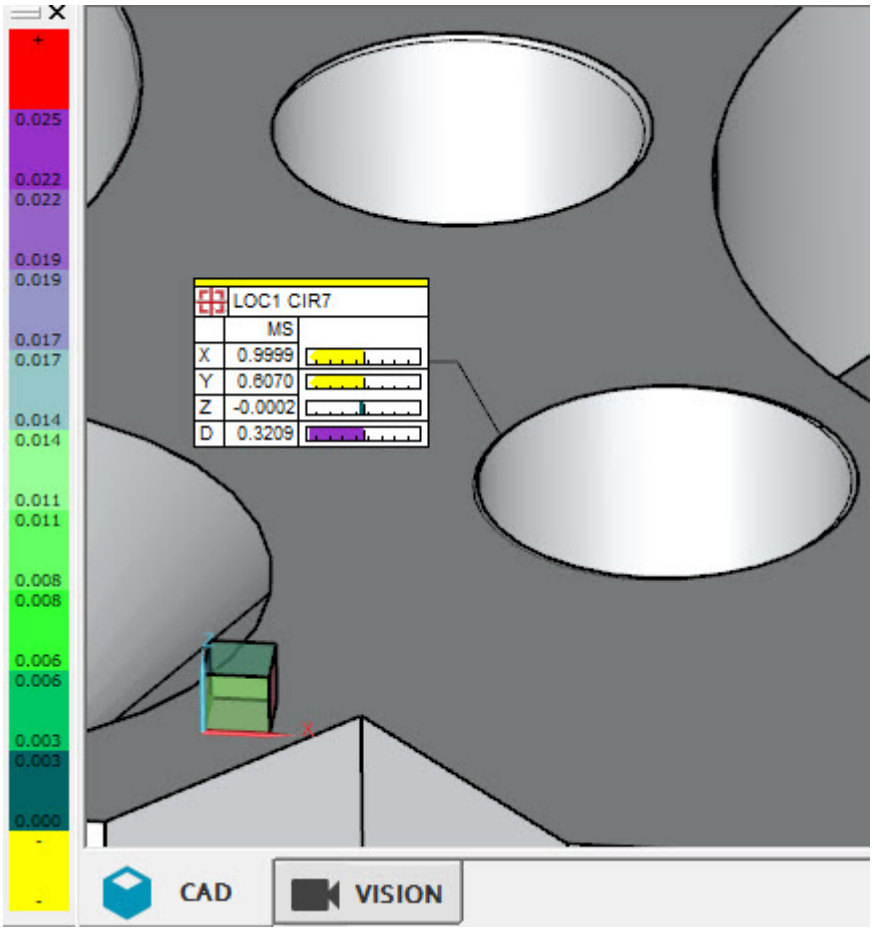
the `ReportTemplate` entry in the **StatusWindow** section of the PC-DMIS Settings Editor. The default template it uses is TEXTONLY.RTP.

Using the Status Window in Accumulation Mode

During execution, the Status window usually only displays the most recently executed feature and dimension. However, you can have PC-DMIS show a list of accumulated executed items by setting the `AccumulateStatusWindowResults` entry in the **Reporting** section to True in the PC-DMIS Settings Editor. With this mode turned on, the contents in the Status window don't get removed until execution finishes. This allows you to show a running list of information during measurement routine execution. Also, while in this mode, PC-DMIS follows the TextReportObject's properties in the Status window's template to determine what information gets sent to the Status window (features, dimensions, alignments, and so forth).

Using the Dimension Colors Window (Dimension Colors Bar)

The **View | Other Windows | Dimension Colors** menu option displays the Dimension Colors Bar. This dockable, non-sizable, bar-like window shows the colors for dimension tolerances and their associated scale values.



Example showing the Dimension Colors bar for a location dimension and associated dimensions.

You can drag and dock the color bar on either the right-side or left-side of the screen.

For details on how to dock and undock user interface elements, see "Docking and Undocking User Interface Elements".

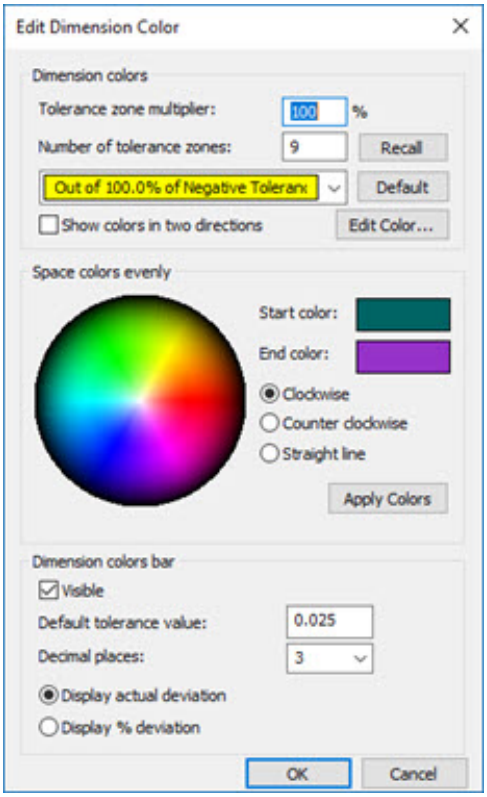
How it Displays

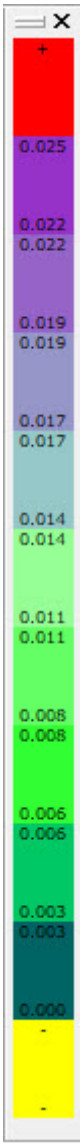
The top of the bar displays the current default tolerance value, which is represented by a label in a white band with its numerical scale value.

The remaining colored bands on the bar consist of the same number of defined tolerance zones as in the **Edit Dimension Colors** dialog box. An additional colored band on the bottom displays "Out of Tolerance (Negative)" (labeled with a "-" sign), and a colored band on the top displays "Out of Tolerance (Positive)", (labeled with a "+" sign).

Access the Edit Dimension Colors Dialog Box

To open the **Edit Dimension Colors** dialog box, right-click on the color bar:

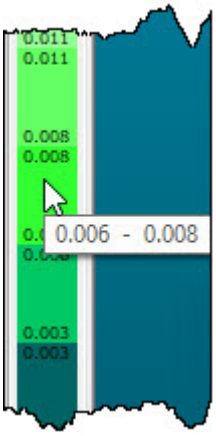




This dialog box defines the dimension colors and tolerance zones. It also contains some settings that determine how the color bar displays. For information on this dialog box, see the "Editing Dimension Colors" topic in the "Editing the CAD Display: Introduction" chapter.

Tooltips for Complete Information

If you move your mouse over a tolerance band, a tooltip appears. It displays the range of values for that tolerance band (lower to higher). The tooltip displays the "Out of Tolerance (Positive)” or "Out of Tolerance (Negative)" label when you position your mouse pointer over the "+” or "-" band, respectively. You cannot modify the decimal places.



Using the Q-DAS Data Editor Window

The Q-DAS Data Editor lets you modify the K-field data in the Q-DAS data file (QdasData.xml) through PC-DMIS.

The **View | Other Windows | Q-DAS Data Editor** menu option displays the Q-DAS Data Editor window.

This window functions the same as other dockable and scrollable windows. It displays scroll bars if the content within the window exceeds the window's size. Additionally, you can dock and undock this window at the bottom or top of the Graphic Display window when you double-click the window's title bar. You can also drag the window and then release it at the desired location. For details on docking and undocking user interface elements, see "Docking and Undocking User Interface Elements".

Q-DAS Data Editor Window

Prerequisites

To modify the K-field data of the dimension in the Q-DAS Data Editor, you need to do the following:

- You need a Q-DAS data file for the measurement routine. The file name has the following format:

  <name of measurement routine>.QdasData.xml

<name of measurement routine> represents the name of the PC-DMIS measurement routine.

For information on how to create a Q-DAS data file, see "Creating the Q-DAS Data File" in the Q-DAS Configurator help file.

- You need to place the cursor on the dimension in the Edit window. If you place your cursor on any command other than the dimension command, Q-DAS Data Editor displays this message:

  "The cursor is not placed on a dimension command."

  When you place the cursor on a dimension command in the Edit window and if no Q-DAS data file is available for the measurement routine, Q-DAS Data Editor displays this message:

  "No QdasData.xml file exists for the measurement routine. Use Q-DAS Configurator to create a QdasData.xml file."

When you save the measurement routine, the changes you made in the Q-DAS Data Editor are also saved.

Suppose that you have the following position dimension `DIM1` command in your measurement routine:

```
DIM1 =POSITION : CIR10

        FEATCTRLFRAME/
SHOWNOMS=NO,SHOWPARAMS=YES,SHOWEXPANDED=YES

CADGRAPH=OFF,REPORTGRAPH=OFF,TEXT=OFF,MULT=10.00,ARROW
DENSITY=100,OUTPUT=BOTH,UNITS=MM

        COMPOSITE=NO,FIT TO DATUMS=YES,DEV PERPEN
CENTERLINE=ON,OUTPUT ALIGNMENT=Datum Reference Frame

        CUSTOMIZED DRF=NO

        STANDARDTYPE=ASME_Y14_5

                SIZE TOLERANCES/1DIAMETER,10,0.2,0.2

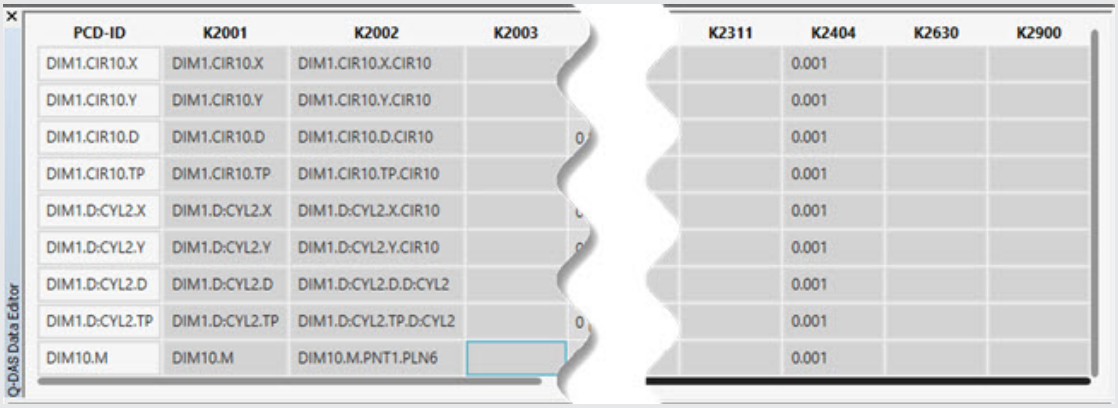
                PRIMARY DIMENSION/
POSITION,DIAMETER,0.2,MMC,D,MMC,,,

                SECONDARY DIMENSION/,0.2,MMC,A,D,MMC,,

                NOTE/DIM1

                FEATURES/CIR10,,
```

When you place the cursor on the above dimension command, Q-DAS Data Editor displays this data:



ClearanceCube Settings

You can use the ClearanceCube Settings window to define the ClearanceCube motion for each feature and tip in the measurement routine.

ClearanceCube Settings Window

PC-DMIS displays the **ClearanceCube Settings** window automatically when you activate ClearanceCube for the measurement routine.

From the **ClearanceCube** toolbar, you can use the **ClearanceCube Settings Window** icon to show or hide this window. You can also open this window from the **View | Other Windows | ClearanceCube Settings** menu option.

You can dock the ClearanceCube Settings window at the top or bottom of the Graphic Display window. To float the ClearanceCube Settings window, press the Ctrl button and then click and drag the window to the desired location.

- **ID(s)** - This list displays one or more feature IDs based on your selection of features in the Edit window. To do this, follow these steps:

  1. Place your cursor on a feature in Command Mode or select a feature in Summary Mode to display or edit the settings for the ClearanceCube.
  2. To edit the ClearanceCube settings for more than one feature at the same time, select them in the Edit window and then make the necessary changes.
  3. From the **ID(s)** list, select Features or Tips. This box appears when you select multiple features and tips in the Edit window.
  4. Based on your selection from the **ID(s)** list, the list shows the features or tips. Select the item in the list for configuration.

If you position your mouse cursor over a command in Command Mode or select a command in Summary Mode that does not require ClearanceCube settings, PC-DMIS displays the message “ClearanceCube is not required for the selected commands”.

- **Activate ClearanceCube Moves** - This switch determines whether you want to use ClearanceCube motion for the features you selected in the **ID(s)** list.

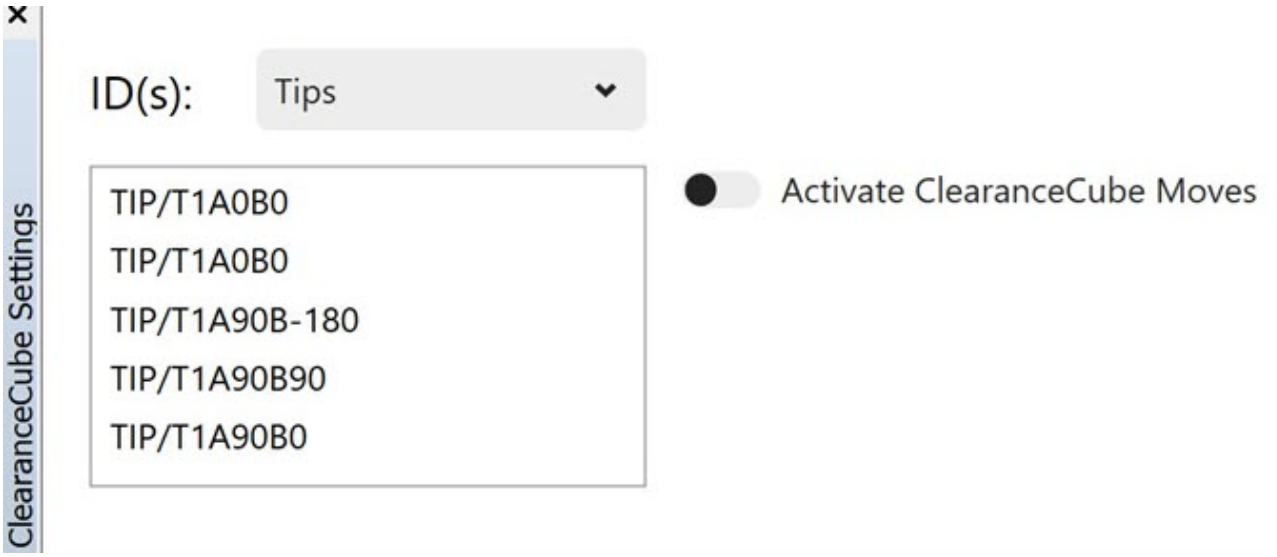
- **Starting Face** - This determines the ClearanceCube face that PC-DMIS moves to before it measures the feature. You have these options:
  - Select a face
  - Use Tip Vector
  - Set the Starting Face to OFF if you only want the ending motion to occur for the feature.
- **Ending Face** - This determines the ClearanceCube face that PC-DMIS moves to after it measures the feature. You have these options:
  - Select a face
  - Use Tip Vector
  - Set the Ending Face to OFF if you only want the starting motion to occur for the feature.

The feature vector determines the default setting for the ClearanceCube **Starting Face** and **Ending Face** options. PC-DMIS marks the **ClearanceCube uses Tip Vector for Start/End Face** check box in the **General** tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**) by default. It is recommended to use the tip vector.

Based on constraints set in the **Constraints** tab, the selection of some axes for the starting and ending faces may not be available.

For Tip Commands

From the **ID(s)** list, select the features or tips. This box appears only when you select multiple features and tips in the Edit window.



ClearanceCube Settings Window - Tips Option

When you select the **Tips** option from the **ID(s)** list, the **ClearanceCube Setting** window only shows the **Activate ClearanceCube Moves** setting.

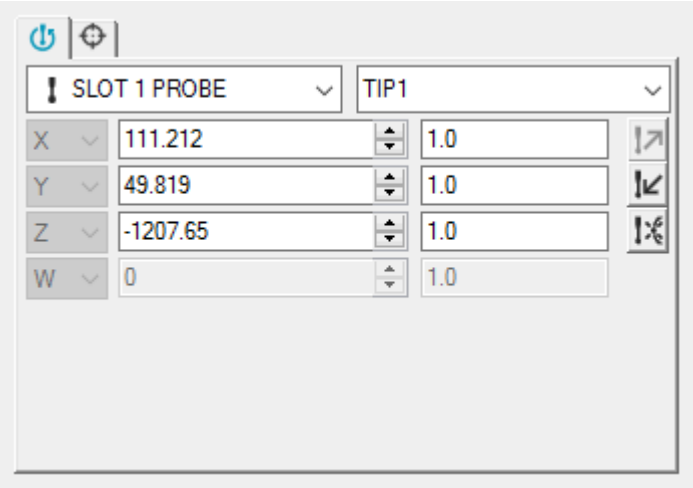
The ClearanceCube Shortcut Menu

In addition to the ClearanceCube Settings dialog box, PC-DMIS provides a right-click menu. To access this menu, follow these steps:

1. If you are in Command Mode, place your cursor on a feature. If you are in Summary Mode, click a feature to select it.
2. Right-click the feature and select the **Path | ClearanceCube** option.
3. From the **Starting Face** and **Ending Face** list, select the face to align the ClearanceCube to. The available options are -X, +X, -Y, +Y, -Z, +Z, Use Tip Vector, and Off.

Using the Probe Toolbox

The **View | Other Windows | Probe Toolbox** menu option displays the Probe Toolbox.



Probe Toolbox showing the Position Probe tab.

The Probe Toolbox lets you perform various probe-related manipulations. It presents tabs and information relative to the type of probe currently used. If you use an optical probe or a laser probe, for example, the tabs that appear are different than for contact probes, providing you the functionality of manipulating parameters specific to those probe types.

Most of the tabs in the Probe Toolbox appear when you view the toolbox embedded within the **Auto Feature** dialog box.

See the documentation sets that apply to your particular configuration for specific information on the Probe Toolbox:

- PC-DMIS CMM (and Portable)
- PC-DMIS Vision
- PC-DMIS Laser

Because the items in the Probe Toolbox are so frequently used when creating Auto features, the Probe Toolbox automatically appears as an embedded portion of the **Auto Feature** dialog box.

Placing and Sizing the Toolbox

Much like the Edit window or the various toolbars available in PC-DMIS, you can dock the Probe Toolbox to the sides of the PC-DMIS application window. You can also float it above other elements.

To dock the Probe Toolbox:

1. Ensure that the Probe Toolbox is in docking mode. (Right-click on the title bar and select **Dockable** from the shortcut menu.)
2. Select the toolbox's title bar with the mouse.

3. Drag the toolbox onto the left or right edge of the PC-DMIS application window.
4. Release the mouse. PC-DMIS docks the toolbox at that location.

To float the Probe Toolbox:

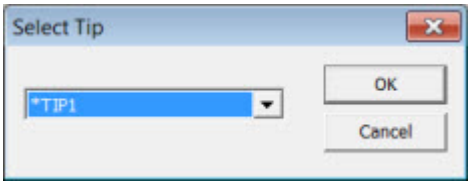
1. Select the toolbox's title bar with the mouse.
2. Drag the toolbox out of its docked position on top of the Graphic Display window and release the mouse. While it floats above the Graphic Display window, it is still in docking mode.
3. Right-click on the title and select **Floating** from the shortcut menu.
4. Drag the toolbox to where you want to place it.
5. Release the mouse. PC-DMIS floats the toolbox at that location.

You can also hold down the Ctrl key while you drag the window to prevent it from docking.

To size the toolbox, select an edge of the toolbox and drag the mouse to a new location.

Selecting a Tip

The **Insert | Parameter Change | Probe | Active Tip** menu item is used to select an active tip. To select a tip, highlight the desired tip ID in the list and select **OK**. The tip is inserted in the Edit window.



Select Tip Dialog Box

Noncalibrated tips have an asterisk before their tip ID # in the list.

Viewing Path Lines

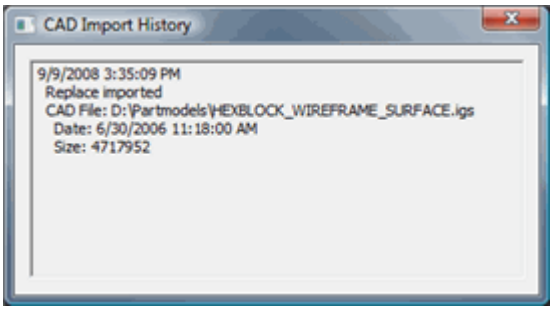
You can select the **View | Path Lines** menu option to draw the current path of the probe in the Graphic Display window.

The software only generates the probe's path lines for features that follow a `MODE/DCC` command. If your measurement routine doesn't have a `MODE/DCC` command, you won't see any path lines.

For more information on working with path lines, see "Showing, Animating, and Moving Path Lines" in the "Editing the CAD Display" chapter.

Viewing CAD Import History

The **View | CAD Import History** menu option displays the **CAD Import History** dialog box.



CAD Import History Dialog Box

This dialog shows information for all the CAD files that have been imported into the current measurement routine. This information includes the following:

- The date and time of the import operation
- The type of import operation (Merge or Replace)
- Whether or not a Direct CAD Interface (DCI) was used to import the model
- The CAD file's name, date, and size in bytes

This information is stored in the measurement routine file, not the CAD model file.

This only tracks import operations taken within PC-DMIS. For example, if you manually replace a measurement routine's CAD file, it is not tracked by the **CAD Import History** dialog box.

Using Toolbars

Using Toolbars: Introduction

In an effort to decrease the time it takes to program your measurement routine, PC-DMIS offers you a variety of toolbars composed of frequently used commands. You can access most toolbars in two ways.

- Select **View | Toolbars** and select a toolbar from the menu.
- Right-click on PC-DMIS's **Toolbar** area and select a toolbar from the shortcut menu provided.

The toolbars provided are discussed in these topics:

- File Operations Toolbar
- Graphic Modes Toolbar
- Graphic View Toolbar
- Graphic Items Toolbar
- Edit Window Toolbar
- Window Layouts Toolbar
- CAD Setup Toolbar
- Measurement Strategy Toolbar
- Auto Features Toolbar
- Measured Features Toolbar
- Constructed Features Toolbar
- Pointcloud Toolbar
- Mesh Toolbar
- Dimension Toolbar
- Alignment Toolbar
- Settings Toolbar

- Probe Mode Toolbar
- Select Tip Toolbar
- Active Arms Toolbar
- Active Rotary Table Toolbar
- ClearanceCube Toolbar
- Wizards Toolbar
- Build and Inspect Toolbar
- QuickMeasure Toolbar
- QuickCloud Toolbar
- Quick Fixture Toolbar

You can also customize and create your own toolbars. For more information, see "Customizing the User Interface" in the "Navigating the User Interface" chapter.

File Operations Toolbar

File Operations Toolbar

Before Certification

File Operations toolbar for PC-DMIS-User

File Operations toolbar for PC-DMIS-Programmer

After Certification

File Operations toolbar for PC-DMIS-User

File Operations toolbar for PC-DMIS-Programmer

You can use the **File Operations** toolbar (**View | Toolbars | File Operations**) to perform these operations:

New File - Click this option to create a new measurement routine.

Open File - Click this option to open an existing measurement routine.

Close File - Click this option to close the active measurement routine.

Quit - Click this option to quit PC-DMIS.

Save File - Click this option to save the current measurement routine.

Save As - Click this option to save the current measurement routine under a different name.

View Certified - Click this option to open the certified version of the measurement routine in Protected Mode.

> This button is available only for certified measurement routines.

Submit - Click this option to submit the current measurement routine for certification and generate a .protect file.

Cancel Submission - Click this option to cancel the submission of the current measurement routine for certification.

> The **Submit** and **Cancel Submission** buttons are available only if you belong to the **PC-DMIS-User** group and you have the Protect Viewer option added to your license.

Certify - Click this option to certify the current measurement routine.

Reject - Click this option to reject the certification for the current measurement routine.

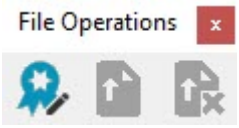
Delete - Click this option to delete all the changes you made after the last certification of the current measurement routine. You can then edit the measurement routine from the beginning.

> The **Certify**, **Reject**, and **Delete** buttons are available only if you belong to the **PC-DMIS-Programmer** group and have the Protect Viewer license enabled.

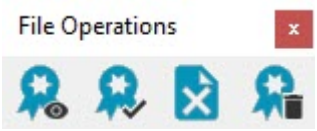
Recertify - Click this option to recertify the current measurement routine.

For complete information about these file operations, see the "Using Basic File Options" and "Using Advanced File Options" chapters in the PC-DMIS Core documentation.

Protected Mode File Operations Toolbar



File Operations toolbar for PC-DMIS-User



File Operations toolbar for PC-DMIS-Programmer

Edit Certified Routine - This button opens the certified measurement routine:

- If you are the creator of the measurement routine, this button opens the certified measurement routine in Edit Mode.
- If you are a member of the **PC-DMIS-Programmer** group and a measurement is submitted for recertification, this button opens the certified measurement routine in Protected Mode.
- If no measurement routine is available for recertification, PC-DMIS displays a message stating that you are not the creator of the measurement routine and it has not been submitted to you for certification.

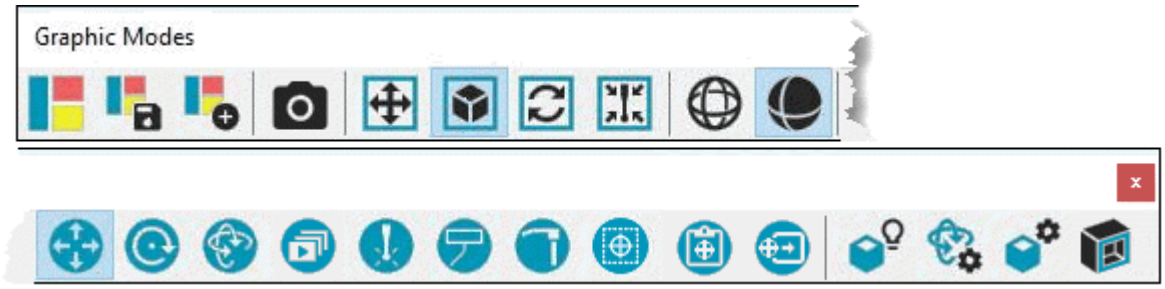
Graphic Modes Toolbar



Graphic Modes Toolbar

You can use the **Graphic Modes** toolbar (**View | Toolbars | Graphic Modes**) to alter the display of the part on the screen. It also allows access to the available modes. This toolbar contains the following icons:

View Setup - Alters the display of the part in the Graphic Display window. See "Setting up the Screen View" in the "Editing the CAD Display" chapter.

Save Views - Saves the view of the part as the current viewset which can later be recalled. See "Working with Viewsets" in the "Inserting Report Commands" chapter.

Create Views - Saves the view of the part as a separate viewset command which can later be recalled. See "Working with Viewsets" in the "Inserting Report Commands" chapter.

Snapshot - Inserts a `SNAPSHOT` command of the current Graphic Display window state into the Edit window. When you execute this command, it inserts an image capture at that state into your report. See "Inserting Snapshots" in the "Inserting Report Commands" chapter.

Scale to Fit - Enlarges or shrinks the views of the graphic in the Graphic Display window to fit your screen. See "Scaling the Drawing" in the "Editing the CAD Display" chapter.

Draw Surfaces - Turns on or off the display of solid CAD surfaces. See "Drawing Surfaces" in the "Editing the CAD Display" chapter.

Repaint the Screen - Refreshes and redraws all the views of the part. See "Repainting the Screen" in the "Editing the CAD Display" chapter.

Center Probe - Centers the probe on the Graphic Display window screen so that the part is animated and the probe is always centered. See "Center Probe" in the "Editing the CAD Display" chapter.

Curve Mode - Places PC-DMIS into Curve Mode (for use with wireframe). See "Switching Between Curve and Surface Modes" in the "Editing the CAD Display" chapter.

Surface Mode - Places PC-DMIS into Surface Mode (for use with surface data). See "Switching Between Curve and Surface Modes" in the "Editing the CAD Display" chapter.

Translate Mode - Places PC-DMIS into Translate Mode. See "Translate Mode" in the "Editing the CAD Display" chapter.

2D Rotate Mode - Two dimensionally rotates the part for the selected view. See "2D Rotate Mode" in the "Editing the CAD Display" chapter.

3D Rotate Mode - Three dimensionally rotates the part for the selected view. See "3D Rotate Mode" in the "Editing the CAD Display" chapter.

2D Section Slide Show - If you have a Pointcloud or Mesh cross section in your measurement routine, this button toggles the 2D section slide show on and off. See "2D View of Cross Sections" in the PC-DMIS Laser documentation.

Program Mode - Uses the probe in either Offline or Online mode to learn and edit your measurement routine. See "Program Mode" in the "Editing the CAD Display" chapter.

Text Box Mode - Places PC-DMIS into a mode that lets you manipulate feature IDs, feature control frames, scan points, and CAD GD&T callouts. You can also use this mode to quickly create and modify Dimension Info and Point Info text boxes. See "Text Box Mode" in the "Editing the CAD Display" chapter.

Quick Fixture Mode - Enters Quick Fixture Mode so that you can move quick fixtures and the part by clicking and dragging them with the mouse. See "Inserting Quick Fixtures" in the "Defining Hardware" chapter.

GD&T Selection Mode (from CAD) - Provides the ability to box-select specific GD&T callouts that are embedded inside the part model and import them into your measurement routine. See "Working with CAD GD&T Callouts" in the "Editing the CAD Display" chapter.

It also provides a right-click shortcut menu to perform other operations on a callout. See "CAD GD&T Callouts Shortcut Menu" in the "Using Shortcut Keys and Shortcut Menus" chapter.

GD&T Selection Mode (from File) - Shows an **Open** dialog box so that you can choose a drawing to import. You can then decide what GD&T tolerances to import using OCR. The software cycles through each GD&T tolerance on the drawing. See "Using GD&T Selection Mode to Create FCFs " in the "Using Geometric Tolerances" chapter.

CAD Lighting - Applies lighting, textures, and transparencies to CAD models. See "Setting up CAD and Graphics" in the "Editing the CAD Display" chapter.

Rotate Options - Changes how PC-DMIS displays items in the Graphic Display window during part rotation. See "Changing Rotation and Other Motion Options" in the "Editing the CAD Display" chapter.

Display Symbols - Defines the symbol style and size used to represent CAD points, scanned points, and feature points in the Graphic Display window. This opens the **Symbols** tab in the **CAD and Graphic Setup** dialog box. See "Modifying Display Symbols" in the "Editing the CAD Display" chapter.

Clipping Planes - Shows cross sections of your part model in the Graphic Display window. This opens the **Clip Planes** tab in the **CAD and Graphic Setup** dialog box. See "Clip Planes Tab" in the "Editing the CAD Display" chapter.

Graphic View Toolbar

Graphic View Toolbar

The **Graphic View** toolbar (**View | Toolbars | Graphic View**) changes how your part is displayed inside the Graphic Display window.

Many of these icons act the same as if you had used the **View Setup** dialog box to affect the view. For information on setting up your views, see the "Setting up the Screen View" topic in the "Editing the CAD Display" chapter.

If you configured the Graphic Display window to show more than one view, some icons affect only the blue pane in the **Views** area of the **View Setup** dialog box.

For example, if you divided your screen into three views by using this icon from the **View Setup** dialog box:

This toolbar contains the following icons:

Graphic Window in X+

Shows the X+ view of the part

Graphic Window in X-

Shows the X- view of the part

Graphic Window in Y+

Shows the Y+ view of the part

Graphic Window in Y-

Shows the Y- view of the part

Graphic Window in Z+

Shows the Z+ view of the part

Graphic Window in Z-

Shows the Z- view of the part

You can also click on a face of the Trihedron Rotation interface on the bottom left of the Graphic Display window to rotate the model and "square up" the view to that face. For more information, see "Using the Trihedron Rotation Interface".

Graphic Window in Isometric

Shows an isometric view of the part

Graphic Window Based on Probe Orientation

Pans, zooms, and rotates the view to look at the part along the probe axis of the current probe's tip angle

Show Graphic Window as Solid

Graphic Display window switches between a wireframe or solid view of the part

Surface Edges

Draws a bold line around edges of surfaces. These are called "surface edges". This icon becomes available when the **Solid** icon is selected. You can customize the color and size of surface edges through the **Wireframe** tab of the **CAD and Graphic Setup** dialog box. For information, see "Wireframe Tab" in the "Editing the CAD Display: Introduction" chapter.

Part Model Transparency

Turns transparency on or off for the part model. This marks or clears the **Enable transparency** check box on the **Lighting** tab of the **CAD and Graphic Setup** dialog box for the part model.

For information on the transparency settings on that tab, see "Lighting Tab" in the "Editing the CAD Display" chapter.

Toggle Graphic Display Window 3D

Displays or hides the 3D Grid in the Graphic Display window.

Graphic Items Toolbar

You can use the **Graphic Items** toolbar (**View | Toolbars | Graphic Items**) to show or hide graphic items in the Graphic Display window. These toolbar icons are available:

Show CAD - Shows the CAD model.

Show GD&T - Shows your CAD model's embedded CAD GD&T callouts or PMI (Product Manufacturing Information).

Show GD&T Notes - Shows your CAD model's embedded GD&T notes. You can only view these embedded CAD elements. You cannot import them as commands into the Edit window.

Characteristics IDs - Shows the characteristic IDs for any CAD GD&T callouts. You can only see a characteristic ID if its corresponding CAD GD&T is also visible (see **Show GD&T** above). For information on characteristic IDs, see the "Showing or Hiding CAD GD&T Characteristic IDs" subtopic under the "Working with CAD GD&T Callouts" topic in the "Editing the CAD Display" chapter.

Show Rotation Widget - Shows a small trihedron and cube in the bottom-left corner of each view of the Graphic Display window. You can click on the cube to rotate the CAD model to a face. You can double-click on the cube to both rotate and scale to fit the CAD model. For more information, see "Using the Rotation Widget" in the "Editing the CAD Display" chapter.

Show Feature Label IDs - Shows the IDs for feature commands that you added to the measurement routine.

Show Point Info Label IDs - Shows the label IDs for point information (Point Info) boxes.

Show DimInfo Label IDs - The label IDs for dimension info (DimInfo) boxes.

Show All Label IDs - Shows all the label IDs above.

Show All COPs - Shows all COPs and associated annotations.

Show All Meshes - Shows all Mesh features and associated annotations.

Activate Colormaps - Shows or hides the active colormap in the Graphic Display window.

- For details on Pointcloud Colormap operators, see the "Pointcloud Operators" section of the PC-DMIS Laser documentation.
- For details on the Mesh Colormap operator, see the "Creating a Mesh Operator" section of the PC-DMIS Laser documentation.

Show All Cross Sections - Shows all measured and nominal Cross Sections, and associated annotations.

Show Probe - Shows the animated probe's model.

Probe Component Draw Options - Shows the **Component Draw Options** dialog box with check boxes for each component. You can mark or clear a check box to show or hide that component respectively.

Show Machine - Shows the animated machine's model. This option is available if you use PC-DMIS in offline mode.

Show Probe Changer - Shows the animated probe changer's model.

Show Fixture - Shows any fixtures you've imported.

Show Clearance Plane - Shows any clearance planes you have defined.

Show ClearanceCube - Shows the ClearanceCube.

Edit Window Toolbar

Edit Window Toolbar

Use the **Edit Window** toolbar (**View | Toolbars | Edit Window**) to quickly access the many Edit window functions.

You can also use the toolbar to manipulate Edit window content in a way that is easy and intuitive to use. The toolbar provides ready access to these important Edit window commands. Some icons only appear if you have the proper configuration.

Execute - This icon runs (or executes) the measurement process for any currently marked features. For more information, see "Executing Measurement Routines" in the "Using Advanced File Options" chapter.

Auto Tune Execution - This icon allows you to teach illumination, magnification, and image processing parameters of your measurement routine commands for the target optical machine. This icon only appears if you have a vision configuration. For more information, see "Using AutoTune Execution" in the PC-DMIS Vision documentation.

Sequential Execution - This icon turns on a sequential execution mode, where execution does not proceed with the execution until it finishes calculating the current feature. For more information, see "Using Sequential Execution Mode" in the PC-DMIS Laser documentation. This icon only appears if you have a laser configuration.

Mark Current Feature - This icon highlights the feature under your cursor and prepares it for execution. For more information, see "Mark" in the "Editing a Measurement Routine" chapter.

Mark All - This icon highlights *all* features in the Edit window. PC-DMIS asks you if you want to highlight features used for the alignment as well. For more information, see "Mark All" in the "Editing a Measurement Routine" chapter.

Clear Mark - This icon removes all highlights from currently marked features within the Edit window. For more information, see "Mark All" in the "Editing a Measurement Routine" chapter.

Insert Breakpoint - This icon inserts a breakpoint at the current cursor location in the measurement routine. For more information, see "Using Breakpoints" in the "Editing a Measurement Routine" chapter.

Remove All Breakpoints - This icon removes any breakpoints from the measurement routine. For more information, see "Remove All" in the "Editing a Measurement Routine" chapter.

Set Start Point - This icon allows you to set the start point for the active learn arm. In the Edit window, click on the command that you want to use for the start point and then click on the **Start Point** toolbar icon. The start point for the current arm will be set to the

command located at the insertion point. You can also set a start point by right-clicking on a command and choosing **Set Start Point**. For more information on multiple arm mode, see the "Using Multiple Arm Mode" chapter. See "Setting Start Points" in the "Editing a Measurement Routine" chapter.

Insert Bookmark - This icon places a bookmark at the current cursor location in the measurement routine. For more information, see "Bookmark" in the "Editing a Measurement Routine" chapter.

Next Bookmark - This icon moves your cursor to the next Edit window location that contains a bookmark in the measurement routine. For more information, see "Next Bookmark" in the "Editing a Measurement Routine" chapter.

Clear All Bookmarks - This icon removes any bookmarks from the measurement routine. For more information, see "Clear All Bookmarks" in the "Editing a Measurement Routine" chapter.

Summary Mode - This icon places the Edit window in Summary Mode. This mode provides you with an expandable and collapsible graphical summary of groups and gage commands in your measurement routine. For more information, see "Working in Summary Mode" in the "Using the Edit Window" chapter.

Command Mode - This icon places the Edit window in Command Mode. This mode allows you to access the various commands that give you the capability to edit various aspects of the measurement routine. For more information, see "Working in Command Mode" in the "Using the Edit Window" chapter.

DMIS Mode - This icon displays the Edit window commands in DMIS format so you can work with the DMIS syntax. If you don't see this icon on your toolbar, select the **Use DMIS Button in Edit window** check box on the **General** tab in the **Setup Options** dialog box. For information on the **General** tab, see "Setup Options: General tab" in the "Setting your Preferences" chapter. For information on DMIS, see https://qifstandards.org/ and "Working in DMIS Mode" in the "Using the Edit Window" chapter.

Cut - This icon removes selected text and commands from the Edit window and stores that information temporarily in the Clipboard to be pasted later. For more information, see "Cut" in the "Editing a Measurement Routine" chapter.

Copy - This icon copies selected text and commands in the Edit window and stores that information temporarily in the Clipboard to be pasted later. For more information, see "Copy" in the "Editing a Measurement Routine" chapter.

Paste - This icon inserts information stored in the Clipboard into the Edit window at the cursor's current location. For more information, see "Paste" in the "Editing a Measurement Routine" chapter.

Define Pattern - This icon opens the **Pattern Setup** dialog box to define the pattern to use with **Paste with Pattern**. For more information, see "Editing Patterns of Features" in the "Editing a Measurement Routine" chapter.

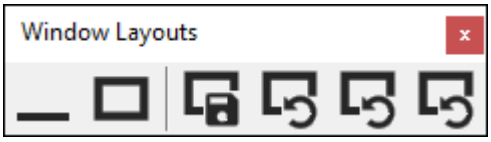
Paste with Pattern - This icon pastes patterned features with their offsets into the measurement routine at your cursor's current location. For more information, see "Editing Patterns of Features" in the "Editing a Measurement Routine" chapter.

Undo - This icon removes the last action that you took in the Edit window. For more information, see "Undo" in the "Editing a Measurement Routine" chapter.

Redo - This icon redoes an action that was removed with **Undo**. For more information, see "Redo" in the "Editing a Measurement Routine" chapter.

Print - This icon immediately sends a report of the current contents of the Edit window to your default printer without displaying any dialog boxes. This option is not available in Summary Mode.

Window Layouts Toolbar



Window Layouts Toolbar

You can use the **Window Layouts** toolbar (**View | Toolbars | Window Layouts**) to store the layout of any open windows, editors, and toolbars. You can click on a stored layout to restore it in your current measurement routine.

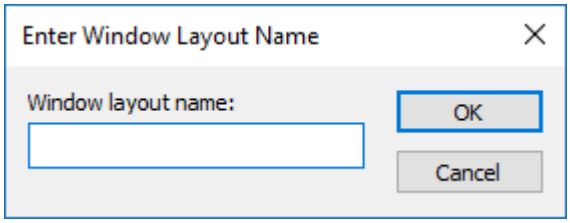
Layouts don't only store positions of toolbars and windows; they also store settings and options associated with the windows and toolbars. If a layout has a certain setting selected, and you then save that layout, the setting gets saved with the layout. If you later deselect that window setting, without overwriting the stored layout, the next time you select the layout, PC-DMIS restores the saved setting.

This toolbar contains the following icons:

Minimize - This icon minimizes the Edit window's size.

Maximize - This icon maximizes the Edit window's size.

Save - This icon displays the **Enter Window Layout Name** dialog box that allows you to save the current position and size of any open windows, editors, or toolbars under a desired layout name:



The **Window Layout Name** box specifies the name of the layout. PC-DMIS also displays this name as a tooltip for the icon associated with the layout. If you don't include a layout name, PC-DMIS uses a default name of "Recall Window Layout".

Once you click **OK**, the layout gets saved and an icon ( ) that represents that layout appears on the toolbar with your layout configuration.

You cannot overwrite an existing layout with a new layout by giving it the same name. If you want to overwrite an existing layout, first delete the existing layout, and then give it the same name.

Restore Saved Layout - This icon restores the stored layout. Any windows, editors, and toolbars are restored to their saved positions. Position your mouse pointer over the icon to show the name of the stored layout.

If you have multiple measurement routines open and have created a stored layout using one of the measurement routines, precedence is given to the measurement routine on which the layout was created. The measurement routine used to create the stored layout then becomes the active measurement routine and displays the stored window layout.

Deleting Saved User Layouts

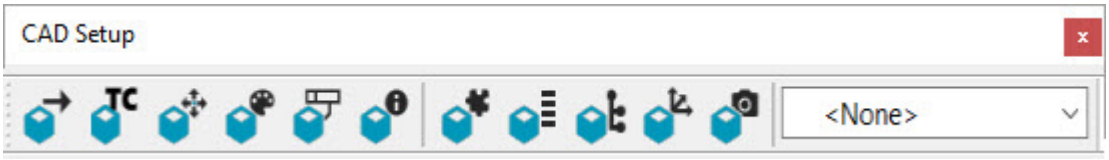
To delete a saved user layout, follow these steps:

1. Right-click on the toolbar area, and select **Customize**. The **Customize** dialog box appears.
2. Press and hold the Shift key on your keyboard.

3. Click and hold the mouse over the icon on the **Window Layouts** toolbar. The icon becomes movable.
4. Drag the icon outside of the toolbar's boundaries.
5. Release the mouse button.

The icon and the layout associated with the icon are deleted.

CAD Setup Toolbar



CAD Setup Toolbar

The **CAD Setup** toolbar contains these options to help you set up and work with a CAD model in the Graphic Display window:

Import from CAD File - Displays the **Import** dialog box so you can navigate to and import a supported part model from your library. Select the **Files of Type** list to view the file types. PC-DMIS remembers the file type that you selected the last time you used this button and defaults to that file type. For more information on importing files, see "Importing CAD Data or Feature Data" in the "Using Advanced File Options" chapter.

Import CAD from Teamcenter - Displays the **Teamcenter Open** dialog box so you can navigate to and import a CAD model from the Teamcenter database. For information on how to import a CAD model, see "Step 3 - Load Supported Models" in the "Using Teamcenter" chapter of the PC-DMIS DCI documentation.

CAD Transform - Shows the **CAD Transform** dialog box so you can transform (translate, scale, and rotate) your CAD model. For information on how to transform your CAD model, see "Transforming a CAD Model" in the "Editing the CAD Display" chapter.

CAD Colors - Shows the **Edit CAD Elements** dialog box so you can change the color of selected elements. For information on these CAD colors, see "Editing CAD Elements" in the "Editing the CAD Display" chapter.

CAD GD&T Options - Shows the **CAD and Graphic Setup** dialog box, **CAD GD&T** tab so you can configure how CAD GD&T callouts appear in the Graphic Display window.

For information on using this tab, see "CAD GD&T Tab" in the "Editing the CAD Display" chapter.

CAD Info - Shows the **CAD Information** dialog box so you can view additional information about the CAD model. For information on CAD information, see "Viewing CAD Information" in the "Editing the CAD Display" chapter.

Assembly - Shows the **CAD Assembly** dialog box so you can create a CAD assembly (a collection of part models), or display and hide parts inside an assembly. For information on CAD assemblies, see "Working with Assemblies of Parts" in the "Editing the CAD Display" chapter.

CAD Levels - Shows the **CAD Levels** dialog box so you can group CAD elements as CAD levels for the currently displayed CAD model. For information on CAD levels, see "Working with CAD Levels" in the "Editing the CAD Display" chapter.

CAD Groups - Shows the **CAD Groups** dialog box so you can group CAD elements as a CAD group. You can also use this to modify groups, delete groups, and view or hide groups in the Graphic Display window. For information on CAD groups, see "Working with CAD Groups" in the "Editing the CAD Display" documentation.

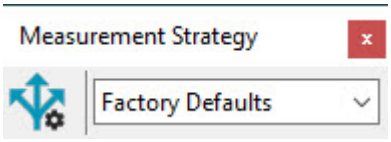
Coordinate System - Shows the **CAD Coordinate System** dialog box so you can create or select coordinate systems for your CAD model. For information on CAD Coordinate systems, see "Working with CAD Coordinate Systems" in the "Editing the CAD Display" chapter.

CAD Model Views - Shows the **CAD Model Views** dialog box so you can define and activate CAD model views. These views show and hide CAD elements similar to CAD groups, but they also include orientation, shading, scaling, and clipping plane information.

The list to the right of the icon contains the available CAD model views. If there are no CAD model views, the list is empty. You can select **<None>** from the list to deactivate a CAD model view. If a CAD model view contains embedded CAD GD&T callouts, this icon ( ) appears next to that item in the list. For information on CAD GD&T callouts, see the "Working with CAD GD&T Callouts" topic in the "Editing the CAD Display" documentation.

For information on CAD model views, see "Working with CAD Model Views" in the "Editing the CAD Display" documentation.

Measurement Strategy Toolbar



Measurement Strategy Editor - This button opens the **Measurement Strategy Editor** (MSE). For more information, see "Using the Measurement Strategy Editor" in the "Setting Your Preferences" chapter. This button appears if you enable the **Using Measurement Strategy Editor** check box in the list of check boxes in the **General** tab of the **Setup Options** dialog box (F5).

Measurement Strategy Group - The list to the right of the button lets you change the default measurement strategy group. A group is a saved set of modified settings for all the Auto features. The list shows all the available groups that you defined in the MSE. If you select a group from this list, that's the default group that PC-DMIS then uses. PC-DMIS uses that group in QuickFeatures and with the Measurement Strategy Widget. For more information, see "Creating QuickFeatures" and "Using the Measurement Strategy Widget" in the "Creating Auto Features" chapter. If the list only contains **Factory Defaults**, then you have not yet created any groups in the MSE.

Auto Features Toolbar

Auto Features Toolbar

With the **Auto Features** toolbar (**View | Toolbars | Auto Features**), you can access the same Auto feature available on the various tabs of the **Auto Features** dialog box.

PC-DMIS determines which Auto features are enabled based on your PC-DMIS configuration and your current probe type. For more information about what Auto features the different configurations support, see "Inserting Auto Features" in the "Creating Auto Features" chapter.

The following icons are available:

Vector Point - Creates an Auto Vector Point feature from the surface vector at the clicked location.

Surface Point - Creates an Auto Surface Point feature at the clicked location.

Edge Point - Creates an Auto Edge Point feature on a line between two surfaces.

Angle Point - Creates an Auto Angle Point feature where three perpendicular surfaces meet.

Corner Point - Creates an Auto Corner Point feature where two lines or surfaces meet.

High Point - Creates an Auto High Point feature at the highest location on the surface.

Line - Creates an Auto Line feature on a line.

Plane - Creates an Auto Plane feature on a surface.

Circle -Creates an Auto Circle feature on a circle.

Ellipse - Creates an Auto Ellipse feature on an ellipse.

Round Slot - Creates an Auto Round Slot feature on a round slot.

Square Slot - Creates an Auto Square Slot feature on a square slot.

Notch Slot -Creates an Auto Notch Slot feature on a three-sided square slot.

Flush and Gap - Creates an Auto Flush and Gap feature to measure the height difference between two mating sheet metal parts. *This becomes available with laser probes.*

Polygon - Creates an Auto Polygon feature from a feature of three or more sides of equal length.

Profile 2D - Creates an Auto Profile 2D feature. *This is available with vision probes.*

Blob - Creates an Auto Blob feature. *This is available with vision probes.*

Cylinder - Creates an Auto Cylinder feature.

Cone - Creates an Auto Cone feature.

Sphere - Creates an Auto Sphere feature.

When you click on an Auto feature icon, the **Auto Feature** dialog box opens and selects that feature type. To create the Auto feature, follow the instructions provided in the "Creating Auto Features" chapter. When ready, press the End key, or click the **Create** button on the **Auto Feature** dialog box to insert the feature into your measurement routine. Before creating your feature, you can remove hits from the hit buffer by pressing the Alt + '-' keyboard combination.

You can click the minimize button on the **Auto Feature** dialog box to *hide* it and still create the selected feature.

Measured Features Toolbar

Measured Features Toolbar

With the **Measured Features** toolbar (**View | Toolbars | Measured Features**), you can force PC-DMIS to accept a given feature type, or you can have it guess and display the feature type for which you are taking hits.

Point - Forces PC-DMIS to accept the Point feature type

Line - Forces PC-DMIS to accept the Line feature type

Plane - Forces PC-DMIS to accept the Plane feature type

Circle - Forces PC-DMIS to accept the Circle feature type

Round Slot - Forces PC-DMIS to accept the Round Slot feature type

Square Slot - Forces PC-DMIS to accept the Square Slot feature type

Cylinder - Forces PC-DMIS to accept the Cylinder feature type

Cone - Forces PC-DMIS to accept the Cone feature type

Sphere - Forces PC-DMIS to accept the Sphere feature type

Torus - Forces PC-DMIS to accept the Torus feature type

Set - Creates a Measured Set of features

Guess - Enables a Guess Mode where the software guesses the feature type based on the number of hits. PC-DMIS draws the guessed feature type in the Graphic Display window after you take each hit.

Guess Mode Preview

PC-DMIS provides a visual preview of the feature type before you actually accept it. For example, if you measure a cylinder, you need to take two sets of four hits, at two different levels along the height of the pin. When you take four hits at the first level, PC-DMIS draws a circle in the Graphic Display window. After you take the second level of hits, PC-DMIS displays two circles, one on each level, that represents the measured cylinder.

The feature is only added to the measurement routine when you press the End key. You can press the '-' or ALT + '-' keys to remove hits.

Forcing a Guessed Feature

If PC-DMIS displays the wrong feature type, you can click a specific feature icon to force PC-DMIS to accept that feature. For example, if you select the **Circle** icon, PC-DMIS is forced to accept the circle feature type as long as you take the minimum number of hits.

Constructed Features Toolbar

Constructed Features Toolbar

From the **Constructed Features** toolbar (**View | Toolbars | Constructed Features**), you can use icons to quickly access the feature construction options available from the **Insert | Feature | Constructed** submenu.

Point - Constructs a point from inputs. For more information, see Point.

Line - Constructs a line from inputs. For more information, see Line.

Plane - Constructs a plane from inputs. For more information, see Plane.

Circle - Constructs a circle from inputs. For more information, see Circle.

Ellipse - Constructs an ellipse from inputs. For more information, see Ellipse.

Round Slot - Constructs a round slot from inputs. For more information, see Round Slot.

Square Slot - Constructs a square slot from inputs. For more information, see Square Slot.

Width - Constructs a width from inputs. For more information, see Width.

Curve - Constructs a curve from inputs. For more information, see Curve.

Cylinder - Constructs a cylinder from inputs. For more information, see Cylinder.

Cone - Constructs a cone from inputs. For more information, see Cone.

Sphere - Constructs a sphere from inputs. For more information, see Sphere.

Surface - Constructs a surface from inputs. For more information, see Surface.

Feature Set - Constructs a feature set from inputs. For more information, see Feature Set.

Filter - Constructs a filter set from a scan, certain constructed features, or another filter set. For more information, see Filter Set.

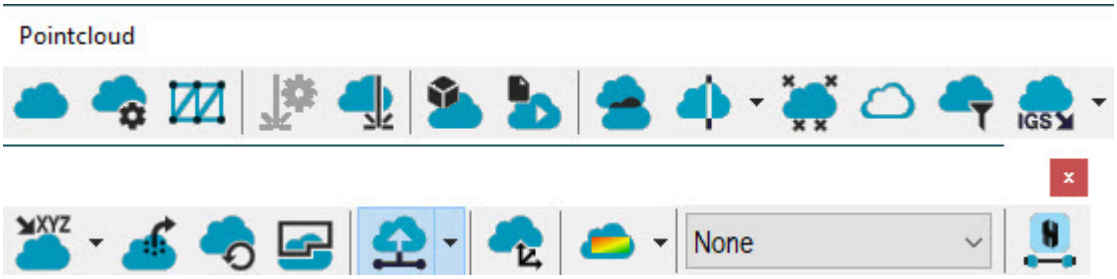
Adjusted Filter - Constructs an adjusted filter from adjusted scan data that was gathered while scanning around sphere, cone, or cylinder features. For more information, see Adjusted Filter.

Generic - Constructs a generic feature based on inputs but modified with expressions. For more information, see Generic.

For information on these items, see the "Constructing New Features from Existing Features" chapter and the "Creating Generic Features" chapter.

For information on inserting Read Points, view the documentation available in the "Creating Generic Features" chapter.

Pointcloud Toolbar

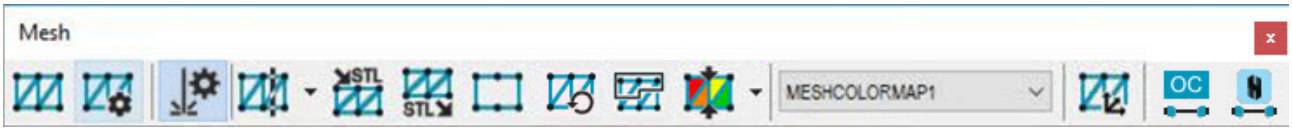


Pointcloud Toolbar

The **Pointcloud** toolbar provides all pointcloud operations, features, and functions. It is accessible from the **View | Toolbars | Pointcloud** menu, depending on your system's configuration.

For details on all Pointcloud toolbar functions, see the topic "Pointcloud Toolbar" in the PC-DMIS Laser documentation.

Mesh Toolbar



Mesh Toolbar

The **Mesh** toolbar provides all mesh operations, features, and functions. It is accessible from the **View | Toolbars | Mesh** menu depending on your system's configuration.

> You must be licensed for Mesh before it is available.

For details on all Mesh toolbar functions, see the topic "Mesh Toolbar" in the PC-DMIS Laser documentation.

Dimension Toolbar

PC-DMIS shows variations of the Dimension toolbar based on the GD&T standard you select.

Dimension toolbar - Shown with the "Use Legacy Dimensions" menu option enabled

Dimension toolbar - "Use Legacy Dimensions" menu option disabled, ISO 1101 2012/2017, ASME Y14.5 – 1994, or ASME Y14.5 2009 selected as the GD&T standard

Dimension toolbar – Use Legacy Dimensions disabled, ASME Y14.5 – 2018 selected as the GD&T standard

Toolbar options that are not compatible with the selected standard are disabled.

The **Dimension** toolbar (**View | Toolbars | Dimension**) is used to quickly access the options available from the **Dimension** menu. The icons for the dimensions below reference the "Using Legacy Dimensions" chapter. If you want to use Geometric Tolerances, see the "Using Geometric Tolerances" chapter.

Location - See Location

Distance - See Distance

Angle Between - See Angle Between

Straightness - See Straightness

Flatness - See Flatness

Circularity - See Circularity

Cylindricity - See Cylindricity

Perpendicularity - See Perpendicularity

Parallelism - See Parallelism

Angularity - See Angularity

Position - See Position

Concentricity - See Concentricity

Coaxiality - See Coaxiality

Symmetry - See Symmetry

Total Runout - See Total Runout

Circular Runout - See Circular Runout

Surface Profile - See Surface Profile

Line Profile - See Line Profile

Size - See Dimensioning Size

Keyin - See Keyin

Datum Definition - See Defining and Using Datums

Alignment Toolbar

Alignment Toolbar

With the **Alignment** toolbar (**View | Toolbars | Alignment**), you can access the same alignment options that are on the **Insert | Alignment** submenu.

The following alignment functions are available:

QuickAlign - Creates alignments from the Edit window with a single click of a toolbar icon. For more information on the QuickAlign functionality, see the "About QuickAlign" topic.

New Alignment - Displays the **Alignment Utilities** dialog box for creating a new alignment in your measurement routine. For information on using the **Alignment Utilities** dialog box, see the "Description of the Alignment Utilities Dialog Box" topic.

Save Alignment - Displays the **Save Alignment As** dialog box to save the current alignment in an external file. External alignments can be recalled by a different measurement routine. For more information on saving alignments, see the "Saving an Alignment" topic.

Recall Alignment - Recalls an alignment that was previously created in the current measurement routine (Internal Alignment) or saved from another measurement routine (External Alignment). For more information on recalling alignments, see the "Recalling an Existing Alignment" topic.

Equate Alignment - Changes the position or orientation of a part, or recovers the alignment when a part has been accidentally moved. For more information on equating alignments, see the "Equating an Alignment" topic.

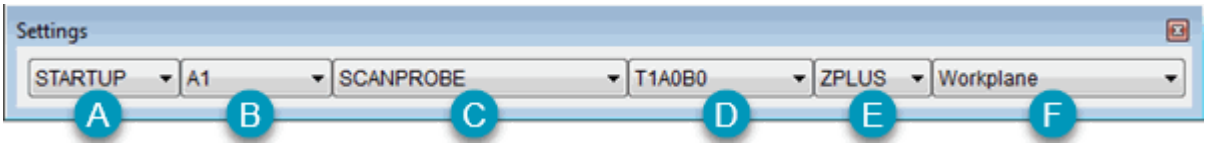
> The **Leapfrog** and **Bundle Alignment** functions below are only available when connected to a Portable system.

Leapfrog - Displays the **Leapfrog / Relocation** dialog box. This menu option is disabled in Offline mode. You must be connected to a physical supported portable

machine for the icon to be active. For more information on leapfrog operations, see the "Performing a Leapfrog Operation" topic.

Bundle Alignment - Creates a bundle alignment. Bundle alignments are used mainly in Portable systems for large or complex measurements to create a number of stations in a common network by moving the same sensor to different positions around the object. For more information on bundle alignments, see the "Using Bundle Alignments" topic in the PC-DMIS Portable documentation.

Settings Toolbar



Settings Toolbar

The **Settings** toolbar (**View | Toolbars | Settings**) contains lists that provide a more convenient way to switch between the some settings. From left to right on the toolbar, these settings are:

A. Views - Saved views of the Graphic Display window

With the **Views** list, you can recall a stored viewset that was created and saved with the active measurement routine.

PC-DMIS inserts a `RECALL/VIEWSET` command into the Edit window.

Command line in the Edit window:

```
RECALL/VIEWSET, view_set_name
```

View_set_name = the name of the view set to recall.

While PC-DMIS is recalling a view, all other functions are temporarily inaccessible.

For information on viewsets, see "Setting Up the Screen View" in the "Editing the CAD Display" chapter, and "Working with Viewsets" in the "Inserting Report Commands" chapter.

B. Alignments - Saved alignments

With the **Alignments** list, you can select a previously saved alignments. These alignments can then be inserted into the Edit window when selected.

See "Saving an Alignment" from the "Creating and Using Alignments" chapter for additional information on how to create and save alignments.

You can control which alignments are displayed in this list by going to the Alignment in the Edit window and changing the value for the `LIST=` portion of the `ALIGNMENT/START` command (for more information, see the "Creating and Using Alignments" chapter).

C. Probes - Defined probe types

With the **Probes** list, you can select probes already defined in your probe file. PC-DMIS inserts a `LOADPROBE` command into the Edit window.

PC-DMIS marks the currently active TProbe in the **Probes List** of the **Settings Toolbar** in a **bold** font weight. If you select a different probe from the list that isn't the physically active TProbe and then take a hit, the software displays a warning message. We recommended that you always use the probe settings of the physically active probe, otherwise your hit data might not be properly corrected for the ball diameter and offset.

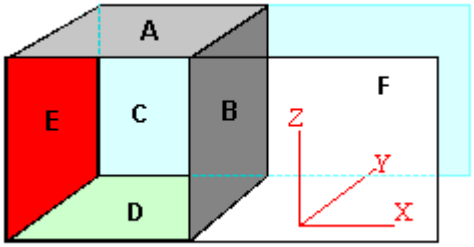
D. Probe Tips - Defined probe tips and probe tip angles

The **Probe Tips** list stores previously defined probe tip angles. See "Add Angles" from the "Defining Hardware" chapter for information on how to create tip angles.

E. Workplane - Available workplanes

The **Workplane** list allows you to change the plane in which you are working. This option does not change the view in the Graphic Display window; it changes only the workplane.

The available workplanes are:



Face	Color	Workplane
A=TOP	Light Gray	ZPLUS
B=RIGHT	Dark Gray	XPLUS
C=BACK	Light Blue	YPLUS
D=BOTTOM	Light Green	ZMINUS
E=LEFT	Red	XMINUS
F=FRONT	Clear	YMINUS

Measured Lines and Workplanes

When creating a measured line, PC-DMIS expects the hits for the line to be taken at a vector perpendicular to the current workplane.

For example, if your current workplane is ZPLUS (with a vector 0,0,1), and you have a block-like part, the hits for the measured line must be on a vertical wall of that part, such as the front or side.

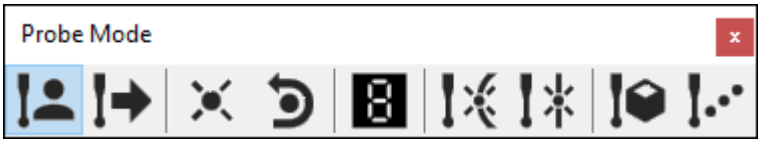
If you then wanted to measure a line feature on the top surface of the part, you would need to switch the workplane to XPLUS, XMINUS, YPLUS, or YMINUS, depending on the direction of the line.

F. Projection Planes - Planes (faces) to which to project certain features

The **Projection Planes** list contains a list of any plane features you have created in your measurement routine. By default, PC-DMIS projects each measured line and circle into your current workplane, so the default item on this list shows **Workplane**. However, you can select a different plane from this list.

PC-DMIS will then project each measured line and circle into the newly selected plane.

Probe Mode Toolbar



Probe Mode Toolbar

The **Probe Mode** toolbar (**View | Toolbars | Probe Mode**) contains icons that you can use to enter the different modes used by the current probe or CMM.

The following describes the available icons:

Manual Mode - This icon places PC-DMIS into Manual Mode. Manual Mode enables you to manually control your machine's movements and measurements. Manual Mode is used on a manual CMM or during the manual alignment portion of a measurement routine that is run on an automatic CMM. When you click this icon, PC-DMIS inserts a `MODE/MANUAL` command into the Edit window at the cursor's location. Edit window commands following this command are executed in Manual Mode.

DCC Mode - This icon places PC-DMIS into DCC Mode. DCC Mode allows supported DCC machines to automatically take over the measurement of your measurement routine. When you click this icon, PC-DMIS inserts a `MODE/DCC` command into the Edit window at the cursor's location. Edit window commands following this command are executed in DCC Mode.

Readouts Mode - This icon becomes available if you use an LK machine and if PC-DMIS is in Online mode. The icon places the probe into Readouts Mode. For more information, see "Placing the Probe into Readouts and Hits Mode" in the PC-DMIS CMM help documentation.

Hits Mode - This icon becomes available if you use an LK machine and if PC-DMIS is in Online mode. The icon places the probe into Hits Mode. For more information, see "Placing the Probe into Readouts and Hits Mode" in the PC-DMIS CMM help documentation.

Take a Hit - For supported probes in Manual Mode, this icon takes a hit at the probe ball location.

Erase Hit - This icon deletes the most recent hit from the hit buffer.

Probe Readouts - This icon the opens the Probe Readouts window. For information on probe readouts, see "Using the Probe Readouts Window" in the "Using Other Windows, Editors, and Tools" chapter.

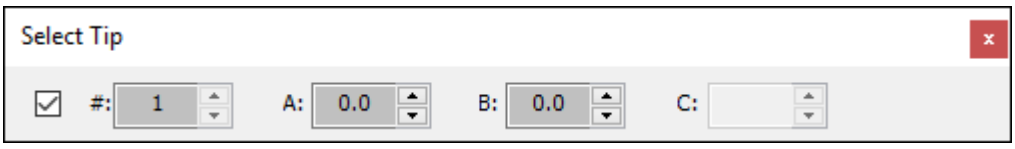
Point AutoTrigger Mode - For supported portable arm machines, this icon inserts a `POINT AUTOTRIGGER` command into the measurement routine. For more information on Point Auto Trigger Mode, see the "Point AutoTrigger area" topic in the "Setting Your Preferences" chapter.

Plane AutoTrigger Mode - For supported portable arm machines, this icon inserts a `PLANE AUTOTRIGGER` command into the measurement routine. For more information on Plane Auto Trigger Mode, see the "Plane AutoTrigger area" topic in the "Setting Your Preferences" chapter.

Find Nominals from CAD Mode - This icon selects the **Find Nominals** check box in the **General** tab of the **Setup Options** dialog box. For more information on that check box, see "Find Nominals" topic in the "Setting Your Preferences" chapter.

Point Only Mode - This icon selects the **Point Only Mode** check box in the **General** tab of the **Setup Options** dialog box. For more information on that check box, see "Point Only Mode" topic in the "Setting Your Preferences" chapter.

Select Tip Toolbar



Select Tip Toolbar

You can use the **Select Tip** toolbar (**View | Toolbar | Tip Selection**) to insert tips (for star probes) and tip angles (for configurations supporting probe head angles and wrist rotation) into your measurement routine on the fly. These can be constrained to allow only existing calibrated tips; or, you can insert any new angle that your probe hardware supports without having to go through the traditional route of accessing the **Probe Utilities** dialog box and then clicking on the **Add Angles** button.

For example, suppose you are learning a feature in Offline Mode, but a fixture holding the part in place won't allow the probe to measure the feature unless you use a different angle. Use this toolbar to quickly visualize and define the desired angle, which allows a much simpler workflow than the traditional procedure. To do this, type the desired angles (or use the up and down increment arrows). With each change in any of the edit boxes, PC-DMIS dynamically inserts the tip or tip angle into your measurement routine and appropriately draws the probe in the Graphic Display window.

The available items are as follows:

Check box - This check box constrains the toolbar, which allows you to select only calibrated tip angles. With this item selected, if you increment one of the A, B, or C angles, it chooses the closest calibrated tip angle and inserts it into the measurement routine.

If you clear this check box, you can define any tip angle increment that is valid for your probe type.

 # box - This box represents the tip number. It applies to probe types that don't have a rotating head or wrist but have multiple physical tips instead. For example, a star probe has five probe tips, each represented by a tip number. Type or select that number in this box to insert the associated TIP command into the measurement routine.

A, B, C boxes - These angle boxes define the A, B, and C angles for the probe head and wrist. Click the arrows to the right of each box to increment or decrement the respective angle to the next valid value.

Active Arms Toolbar

Active Arms Toolbar

The Active Arms toolbar (**Operation | Enter Multiple Arm Mode**) is used to manipulate multiple arms.

Arm1 Active - This corresponds to the primary arm. When selected, Arm1 is considered active.

Arm2 Active - This corresponds to the secondary arm. Only one arm can be active at a time. When selected, Arm2 is considered active.

Execute on Arm1 - This executes the measurement routine on Arm1.

Execute on Arm2 - This executes the measurement routine on Arm2.

Move to Arm1 Start Point - This moves the cursor in the Edit window to the top of the Arm1 measurement routine starting point.

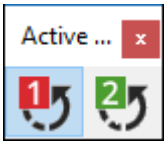
Move to Arm2 Start Point - This moves the cursor in the Edit window to the top of the Arm2 measurement routine starting point.

Execute from Start Point - This starts measurement routine execution for both arms at the currently defined start point. You can also execute commands tied to a specific arm by clicking the colored check mark icon that corresponds to the active arm.

The **Active Arms** toolbar is available if the Multiple Arm Mode add-on package has been purchased for your system.

See the "Using Multiple Arm Mode" chapter for more information on setting up and using multiple arm CMMs. Also, see the "Assigning a Command to an Arm" topic from that chapter for additional information on using this toolbar.

Active Rotary Table Toolbar



Active Rotary Table Toolbar

The **Active Rotary Table** toolbar (**View | Toolbars | Active Rotary Table**) selects which of the two rotary tables is the active table. This toolbar becomes available when you set up the rotary tables from the **Edit | Preferences | Rotary Table Setup** menu option. For more information, see "Defining the Rotary Table" in the "Setting Your Preferences" chapter.

ClearanceCube Toolbar

ClearanceCube Toolbar

Use the **ClearanceCube** toolbar (**View | Toolbars | ClearanceCube**) to enable or disable options related to ClearanceCube functionality. See "Using the ClearanceCube" in the "Editing the CAD Display" chapter.

The following icons are available:

ClearanceCube Definition - This icon displays the **ClearanceCube Definition** dialog box. For more details on the dialog box, see the "(Simple) ClearanceCube Definition" topic. You can also press Alt + C to open the dialog box.

Activate ClearanceCube Motion - This icon enables or disables ClearanceCube motion.

- If enabled, your measurement routine uses the ClearanceCube to control its motion and *disables clearance planes*.
- If disabled, your measurement routine uses existing clearance plane commands to control its motion.

> You cannot deactivate ClearanceCube if any feature in a measurement routine uses ClearanceCube motion.

Show ClearanceCube - This icon shows or hides ClearanceCube in the Graphic Display window.

To increase transparency through ClearanceCube in the Graphic Display window, select the **High quality transparency** check box in the **OpenGL** tab of the **CAD and Graphic Setup** (**Edit | Graphic Display Window | OpenGL**) dialog box.

ClearanceCube Settings window - This icon shows or hides ClearanceCube Settings window.

Wizards Toolbar

Wizards Toolbar

The icons on this toolbar are bound to external wizards that come installed with PC-DMIS. These wizards serve to increase the usability for new users who are still learning how to use the application.

These wizards are available:

3-2-1 Alignment Wizard - This wizard walks you through two basic types of alignments: a 3-2-1 alignment and a two circle alignment.

CAD Import Wizard - This wizard allows you to import single or multiple CAD models into the Graphic Display window. Click the icon and a dialog box appears. Select one or more files to import and then click **Open**. This replaces any CAD data that already exists in the window.

Data Field Edit Wizard - This wizard lets you replace certain fields in the Edit window that you cannot replace using the **Replace** dialog box. See "Editing Data Fields" in the "Editing a Measurement Routine" chapter.

DMIS Out Wizard - This wizard helps you export a DMIS output file of your inspection report.

Iterative Alignment Wizard - This wizard walks you through the steps to create an iterative alignment and explains the rules behind the inputs to the alignment.

Multiple Execution Wizard - This wizard lets you loop your measurement routine execution indefinitely or a specified number of times. You can also choose the specific message to display between iterations.

Probe Wizard - This wizard demonstrates how to define a probe and enables you to calibrate the newly defined probe.

Database Wizard - This wizard helps you create and register ODBC databases. This only appears if your license was configured with the **Integrated Stats** option.

Decremented Functionality

The PCD2Excel Wizard (PCD2excel.exe) is no longer supported and is no longer available from the user interface. It does not support Geometric Tolerance commands. Please use the Excel Form Report instead (**Insert | Report Command | Excel Form Report**).

For details on how to use the Excel Form Report, see the "Using the Excel Form Report Command" section of the PC-DMIS Toolkit Modules documentation.

While we recommend that you use the Excel Form Report above, the PCD2Excel Wizard is still available in the "*C:\Program Files\Hexagon\PC-DMIS 2026.2 64-bit\en*" folder of the PC-DMIS installation location.

The PCD2Excel Wizard will be removed in a future version.

PCD2Excel Wizard - This wizard exports your PC-DMIS measurement routine data into a Microsoft Excel file of your choice. To configure the wizard's options, click **Configure**. For information on the configuration options, see the "Configuring Excel Output" topic.

Excel 2003 or later is required for the PCD2Excel Wizard to function properly.

Configuring Excel Options

This topic covers the configuration options for the PCD2Excel Wizard.

The PCD2Excel Wizard (PCD2excel.exe) is no longer supported and is no longer available from the user interface. It does not support Geometric Tolerance commands. Please use the Excel Form Report instead (**Insert | Report Command | Excel Form Report**).

For details on how to use the Excel Form Report, see the "Using the Excel Form Report Command" section of the PC-DMIS Toolkit Modules documentation.

While we recommend that you use the Excel Form Report above, the PCD2Excel Wizard is still available in the "*C:\Program Files\Hexagon\PC-DMIS 2026.2 64-bit\en*" folder of the PC-DMIS installation location.

The PCD2Excel Wizard will be removed in a future version.

The available configuration options are:

Active measurement routine - Displays the name of your current measurement routine.

Output file - Defines the file name and location. The **File name** box defines the name of the Microsoft Excel file to which the output is sent. You can type the full pathway, or you can click **Browse** to locate and select an existing file name.

Type - Defines the output type. It contains these options:

> **Excel** - Sends the output to an Excel formatted file.
>
> **CSV** - Sends the output to a plain-text Comma Separated Value (CSV) file. You can choose a different delimiting character in **Separator**.
>
> **Show Excel** - If marked, Excel appears during the export process. If cleared, Excel runs hidden in the background.
>
> **Separator** - Determines the separator, or delimiting character, to use when this exports to a CSV file. The default is a comma character (,).

Overwrite mode - Defines what happens when data is sent to an existing file.

> **No** - Existing dimensional data is not overwritten. New values for existing dimensions are ignored. Only entirely new dimensions are added to the output file.
>
> **Yes** - Existing dimensional data is overwritten with the latest information.
>
> **Add** - Existing data is not overwritten with new values. The new values for existing dimensions are appended.

Export multiple instances - Determines the order in which multiple instances of a feature being executed appear in the exported file. Multiple instances result when a feature is executed multiple times due to a loop or some other execution branching.

> **By position** - Multiple instances are exported using their top-to-bottom position in the measurement routine.
>
> **By execution** - Multiple instances are exported based on the execution order of the last time the measurement routine was executed. For example, a branching conditional statement that skips over some dimensions during execution causes intervening dimensions to be ignored in this export as well.

PC-DMIS statistics - Determines if `PC-DMIS STATS/ON` or `TRACEFIELD` commands are required to export the data.

> **Use STATS/ON and STATS/OFF** - If marked, you *must* include dimension (or the Geometric Tolerance dimension) commands between the `STATS/ON` and `STATS/OFF` commands in your measurement routine; otherwise, the wizard does not export data to the Excel file. If you clear this check box, all dimension commands get exported into the Excel file. See the "Tracking Statistical Data" chapter.
>
> **Use TRACEFIELD** - This becomes available for selection if you use `STATS/ON` and `STATS/OFF` .

Headers - Determines how the header data for the measurement routine is written to the output file.

Measurement routine name - If marked, the measurement routine names are included in the output file.

Short - The file name is a shortened format and shows just the file name, not the full pathway.

Full - The file name includes the full pathway.

Part name - If marked, the part name is included in the output file.

Revision number - If marked, the revision number is included in the output file.

Serial number - If marked, the serial number is included in the output file.

Statistic count - If marked, the number of transactions or runs is included in the output file.

Data and time - If marked, the current date and time are included in the output file.

Dimension - Determines how the dimensional data appears in the output.

By row - Dimensions are laid out horizontally

By column - Dimensions are laid out vertically.

Header start row and column - Defines the starting location where you want the header information to appear. The values of 2 and 2 mean it begins the second row down and the second column to the right.

Data start row and column - Defines the starting location where you want the dimensional data to appear. The values of 9 and 2 means it begins on the ninth row in the second column.

Ignore FCFs - If marked, PC-DMIS does not pass Geometric Tolerance commands to the Excel file. See the "Using Geometric Tolerances" chapter.

Units - If marked, the measurement units used by each dimension are included in the export. For example, angle measurements show DEG for degrees, size measurements show MM for millimeters or IN for inches.

Fields label - Determines how labels appear next to data fields in the output.

Once - Field labels appear only once after the heading information and before all the dimensions are listed. These are either column headings or row headings based on the **By row** or **By column** setting.

Always - Field labels appear before each dimension.

All fields - If you mark **Always**, this check box becomes available for selection. If you mark **All Fields**, all the labels appear. These are: DIMENSION, DESCRIPTION, FEATURE, AXIS, SEGMENT, NOMINALS, MEAS, +TOL, -TOL, BONUS, DEV, OUTTOL, DEVANG, Datum Shift Effect, Unused Zone, Shift X, Shift Y, Shift Z, Rotation X, Rotation Y, and Rotation Z.

If cleared, only these labels appear: DIMENSION, DESCRIPTION, AXIS, NOMINALS, MEAS, +TOL, -TOL, DEV, and OUTTOL.

Blank row/column between dimensions - If marked, this inserts a blank row after each dimension.

Defaults - This button creates a defaults file (Defaults.p2x) that stores this dialog box's settings. When you click this button, PC-DMIS automatically updates the contents of the defaults file without showing a message.

PC-DMIS uses this defaults file in these cases:

- For new measurement routines
- For the current measurement routine if PC-DMIS cannot locate the routine-specific settings file (Note that PC-DMIS creates a routine-specific .p2x file in the same directory as the measurement routine whenever you first access this dialog box. It then modifies that routine-specific file whenever you click **Continue**.)

PC-DMIS attempts to save the Defaults.p2x file in a Wizards folder under where you installed PC-DMIS. You need to first create the Wizards folder inside the installation folder. If that folder doesn't exist, nothing happens when you click **Defaults**. You can view this defaults file in any text editor.

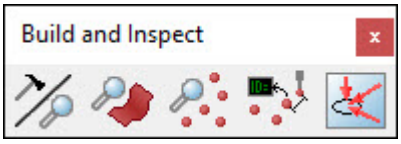
Running the Wizard Unattended

You can tell PC-DMIS to run the PCD2Excel wizard without any human intervention. After configuring the wizard, insert `EXTERNALCOMMAND` into your measurement routine and add an 'A' parameter to the command so that it looks something like this:

```
EXTERNALCOMMAND/DISPLAY ; C:\Program Files\Hexagon\PC-DMIS 2026.2 64-bit\en\Wizards\PCD2EXCEL.EXE A
```

This tells the wizard to run in unattended mode. If you're using a non-English version, instead of "en" in the pathway, use the two-letter subdirectory for your language.

Build and Inspect Toolbar



Build and Inspect Toolbar

This toolbar is used when measuring a part with a portable measurement device. For information on this toolbar, see the "Build and Inspect Toolbar" topic in the PC-DMIS Portable documentation.

QuickMeasure Toolbar

The **QuickMeasure** toolbar models the typical flow of operation for the software's various supported configurations. You can access it from the **View | Toolbars | QuickMeasure** menu.

The toolbar uses drop-down menus for many of the buttons. PC-DMIS stores the last-selected option for these buttons and displays it the next time you access the **QuickMeasure** toolbar.

If needed, you can add the drop-down menus to other toolbars from the **View | Toolbars | Customize** menu option. For information on how to customize toolbars, see "Customizing Toolbars" in the "Navigating the User Interface" chapter.

For CMM and Vision

From left to right, the icons on the **QuickMeasure** toolbar for PC-DMIS CMM or vision model the typical flow of operation on a system configured for CMM or vision.

QuickMeasure toolbar for CMM and vision users

For information on this toolbar, see "CMM QuickMeasure Toolbar" in the "PC-DMIS CMM" documentation.

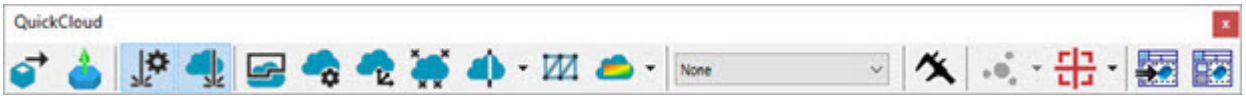
For Portable

From left to right, the icons on the **QuickMeasure** toolbar for PC-DMIS Portable model the typical flow of operation on a portable machine. This toolbar is only available for selection if your version of PC-DMIS is configured to work with a portable measuring device.

QuickMeasure toolbar for Portable users

For information on this toolbar, see the "Portable QuickMeasure Toolbar" topic in the "PC-DMIS Portable" documentation.

QuickCloud Toolbar



QuickCloud Toolbar

The **QuickCloud** toolbar is only available when PC-DMIS is licensed and configured for Portable devices. It provides the buttons to complete all the steps for working with pointclouds (COP).

For more information on this toolbar, see the "QuickCloud Toolbar" topic in the "PC-DMIS Portable" documentation.

For details on all Pointcloud toolbar functions, see the "Pointcloud Toolbar" topic in PC-DMIS Laser documentation.

Quick Fixture Toolbar

To show or hide the **Quick Fixture** toolbar, do one of the following:

- On the Graphic Modes toolbar, select the **Quick Fixture Mode** icon ( ).
- Select **Operation | Graphic Display Window | Change Screen Mode | Quick Fixture Mode**.

When the toolbar appears, PC-DMIS permanently docks the **Quick Fixture** toolbar vertically to the right of the Graphic Display window.

The toolbar provides drop-down functionality for some of the buttons. PC-DMIS stores the last selected option for each of these buttons and displays it the next time the software shows the **Quick Fixture** toolbar.

The **Drop**, **Level**, **Rotate**, and **Square** buttons are mode buttons. The active mode has a blue highlight. While a mode is active, you can apply it to any component by clicking that component in the Graphic Display window. The Quick Fixture gizmo, by contrast, acts on a single selected component. For gizmo-based moving, rotating, aligning, and dropping, see "Using Quick Fixture Mode".

Drop - Drops the selected quick fixture onto the object directly below it in the Graphic Display window. If there is nothing in the Z minus direction, then nothing happens. If there is, then the fixture drops down until it touches the object.

Level - Takes the normal surface vector of where you just clicked and squares that up with the machine coordinate system.

Rotate - Takes the point where you just clicked and drops that invisible point on to the closest edge. It then squares up the vector that is tangent to the curve at the drop point. The rotate is a 2D squaring, looking down the current view normal.

Square - Squares up the selected quick fixture so that its axes are parallel to the CAD axes shown by the trihedron.

Link - Enters a grouping mode that groups all on-screen fixture components together so that dragging or rotating one fixture drags or rotates them all together. When it is cleared, you can manipulate the fixture components individually.

Load QuickFixture file - Loads a previously saved QuickFixture (.qfxt) file into the Graphic Display window.

Save QuickFixture file - Saves the on-screen fixture components as a QuickFixture (.qfxt) file that you can reload in other measurement routines.

Export Draw file - Exports the on-screen fixture components as a .draw file. If there is more than one fixture on the screen, then PC-DMIS exports them all as a single set.

Delete - Deletes the selected quick fixture component from the Graphic Display window.

The per-axis Move and Rotate buttons (X, Y, Z, XY, YZ, ZX) that appeared on this toolbar in earlier versions have been removed. To move and rotate components interactively, use the Quick Fixture gizmo. For more information, see "Using Quick Fixture Mode".

Defining Hardware

Defining Hardware: Introduction

This chapter describes all of the options associated with defining the hardware used to measure parts. These include the definition and calibration of your probe with its probe tips; the creation and use of a virtual machine; the creation, positioning, and use of quick fixtures; the calibration of probe changers; the creation of animated probe changers; information on working with rotary tables; and configuring advanced mouse devices.

These are discussed in the following topics:

- Defining Probes
- Defining Machines
- Inserting Quick Fixtures
- Defining Probe Changers
- Showing an Animated Probe Changer
- Protecting Probes from Probe Changer Collisions
- Working with Rotary Tables
- Configuring Advanced Mouse Devices
- Working with Environment Builder

Defining Probes

One of the first steps in programming is to define which probe to use during the inspection process. Because probe definition and calibration processes are often different depending on your specific configuration of PC-DMIS, this information is instead covered in the documentation for your configuration. Consult the appropriate documentation below for information on setting up, calibrating, and using an appropriate probe for your specific situation:

- PC-DMIS CMM
- PC-DMIS Vision
- PC-DMIS Laser

- PC-DMIS Portable

You use the **Probe Utilities** dialog box to define probes. You can also manually define probes by editing the usrprobe.dat file.

For Maestro CMM users, see the "Working with Environment Builder" section of the "Defining Hardware" chapter on how to use the Environment Builder to define your probe assemblies.

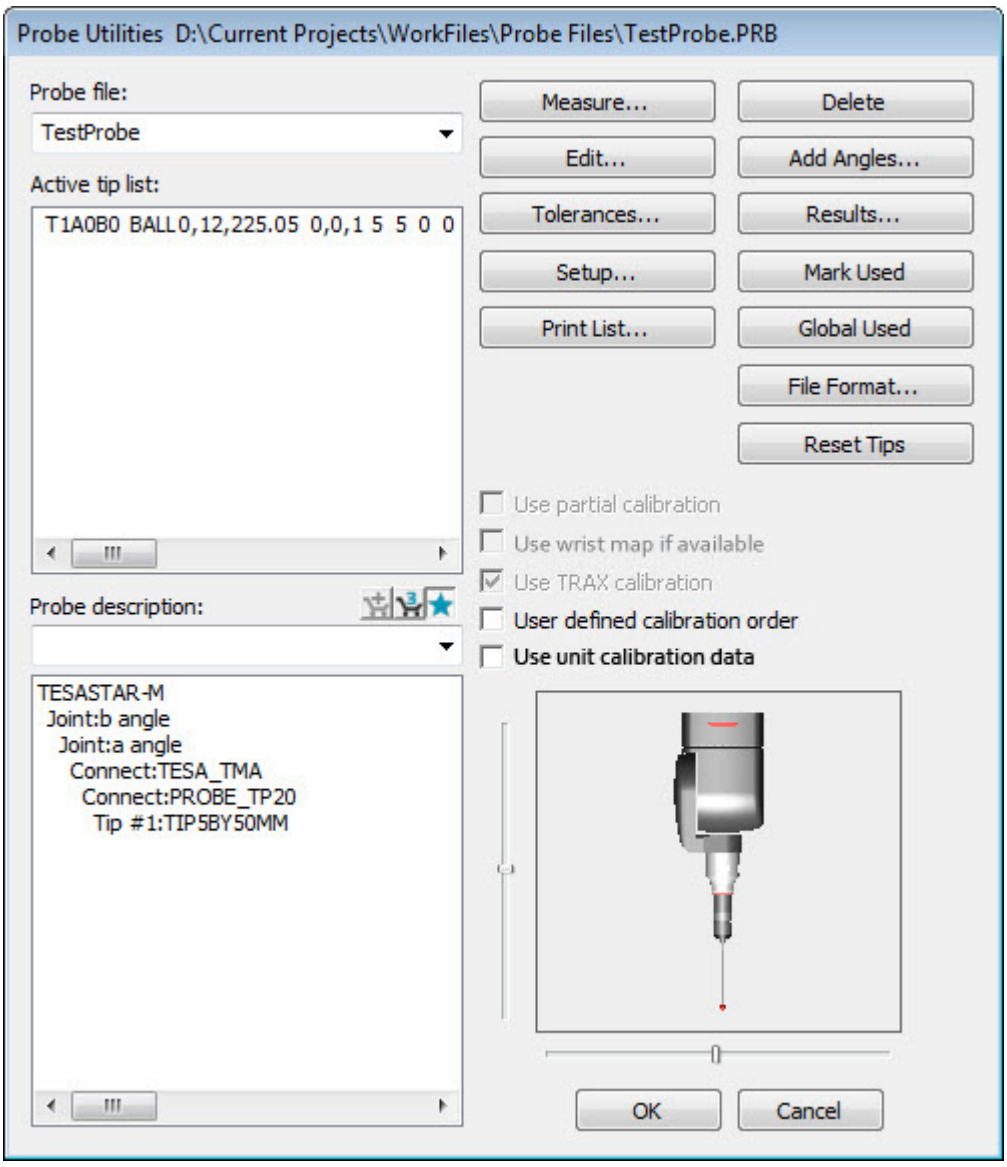
Click this icon from the **Wizards** toolbar to access the PC-DMIS Probe Wizard.

You can use the Check Calibration Limits command to check for errors and raise alerts during execution. For more information on this command, see "About Check Calibration Limits" in the PC-DMIS Toolkit Modules documentation.

You can enable the Leg Collision check. For more information, see "CMM Limits area".

Understanding the Probe Utilities dialog box

The **Probe Utilities** dialog box displays probe data for the active tip. You can use this dialog box to create new probe files, access previously-defined files, and edit a probe file. You can also calibrate probes. You can also select the Load Probe command of your measurement routine in the Edit window and then press F9 to display the **Probe Utilities** dialog box. To display the dialog box, select **Insert | Hardware Definition | Probe**.



Probe Utilities Dialog Box

The **Probe Utilities** dialog box image is intended to show all possible options and is for reference only. The options that appear depend on your PC-DMIS license settings, the PC-DMIS product being run, and how the measurement routine is written. Not all options are available at the same time.

Probe File Name

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

The **Probe file** list displays the probe file loaded for your current measurement routine. To load a different probe file, click the drop-down arrow to display all the probe files saved. The probes are listed in alphabetic order, making it easy to locate a specific probe.

PC-DMIS stores probe files in a default directory when you install PC-DMIS. When PC-DMIS searches for a probe file to load, it searches in this directory unless you've changed the search path. For information, see "Specifying Search Paths" in the "Setting your Preferences" chapter.

PC-DMIS stores the probe files by default in the "C:\Users\Public\Public Documents\Hexagon\PC-DMIS\2026.2" folder. This is detailed in the "Understanding File Locations" topic unless you've changed the search path.

To create a new probe file:

1. Highlight the current name in the **Probe file** drop-down list.
2. Type in a new name.

Use only letters, numbers, and the underscore character (_) in a probe file name. PC-DMIS does not allow a period or any of these characters: < > : " / \ |

Because PC-DMIS does not allow a period, do not type the .prb extension. PC-DMIS adds it for you.

A probe file name is limited to 180 characters. If you type a longer name, PC-DMIS displays a message and shortens the name to 180 characters.

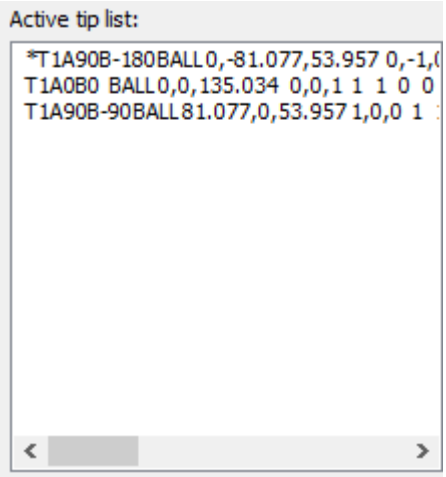
For the full list of naming rules, see "Setup Options: ID Setup tab" in the "Setting Your Preferences" chapter.

If a probe file has already been saved under the keyed-in name, PC-DMIS loads the previously saved file into the current measurement routine.

Active Tip List

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

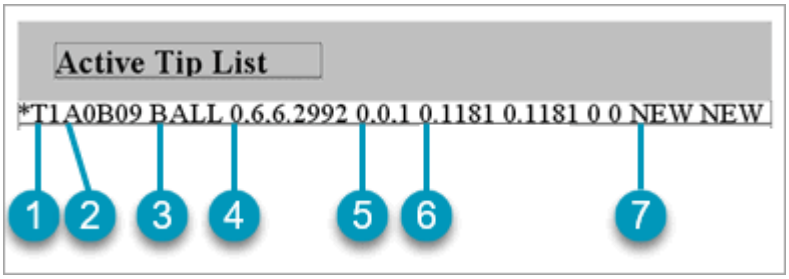
PC-DMIS is capable of storing data that describes a large number of probe tips. This data includes the probe tip's ID, rotation, type, location, direction, diameter and thickness, date and time of calibration, and any non-calibrated tips. These are all stored inside the **Active tip list**.



Active tip list Area

The list can display up to 32767 probe tips. This number may be limited by the amount of disk space available on your system.

PC-DMIS describes a probe according to the following criteria:



Tip List Description

1. ***TIP ID#*** *- This ID is the permanent number that PC-DMIS assigns to a tip when it is loaded into memory.*
2. ***Tip Rotation*** *- This field displays the rotation of the tip in the vertical (A) and horizontal (B) direction*
3. ***Tip Type*** *- This field displays the probe type (BALL, DISK, TAPER, SHANK, OPTICAL).*
4. ***X,Y,Z Location*** *- These values describe the location of the tip. This location is in relation to the bottom of the Z rail.*
5. ***I,J,K Direction*** *- These values describe the direction of the probe tip. This vector goes from the center of the probe tip towards the Z rail.*
6. ***Diameter and Thickness*** *- These values describe the diameter of the tip and the thickness of SHANK and DISK probes. PC-DMIS defines these values when the probe is loaded. (To change a field, see "Edit Tool".)*
7. ***Date and Time*** *- These boxes indicate the most recent date and time the probe tip was calibrated. If a new tip is created without being calibrated, PC-DMIS will display "NEW" for the date and time values. If an old probe tip is loaded and the date and time information is unavailable, PC-DMIS will display "UNKNOWN" for the values. Only probe tips that are actually calibrated have their time and date values updated.*

***(asterisk) -** An asterisk (*) to the left of the tip identifies any noncalibrated tips.*

Adding Tips to the List

You can use the **Add Angles** button to define new tips and add them to the list. To do this, see the "Add Angles" topic.

Editing Tip Data

1. Highlight the desired active tip in the **Active tip list**.
2. Click the **Edit** button to show the **Edit Probe Data** dialog box.
3. Modify the displayed values.
4. Click **OK** to save your changes.

Non-calibrated tips have an asterisk before their Tip ID # in the **Active tip list**.

Setting the Calibration Order

The calibration order is determined by the order in which the tips are chosen from the list box.

To set the calibration order:

1. From the **Probe Utilities** dialog box, click **Measure** to show the **Measure Probe** dialog box.
2. From the **Measure Probe** dialog box, **Calibration Mode** area, select the **User Defined** option. (See the "Measure" topic.)
3. Hold down the Ctrl key on the keyboard.
4. With your left mouse button, select the tips from the **Active tip list** for calibration. A number representing the index of the tip measurement order appears next to each Tip ID as you select it.

If you do not select any tips, PC-DMIS prompts if you want to measure all tips.

Selecting a Tip to Use

You can define a specific probe tip to use in your measurement routine in these ways:

- Type TIP in the Edit window's Command Mode and press the Tab key on your keyboard.
- Select the probe tip from the list on the Settings toolbar.

The Edit window command line for a sample tip would read:

```
TIP/T1A0B0, SHANKIJK=0, 0, 1, ANGLE=0
```

Until PC-DMIS encounters another TIP command in the measurement routine flow, it uses that tip.

Deleting a Tip or Wrist Angle

To delete one or more tips from the **Active tip list**:

1. Select the item or items to be removed.
2. Click the **Delete** button.

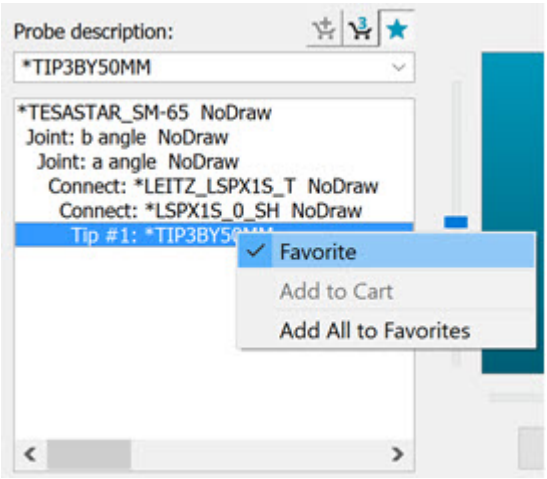
PC-DMIS also allows specific wrist angles to be removed from the **Active tip list**. If you delete a tip or probe head, PC-DMIS also deletes all related wrist angles from the file.

This option deletes the tip from the **Active tip list** and removes it from the file of tips known to the system.

Probe Description

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

The **Probe description** area consists of the list of available probe options in alphabetical order and a box that displays the probe components.



Probe description Area

From this area, you can do the following:

- Define the probe, extensions, and one or more tips that you can use in the measurement routine.
- Create a list of your favorite probe components.
- Add the probe and its components to the PC-DMIS shopping cart. You can then purchase the items from the Hexagon eStore or generate a purchase request.

You can right-click on a probe component to display these menu options:

Favorite - This item adds the component to your list of favorites. To add a component to the list, select the component, right-click, and then select **Favorite**. The check mark beside the menu item indicates that it is already in the list. To remove a component from the list, right-click on the added component and select **Favorite**.

The FavoriteProbeHardwareComponents.xml file saves the list of your favorite probe components. The default folder location is:

C:\ProgramData\Hexagon\PC-DMIS\<version>

Where <version> is the PC-DMIS version.

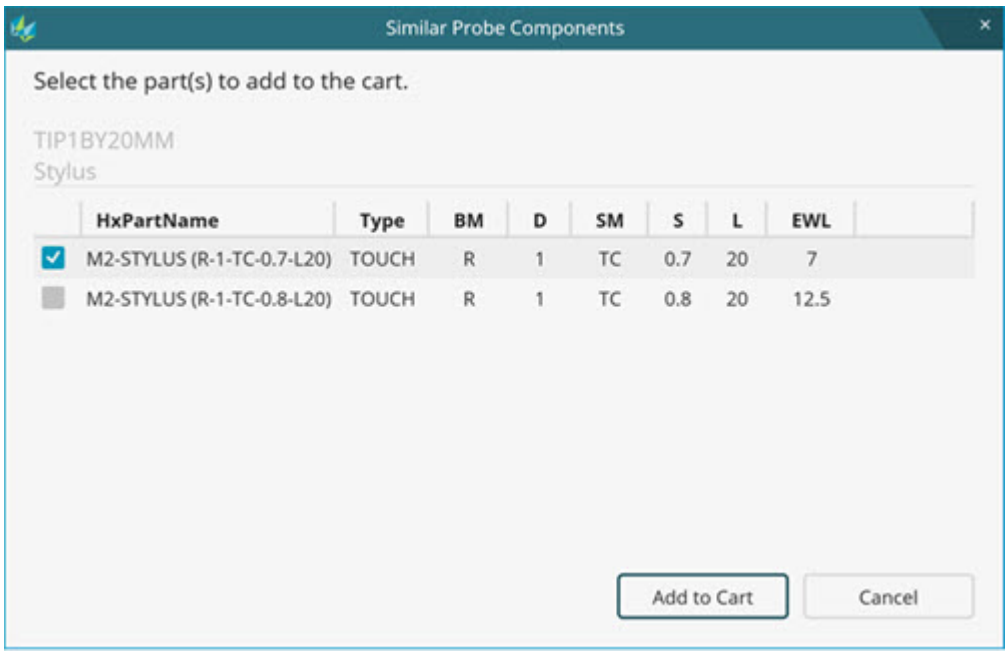
If you want to use the same list of favorites on your other computers, you need to copy the FavoriteProbeHardwareComponents.xml file from this computer and overwrite the file in all other computers.

Add to Cart - This item adds the component to the PC-DMIS shopping cart. This item is available only if the probe component has a Hexagon part number. This item is not available if the component has already been added to the cart.

Add All to Favorites - This item adds all the components of the selected probe file to your list of favorites.

Once you add the component to your list of favorites, the asterisk character (*) appears before the name of the component.

Add to Cart - To add a component to the cart, select the component and then click this icon. This icon is available only if the probe component has a Hexagon part number. For a selected stylus or extension of specified length, multiple part numbers might be available in the Hexagon catalog. The part numbers can be stylus or extensions made from different material or stem diameters. PC-DMIS checks for similar parts. If there are any available, PC-DMIS displays a menu to select the required parts.



Similar Probe Components Dialog Box

Mark the check box to select the required parts. To add the selected parts to the cart, click **Add to Cart**. To increase the quantity of the same part, click **Add to Cart** again. With each click, the quantity increases by one. Click **Cancel** to close the dialog box without adding anything to the cart.

In the top-right of the dialog box, you can click the icon to display the legend table which you can use to view material and technical terminology.

Material

AL - Aluminum

CE - Ceramic

CF - Carbon Fiber

DA - Dispal

DC - Diamond Coated

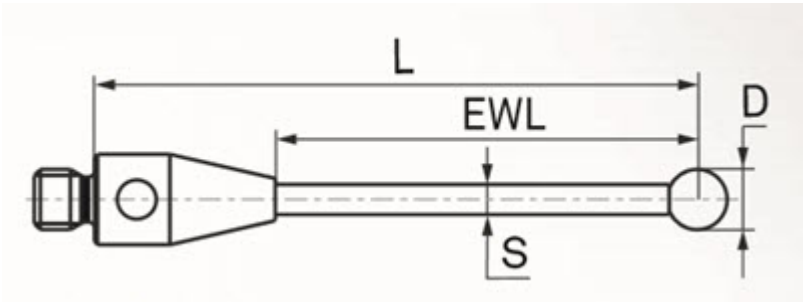
DS - Diamond Sphere

R - Ruby

SN - Silicon Nitride

SS - Stainless Steel

Technical



L - Length (mm)

D - Diameter (mm)

D1 - Extension End Pieces Diameter (mm)

S - Stem (mm)

SP - Span (mm)

EWL - Effective Working Length (mm)

View/Edit Cart - This icon displays the number of components in the cart. Click the icon to open the **PC-DMIS Shopping Cart** dialog box. For information on this dialog box, see "Shopping Cart".

Favorites - This toggle icon displays either your list of favorites or the complete list of probe options. If you select this icon, the list displays only the favorites that are available at the connection point. If you do not select the icon, the list displays all of the probe options.

Edit Probe Components

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

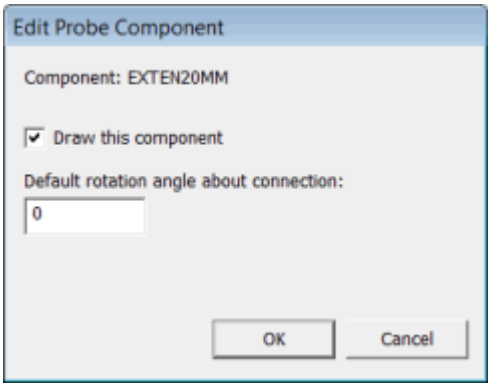
You can double-click on a component in the **Probe description** area (in the Probe Utilities dialog box) to open the **Edit Probe Component** dialog box. You can use this dialog box to hide some probe graphics to provide a better view of the features. This is useful in cases where the part geometry is particularly dense.

You can also do this from the **Graphic Items** toolbar with the **Probe Component Draw Options** button . For more information see "Showing and Hiding Probe Components".

The options that appear in this dialog box depend on the component you selected.

Default Options

The following two options apply to all components:



Edit Probe Component dialog box

Draw this component - If you select this check box, PC-DMIS draws the component in the Graphic Display window.

PC-DMIS organizes the different components in a hierarchical list. This means:

- When you choose to hide a component, PC-DMIS also hides any components above that component.
- When you choose to show a component, PC-DMIS also shows any components below that component.

Default rotation angle about connection - This value defines a rotation angle about the connection. The rotation angle is primarily used to manually define the angle of knuckle attachments. You can type any angle from +180° to -180°. 0 is the default angle.

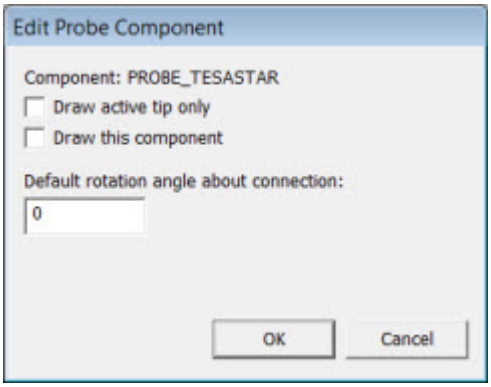
To hide probe graphics:

1. In the **Probe description** area, locate the part of the probe that you want to hide from view.
2. Double-click on that probe component to show the **Edit Probe Component** dialog box.
3. Clear the **Draw this component** check box.
4. Click the **OK** button to close the **Edit Probe Component** dialog box. Notice that PC-DMIS redraws the probe graphics without the indicated component and all other components above it in the **Probe Utilities** dialog box.

Additional Option for Star Probe Components

If you have a star probe, you can make it so that only the current tip is visible in the Graphic Display window. You can do this with the **Draw Active Tip only** check box in the **Edit Probe Component** dialog box.

To see the check box, from the **Probe Description** area, double-click on the probe head component.

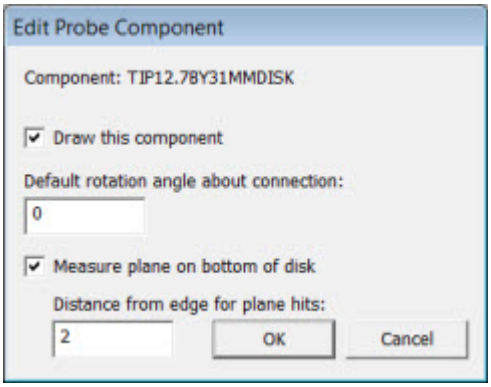


Edit Probe Component dialog box - Star Probe

Draw active tip only - If you select this check box, PC-DMIS hides any non-active probe tips instead of merely highlighting the active probe tip in the Graphic Display window. If you clear this check box, PC-DMIS highlights the active probe tip as usual.

Additional Options for Disk Stylus Components

For calibration of a disk stylus when used with an analog probe, two additional options are included.



Edit Probe Component dialog box - Disk Stylus

Measure plane on bottom of disk

- If you select this check box, four hits are taken on the bottom of the disk to calculate a plane and therefore determine a measured vector associated with the plane of the disk.
- If you clear this check box, PC-DMIS does not take any plane hits, and there is no measured vector. The vector for the plane of the disk is the theoretical value from the model of the probe.

  For a new probe, the default value is determined by the `ProbeQualAnalogDiskUsePlaneOnBottom` entry in the **ProbeCal** section of the PC-DMIS Settings Editor. If this entry is set to 1, PC-DMIS measures the plane. If this entry is set to 0, PC-DMIS does not measure the plane.

Distance from edge for plane hits

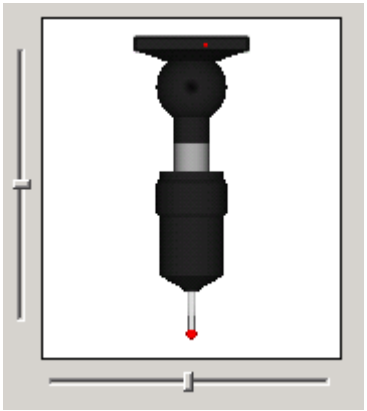
When you measure the plane, PC-DMIS distributes the hits in a circular pattern from this distance back from the outer edge of the disk. The radius for the pattern of the plane hits is the disk radius minus this distance.

For a new probe, the default value is determined by the `ProbeQualAnalogDiskBottomHitsDistanceFromEdge` entry in the **ProbeCal** section of the PC-DMIS Settings Editor. The units for this entry are always in millimeters. However, the value that you enter in the **Distance from edge for plane hits** box is in the units of the measurement routine that you are using (that is, either inches or millimeters).

> In 2012 MR1 and higher, the `ProbeQualAnalogDiskBottomHitsDistanceFromEdge` and `ProbeQualAnalogDiskUsePlaneOnBottom` entries provide the initial defaults for new probes. You can then define specific settings for individual probes in the **Edit Probe Component** dialog box.

Previewing your Probe Configuration

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)



Graphical view of a probe and sliders

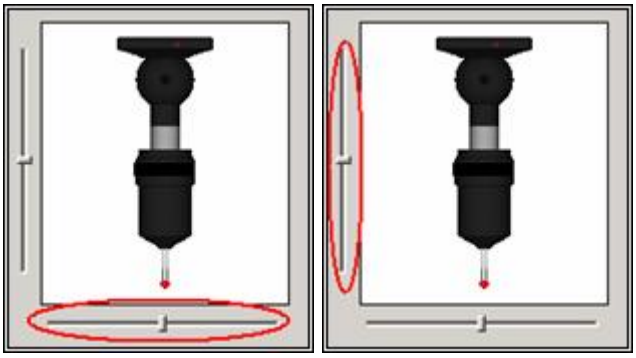
The graphical view of the **Probe Utilities** dialog box provides you with the ability to preview graphically:

- The components of your probe.
- The various AB angle positions in the **Active tip list** box.
- A complete 3D rotation of the probe.

Viewing Components: Once selected as a part of the probe, a component of the probe's configuration automatically appears in the graphical view of the **Probe Utilities** dialog box.

Viewing AB Angle Positions: Select an AB angle position from the **Active tip list**, and the graphical view of the probe dynamically changes to match what the current probe configuration looks like with the selected AB angle.

Rotating the Probe in 3D: Move the sliders located below and to the left of the probe's graphical view to rotate the view of the probe. The slider below rotates the probe horizontally. The slider to the left rotates the probe vertically.



Horizontal Slider, rotates display horizontally (left), and Vertical Slider, rotates display vertically (right)

Available Tip Types

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

PC-DMIS provides the following types of tips in the **Probe description** list:

If a tip needs to be added to the list of available tips, contact Hexagon Technical Support. Only authorized personnel are allowed to create additional tip files.

Ball - This defines a spherical probe. The user is able to edit the nominal diameter and thickness of the probe using the **Edit** button. The direction of the probe must also be defined.

Disk - This defines a disk probe. The user is able to edit the nominal diameter and thickness of the probe using the **Edit** button. The direction of the probe must also be defined.

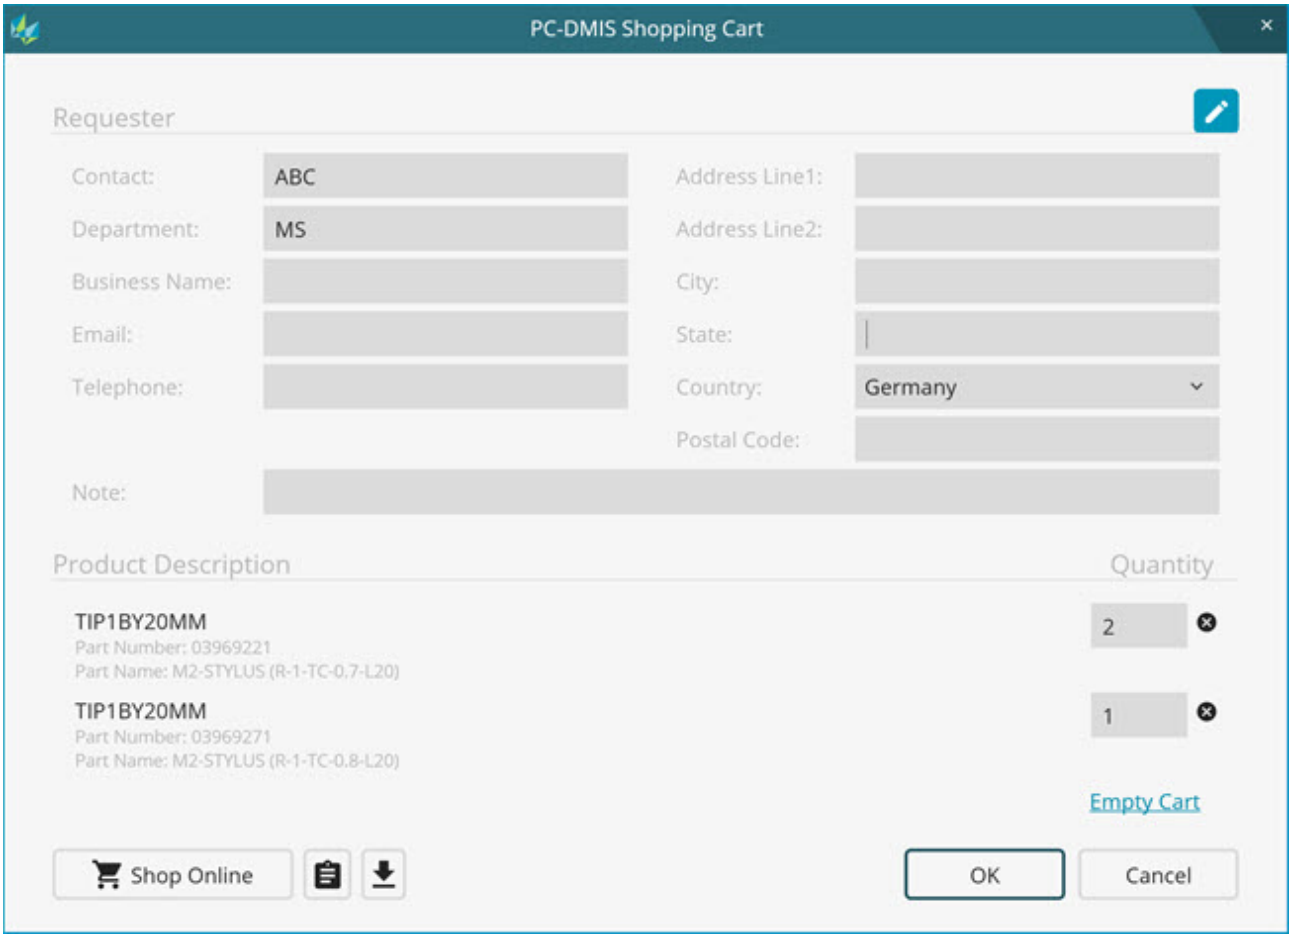
Optical - This option is only available if the optical tip is defined as a hard probe. This option defines an optical probe. The user is able to edit the nominal diameter of the probe using the **Edit** button. The direction of the probe must also be defined.

Shank - This defines a shank or barrel probe. The user is able to edit the nominal diameter and thickness of the probe using the **Edit** button. The direction of the probe must also be defined.

Shopping Cart

PC-DMIS lets you add the probe components to the shopping cart from the **Probe Utilities** dialog box.

To view and edit the shopping cart, click the **View/Edit Cart** icon to open the **PC-DMIS Shopping Cart** dialog box.



PC-DMIS Shopping Cart Dialog Box

Requester - This area displays the requester details, such as the contact person's name, department, address, and so forth. To edit the details, click the **Edit** icon .

Product Description - This column displays the probe's component name, part number, and part name (if available).

Quantity - This box sets the number of components that you want to include in your purchase request or order. To remove the component from the cart, click the **Remove** icon .

Empty Cart - This link deletes all the items from the shopping cart.

Shop Online - This button completes the online shopping if an online store is available for the country where you want to ship your part. Once you click this button, PC-DMIS creates

and opens the link in your default browser. You can then see your selected items in the cart and complete your purchase.

Copy web address into clipboard - This button lets you copy the web address on the clipboard. If your computer is not connected to the internet, you can copy the link and then send it to the computer where internet is available to shop online.

Download Purchase Request - This button opens the **Save As** dialog box to let you save a purchase request in a Portable Document Format (.pdf). You can use the purchase request for further approval process in your organization.

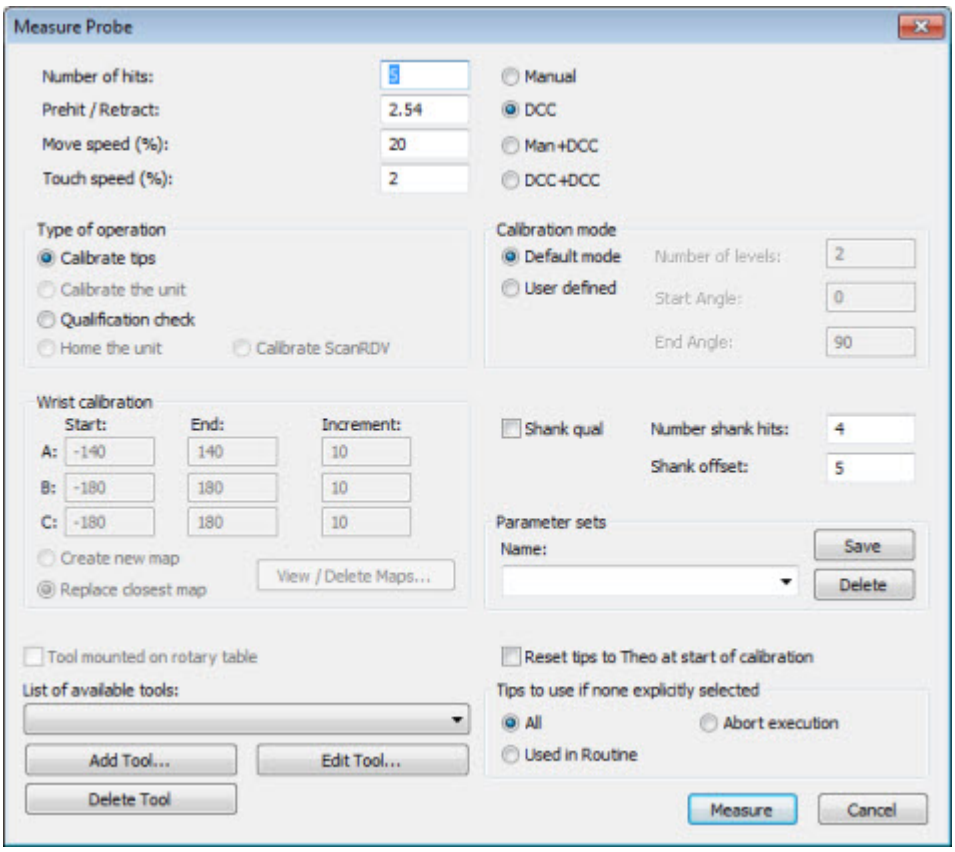
OK - This button saves the changes made to the shopping cart.

Cancel - This button closes the dialog box without saving any changes.

Measure

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

The **Measure** command button allows you to calibrate probe tips selected from the **Active tip list** of the **Probe Utilities** dialog box. When you click this button, the **Measure Probe** opens.



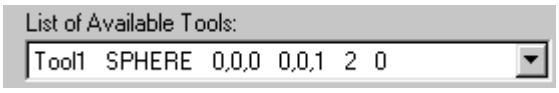
Measure Probe Dialog Box

For information on the options in this dialog box and on how to calibrate probe tips, see "Calibrating Probe Tips" in the PC-DMIS CMM documentation.

For information on adding, editing, and deleting calibration tools, see the topics below.

List of Available Tools

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)



The **List of Available Tools** drop-down list displays the available calibration tools. PC-DMIS uses probed hits on the calibration tool to calibrate the selected probe. PC-DMIS only uses spherical tools.

The type of tip you calibrate may affect where and how you take hits on the calibration tool. Consider what happens during calibration with these different probe tip types:

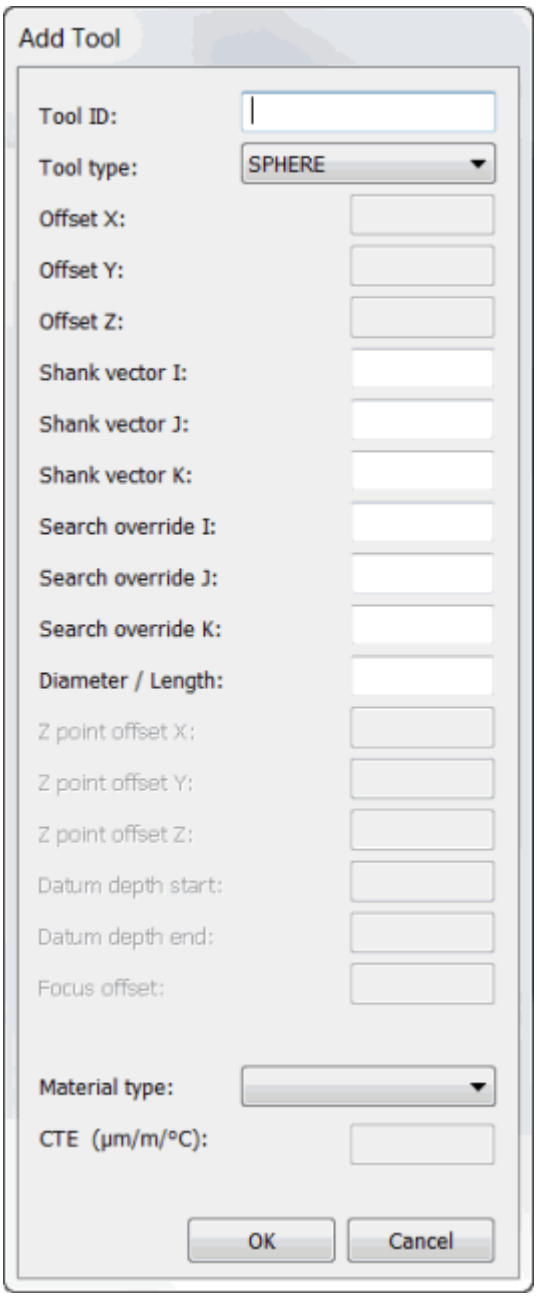
- **Ball Tip** - PC-DMIS prompts you to enter the number of hits to be taken on the tool and then asks you to take the hits.

- **Disk Tip** - If Mode = MANUAL, PC-DMIS prompts you to take six hits on the calibration tool. Take three hits above the equator of the sphere and three below the equator. If Mode = DCC, the location of the calibration tool must previously be known.
- **Taper Tip** - PC-DMIS prompt you to take six hits on the sphere with the tapered part of the probe. The spherical tool is, in effect, being used as the probe to measure the taper tip as a cone. The first three hits need to form a plane that is approximately perpendicular to the cone centerline. If a small taper probe is being used, it is best to use a small spherical tool to perform this operation.
- **Barrel/Shank Tip** - PC-DMIS prompts you to take four hits in a planar cross section of the sphere to form a circle. The hits must be made with the same part of the probe that will be used for inspection. After you take the four hits, PC-DMIS prompts you to touch the sphere once with the bottom surface of the probe.
- **Optical Tip** - This option is only available if the optical tip is defined as a hard probe.

Add Tool

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

The **Add Tool** button displays the **Add Tool** dialog box. To access this button, select the **Measure** button in the **Probe Utilities** dialog box (**Insert | Hardware Definition | Probe**).



Add Tool Dialog Box

The **Add Tool** dialog box allows you to store data that describes the qualification tools. Each tool is assigned a sequential ID number.

Once you define a new tool, PC-DMIS inserts it in the **List of available tools** list in the **Measure Probe** dialog box.

You must define at least one probe tip before you can measure a calibration tool.

To add a tool to the **List of available tools** list, select the **Add Tool** button to open the **Add Tool** dialog box.

You can define these items:

Tool ID - In this box, type the name of the tool you are defining.

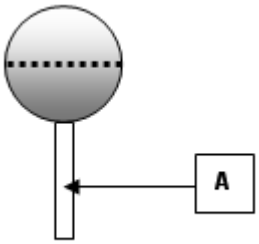
Tool type - Select the type of calibration tool. Some items are available for selection only if you use a specific probing system.

- SPHERE
- SPHERE(ARM 2)
- POLYHEDRAL
- POLYHEDRAL(ARM 2)
- RING
- RING(ARM 2)

  Ring tools are only used with vision probing systems. See the PC-DMIS Vision documentation for information on how to use this tool to calibrate.

Offset X, Y, Z - These X, Y, and Z values define the location of the calibration tool in machine coordinates. To recalibrate a tip, highlight the desired tip in the **Active tip list** option. Proceed to use the **Measure** button to calibrate the probe tip. (See "Previewing your Probe Configuration".)

Shank Vector I, J, K - These values define the vector of the shaft on the tool. PC-DMIS uses these values during calibration to avoid the shaft.



Example showing a shaft (A) on the spherical tool.

Search Override I, J, K - These boxes define a vector that PC-DMIS uses to determine the most efficient order to measure all the tips. This is enabled when you select the **User defined calibration order** check box in the **Probe Utilities** dialog box. For more information, see "User Defined Calibration Order check box".

Diameter / Length - This box displays the diameter or length of a spherical calibration tool.

The **Z point offset X**, **Z point offset Y**, **Z point offset Z**, **Datum depth start**, **Datum depth end**, and **Focus offset** options become enabled only if you are running PC-DMIS Vision. See the PC-DMIS Vision documentation for descriptions of those items.

Material type - This list contains standard material types. When you select a material, its coefficient of thermal expansion (CTE) appears in the **CTE** box.

Delete Tool

The **Delete Tool** command button allows you to remove a tool that is no longer needed in the **List of Available Tools** list.

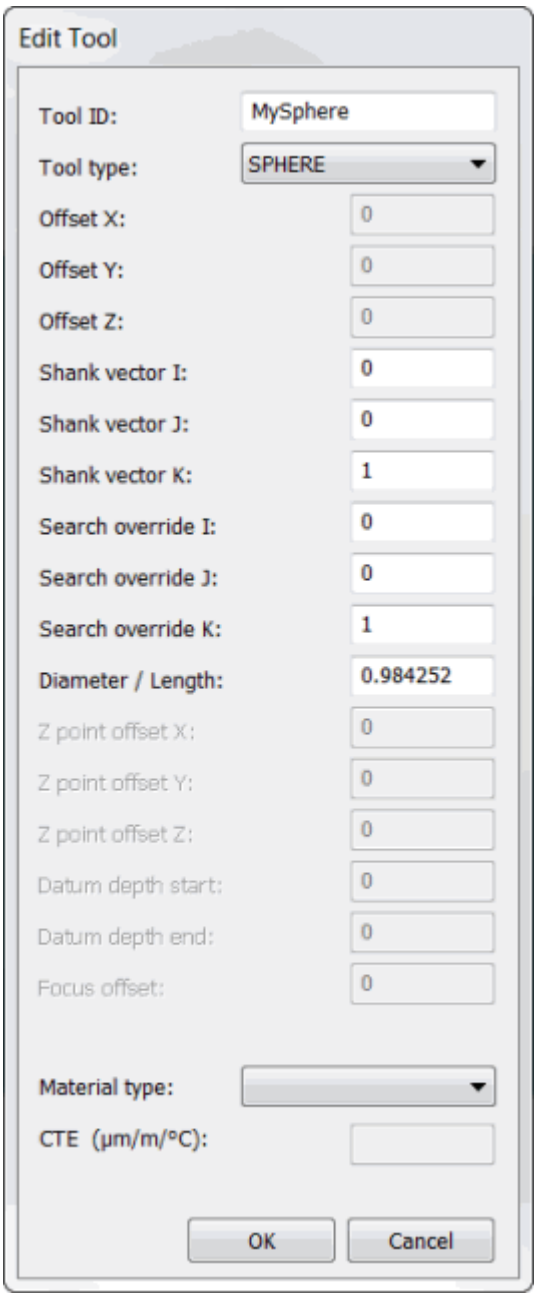
To remove a tool:

1. From the **List of Available Tools**, select the desired tool ID.
2. Click the **Delete Tool** button.

Edit Tool

You can use the **Edit Tool** command button to edit a calibration tool that already exists in the **List of available tools** list in the **Measure Probe** dialog box.

The **Edit Tool** button displays the **Edit Tool** dialog box. To access this button, select the **Measure** button in the **Probe Utilities** dialog box (**Insert | Hardware Definition | Probe**).



Edit Tool Dialog Box

The **Edit Tool** dialog box has the same options as the **Add Tool** dialog box. For information about the options, see "Add Tool".

Notes on the Add Angle option

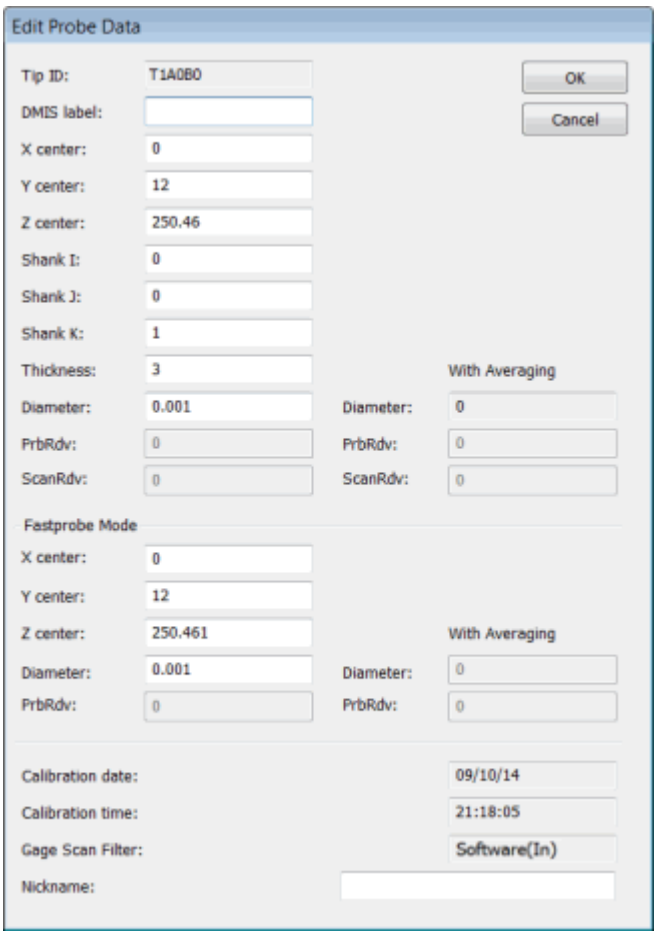
- Automatic probe calibration can only be done using a spherical probe and spherical qualification tool.
- The X, Y, and Z coordinate of the center of the tool that is being used must reflect the current position of the tool on the table. If this is not the case, answer YES to the question, "Has probe position moved?"

- When measuring AB positions under operator control, PC-DMIS automatically rotates the probe head to the next manual position when the current position is completed. Be sure the probe clears the tool before you press the END key.
- If the calibration tool position has changed or you need to add new angles to the list of tips, you can mark the needed angles in the **New Angles List** box. You must also mark the default position of the probe tip (normal to the shaft of the tool). PC-DMIS first executes the angle that is normal to the tool, and then executes the other marked angles.
- If the automatic AB calibration is stopped before it has finished measuring all the appended positions, PC-DMIS asks you if you want to keep the partial calibrated data before quitting.

Edit Probe Data

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

You can use the **Edit** button to modify the highlighted tip's details. Highlight the desired tip in the **Active Tip List** and click the **Edit** button in the **Probe Utilities** dialog box to open the **Edit Probe Data** dialog box.



Edit Probe Data Dialog Box

The following items are available in this dialog box:

TIP ID

This box contains the permanent number that PC-DMIS assigns to a tip when it is loaded into memory. You cannot edit this value. It is shown for display purposes only; however, you can define a more descriptive identification by using the Nickname box.

DMIS Label

This box displays the DMIS label. When importing DMIS files, PC-DMIS uses this value to identify any SNSDEF statement inside the imported DMIS file.

X, Y, and Z Center

These values describe the location of the tip. This location is in relation to the bottom of the Z rail.

Shank / Optical Vector I, J, K

These values describe the direction of the probe tip shank if you're using a probe tip. This vector goes from the center of the probe tip towards the Z rail. If you're using an optical probe, these values describe the direction of the optical device.

Diameter of the ball tip

This box contains the diameter of the tip.

The diameter for probes on non-portable machines may vary with the current part temperature if you mark the **Temperature compensation enabled** check box inside of the **Temperature Compensation** dialog box and choose a compensation method where PC-DMIS does the part compensation rather than the machine controller. The **Temperature Compensation** dialog box is accessible by pressing F9 on a TEMPCOMP command. See "Temperature Compensation Enabled" under "Compensating for Temperature" in the "Setting Your Preferences" chapter.

Thickness of the ball tip

This box contains the thickness of the tip. It defines the usable and graphical height/ thickness of the ruby tip. PC-DMIS applies this value during the disk probe calibration procedure to move the probe north or south of the equator. In the case of a disk probe, for example, you might need to adjust this value down to make the probe qualify better.

PrbRdv

The **PrbRdv** box defines *a radial deviation for the calibrated size of the tip.*

When you execute the probe calibration, PC-DMIS does one of two things:

1. If you have a machine configuration where PrbRdv applies, the calibration process automatically sets the tip size to the theoretical value, calculates, and then saves a **PrbRdv** value.

2. If you have a machine where PrbRdv does not apply, the calibration automatically sets the **PrbRdv** value to zero, calculates, and then saves a tip size slightly different from the theoretical value.

The **Edit Probe Data** dialog box is merely used to edit the tip size and/or PrbRdv if needed for some reason after calibration. If you re-calibrate, the resulting values come from the calibration, not from whatever may have been manually entered into this dialog box prior to calibrating.

This box is only available for selection if you use an analog probe on certain machines.

ScanRdv

Some machines that support **PrbRdv** allow for a different **ScanRdv** value. The **ScanRdv** box on the **Edit Probe Data** dialog box has the same meaning as PrbRdv in that it is a radial deviation for the calibrated size of the tip. The difference is that this applies to scan operations, whereas **PrbRdv** applies to taking individual hits.

With Averaging

If you're using tip averaging, additional Diameter, PrbRdv, ScanRdv values appear to show what the values would be if size averaging is utilized. For information on tip averaging, see the "Probe Setup" topic.

Because Fast Probe Mode is something that only applies to individual hits and not scans, ScanRdv does not exist for Fast Probe Mode.

Fast Probe Mode

The **Fast Probe Mode** area contains several read-only fields that show what the same tip values would be if Fast Probe Mode is used (or Fast Probe Mode with Tip Size Averaging).

- X center
- Y center
- Z center
- Diameter
- PrbRdv
- With Averaging - Diameter and PrbRdv

For information on Fast Probe Mode, see "Using Fast Probe Mode" under "Motion Commands" in the "Using the Edit Window" chapter.

For information on tip averaging, see the "Probe Setup" topic in this chapter.

Calibration Date and Time

These values indicate the most recent date and time the probe tip was calibrated. These values are available for viewing in the **Edit Probe Data** dialog box by clicking the **Edit** button on the **Probe Utilities** dialog box.

If a new tip is created without being calibrated, PC-DMIS will display NEW for the date and time values. If an old probe tip is loaded and the date and time information is unavailable, PC-DMIS will display UNKNOWN for the values. Only probe tips that are actually calibrated have their time and data values updated.

Gage Scan Filter

The **Gage Scan Filter** box in the Edit Probe Data dialog box displays the type of gage scan filter compensation for the selected probe tip: None, Software, or Hardware.

It also indicates how the gage scan filter was calibrated:

- (In) - with an inside circle
- (Out) - with an outside circle
- (Both) - with both an inside circle and an outside circle

For more information about the gage scan filter, see the "Enabling the Gage Scan Filter" topic in the "PC-DMIS CMM" documentation.

Nickname

The **Nickname** box on the Edit Probe Data dialog box is used to provide a more descriptive name to the selected probe Tip ID.

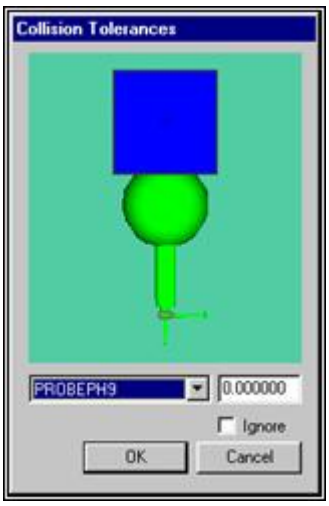
For example, if you named your probe tip, "MyTip" in the **Nickname** box, PC-DMIS uses "MyTip" in the user interface for that probe tip in dialog boxes, messages, on reports, etc. If you don't define an ID, PC-DMIS uses the default generated Tip ID instead.

Collision Tolerance

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

Collision Detection (CD) in PC-DMIS is designed to detect collisions between the probe and CAD surfaces.

Collision tolerances are specified in the **Collision Tolerances** dialog box. Click on the **Tolerances** button in the **Probe Utilities** dialog box to access this option.



Collision Tolerances Dialog Box

For additional information on Collision Detection, see "Detecting Collisions" in the "Editing the CAD Display" chapter.

Specifying Collision Tolerances

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

Collision tolerances are specified in the **Collision Tolerance** dialog box. This dialog box can be activated by clicking the **Tolerances** button in the **Probe Utilities** dialog box.

In the edit box, you can specify a positive or negative value for each probe component selected from the drop-down list. This effectively changes the size of that component.

- A positive number will increase the size of the component, so a collision is detected if that component comes within the specified distance of the part.
- A negative distance decreases the size of that portion of the probe, having the opposite effect of a positive distance.

You can also choose to ignore a probe component by selecting the **Ignore** check box. PC-DMIS ignores that probe component when checking for collisions. This may be useful with a tip, where collisions are expected to occur when taking hits.

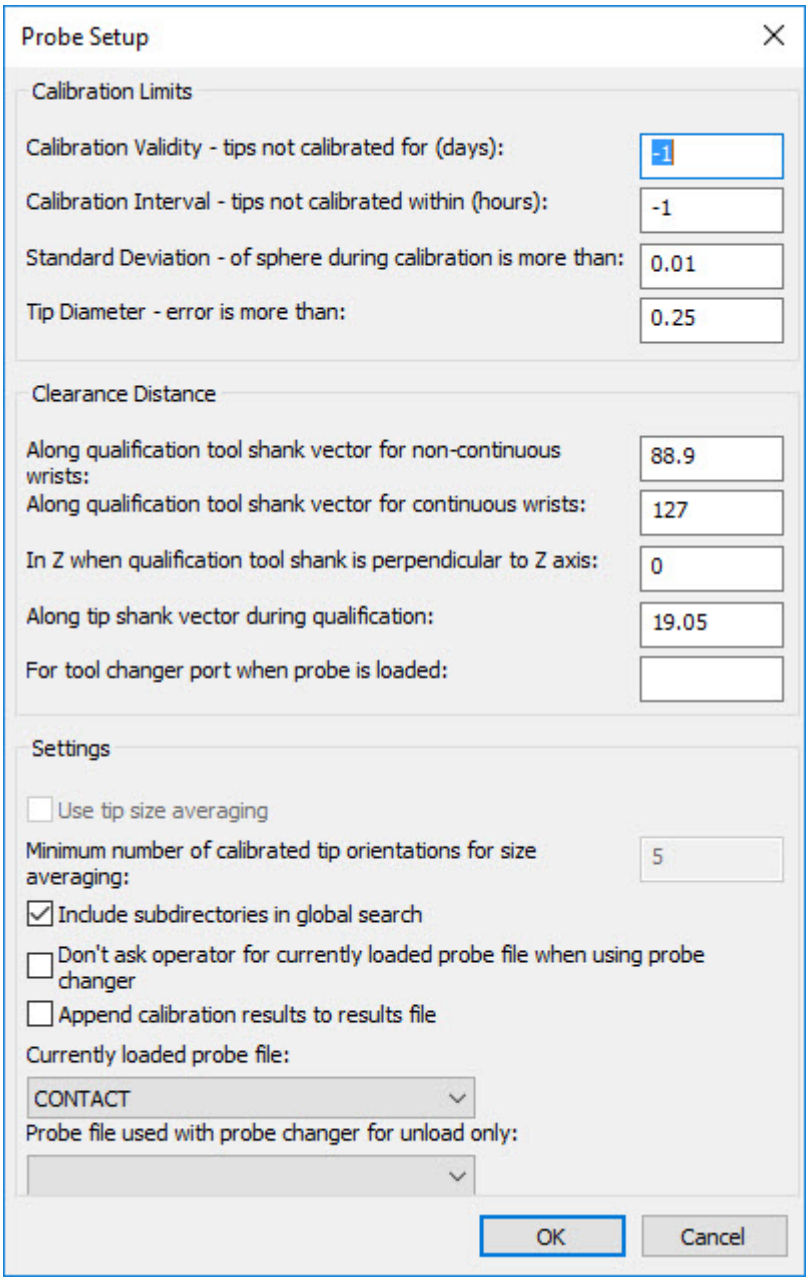
Once you start collision detection by selecting the **Collision Detection** menu option, PC-DMIS's internal CAD engine performs all the calculations required to detect a collision. Any collisions detected are displayed in the **Collision Detection** dialog box. This dialog box reports the results in the Probe Display window of the dialog box and saves them for later use in drawing the Edit Path lines.

For additional documentation regarding the Collision Detection option, see "Detecting Collisions" in the "Editing the CAD Display" chapter.

Probe Setup

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

The **Setup** button in the **Probe Utilities** dialog box displays the **Probe Setup** dialog box:



Probe Setup Dialog Box

This dialog box further customizes your probe settings. PC-DMIS uses most of these settings globally for all probe files. Note, however, that the **Use tip size averaging** check box applies only to the current probe file.

You can use the options in this dialog box to change or select the following information:

Calibration Limits

The Check Calibration Limits command checks the calibration limits for all the tips that are used in the active measurement routine. The command also checks the limits when you open the measurement routine or edit the probe file. PC-DMIS warns you if any value goes above a limit.

For more information on this command, see "About Check Calibration Limits" in the PC-DMIS Toolkit Modules documentation.

You can set four types of calibration limits:

Calibration Validity - tips not calibrated for (days): - This item sets the limit based on the number of days that you can use a tip after calibration. If you don't want to receive any warning, set this item to a negative number. The default value is -1.

Calibration Interval - tips not calibrated within (hours): - This item sets the limit based on the time interval in hours within which all the tips in the active measurement routine should be calibrated. If you don't want to receive any warning, set this item to a negative number. The default value is -1.

Standard Deviation - of sphere during calibration is more than: - This item sets the limit to the standard deviation to accept tip calibration. During tip calibration, PC-DMIS calculates the standard deviation for the sphere measurement. The measurement units are the same as those used by your measurement routine.

Tip Diameter - error is more than: This item sets the limit to the deviation of the tip diameter from its nominal value. During tip calibration, PC-DMIS calculates the tip diameter for the measurement. The measurement units are the same as those used by your measurement routine.

Clearance Distance

Along qualification tool shank vector for non-continuous wrists: - This item is the distance the machine moves away from the qualification tool in the direction of the shank vector. During calibration, this item is useful to avoid collisions with the tool when PC-DMIS changes to a new AB tip angle. The measurement units are the same as those used by your measurement routine.

Along qualification tool shank vector for continuous wrists: - This item is the distance the machine moves away from the qualification tool in the direction of the shank vector. This is the same as the above setting except it is used with continuous wrists. Since continuous wrists are somewhat larger, they need more clearance. The measurement units are the same as those used by your measurement routine.

In Z when qualification tool shank is perpendicular to Z axis: - This item defines the clearance distance in the Z axis when the qualification tool's shank is perpendicular to the Z axis. When the qualification tool is mounted on a horizontal shank, it sometimes needs extra Z clearance movement, especially on horizontal

arm machines, to avoid collisions. The measurement units are the same as those used by your measurement routine.

Along tip shank vector during qualification: - This item defines a clearance distance that is added to the retract move during qualification that is based on the tool diameter. If you do not want to retract by even that tool diameter base value, you can set this value to a negative number to offset part of this retract distance.

This item sets the value for the `AutoQualClearanceTipDirection` entry in the **User_Option** section of the PC-DMIS Settings Editor. The default value is 0.75 inches (19.05 mm). The measurement units are the same as those used by your measurement routine.

For tool changer port when probe is loaded: - This item defines a probe-specific port clearance distance that overrides the port clearance distances defined on the probe changer. If you use this item, you won't have to continually update port clearances in your probe changer setup when you switch between measurement routines with different probe configurations for a given port.

See "Using Probe-Specific Port Clearance Distances" in the "Defining Hardware" chapter.

Settings

Use tip size averaging - This check box determines whether tip-size averaging is required.

Minimum number of calibrated tip orientations for size averaging: - This item defines the minimum number of validly calibrated tip orientations that must be present for averaging to take place. The default value is 5 and can never go below 2. This item sets the value for the `MinimumTipOrientationsForSizeAveraging` entry in the **USER_Probecal** section of the PC-DMIS Settings Editor.

The **Use tip size averaging** option averages the calibrated tip size for all AB tip angles used for a physical tip.

Normally, when a physical tip is calibrated at a specific AB tip angle, the calibration results include the measured tip size when calibrated at that angle. These stored tip sizes may vary slightly even though they all use the same physical tip.

In some very specific cases, select this check box to improve the overall measurement accuracy.

This option is not intended for general use. Generally, you should only select this check box if recommended to do so by the machine's manufacturer for your specific configuration. Misuse may cause loss of accuracy.

If you select this check box, the following occurs:

- After PC-DMIS completes a given calibration, it averages the tip size for all *calibrated* AB tip angles for that same physical tip, regardless of whether you included them in the same calibration or not.
- PC-DMIS excludes *non-calibrated* AB tip angles which use that same tip from the averaging calculation.
- PC-DMIS excludes any AB tip angles in the current calibration that exceed the warning limits for standard deviation or for size deviation from the nominal from the averaging calculation. However, their sizes are still set to the calculated average value for that physical tip.

By default, you must have at least five validly calibrated tip locations before size averaging takes place. You can use the `MinimumTipOrientationsForSizeAveraging` entry in the **USER_Probecal** section of the PC-DMIS Settings Editor to specify a different minimum number, but you must have at least two.

Include subdirectories in global search - If you select this check box, the **Global Used** search includes subdirectories. See "Global Used".

Don't ask operator for currently loaded probe file when using probe changer - When you first start PC-DMIS, it doesn’t know what may have taken place on the machine while PC-DMIS wasn’t running. By default, it prompts you to confirm or select the currently-loaded probe before you attempt the first change after startup. If you select this check box, PC-DMIS assumes that the last-known loaded probe is still correct, and it doesn't prompt you for confirmation.

Append calibration results to results file - This item determines whether existing calibration results report data is overwritten or appended during the next calibration.

Currently loaded probe file: - If you're using a probe changer, PC-DMIS needs to know what (if anything) needs to be dropped off first. To provide that information, this list displays what is currently loaded on your machine and allows you to manually specify it.

Probe file used with probe changer for unload only: - This list lets you choose a dummy probe file used to force an unload of the current probe without loading a new probe from the probe changer. See "To Drop off a Probe without Picking Up a New Probe" in the "Defining Hardware" chapter.

Print List

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

The **Print List** command button is found on the **Probe Utilities** dialog box and displays the **Print** dialog box.

When you click the **OK** button on this dialog box, PC-DMIS prints a list of calibrated and non-calibrated tip angles in a table. These are the same tip angles listed in the Active Tip List. Each row of the table contains a tip angle while the columns display the XYZ, IJK, diameter, and thickness values for each tip angle. It also displays the date and time of the calibrated tip angles.

If a tip angle hasn't been calibrated or if there's a Diameter, Date, or Time error, the list shows the tip in red text.

Example Printout

Below, you can see example printouts of the active tip list for a contact probe and a laser probe:

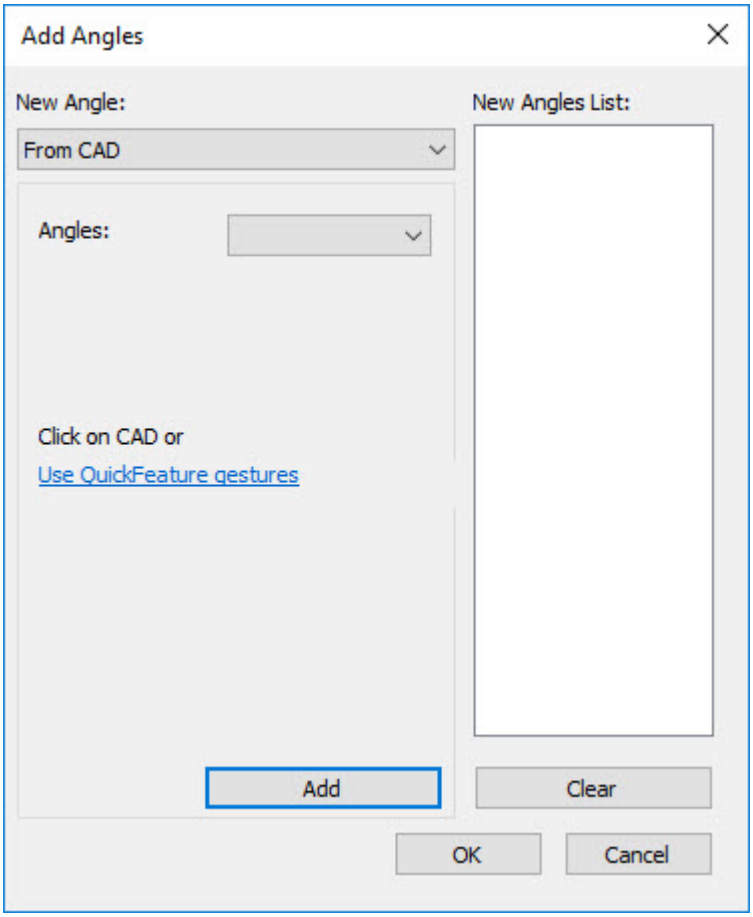
Example Printout of Active Tips for a laser probe

Add Angles

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

The **Add Angles** command button is on the **Probe Utilities** dialog box. This button is available only if the probe head has the capability to rotate in your probe configuration.

Click the **Add Angles** button to open the **Add Angles** dialog box.



Add Angles Dialog Box

The **Add Angles** dialog box has the following parameters:

New Angle - The list displays four options to add angles:

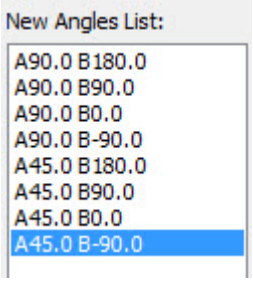
- **Single** - This option lets you add AB positions one at a time into the **New Angles List** box.
- **Multiple** - This option lets you add equally-spaced angles.
- **From CAD** - This option is available only if CAD is available in the active measurement routine. This option lets you select the CAD surface and adds recommended angle into the **New Angles List** box.

- **From Grid** - This option lets you view and select angles with the use of an angle grid.

Add - This button adds the angle into the **New Angles List** box.

Clear - This button removes the list of angles from the **New Angles List** box.

New Angles List Box



New Angles List Box

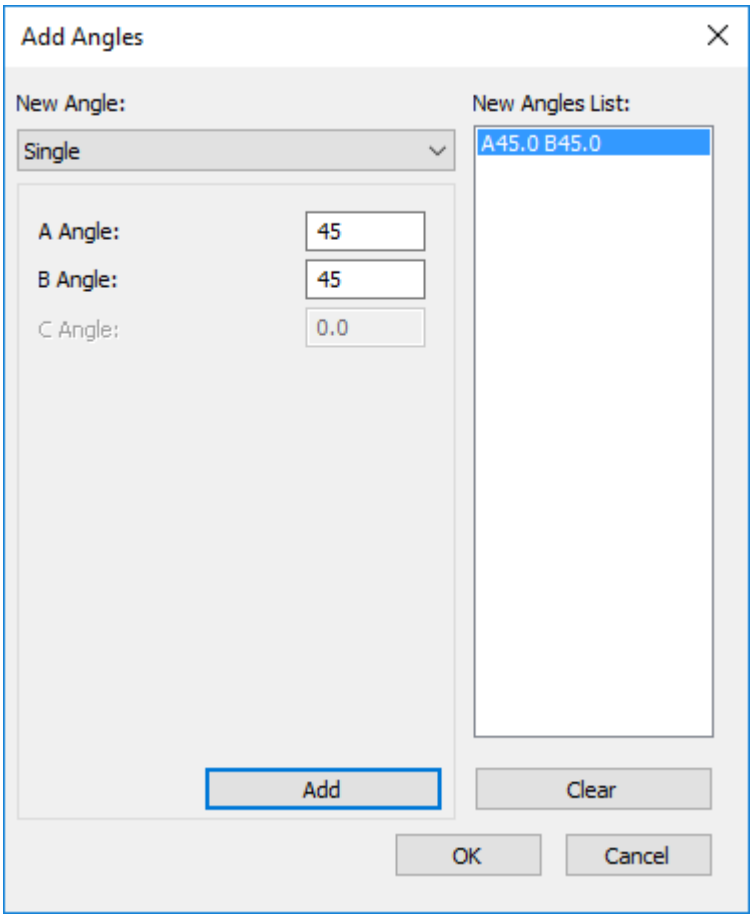
The **New Angles List** box contains the list of AB angles that you added from the options available in the **New Angle** list.

Select an angle to see the angle's position on the CAD in the **Probe Utilities** dialog box.

To remove an angle from the **New Angles List** box, right-click and select **Remove**. To remove all the angles from the **New Angles List** box, click the **Clear** button.

Add Single Angle

The **Single** option lets you add AB positions one at a time into the **New Angles List** box.



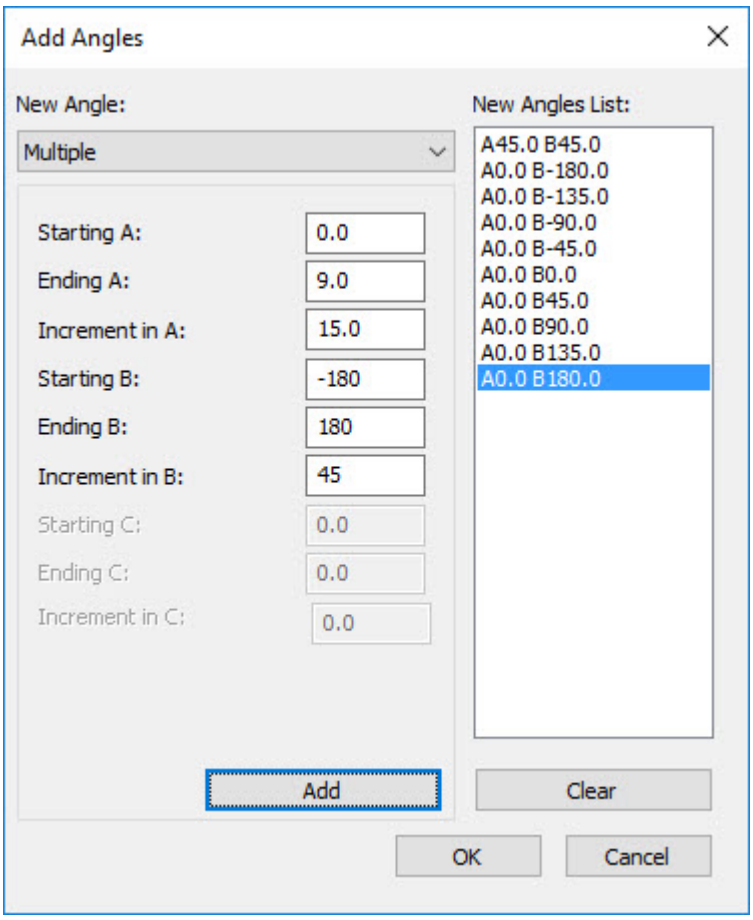
Add Angles Dialog Box - Single Option

In the **A Angle**, **B Angle**, and **C Angle** boxes, type angles and click the **Add** button.

The individual angle you specified appears in the **New Angles List** box.

Add Multiple Angles

The **Multiple** option lets you add equally-spaced angles into the **New Angles List** box.



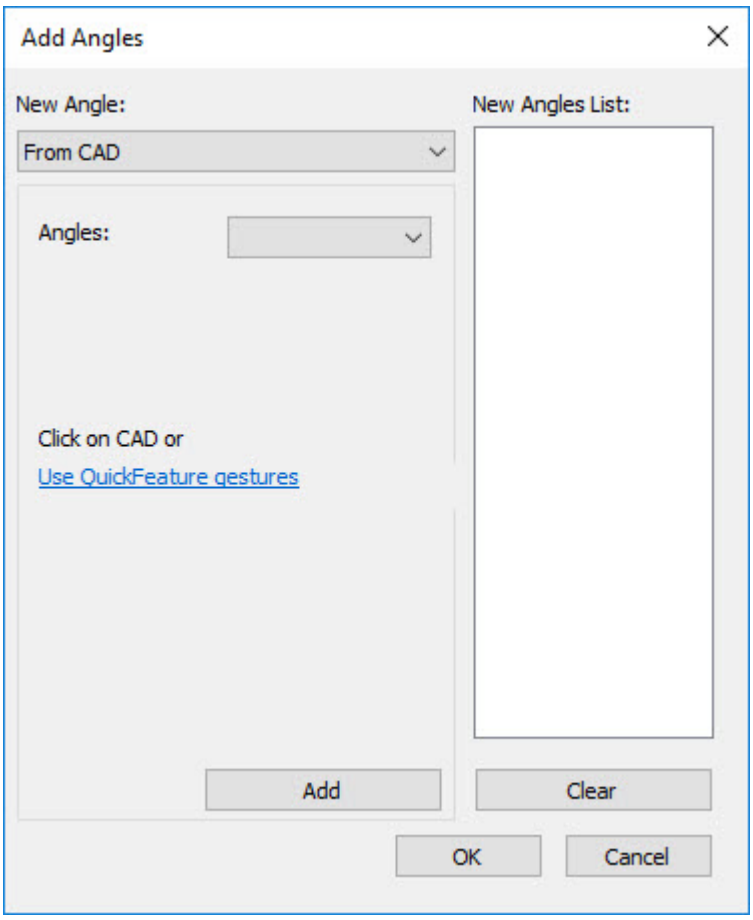
Add Angles Dialog Box - Multiple Option

To add the new angles, perform the following steps:

1. Enter the necessary information in each available angle box (**Starting A**, **Ending A**, **Increment in A**, **Starting B**, **Ending B**, and **Increment in B**).
2. Click the **Add** button. PC-DMIS displays the equally-spaced angles in the **New Angles List** box.

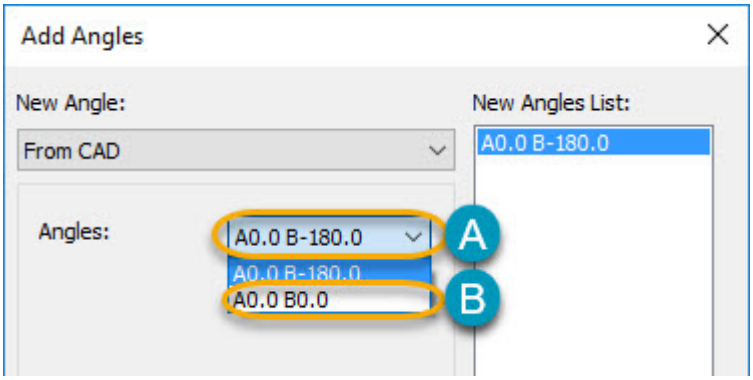
Add Angles from CAD

The **From CAD** option is available only if CAD is available in the active measurement routine. This option lets you select the CAD surface and add the recommended angle into the **New Angles List** box.



Add Angles Dialog Box - From CAD Option

If you select this option, you can either click on the CAD surface or use the QuickFeature gesture. PC-DMIS calculates the recommended and alternate angles wherever possible. Both angles are available to select from the **New Angles** list.

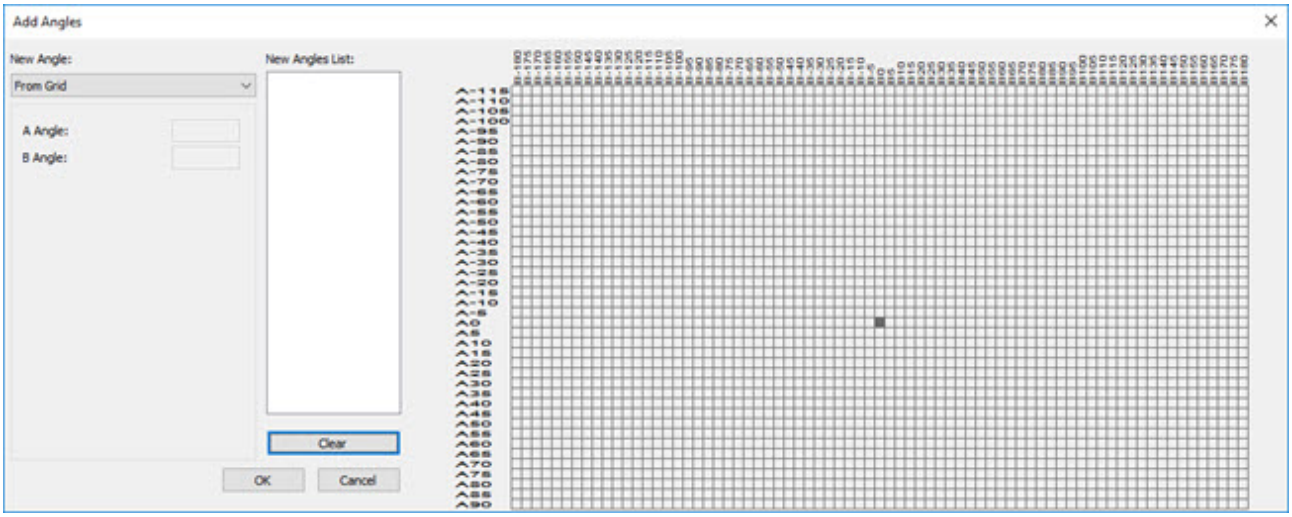


A. For the recommended angle, click on the CAD surface or use the QuickFeature gesture. PC-DMIS automatically adds the angle into the **New Angles List** box.

B. For the alternate angle, from the **Angles** list box, select the alternate angle and click the **Add** button to add the angle into the **New Angles List** box.

Add Angles from Grid

The **From Grid** option lets you view and add angles from the angle grid. The angle grid displays all of the available A-angle positions down the side of the dialog box. It displays the B-angle positions along the top of the dialog box.



Add Angles Dialog Box - From Grid Option

To add a new angle from the grid, perform the following steps:

1. Position your mouse pointer over the grid. The **A Angle** and **B Angle** boxes display the angle dynamically as you move your mouse pointer on the grid to determine the angle.

2. Find the row of the A angle you want to add. Then find the column with the appropriate B angle.

3. Click the box in the grid where the desired A and B angles intersect. The selected box turns red, and PC-DMIS inserts the selected AB angle positions into the **New Angles List** box.

To clear a selected AB angle position, click one of the red boxes again. PC-DMIS then removes the AB angle positions associated with that box from the **New Angles List** box.

Supported QuickFeature Gestures to Add Angle

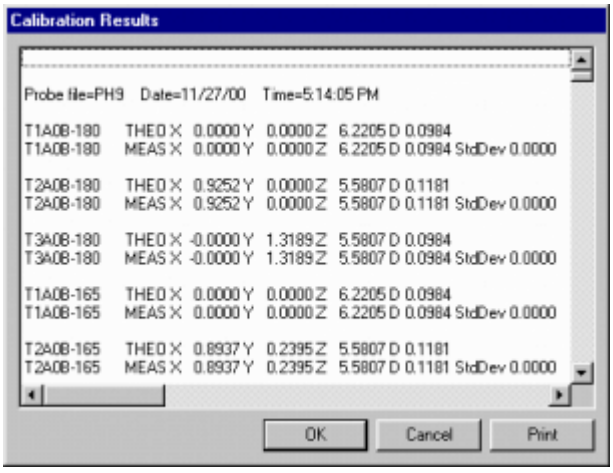
PC-DMIS supports the list of QuickFeature gestures in the following table:

QuickFeature	Gesture
Vector Point, Edge Point, Angle Point	Press Ctrl + Shift and click on the CAD element.
Plane, Circle, Ellipse, Cylinder, Sphere	Press Ctrl + Shift and click on the CAD element.
Square Slot	Press and hold Shift, (1) hover the pointer over one edge of the slot, click and drag the pointer for a short distance along the edge to highlight it; then (2) move the pointer to an adjacent edge. Once the entire slot is highlighted, (3) release the mouse button to create the feature.
Round Slot	Press and hold Shift, (1) hover the pointer over one of the circular ends of the slot, and click and drag the pointer a short distance along the curve to highlight it; then (2) move the pointer to a straight side. Once the entire slot is highlighted, (3) release the mouse button to create the feature.

Results

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

The **Results** command button is found on the **Probe Utilities** dialog box. It is used to display the results of the most recent probe calibration in the **Calibration Results** dialog box.



Results Dialog Box

In addition to displaying the probe's diameter and thickness, the dialog box also provides the standard deviation of the sphere. These measured results are used to verify the accuracy of the calibration.

PC-DMIS shows results up to six decimal places.

Mark Used

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

The **Mark Used** command button is found on the **Probe Utilities** dialog box.

This option automatically searches the current measurement routine for AB angles. PC-DMIS then adds any AB angles that are found to the current probe configuration.

If you select the **Automatically Adjust Probe Head Wrist** check box (located on the **General** tab in the **Setup Options** dialog box) and click the **Mark Used** button, PC-DMIS may not select all the probe tips for calibration. For more information about the **Automatically Adjust Probe Head Wrist** check box, see the "Automatically Adjust Probe Head Wrist" topic in the "Setting your Preferences" chapter.

Global Used

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

The **Global Used** command button is in the **Probe Utilities** dialog box.

The **Global Used** button searches for tips used in other measurement routines by the currently-active probe file. It then adds them to the **Active tip list** and marks them for calibration.

By default, this button searches through any measurement routine subdirectories. You can control whether or not this button searches these subdirectories by using the **Include subdirectories in global used search** check box in the **Probe Setup** dialog box.

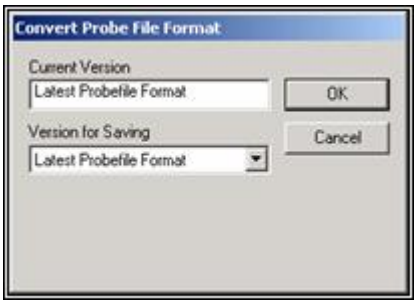
File Format

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

File Format

The **File Format** command button is found on the **Probe Utilities** dialog box.

The **File Format** button saves the existing probe file into a format compatible with previous versions of PC-DMIS. When you click the **File Format** button, the **Convert Probe File Format** dialog box appears.



Convert Probe File Format Dialog Box

The dialog box contains these two items:

- **Current Version** box - This lists the current version of PC-DMIS.
- **Version for Saving** list - This contains the probe file format types you can save the probe file as.

Reset Tips

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

Reset Tips

The **Reset Tips** button resets any selected tips in the Active Tip List so that they are no longer calibrated. This provides you with a quick way to reset tip data back to their theoretical values. Previously, you had to delete and then add the tip back in to accomplish this same thing.

If you do not have any tips selected when clicking this button, you will be prompted to confirm whether or not you want to reset all the tips. If you choose **Yes**, then all the tips will be reset, otherwise no action will be taken.

Use Partial Calibration check box

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

When using the Renishaw scan-based method to calibrate a Renishaw analog probe (such as the SP25, SP600, or SP80), the first time it's calibrated using the Scan method you must perform the full calibration that runs the entire series of scans. After this full calibration, you can choose a more simplified calibration.

- Full calibration calculates all the analog probing coefficients in addition to the tip offset and tip size.
- Partial (simplified) calibration works just like a non-analog probe calibration: it consists of discrete hits (no scans) and only calculates the tip offset and tip size; the analog probing coefficients remain unchanged.

To perform the simplified calibration, follow this procedure:

1. Select **Insert | Hardware Definition | Probe** to display the **Probe Utilities** dialog box.
2. Load a Renishaw analog probe from the **Probe File** list.
3. Select the **Use Partial Calibration** check box. This remains disabled for probes that do not apply.
4. Select one or more already calibrated probe tips from **Active Tips List**.
5. Click the **Measure** button. The **Measure** dialog box appears.
6. Make changes as needed on the **Measure** dialog box. If you define any named parameter sets, PC-DMIS stores the state of the **Use Partial Calibration** check box in the set for future use.
7. Click **Measure**. Follow any on-screen prompts. PC-DMIS performs the simplified calibration.

The `ProbeUsePartialCalibration` entry in the **ProbeCal** section in the PC-DMIS Settings Editor stores the default for whether or not this check box is selected when you define a new probe file.

Use Wrist Map If Available check box

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

The **Use Wrist Map If Available** check box determines whether or not PC-DMIS uses a wrist map (also known as an "error map") file when you calibrate AB angle tips on probe configurations that use an indexable wrist. If you select this check box, PC-DMIS searches for the wrist map file (a file named *abcomp.dat*) on your computer. If it finds the file, PC-DMIS compensates for the wrist's error data when it calibrates the AB angle tips.

For information on creating the wrist map file, see the "Calculate Error Map" topic in the "Using a Wrist Device" chapter of the PC-DMIS Core documentation.

Use TRAX Calibration check box

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

When calibrating an analog probe on some machine types, particularly when using the Leitz interface, there is typically a choice of whether or not to use the TRAX calibration algorithm for calculating the calibration coefficients. You can choose which calibration algorithm is used by selecting or clearing the **Use TRAX Calibration** check box. Previously, this setting was controlled in the PC-DMIS Settings Editor by modifying the `DISABLETRAXCAL` option.

- If you select this check box, PC-DMIS uses the TRAX calibration algorithm. The TRAX algorithm is optimized for use with scanning, so you get the best scanning results using this method. It also usually produces good results for discrete point measurements as well.
- If you clear this check box, the algorithm used depends on whether or not your machine supports the VFT (Vibration Free Transmission) calibration methodology. If it is supported, VFT is used; otherwise, the PMM algorithm is used.

The selected algorithm only applies to the currently selected tips at the time of calibration. You can change this option later for different groupings of tips as needed. The type of algorithm you chose can also be stored and recalled using named parameter sets. See the "Parameter Sets area" topic in the PC-DMIS CMM documentation.

Note that this check box does not change the distribution of discrete hits that are collected. It defines the math algorithm used to process the data after the calibration finishes. In the VFT case, it also results in a set of scans being performed after the discrete hits so that the calibration automatically includes both discrete hit data and scan data.

When to select the TRAX check box or not

The normal expected usage would be as follows:

- Do NOT select the TRAX check box on machines that support VFT so that it uses the VFT specific calibration.
- DO select the TRAX check box on non-VFT machines so that it uses the TRAX algorithm instead of the PMM algorithm.

TRAX is still available for VFT capable machines as an alternative to VFT in case of unexpected issues but is expected to be less accurate on these machines than the VFT calibration.

PMM is still available as an alternative to TRAX on non-VFT machines but is rarely used. TRAX is superior to PMM for scanning and usually just as good or better for discrete hits. There may be a few circumstances, usually limited to actual PMM machines, where the PMM algorithm might be slightly more accurate than TRAX if the inspection is only using discrete hits.

If you're unsure about when to switch calibration algorithms, consult with the creators of your particular machine. They can recommend the best practice for that machine and for particular situations.

User Defined Calibration Order check box

(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

The **User Defined Calibration Order** check box is used to determine the order PC-DMIS takes to measure selected tips.

If you select this check box, PC-DMIS measures the tips in the order defined by the user when marking the tips for calibration in the **Active Tip List**. (See "Active Tip List") If no tips are chosen, PC-DMIS uses the I, J, K vectors defined in the **Search I, J, K** boxes in the **Edit Tool** or **Add Tool** dialog boxes to determine the most efficient order to measure all the tips.

If you do not select this check box, PC-DMIS measures the tips in an order that it determines to be the most efficient. When this happens, PC-DMIS ignores the order that was given to selected tips in the **Active Tip List**. PC-DMIS also uses the calibration tool vector to determine the most efficient order to measure.

Use Unit Calibration Data

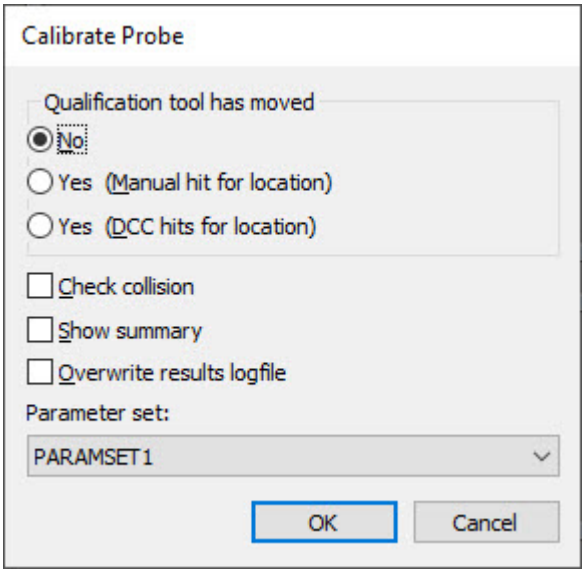
(This item pertains to the **Probe Utilities** dialog box, accessible through **Insert | Hardware Definition | Probe**.)

The **Use Unit Calib Data** check box only appears on the dialog box if you have already performed a unit calibration. If this check box is not selected, PC-DMIS uses the standard calibration. Selecting this check box allows you to use the unit calibration data. See "Calibrate the Unit" in the "Calibrating Probe Tips" topic for additional information.

AutoCalibrate Probe

The Autocalibrate command automatically calibrates the current probe during measurement routine execution. PC-DMIS begins the calibration routine once it executes the command.

To insert this command, select **Insert | Calibrate | AutoCalibrate Probe** from the menu to open the **Calibrate Probe** dialog box.



Calibrate Probe Dialog Box

An example for the Edit window code for this command reads:

```
AUTOCALIBRATE/PROBE, PARAMETER_SET=, QUALTOOL_MOVED=Y/Y/N,
CHECK COLLISION=Y/N, SHOW_SUMMARY=Y/N,
OVERWRITE_RESULTSFILE=Y/N
```

`PARAMETER_SET=` This field specifies the name of a defined set of probe qualification parameters. A default set named `ALL-TIPS-WITH-DEFAULTS` is always available and calibrates all tips defined for the current probe. It uses the default set of qualification parameters, which are the last ones that were used interactively. To create your own parameter sets, see "Parameter Sets".

`QUALTOOL_MOVED=` This field sets your response to the computer's query of whether or not the calibration tool has moved. It can be set to one of these three options:

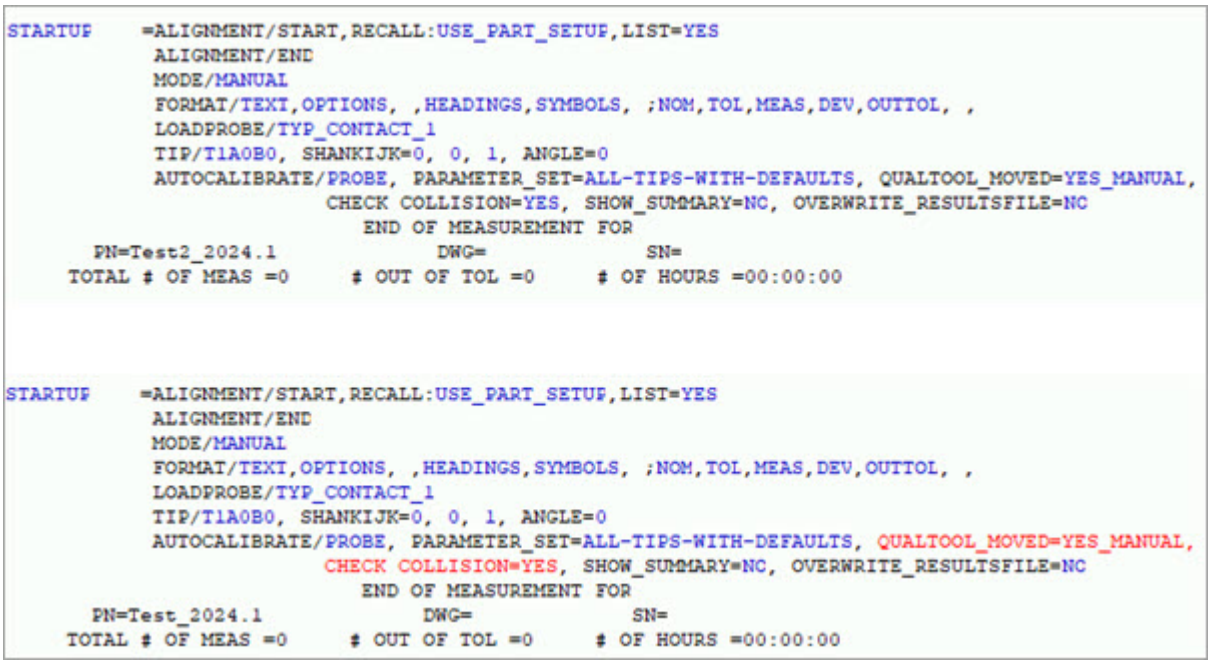
- NO - This means the calibration tool has not moved.
- YES_MANUAL - This means the calibration tool has moved, but PC-DMIS requires you to take a manual hit to locate the sphere.

- YES_DCC - This means the calibration tool has moved but PC-DMIS should use DCC hits to attempt to locate the calibration tool. You may use this option when you have repositioned the qualification tool to nearly the same previous location.

`CHECK COLLISION=` Starting with PC-DMIS version 2024.2, this field is only enabled when `QUALTOOL_MOVED=NO` . If `QUALTOOL_MOVED=NO` and `CHECK COLLISION=YES` , PC-DMIS enables the Leg Collision check on both Bridge and horizontal/dual arm machines. If you have a vertical machine, this option is only available on the vertical calibration tools. PC-DMIS does not support this functionality on star probes or laser sensors.

If you open a measurement routine earlier than version 2024.2 and it has the `QUALTOOL_MOVED=YES` and `CHECK COLLISION=YES` defined, the `AUTOCALIBRATE` command in the Edit window displays these fields in red.

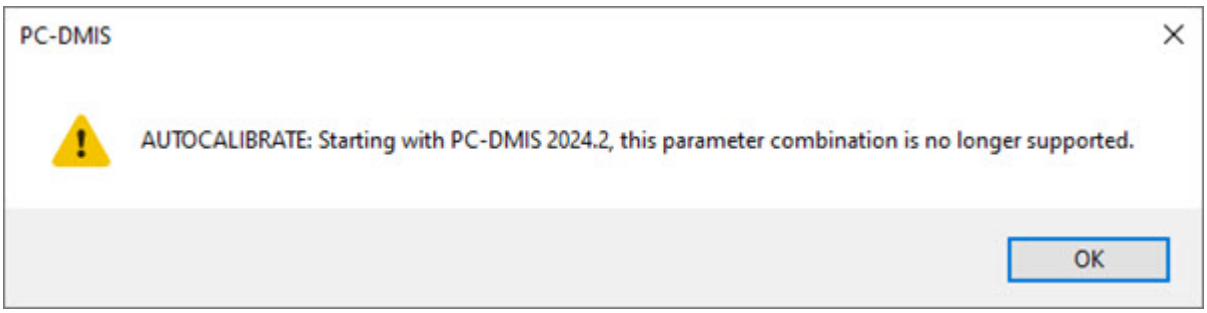
For example, the top code snippet in the image below shows a measurement routine created in PC-DMIS 2024.1 with `QUALTOOL_MOVED=YES_MANUAL` and `CHECK COLLISION=YES` . When you open this same measurement routine in PC-DMIS 2024.2, the software displays those fields in red in the Edit window as shown at the bottom of the image below.



Example of an AUTOCALIBRATE command in version 2024.1 (top) and version 2024.2 (bottom).

If you execute the PC-DMIS 2024.1 measurement routine in PC-DMIS 2024.2, it will perform the collision detection.

When you save the 2024.2 version of that measurement routine, PC-DMIS shows this message:



The next time you open the same measurement routine in PC-DMIS 2024.2, the software updates the AUTOCALIBRATE command as shown below:

```
STARTUP    =ALIGNMENT/START,RECALL:USE_PART_SETUP,LIST=YES
            ALIGNMENT/END
            MODE/MANUAL
            FORMAT/TEXT,OPTIONS, ,HEADINGS,SYMBOLS, ;NOM,TOL,MEAS,DEV,OUTTOL, ,
            LOADPROBE/TYP_CONTACT_1
            TIP/T1A0B0, SHANKIJK=0, 0, 1, ANGLE=0
            AUTOCALIBRATE/PROBE, PARAMETER_SET=ALL-TIPS-WITH-DEFAULTS, QUALTOOL_MOVED=YES_MANUAL,
                         CHECK COLLISION=NO, SHOW_SUMMARY=NO, OVERWRITE_RESULTSFILE=NO
                            END OF MEASUREMENT FOR
      PN=Test_2024.1              DWG=              SN=
    TOTAL # OF MEAS =0      # OUT OF TOL =0      # OF HOURS =00:00:00
```

SHOW_SUMMARY= This YES / NO field determines whether or not PC-DMIS displays a summary of the calibration.

OVERWRITE_RESULTSFILE= This YES / NO field determines whether or not PC-DMIS overwrites or appends information sent to the results file. This is the same results file that's referenced when calibrating interactively.

In this example, the AUTOCALIBRATE command performs the calibration using a custom parameter set named PARAMSET1. The ASSIGN commands get the parameter set name from the command. The COMMENT command then displays the parameter set name in an Operator comment:

```
AUTOCALIBRATE/PROBE, PARAMETER_SET=PARAMSET1,
QUALTOOL_MOVED=NO,

CHECK COLLISION=Y, SHOW_SUMMARY=NO,
OVERWRITE_RESULTSFILE=NO

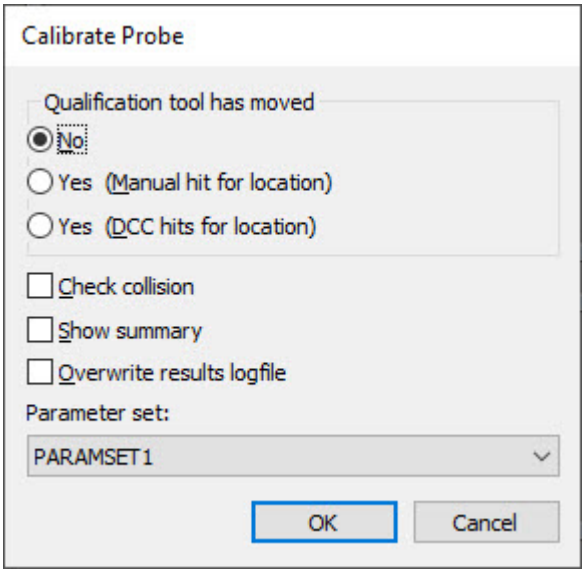
ASSIGN/AC=GETCOMMAND("Autocalibrate Active Probe",
"UP", 1)

ASSIGN/PSET=GETTEXT("Parameter Set",0,AC)

COMMENT/OPER,NO,FULL SCREEN=NO,AUTO-CONTINUE=NO,

"The parameter set is " + PSET
```

You can press F9 on the command block to edit the command block through the **Calibrate Tip** or **Calibrate Probe** dialog box:



Calibrate Probe Dialog Box

If the Leg Collision check is disabled, the **Check collision** check box is unavailable and unmarked.

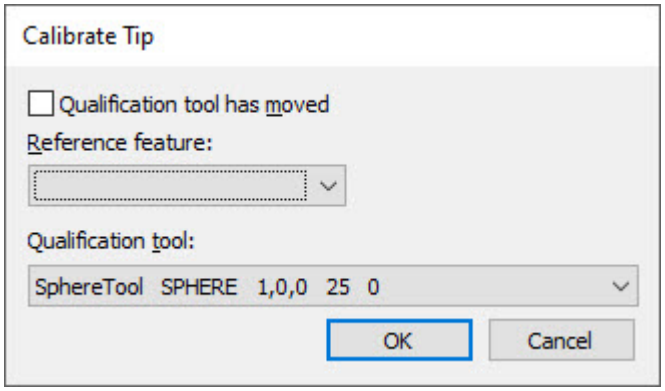
You can also insert a command to automatically calibrate multiple arms. For more information, see "Performing an Automatic Calibration" in the "Using Multiple Arm Mode" chapter.

To Automatically Calibrate a Single Tip

You can also perform an automatic calibration of the active tip by following this procedure:

1. Click the **Command Mode** button from the Edit Window toolbar to place the Edit window in Command Mode.
2. From the **Settings** toolbar, select the tip you want to calibrate. A new `TIP` command appears in the Edit window.
3. PC-DMIS requires a measurement of your calibration sphere in order to do this type of calibration. Create or insert a measured or auto sphere feature of the calibration tool to use in the calibration process. This sphere feature must appear sometime *after* the `TIP` command in the Edit window.
4. On any line following the sphere feature you'll be using, access the **Insert | Calibrate | Single Tip** menu option.
5. PC-DMIS inserts a `CALIBRATE ACTIVE TIP WITH FEAT_ID` command block into the Edit window. Note that this command does not communicate at all with the actual machine controller but instead sends data to the probe file.

6. Click anywhere on this command block, and press F9. The **Calibrate Tip** dialog box appears.



Calibrate Tip Dialog Box

7. Select the sphere feature to be measured by the selected tip from the **Sphere Feature** list.

8. Select the desired calibration tool from the **Qualification Tool** list.

9. If the calibration tool has moved since your last calibration, mark the **Qualification tools has moved** check box.

10. Click **OK** to update the calibration command block with your changes. For example, this example command block shows that the calibration tool is named *MyTool*, and that the sphere feature to use for this calibration is *SPH1*.

```
CALIBRATE ACTIVE TIP WITH FEAT_ID=SPH1,
QUALTOOL_ID=MyTool, MOVED=NO
Axis     THEO         MEAS         DEV          STD DEV
X        0.0000       8.0080       8.0080       -
Y        0.0000       1.0000       1.0000       -
Z        0.0000       0.9500       0.9500       -
DIA      2.0000       1.0000       1.0000       0.0000
```

11. Mark this command block and execute the measurement routine. PC-DMIS calibrates the active tip when it reaches this command block.

Custom Probe

You can define a custom probe by selecting **Edit | Preferences | Custom Probe Builder Utility** from the main menu. You can use the **Custom Probe** option to define custom probes that you can then insert into measurement routines.

When you select the **Custom Probe** option from the **Preferences** submenu, PC-DMIS displays a prompt, asking if you want to open an existing Probe Builder data file (*.dat) or create a new one.

Create a New Custom Probe

1. At the prompt, click **New** to display the **New** dialog box.
2. Navigate to the folder where you want to store the Custom Probe Builder file.
3. Type the name of the new custom probe data file (*.dat) and then click **OK**. The probe file is created and the Custom Probe Builder Utility dialog box appears.

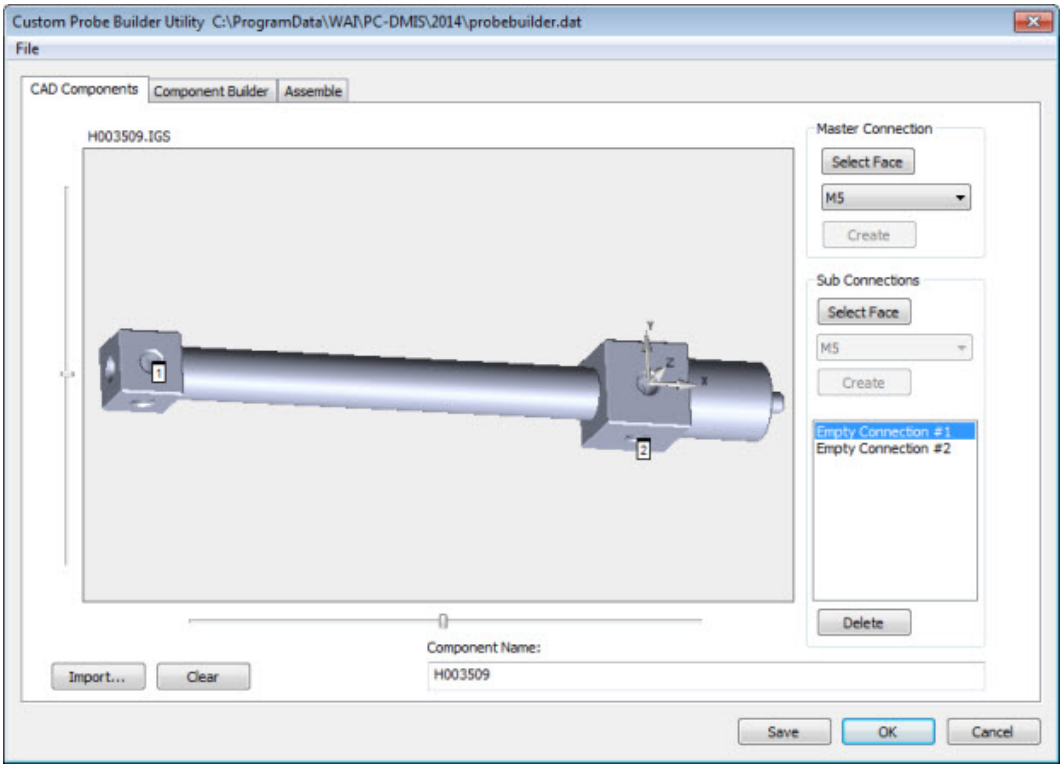
Open an Existing Custom Probe

1. At the prompt, click **Open** to display the **Open** dialog box.
2. Navigate to the folder where the Custom Probe Builder (*.dat) file is located.
3. Select the file and click **Open**. The **Custom Probe Builder Utility** dialog box appears.

You can manually define a custom probe by editing the usrprobe.dat file. For details, see the "Editing the usrprobe Data File" topic.

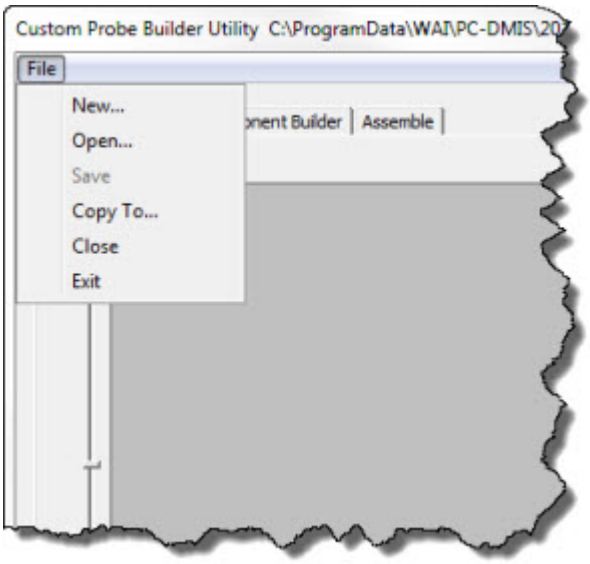
Custom Probe Builder Utility

Use the **Custom Probe Builder Utility** to create a custom probe. You can then use this probe in new or existing measurement routines.



Custom Probe Builder Utility Dialog Box - CAD Components Tab

Custom Probe Builder Utility File Menu

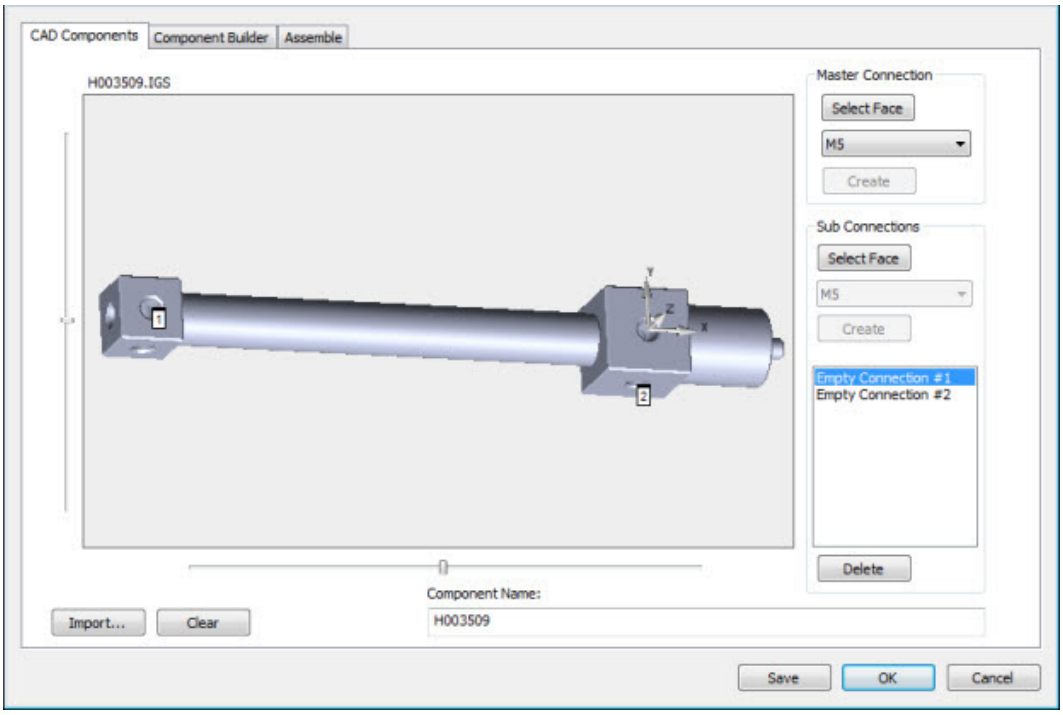


Custom Probe Builder Utility Dialog Box - File menu Options

The **File** menu options for the **Custom Probe Builder Utility** are:

- **New** - Displays the **New** dialog box. You can use this to enter the filename of the new .dat custom probe file. You can then navigate to a location on a local or network drive to store the file.
- **Open** - Displays the **Open** dialog box. You can navigate to a location on a local or network drive to open an existing custom probe .dat file.
- **Save** - Saves any changes made to the current .dat custom probe file.
- **Copy To** - Opens a **Copy part file to** dialog box. You can then browse to a location to save the current .dat part file.
- **Close** - Closes the current .dat file.
- **Exit** - Exits the utility.

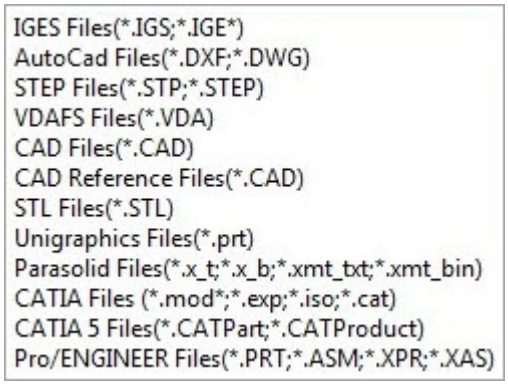
Custom Probe Builder Utility - CAD Components Tab



Custom Probe Builder Utility Dialog Box - CAD Components Tab

The options available on the dialog box are:

- Click **Import** to import most of the formats PC-DMIS allows from the local or network drive location into the measurement routine. These are the allowed file types.



- Click **Clear** to clear any unsaved work and start work on another item.
- Click **Save** to save any changes to the defined custom probe .dat file. The dialog box remains open if you need to make additional edits.
- Click **OK** or **Cancel** to close the dialog box. The application does not automatically save your changes. Make sure you click **Save** prior to clicking **OK** or **Cancel**.

Defining the Master Connection

The Master Connection defines the main connection point of a component once you add it to an assembly. It also serves to define the alignment of the assembly. Left-click a surface or feature on the CAD model to create the master connection points.

To configure a master connection type:

1. Click **Import** to open a CAD file. Once it imports, you can interact with the model and define connection points for other probe components.

   > If you opened a file with all your connection points defined, click the **Component Builder** tab to build custom probe components.

   You can zoom and rotate the image in the dialog box's graphic area similar to the PC-DMIS Graphic Display window. For example, you can press Ctrl + Z to re-draw the image to fit entirely within the graphics area. Use the sliders along the bottom and left of the graphic area to manipulate the CAD model.

2. Click the **Select Face** button from the **Master Connection** section to place the dialog box into a selection mode. The dialog box remains in this mode until you click the **Select Face** button again or you define a master connection.

3. From the list in the **Master Connection** area, select a connection type.

   
   Custom Probe Builder Utility Dialog Box - CAD Components Tab Master Connection Types menu

4. Click the surface or feature for the master connection. The software highlights the selected surface.

5. Click **Create** to finalize the master connection. The alignment updates to the selected feature with the Z axis perpendicular to it.

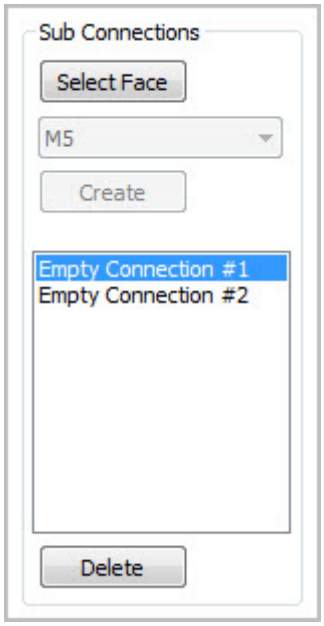
Defining Sub Connections

You can connect other components to sub connections to create an assembly. The Master Connection of one component connects to the selected sub connection of another component. For details on creating assemblies, see the topic "Custom Probe Builder Utility - Assemble Tab".

To define sub connections:

1. Click the **Select Face** button from the **Sub Connections** section to place the dialog box into a selection mode. The dialog box remains in this mode until you click the **Select Face** button again.

2. Select a connection type from the list in the **Sub Connection** area.
3. Click the surface or feature for the sub connection. The software highlights the selected surface.
4. Click **Create** to finalize the sub connection. Once you create the sub connection, the **Create** button is disabled until you select another feature. Create as many sub connections as needed. As you create sub connections, they appear in the lower list box as "Empty Connection #1", "Empty Connection #2", and so forth.



Custom Probe Builder Utility Dialog Box - Sub Connections Area

When you click **Create**, the software disables the lower connection type list box.

5. You can delete connections. Select one or more connections, then click **Delete**.
6. Once you have defined all master and sub connections, in the Component Name box, enter a name for the new component, then click **Save**. The dialog box remains open so you can build components from the **Components Build** tab or probe assemblies from the **Assemble** tab.
7. Click **OK** to exit the utility or click **Cancel** to exit the utility.

Custom Probe File Format

The software saves your custom probe configuration as a .dat file. This uses the same format as the probe.dat file.

```
ITEM:5H003512 M5

cadgeom 0.000 0.000 0.000 1.000 0.000 0.000 0.000 1.000
0.000 0.000 0.000 1.000 -1 5 H003512.draw

connect -1.108 -27.715 -113.565 0.508 0.759 0.408 M5

connect 2.859 33.883 -112.237 0.479 -0.789 -0.384 M5
```

Custom Probe Builder Utility - Component Builder Tab

You can use the **Custom Probe Builder Utility Component Builder** tab to create custom probe components from element types.

To build a probe component:

1. In the **Component Name** box, enter a unique name.
2. From the **Element Type** area, select the type of element to create. You can create tips, extensions, or polygons. You can combine multiple elements of the same type to create more advanced components. However, you cannot create an extension and add a tip onto it from this tab.

   For example, to create a tip named "Tip1" from two tip element types (a Cylinder and a Sphere) you would:

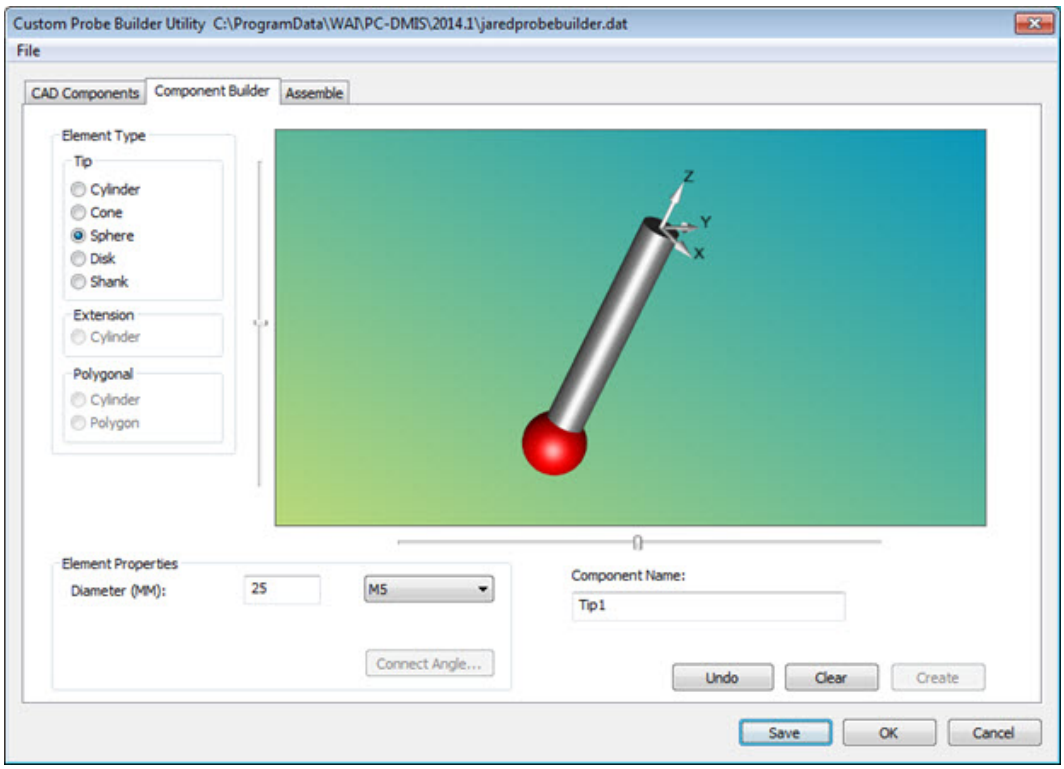
   a. Enter "Tip1" in the **Component Name** box.

   b. Select **Cylinder** from the **Tip** area of the **Element Type** section.

   c. Enter the diameter and height values for the cylindrical tip in the **Diameter** and **Height** boxes that appear, and then click **Create**.

   d. Select **Sphere** in the **Tip** area.

   e. Enter the diameter of the sphere in the **Diameter** box and click **Create**. The software draws each element in the dialog box's graphic area.



Custom Probe Builder Utility - Component Builder tab with a custom probe defined

f. Click **Save** to save your work.

The software indicates terminating elements in red. Terminating elements are the **Sphere**, **Disk**, and **Shank** tips. You cannot append other elements onto them. The example above shows a terminating **Sphere** tip connected to a non-terminating **Cylinder** tip.

The software indicates non-terminating elements in gray. Non-terminating elements are the **Cylinder** and **Cone**.

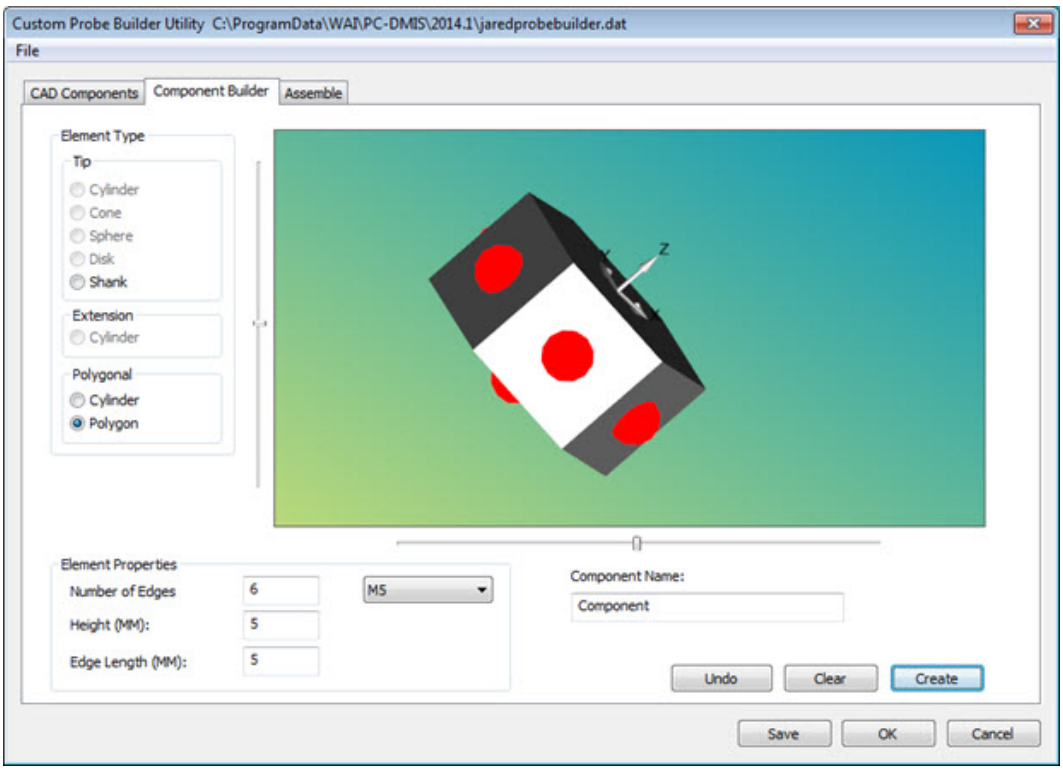
The software requires a unique name for each custom probe saved. If you want to continue to build a new component, click **Clear** to remove the current component.

About Element Properties

The **Element Properties** area changes based on the **Element Type** selected. All elements allow you to specify the connection type available from the drop-down list.

- Cylinders, Disks, and Shanks have **Diameter** and **Height** properties.
- Spheres have a **Diameter** property.
- Cones have **Diameter**, **Height**, and **Minor Diameter** properties.
- Polygons have **Number of Edges**, **Height**, and **Edge Length** properties.

For example, a Polygon component has these element properties:



Custom Probe Builder Utility - Component Builder tab with a Polygon created

Using Create, Undo, Save, and Clear

The **Create** button temporarily stores the built component. This lets you combine multiple element types of the same category together.

The **Undo** button removes the most recently created element from the current component. You can click **Undo** multiple times to remove each successive element until the graphic area empties.

The **Clear** button discards any created items or selected options and lets you start over with the creation process. If you have not saved your work, this permanently removes the current component.

The **Save** button saves your work to the .dat file you opened when you started the **Custom Probe Builder Utility**. Once you save a component, you can then use the **Clear** button to safely remove your work and clear the dialog box in order to create new components. This makes it so you don't have to close and reopen the dialog box to create new element types.

Zooming and Rotating

You can pan, zoom, rotate, and size the image in the graphic area:

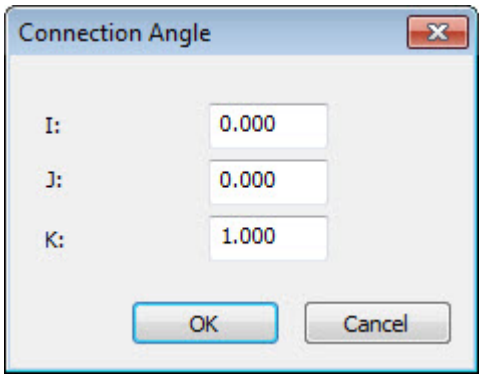
- To re-draw the image to fit entirely within the graphic area, press Ctrl + Z.
- To rotate the image three-dimensionally, press Ctrl, right-click, and then drag the cursor.

Creating a Cut Cylinder

From the **Extension** section, use the **Cylinder** option to cut a cylindrical extension at a defined angle. You can then attach the next extension at that angle to create a bend in the extension.

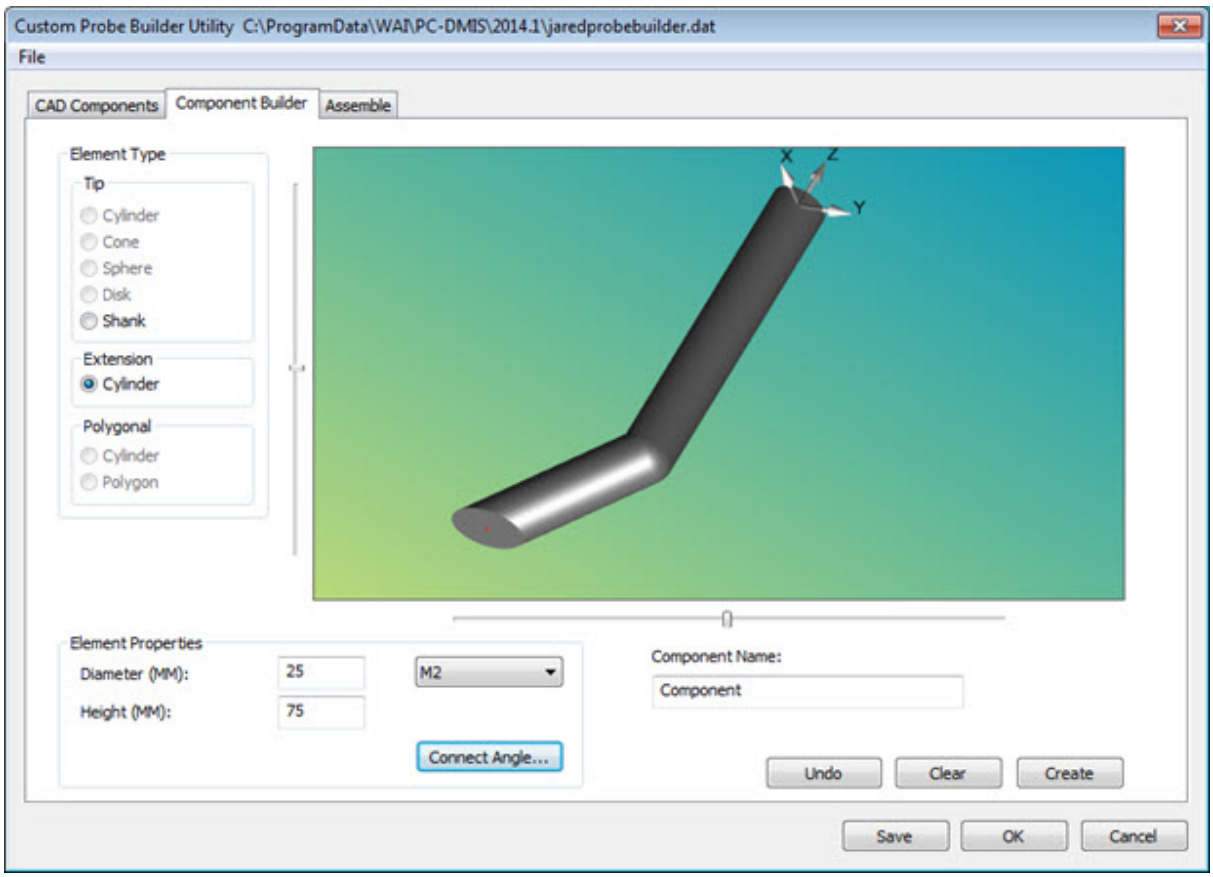
To create a cut cylinder:

1. In the **Component Name** box, enter the name of the cut cylinder.
2. In the **Extension** area of the **Component Builder** tab, click the **Cylinder** option to enable the **Connect Angle** button in the **Element Properties** area.
3. Click the **Connect Angle** button to display the **Connection Angle** dialog box.



Connection Angle dialog box

4. Enter the desired vector values and then click **OK**. These determine the angle that the software uses to cut the cylinder.
5. From the **Element Properties** area, in the **Diameter** and **Height** boxes, enter the diameter and height values for the cylinder.
6. Click the **Create** button to display the cut cylinder.

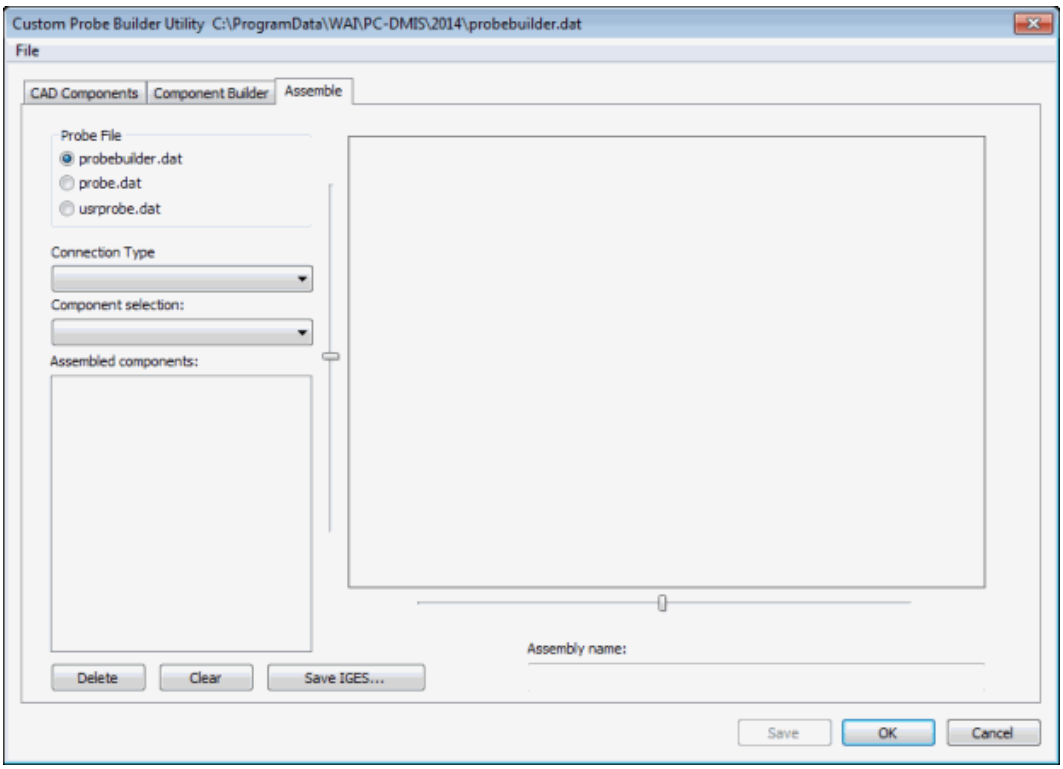


Custom Probe Builder Utility - Component Builder tab showing a sample Cut Cylinder

7. Click the **Save** button to save the new component.

Custom Probe Builder Utility - Assemble Tab

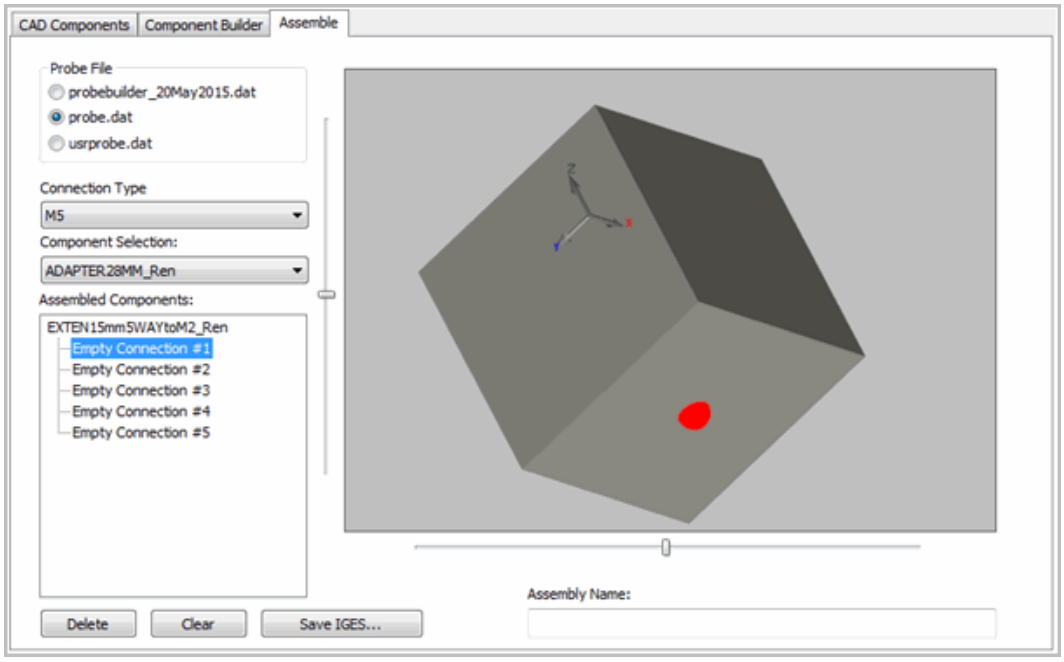
You can use the **Assemble** tab to assemble a custom probe component.



Custom Probe Builder Utility Dialog Box - Assemble Tab

To create an assembly from various components:

1. From the **Probe File** section, select a file.
2. From the **Connection Type** list, select the appropriate type of connection.
3. From the **Component Selection** list, select a component. The software updates the list based on the **Probe File** selection. The software uses the list to create an assembled component from the files, and then it sorts all the items in the list by their connection types. For example, if Connection #1 is defined as an M8 connection, only items that can connect to an M8 connection are available in the list.



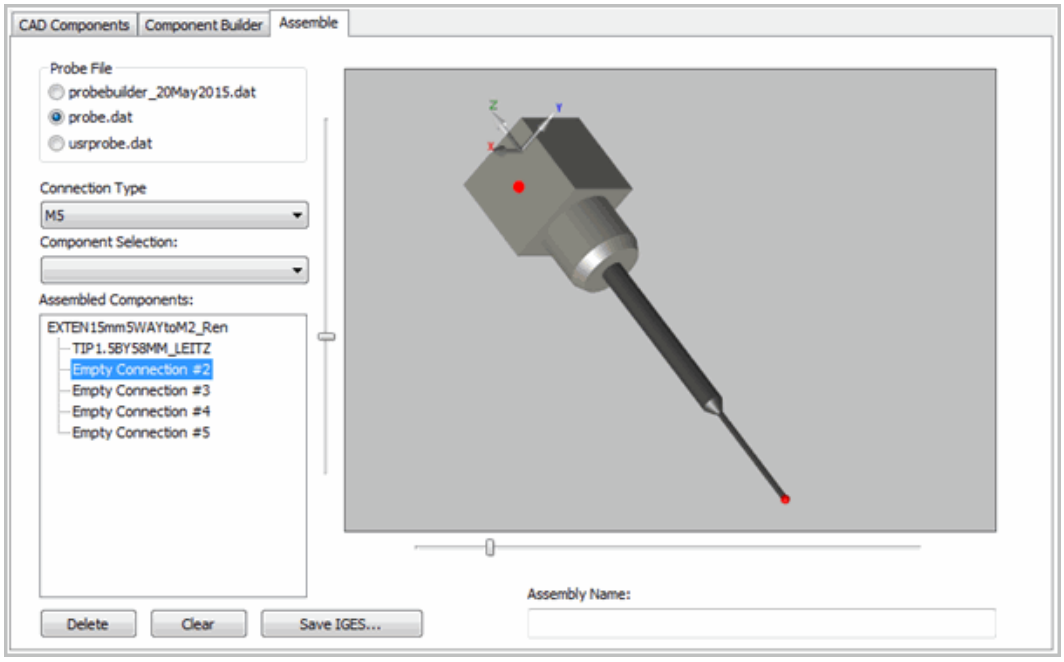
Custom Probe Builder Utility - Assemble tab showing the start of an assembly build

For example, in the **Assemble** tab shown above:

- The "probe.dat" file is selected in the **Probe File** area.
- The "ADAPTER28MM_Ren" component (found in the "probe.dat" file) is selected from the **Component Selection** list.
- The component is drawn in the graphic area. The red dot identifies the first available (empty) connection. You can zoom and rotate the image. For example, if you press Ctrl + Z on your keyboard, the software zooms the image to fit entirely within the graphic area.
- The **Assembled Components** area displays a tree view of the selected component and highlights the first empty connection. Each time you fill an empty connection, the software automatically selects the next available empty connection port. To remove a connection, you can left-click the item, and then click **Delete**.
- Once you add a component to the **Assembled Components** tree, the software enables the **Delete**, **Clear**, and **Save IGES** buttons.

4. From the **Probe File** area, select another file or use the currently selected file to continue to build the assembly.

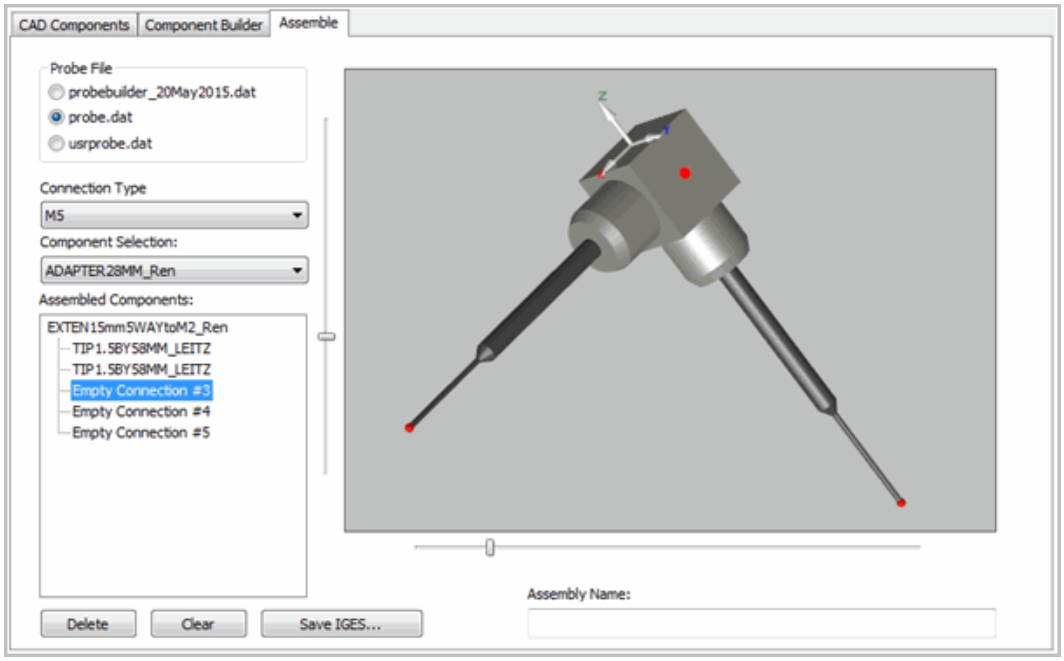
> At any point, you can change the **Probe File** option and select items you created in the **Component Builder** tab.



Custom Probe Builder Utility - Assemble tab showing the continuation of an assembly build

5. From the **Connection Type** list, select a new connection type. If an assembly already exists, a prompt asks if you want to clear the current build. Click **Yes** to clear the build and start over, or click **No** to return to the current build.

6. From the **Component Selection** list, select new components to add to the connections. Some components may have more connections that you can add onto, while others may end with terminating elements (Spheres, Disks and Shanks) as shown below:



Custom Probe Builder Utility - Assemble tab showing the completion of an assembly build

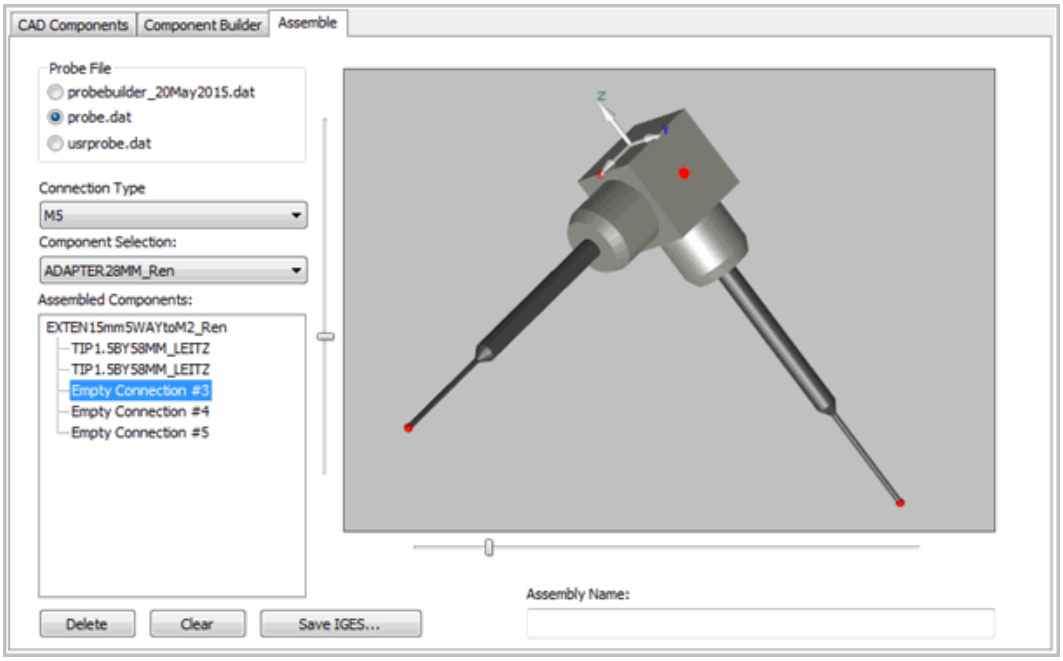
7. Update the assembly with any of these options:

- The **Delete** button works similar to the **Delete** button on the **Probe Utilities** dialog box. If you build a branch on the tree that contains multiple items, you can delete the entire branch or just portions of it. The **Delete** button only removes the selected item in the tree along with any attached components.
- The **Clear** button clears the entire tree and the graphic area.
- The **Save IGES** button saves the imported model to an IGES file. A standard **Save As** dialog box appears so you can specify a unique file name.

8. In the **Assembly Name** box, enter a name for the assembly, and then click **Save**.

Modifying the Rotation Angle of a Component

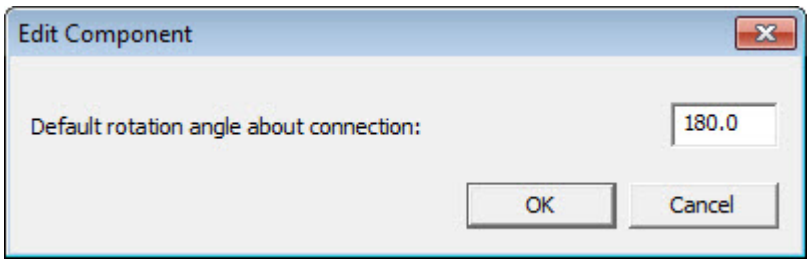
If a connected component has an incorrect orientation, you can rotate it.



Custom Probe Builder Utility - Assemble tab showing connectors requiring an orientation change

To correct the orientation of a connection:

1. Right-click an item in the connector tree to open the **Edit Component** dialog box.



Edit Component dialog box

2. In the **Default rotation angle about connection** box, enter the angle (any angle from +180° to -180° inclusive). 0 (zero) is the default angle.

3. Click **OK** to rotate the component in the graphic area.
4. Click **Save**.

Creating and Using Connection Points on a Polygon Element Example

Creating Connection Points

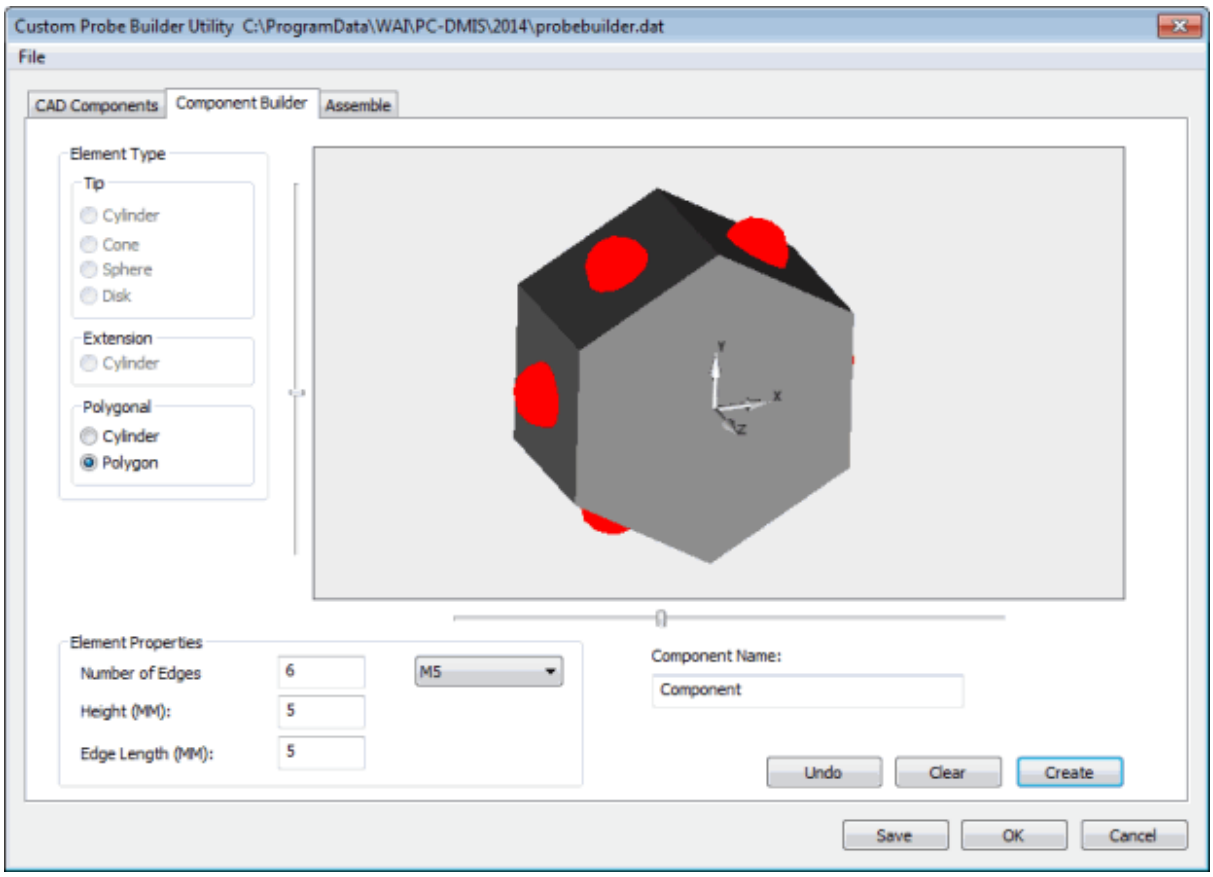
Connection points are used to define the faces to be used to attach components to when building an assembly. This allows more control over your assembly.

To create connection points on a Polygon element:

1. Select the **Polygon** option from the **Polygonal** section of the **Component Builder** tab.
2. Adjust the **Element Properties** as needed.

   The **Number of Edges** box accepts a minimum value of 3 and a maximum value of 20. If you enter a value less than 3, the box is reset to 3; if you enter a value greater than 20, the box is reset to 20.

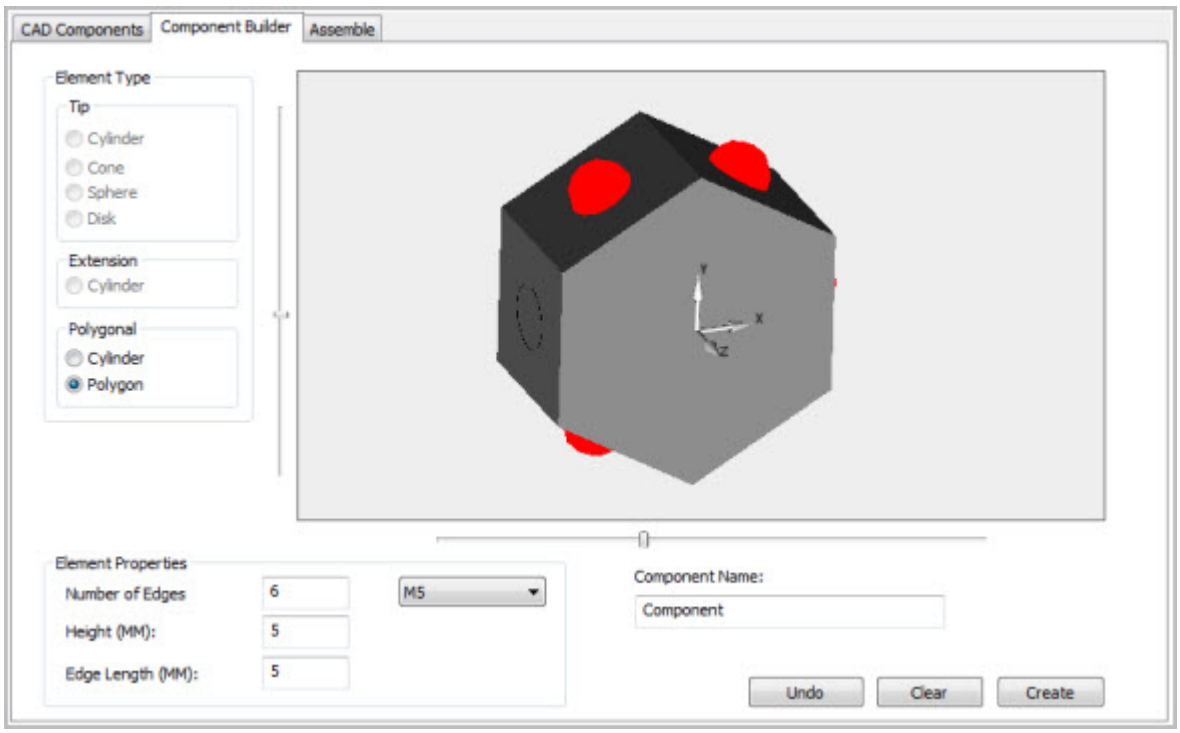
3. Enter a unique name for your component in the **Component name** section then click **Create**.



Custom Probe Builder Utility - Component Builder tab showing a polygon and its default connection points

A basic polygon is displayed with red connection dots. The red connection dots are displayed on five of the sides. Each dot represents a connection point that can be used in an assembly.

4. To manage which connection points are available for a particular assembly, click any of the connection point dots to disable or enable. In the image below, the front (left side) face connection is disabled. Clicking a disabled point re-enables it.



Custom Probe Builder Utility - Component Builder view of a connection point disabled

5. When all the properties and connection points have been defined, click **Save**. If this is a new component, enter a name in the **Component Name** field and then click **Save**.

Using Connection Points

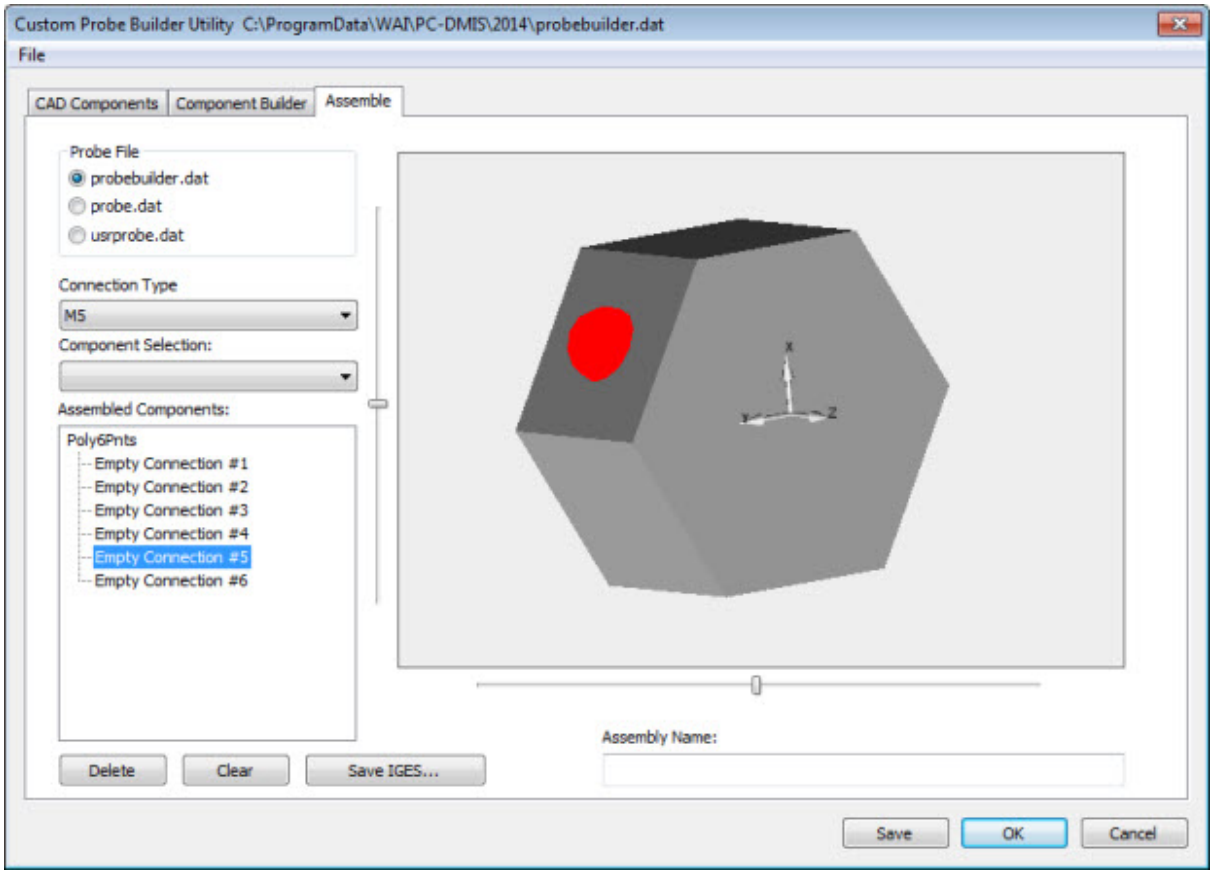
Once the changes in the **Component Builder** tab have been saved, they can be used to assemble a custom probe.

To assemble a custom probe using the built component:

1. Click the **Assemble** tab.
2. In the **Probe File** section, click the file name used to save your changes.
3. Click the type of connection from the **Connection Type** list. The components in the **Component Selection** list update based on the type of connection selected. Only items that connect to this connection type are listed.
4. The component assembly is detailed in the **Assembled Components** section. Click the connection you want to begin building on in the **Assembled Components** tree. The first "empty" connection is always selected by default and is highlighted. If the selected connection face is empty, it shows the red connection dot. Rotate the image if you can't initially see it.
5. Select a component from the **Component Selection** list.

   The selected connection in the **Assembled Components** section is the face that is updated when you begin building your assembly. To work on another face, click a different connection in the **Assembled Components** section. The selected face is

updated with the red connection dot to signify it is the face the next selected component is built onto.



Custom Probe Builder Utility - Assemble tab showing a polygon and the Connection #5 connection point

A face that already has a component connected to it can be replaced with a new component:

a. Click the component to be replaced in the **Assembled Components** tree.

b. Select a new component from the **Component Selection** list to replace it.

Remove a component from a connection point without replacing it:

a. Click the component in the tree to be deleted.

b. Click **Delete**.

6. Once you've selected the face to work on, click the next component from the **Component Selection** list. The selected item is automatically attached to the targeted face - the face with the red connection dot on it.

7. Repeat as needed until your assembly is complete.

8. When finished, type a name for your assembly in the **Assembly Name** box.

9. Save the changes:

- Click **Save IGES** to save the assembly as an IGES file.
- Click **Save** to save the assembly into the .dat file created or opened in the current session

Migrating Measurement Routines Between Machines Using PH10 and Tesa Star M Probes

In the **Option** section of the PC-DMIS Settings Editor, PC-DMIS provides the `AutoAdjustTesaM5Degrees` entry to assist in migrating measurement routines between two machines that use a PH10 probe on one machine and a Tesa Star M probe on the other. Both machines must have probe files with the same name (although the probe files themselves will be different).

- If the entry is set to 1, when a measurement routine that was created initially on one of these machines is then loaded onto the other, PC-DMIS converts any active `TIP/` commands to the closest AB tip angle based on the index increment. If any angles are converted, a message box appears displaying them.
- If the entry is set to 0, PC-DMIS does not perform this angle adjustment.

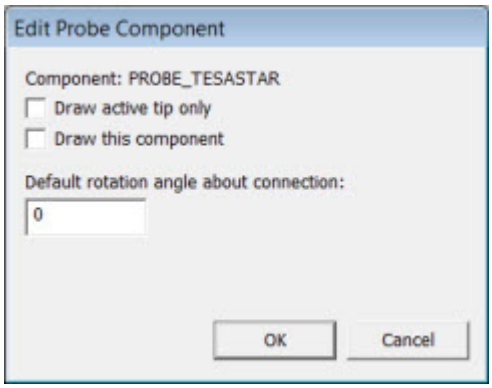
For details, see the "AutoAdjustTesaM5Degrees" topic in the "Option" section of the PC-DMIS Settings Editor documentation.

Showing and Hiding Probe Components

You can show or hide probe components in one of two ways:

From within the Probe Utilities Dialog Box

1. From the Edit window, select a `LOADPROBE` command.
2. Press F9 to access the **Probe Utilities** dialog box.
3. From the **Probe description** area, double-click on the probe component you want to show or hide to open up the **Edit Probe Component** dialog box.



Edit Probe Component Dialog Box

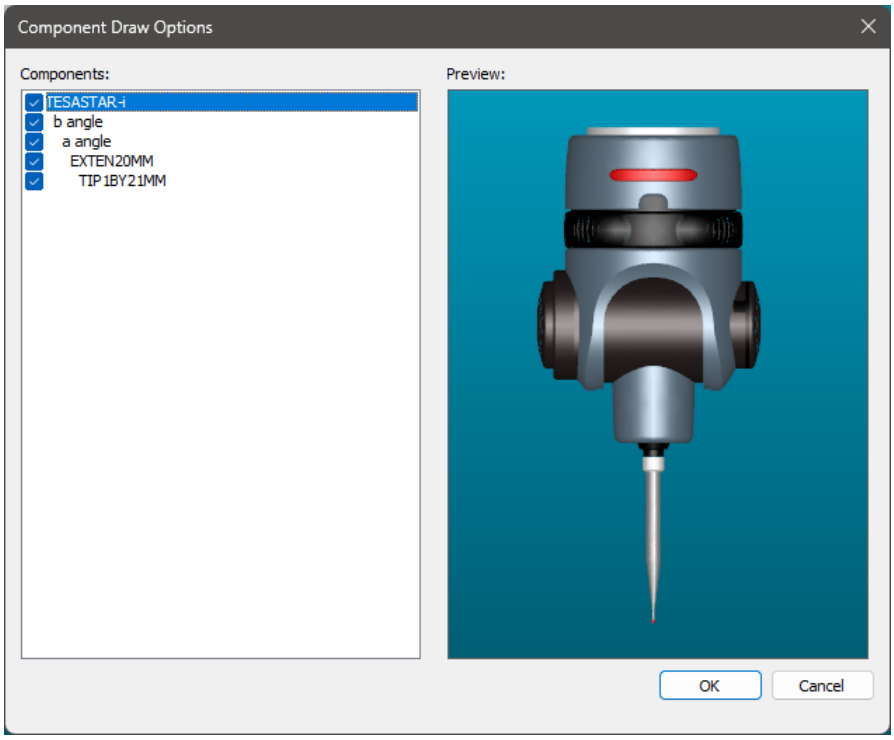
4. Mark or clear the **Draw this component** check box to show or hide that component.
5. Click **OK**.

PC-DMIS organizes the different components in a hierarchical list. This means:

- When you choose to hide a component, PC-DMIS also hides any components above that component.
- When you choose to show a component, PC-DMIS also shows any components below that component.

From the Graphic Items Toolbar

1. From the toolbar area, right-click and choose **Graphic Items** to show the **Graphic Items** toolbar.
2. From the toolbar, click the **Probe Component Draw Options** button to show the **Component Draw Options** dialog box.



Component Draw Options Dialog Box

3. From the **Components** list, mark or clear the component's check box to show or hide that component.
4. Click **OK**.

PC-DMIS organizes the different components in a hierarchical list. This means:

- When you choose to hide a component, PC-DMIS also hides any components above that component.
- When you choose to show a component, PC-DMIS also shows any components below that component.

Editing the usrprobe.dat Data File

This topic describes how probes are created and stored in the probe.dat when you define probes in PC-DMIS. You can use this information as a model to manually create probes in the usrprobe.dat file.

Definition of the Probe.dat

The **probe.dat** file controls the graphical and numerical representation of the probe system for PC-DMIS. If you need a custom probe or probe system within PC-DMIS, you need to first define it in the probe.dat file. You need to strictly follow a specific format to define it.

The content below describes the format and rules of the format with a list of the commands and their definitions.

```
ITEM:TIP2BY20MM M2
```

In the above code snippet, the following rules apply:

1. The first set of characters following the colon "**ITEM:**" is the name that appears in the **Probe Utilities** dialog box when you construct a probe setup. The text following the colon after the keyword **ITEM:** is a unique name of your choice to identify the probe configuration.

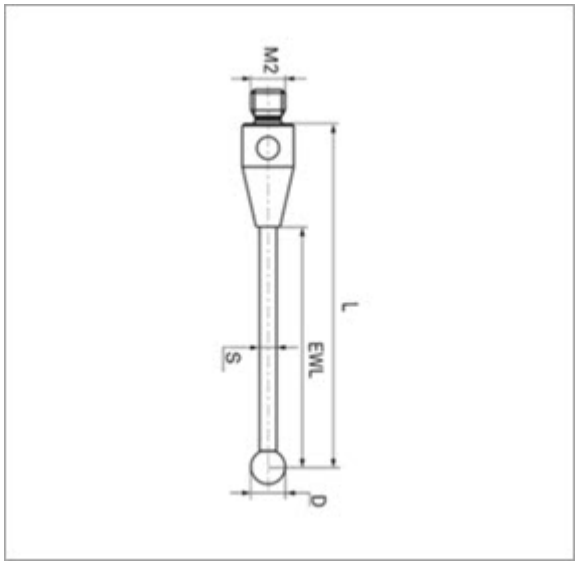
   You can find details in the **Format of the Probe or Probe System ITEM** section below.

2. The second set of characters, "**M2**" in the above example, defines the type of thread or connection type this item has.

The following information lists and defines the probe builder commands:

`EffectiveWorkingLength`
This parameter defines the depth that you can insert the probe assembly into a feature that allows a valid measurement with the probe tip. This is a way for you to define the usable length of the probe assembly to something less than its total length if needed or desired and only applies to cylinder features.

The default Effective Working Length (EWL) value is the distance from the center of the tip's ball to the end of the stylus.



Example details of an M2 stylus showing the Effective Working Length (EWL)

If you do not set a value, PC-DMIS uses the default value for this parameter.

`begintip`
The start of a tip definition.

`endtip`
The end of a tip definition.

`ribcount N`
Defines the number of lines in a circular feature.

N - The number of lines seen in a circular feature. This is an integer from 2 to 1000, inclusive.

`line x1 y1 z1 x2 y2 z2`
Defines a line feature.

x1, **y1**, **z1** - The coordinate location starting point of the line.

x2, **y2**, **z2** - The coordinate location end point of the line.

`sphere x y z d`
Defines a sphere feature.

x, **y**, **z** - The center coordinate location of the sphere.

d - The diameter of the sphere.

`cutsphere x y z i j k d t b`
Defines a cut sphere feature.

x, **y**, **z** - The center coordinate location of the sphere.

d - The diameter of the sphere.

i, **j**, **k** - The vector perpendicular to the sphere top and bottom.

t, **b** - The location of the top and bottom as follows:

- Top = (x,y,z) + t * (i,j,k)
- Bottom = (x,y,z) - b * (i,j,k)

`cylinder x1 y1 z1 x2 y2 z2 d`
Defines a cylinder feature.

x1, **y1**, **z1** - The coordinate location of the top of the cylinder.

x2, **y2**, **z2** - The coordinate location of the bottom of the cylinder.

d - The diameter of the cylinder.

`cone x1 y1 z1 d1 x2 y2 z2 d2`
Defines a cone feature

x1, **y1**, **z1** - The coordinate location of the top of the cone.

x2, **y2**, **z2** - The coordinate location of the bottom of the cone.

d1 - The diameter at the top of the cone.

d2 - The diameter at the bottom of the cone.

`ring x1 y1 z1 i1 j1 k1 d1 d2`
Defines a ring feature.

x1, **y1**, **z1** - The center coordinate location of a ring.

i1, **j1**, **k1** - The vector of the ring with respect to the current coordinate system of the probe definition.

d1 - The diameter of the outside of the ring.

d2 - The diameter of the inside of the ring.

`comment text`
An author message that describes the code or important information related to the code. The probe system does not act upon the text that follows the comment command.

`hotspot x1 y1 z1 i1 j1 k1 d1 t1 type`
Defines a hotspot command.

x1, **y1**, **z1** - The coordinate location of the center of the probe tip.

i1, **j1**, **k1** - The vector of the probe tip, usually 0,0,1.

d1 - The diameter of the tip.

t1 - The thickness of the tip (for disk probe).

type - The type of probe (ball, shank, disk, and so on).

`opticalcenter x1 y1 z1 i1 j1 k1 sch=1 minf maxf optics_type min_na max_na mag type`
Defines an optical center.

Example 1:

```
opticalcenter x1 y1 z1 i1 j1 k1 sch=2 ot magsteps fov1
fov2...fovmagsteps, na1, na2,...namagsteps, auxlensmag
type
```

x1, **y1**, **z1** - The center location of the center of the probe tip.

i1, **j1**, **k1** - The vector of the probe tip, usually 0,0,1.

sch - The schema number for the optical center data.

ot - The optics_type (1: encoder infinite zoom, 2: fixed optics, 3:nonencoder zoom, 4:encoder discrete zoom, 5: turret microscope, 6: DCC turret microscope).

magsteps - The count of FOV (Field of View) and numeric aperture values.

fov - The X FOV size for each magnification step or min and max if infinite zoom.

na - The numeric aperture for each magnification step or those corresponding to the min and max FOV size if infinite zoom.

auxlensmag - The magnification of any attached auxiliary lens.

type - The type of probe (ball, shank, disk, camera, and so on).

Example 2:

opticalcenter x1 y1 z1 i1 j1 k1 sch=3 ot magsteps fov1 fov2...fovmagsteps, na1, na2,...namagsteps QRDsteps qrdfovsize1 qrdfovsize2… qrdfovsizeQRDsteps qrd1 qrd2…qrdQRDsteps auxlensmag type

x1, **y1**, **z1** - See above.

i1, **j1**, **k1** - See above.

sch - See above.

ot - See above.

magsteps - See above.

fov - The X FOV size for each magnification step or min and max if infinite zoom.

na - See above.

QRDsteps - The count of qrdfovsize (QRD FOV size in X) and qrd (quadratic region depth) values.

auxlensmag - See above.

type - See above .

`connect x1 y1 z1 i1 j1 k1 take`

Defines a connection point.

x1, **y1**, **z1** - The location of a connection point on the probe system.

i1, **j1**, **k1** - The vector of the connection based on its orientation to the current coordinate system of the probe system. It always points toward the center.

take - The type of thread or connection type that the connect point is compatible with.

`autojoint x1 y1 z1 I1 j1 k1 ina inc sa ea label`

Defines an auto joint feature.

x1, **y1**, **z1** - The location of the joint with respect to the current coordinate system.

i1, **j1**, **k1** - The vector of the joint based on the current coordinate system. It points back toward the startup location.

ina - The default initial angle of this joint.

inc - The increments of this joint.

sa - The starting angle of this joint.

ea - The ending angle of this joint.

label - The name of the joint that appears in the **Probe Utilities** dialog box.

`manualjoint x1 y1 z1 i1 j1 k1 ina inc sa ea label`

Defines a manual joint feature.

x1, **y1**, **z1** - The location of the joint with respect to the current coordinate system.

i1, **j1**, **k1** - The vector of the joint based on the current coordinate system. It points back toward the startup location.

ina - The default initial angle of this joint.

inc - The increments of this joint.

sa - The starting angle of this joint.

ea - The ending angle of this joint.

label - The name of the joint that appears in the **Probe Utilities** dialog box.

```
face N x1 y1 z1 ... xN yN zN
```
Defines a face feature.

N - The number of corner points on the given face.

x1, **y1**, **z1** through **xN**, **yN**, **zN** - The coordinates of each corner point of the face.

```
solid N
```
Defines a solid feature.

solid - Applies shading. If you don't use the **solid** command, the faces appear as wireframes. You use this with the "**face**" command to indicate the number (**N**) of "face" commands.

N - The number of face commands which follow. This determines the number of faces to which to apply shading.

```
cadgeom X Y Z II IJ IK JI JJ JK KI KJ KK Level FileName
```
Defines the CAD geometry transformation movements for a specific CAD file.

X, **Y**, **Z** - The coordinate location start point. Moves the origin of the CAD file to the start point of the drawing for the probe file.

II - **KK** - The set of three transformation matrices to rotate the CAD csy to the probe csy. If no changes are required, the nominal values would be:
```
cadgeom X Y Z 1 0 0 0 1 0 0 0 1 Level FileName
```

Level - The CAD level number as assigned from within PC-DMIS. If no CAD level exists or if there are multiple levels, you may need to create a new level inside PC-DMIS.

FileName - A .draw file which is nothing more than a renamed .cad file.

```
cutcylinder X1 Y1 Z1 X2 Y2 Z2 I2 J2 K2 Diameter
```
Defines the cut cylinder geometry transformation for a specific CAD file.

X1, **Y1**, **Z1** - The coordinate location start point for the cut cylinder. This moves the origin of the CAD file to the start point of the drawing for the probe file.

X2, **Y2**, **Z2** - The cylinder edge coordinate location of the drawing for the probe file.

I2, **J2**, **K2** - The edge vector of the cut cylinder.

Diameter - The diameter value of the cut cylinder.

Format of the Probe or Probe System ITEM

Each new probe configuration that is defined in PC-DMIS is added to the file "probe.dat". It begins with the "**ITEM:**" command. This command contains both a distinct naming description and a connection identifier. This identifier specifies the type of object to which it can connect, as described above. Below, you can see the available connection identifiers with a brief description. For a probe tip, only the second line of the probe configuration must be a "**begintip**" command, and the very last line a "**endtip**" command.

To define a probe configuration, you must work with a top-down approach. This means that your initial starting point is x=0, y=0, z=0 and everything is drawn from that point down. Consequently, all z values should have a negative value. Also, for most items, the 0, 0, 0 location is the center of the item. This makes it possible to have both positive and negative numbers in both the X and Y directions. Positive X always moves from left to right initially, and Positive Y always moves from front to back as if you were looking FROM the positive Z direction.

The only two commands that define an active configuration are "**hotspot**" for tips and "**connect**" for all others. You must have one of these two commands present in any configuration, but they are never present at the same time.

- "**hotspot**" defines the center location of any portion of a configuration that can be used to actually touch a part for measurement purposes.
- "**connect**" defines any location where another item can be added to the current item. Each connection must include a Connection Identifier to define the type of item it can take.

The two commands that can change the coordinates system of the probe configuration are "**autojoint**" and "**manualjoint**". Take special care when you use any of these two commands, because each command transfers the origin of the configuration to the center of the joint. Keep in mind that the first "joint" command changes the axes of the coordinate system. What was the -Z direction now becomes the +X direction, and what was the +X direction now becomes the +Z direction. Y remains the same. These commands are usually used in pairs. For example, one command controls the B rotation of a PH9 while a second controls the A rotation of a PH9. Also, the first command of the pair always controls the B rotation and the second always controls the A rotation.

Connection Identifier Listing

M2
Specifies that it can connect a M2 threaded device.

M3
Specifies that it can connect a M3 threaded device.

M4
Specifies that it can connect a M4 threaded device.

M5
Specifies that it can connect a M5 threaded device.

M8
Specifies that it can connect a M8 threaded device.

QC
Specifies that it can connect a Quick Connect device.

ARM
Specifies that it connects directly to the machine arm.

OPT
Specifies that it can connect to a Renishaw Optical lens that works with the VP2 and VP1 optical probes.

DEA
Specifies that it connects with the DEA old style probe head including their rotary head.

LEITZ1
Specifies that it can connect a Leitz M5 threaded device.

LEITZ1ANALOG
Specifies that it can connect a Leitz M5 threaded device on an analog probe head.

FIXEDOPTICS
-

ZOOMOPTICS
-

TESAOVP
-

TKJ
Specifies that it is a Tesa Kinematic Joint.

SENMATION
Specifies that it is a Senmation joint (a joint to change sensors).

Analog Probe Scanning Parameters

You can download a .pdf document from the link below to review analog probe scanning parameters for the following probes:

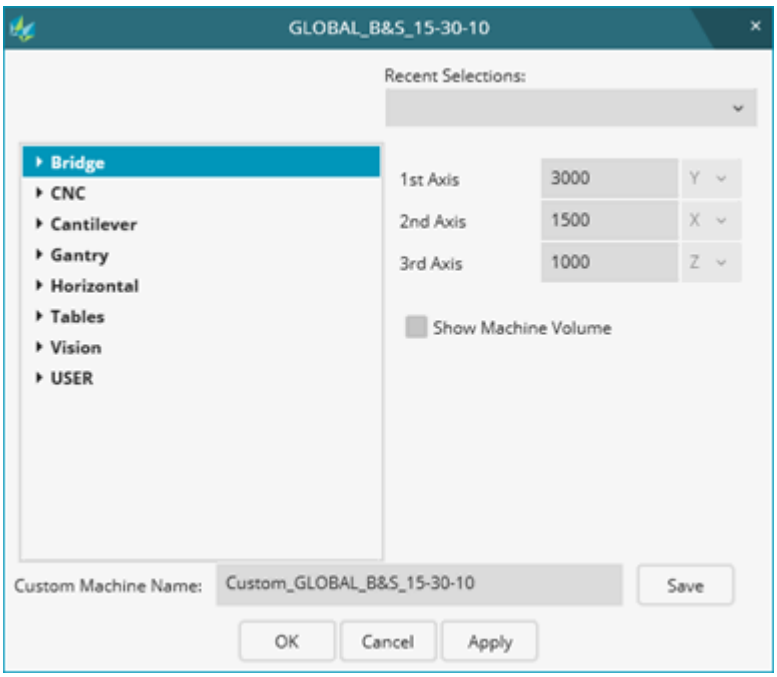
- SP600
- SP80
- SP25
- LSP-X3c/t
- LSP-X5
- LSP-X1s/c/h
- LSP-X1m

To get the file:

1. In your Internet browser, access this site: https://downloads.ms.hexagonmi.com/docs/FilesInHelps
2. Download the file "Scanning Parameters - H006908 PRB Params.pdf".

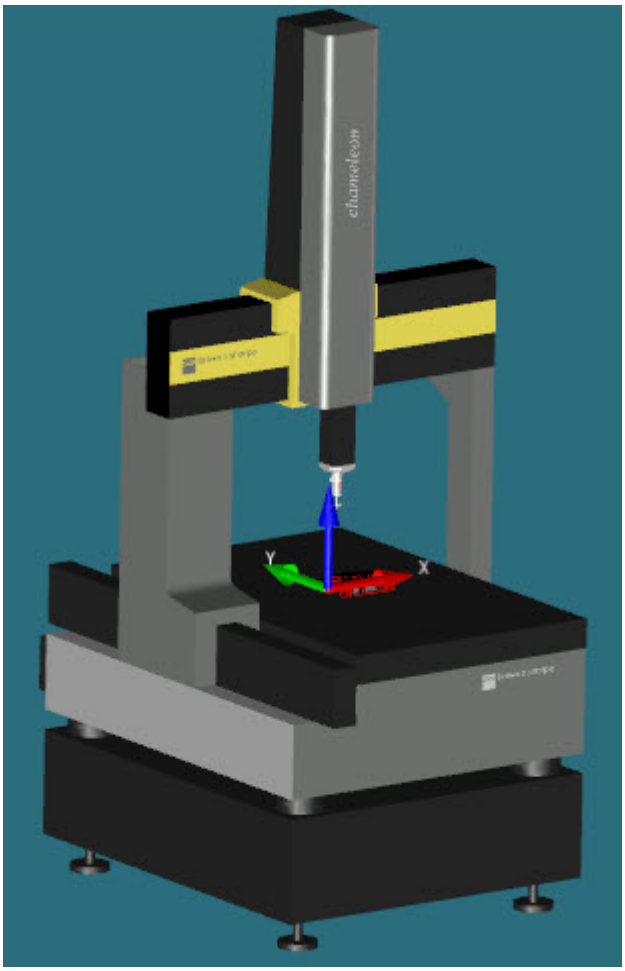
Defining Machines

If you use PC-DMIS in offline mode, the **Insert | Hardware Definition | Machine** menu option displays the **Load Virtual Machine** dialog box.



Load Virtual Machine Dialog Box

With this dialog box, you can select or create a virtual measuring machine or virtual table that is displayed and animated in the Graphic Display window along with the probe and part model.

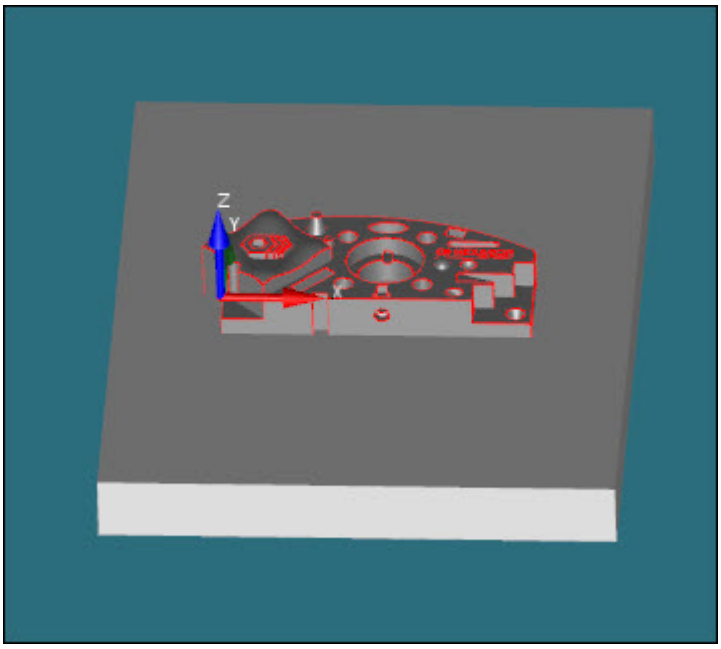


A sample virtual machine

If you import both a part model and a machine model into the Graphic Display window, and you don't have any outstanding manual machine offsets or rotations, PC-DMIS automatically positions the part model to the machine model's table.

If you have manual x,y,z, offsets or rotations from the **Part/Machine** tab of the **Setup Options** dialog box, you need to use that tab's **Auto Position** button to position the part model to the machine table. For more information on the **Auto Position** button, see the "Part Setup area" topic in the "Setting Your Preferences: Introduction" chapter.

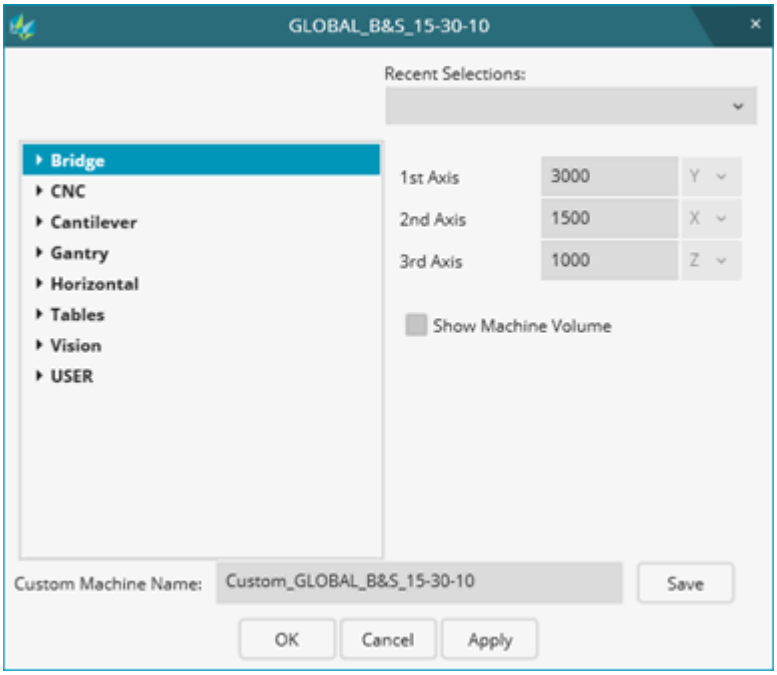
You may not want to show a full virtual machine and instead may only want to display a virtual table (or CMM baseplate). You can do this by choosing an option from the **Tables** category from the list of machines.



A sample virtual table

The virtual table comes from a list of tables defined in the tablesonly.dat file. You can modify the .dat file to contain tables that match what you need.

About the Load Virtual Machine Dialog Box



Load Virtual Machine Dialog Box

This dialog box is available only if you use PC-DMIS in offline mode.

List of machines - The expandable list on the left of the dialog box, shows the major categories of machines as well as virtual tables (in the **Tables** category).

When you expand a list, it shows the various machine brands. When you expand a brand, you can see the major machines available on the market for that brand. When you select a machine from this list, a preview of the machine appears in the Graphic Display window. PC-DMIS also creates an automatic custom name in the **Custom Machine Name** box for the machine in case you want to modify the machine's limits.

Recent Selections - This list contains the most recent (last five) machines that you selected with **OK** or **Apply**. This list remains across later versions of PC-DMIS. You can remove them from this list by resetting the product with the **Reset Product** button in the PC-DMIS Settings Editor.

1st, **2nd**, and **3rd** Axis - These boxes define the travel limits of the virtual machine. For more information, see "Additional Information on the Machine's Axes" below.

Show Machine Volume - This check box shows the machine's current volume as a green box. The green box appears when you click **OK** or **Apply**.

Custom Machine Name - This shows an automatic name you can use whenever you preview a machine. The name is the machine's name with a "Custom_" prefix. You can modify this to something different if needed.

Save - This saves the custom machine in a **USER** category of the list of machines. Custom machines are saved in the usermachine.dat file.

OK - This accepts the selected machine and any modifications and closes the dialog box. It inserts a `LOADMACHINE` command into the Edit window.

Apply - This does the same as **OK** except it does not close the dialog box.

Cancel - This closes the dialog box without accepting any changes.

Selecting or Creating a New Animated Machine for Display

If you use PC-DMIS in offline mode, you can use the **Load Virtual Machine** dialog box (**Insert | Hardware Definition | Machine**) to select or create a virtual machine or table to use in PC-DMIS's Graphic Display window.

Selecting an Existing Machine or Table

The **Load Virtual Machine** dialog box contains a list of machine and table models that you can add into the Graphic Display window. These are organized by type in an expandable / collapsible **Name** list.

To add a virtual machine:

1. From the list of machines, expand a category type to see the brands within that category.
2. Expand the desired brand name.
3. Select a machine to see a preview of the machine in the Graphic Display window.
4. Click **Apply** or **OK** to accept a machine and insert a `LOADMACHINE` command into the Edit window. This command also shows the machine's model into the Graphic Display window.

To add only a virtual table:

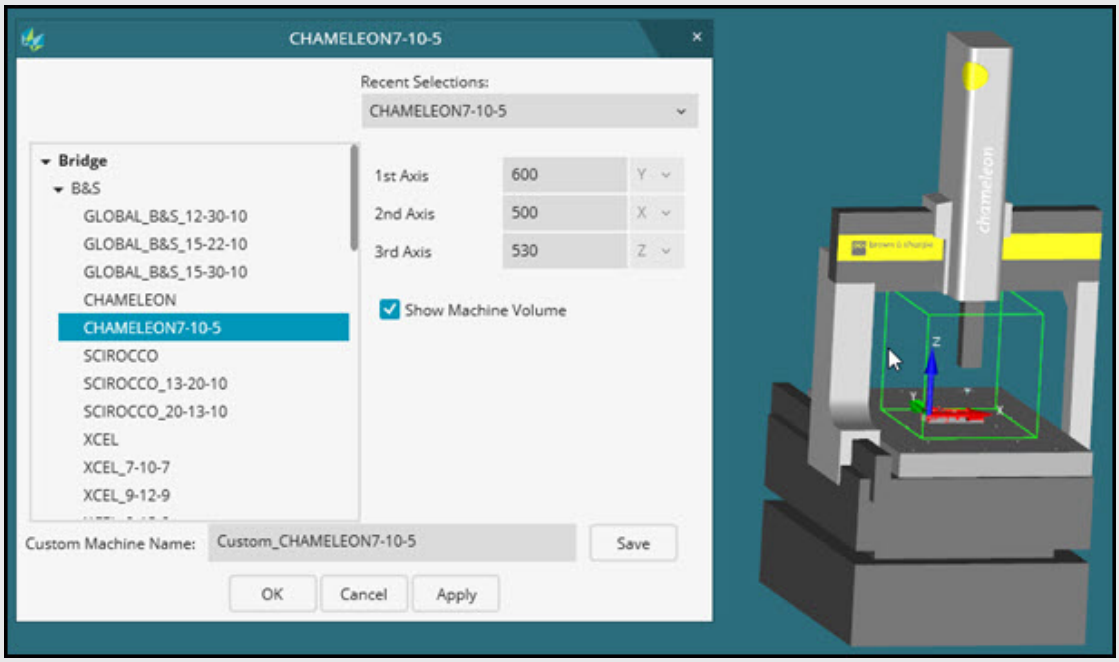
1. From the list of machines, expand the **Table** category.
2. Expand the **Size** list.
3. Choose a table to see a preview of the table in the Graphic Display window.
4. Click **Apply** or **OK** to accept a table and insert a `LOADMACHINE` command into the Edit window. This command also shows the table into the Graphic Display window.

Modifying and Saving a Custom Machine

You can change a machine's limits on the fly for any machine and store it as a custom machine.

1. From the list of machines, select an existing machine. PC-DMIS automatically shows a preview of the current machine. PC-DMIS also automatically creates a temporary custom machine name for you in the **Custom Machine Name** box. The custom name is the machine's name preceded by a "Custom_" prefix.
2. If you don't like the automatic name, type a new name for the machine. If you use spaces, the software converts them to underscore characters.
    - Specify the 1st axis by selecting X, Y, or Z from the **1st axis** list. Type the length of the machine's base in the **1st axis** box.
    - Specify the 2nd axis by selecting X, Y, or Z from the **2nd axis** list. Type the width of the machine's base in the **2nd axis** box.
    - Specify the 3rd axis by selecting X, Y, or Z from the **3rd axis** list. Type the height of the machine in the **3rd axis** box.
3. Click **Apply** to insert a `LOADMACHINE` command and a machine model in the Graphic Display window with those values. The "usermachine.dat" file is not actually modified until you click **Apply** or **OK**. If you click **Cancel** all changes are ignored.
4. If you want to save the customized machine, click **Save** to add the saved machine into the dialog box. PC-DMIS adds the machine under the **USER** category.

For example, suppose that you have a machine that's similar to another machine, but it has a smaller volume. You don't have to recreate the entire machine. Instead, you can modify the axis values of the similar machine to reflect your machine's volume for the current measurement routine. When you click **Apply**, PC-DMIS applies these changes internally to the `LOADMACHINE` command.



A Chameleon machine with a modified, smaller volume

You cannot edit the `LOADMACHINE` command in the Edit window. To make changes to the machine, press F9 on the **Load Virtual Machine** dialog box and make your changes there.

Additional Information on the Machine's Axes

The 1st axis defines the length of the machine's base in the direction that the bridge moves (for bridge machines), or the length of the base in the direction that the vertical carriage moves (for horizontal arm machines). This is usually the X axis for most horizontal arm machines, and either the X or the Y axis for most vertical arm machines.

The 2nd axis defines the width of the base in the direction that the carriage moves (for a bridge machine) or the direction the arm moves (for a horizontal arm machine). This is the vertical Z axis for most horizontal arm machines and either the X or the Y axis for most

vertical arm machines. This differs from the machine volume. The volume defines the distance the arm can reach. Most arm machines have a volume just over 50% of the width.

The 3rd axis defines the height of the machine from the top of the base to the bottom side of the bridge for a bridge machine, or the extent of the vertical axis for a horizontal arm machine. This is the vertical Z axis for most bridge machines and the Y axis for most horizontal arm machines. At this time only the following axis configurations are allowed:

- Generic Bridge with Y, X, Z or X, Y, Z
- Generic Arm with X, Y, Z

Additional Information for Creating Multiple Arm Machines

If you use PC-DMIS in offline mode, you can also create and place a simulated multiple-arm machine into the Graphic Display window.

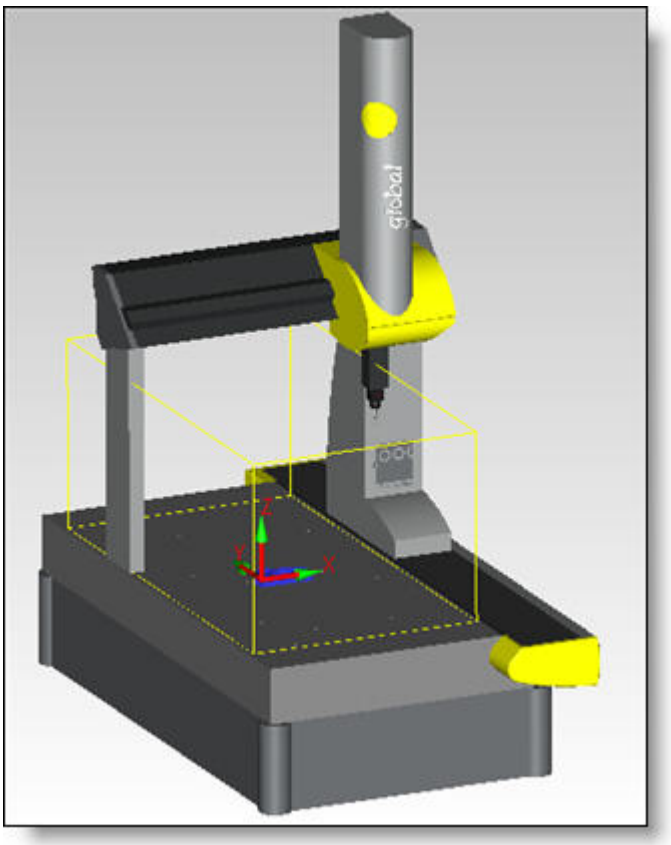
1. Follow PC-DMIS multiple-arm setup procedures.
2. Enter multiple arm mode. The **Active Arms** toolbar appears. This enables the **Dual Horizontal Arm** option from the **Machine Type** area.
3. Create a multiple arm measurement routine.
4. Follow the "Selecting or Creating a New Animated Machine for Display" procedure (make sure you select the **Dual Horizontal Arm** option button from the **Machine Type** area).
5. The Graphic Display window should now show a dual arm machine when finished.

Displaying Existing Animated Machines in the Graphic Display Window

If you use PC-DMIS in offline mode, you can display a representation of an animated measuring machine in the Graphic Display window. To do this, access the **Machine** dialog box (**Insert | Hardware Definitions | Machine**), and select a machine from the **Name** list.

PC-DMIS automatically displays the selected machine in the Graphic Display window along with the part's CAD model.

To display the machine's volume, click the **Show Machine Volume** check box, and click **Apply**. This draws a yellow cube on the machine's tabletop that represents the range of motion the probe can move to using that machine (see the example graphic below).



Sample machine and machine volume shown in the Graphic Display window

Click **OK** to accept the display of the machine.

PC-DMIS also inserts a `LOADMACHINE/NAME` command into the Edit window, where NAME is the machine's name.

If you import both a part model and a machine model into the Graphic Display window, and you don't have any outstanding manual machine offsets or rotations, PC-DMIS automatically positions the part model to the machine model's table.

If you have manual x,y,z, offsets or rotations from the **Part/Machine** tab of the **Setup Options** dialog box, you need to use that tab's **Auto Position** button to position the part model to the machine table. For more information on the **Auto Position** button, see the "Part Setup area" topic in the "Setting Your Preferences: Introduction" chapter.

Creating a Relationship between the Machine and the Part

You can create a relationship between the machine model and the CAD model by changing the XYZ offsets and rotations to establish the proper orientation between the two models. You can do this by using the **Quick Fixture Mode** to change the part's orientation

or by using the **Part/Machine** tab of the **Setup Options** dialog box. Or you can use a combination of the two approaches.

Using the Quick Fixture Mode

1. From the **Graphic Modes** toolbar, click **Quick Fixture Mode** ( ) to enter Quick Fixture Mode and display the **Quick Fixture** toolbar.
2. Use your mouse and the **Quick Fixture** toolbar to properly orient your part.
    - From the drop-down icon on the **Quick Fixture** toolbar, select **Level** ( ) to level your part to the machine model's table surface.
    - From the drop-down icon on the **Quick Fixture** toolbar, select **Drop** ( ) to set your part onto the machine model's table surface.
    - Right-click on the part model to rotate and move your part as needed.

When you then switch to a different mode, the part model remains fixed at its final position.

For more information on how to use this mode, see "Using Quick Fixture Mode" in the "Defining Hardware" chapter.

For information on the **Quick Fixture** toolbar, see "Quick Fixture Toolbar" in the "Using Toolbars: Introduction" chapter.

Using the Part/Machine Tab

1. Press F5 to access the **Setup Options** dialog box.
2. Select the **Part/Machine** tab.
3. In the **Part Setup** area, click the **Auto Position** button to have PC-DMIS automatically position your part model on the machine model's table surface.
4. If you want more direct control over placement of your part model, modify the items directly in the **Part Setup** area.

See "Setup Options Mode: Part / Machine tab" topic in the "Setting Your Preferences" chapter.

Removing the Animated Machine from the Graphic Display Window

1. Access the Edit window.
2. Place it in Summary Mode or Command Mode.

3. Delete the entire `LOADMACHINE` command. PC-DMIS removes the display of the machine.

Permanently Deleting an Animated Machine

1. Access the **Load Virtual Machine** dialog box (**Insert | Hardware Definition | Machine**).
2. Select the machine to delete from the **Machine Name** list.
3. Click the **Delete** button.
4. Click **Apply** or **OK**. PC-DMIS removes the machine from the **Machine Name** list and removes the display of the machine. This also deletes the machine from the "usermachine.dat" file.

The "usermachine.dat" file is not actually modified until you click **Apply** or **OK**. If you click **Cancel** all changes are ignored.

Editing the usermachine.dat Data File

The machines listed in the dialog box come from two .dat files:

- The file "machine.dat" contains the default machine descriptions supplied by the PC-DMIS developers.
- The file "usermachine.dat" contains the machine descriptions of any machines the user has created and saved.

If there is no "machine.dat" file, the list of machines only displays the **No Machine** item.

You can use the information in machine.dat as a model to manually create your own machines in the usermachine.dat file. For information on where these files are stored, see "Understanding Data Files" in the "Setting Your Preferences" chapter.

Definitions of the machine.dat and usermachine.dat Files

The machine.dat file controls the graphical and numerical representation of the default machines available in PC-DMIS. If you need a custom machine or machine system within PC-DMIS, you need to define it in the usermachine.dat file. The usermachine.dat file follows the same format, but it holds custom machines.

You need to strictly follow a specific format to define the machine.

This example describes the format and rules of the format with a list of the commands and their definitions.

```
ITEM:2000_20-12-18_ARM1 ARM
```

In the above code snippet, the following rules apply:

1. The first set of characters following the colon "**ITEM:**" is the name that appears in the **Load Virtual Machine** dialog box when you construct a machine setup (see the example dialog box image below). This is a unique name of your choice to identify the machine configuration.

   You can find details in the **Format of the Machine or Machine System ITEM** section below.

2. The second set of characters, "**ARM**" in the above example, defines the type of machine connection.

The following information lists and defines the machine builder commands:

```
ITEM:<machine name>
```

Specifies the machine name displayed in the **Load Virtual Machine** dialog box in PC-DMIS.

```
ITEM <connection type>
```

Defines the type of connection. The `ARM` connection type is used in the above example. This doesn't mean much in the case of a machine start, however.

```
cadgeom n1 n2 n3 n4 n5 n6 n7 n8 n9 n10 n11 n12 n13
<draw_file_name.draw>
```

Defines the position and rotation of the layers within the DRAW file:

```
n1 n2 n3
```

The X Y Z coordinate location from the origin of 0,0,0.

```
n4 n5 n6
```

The I J K vector for the X+ side of the layer.

```
n7 n8 n9
```

The I J K vector for the Y+ side of the layer.

```
n10 n11 n12
```

The I J K vector for the Z+ side of the layer.

```
n13
```

The layer to display. All previous "n" values are applied to this layer.

```
draw_file_name.draw
```

The DRAW file that the software uses to get the layer data. This file is located in the "models\cmm" sub-folder in the PC-DMIS install directory.

```
tablecenter n1 n2 n3 n4 n5 n6
```

Defines the position of the machine table within the DRAW file:

```
n1 n2 n3
```

The distance of the center (XYZ) of the plate from the origin of the DRAW file.

```
n4 n5 n6
```

The I J K vector of the plate.

```
<joint type> n1 n2 n3 n4 n5 n6 n7 n8 n9 n10 <joint name>
```

Defines the type of joint used within the DRAW file:

```
<joint type>
```

The type of joint used. The options are "autojoint", "linearjoint", and "manualjoint".

```
n1 n2 n3
```

The X Y Z coordinate location from the origin 0,0,0.

```
n4 n5 n6
```

The I J K vector.

```
n7 n8
```

The angular offset value (`n7`) and the increment value (`n8`). These are mainly used for autojoint configurations and are typically set to 0 0 in most other configurations.

```
autojoint 244.147 -151.141 -586 0 0 1 0 0.01 -360 360 w axis
```

The example shows that the configuration starts at 0 (`n7`) and rotates in 0.01 (`n8`) degree increments.

```
n9 n10
```

The minus and plus motion for the defined axis. The first number (`n9`) is always a negative value or zero while the second number (`n10`) is always a positive number or zero.

```
<joint name>
```

A unique user-defined name for the joint for each ITEM definition. You can use space characters in the joint name.

```
connect n1 n2 n3 n4 n5 n6 <probe connection type> <joint type>
```

The machine position in relation to the last linear joint at which the probe connects:

```
n1 n2 n3
```

The X Y Z coordinate location of the probe connection from the last linear joint position.

```
n4 n5 n6
```

The I J K vector for the probe connection.

```
<probe connection type>
```

The machine-to-probe connection type. This is typically defined as `ARM` .

`connectprev <command command_args>`
The number of joints to back up to in a machine configuration. The limit is three.

`connectprev` - Back up to the first previous joint.

`connectprevprev` - Back up to the second previous joint.

`connectprevprevprev` - Back up to the third previous joint.

`<command command_args>` - The command related to the joint type and its arguments.

```
ITEM:GLOBAL_DEA_7-7-5_ROTAB ARM
cadgeom 0 0 0 1 0 0 0 1 0 0 0 1 1 global_DEA_7-7-5.draw
autojoint 0 0 0 0 1 0 0 0 -700 0 y axis
cadgeom 0 0 0 0 1 0 1 0 0 0 1 0 2 global_DEA_7-7-5.draw
autojoint 0 0 0 -1 0 0 0 0 0 700 x axis
cadgeom 0 0 0 0 1 0 0 0 1 1 0 0 3 global_DEA_7-7-5.draw
autojoint 0 0 0 0 1 0 0 0 -500 0 z axis
cadgeom 0 0 0 0 -1 0 1 0 0 0 0 1 4 global_DEA_7-7-5.draw
connect 0 0 0 0 0 1 ARM
connectprevprevprev autojoint 244.147 -151.141 -586 0 0 1 0
0.01 -360 360 w axis
cylinder 0 0 0 0 0 25 500
tablecenter 0.0 0.0 25.0 0 0 1
```

Format of the Machine or Machine System ITEM

Each new machine configuration defined in PC-DMIS is added to the machine.dat file. It begins with the "**ITEM:**" command. This command contains a distinct and descriptive name and a connection identifier. This identifier specifies the type of object it can be connected to as described above. Below, you can see the available connection identifiers with a brief description.

To define a probe configuration, you must work with a top-down approach. This means that your initial starting point is x=0, y=0, z=0, and everything is drawn from that point down. Consequently, all z values should have a negative value. Also, for most items, the 0, 0, 0 location is the center of the item. This makes it possible to have both positive and negative numbers in both the X and Y directions. Positive X always moves from left to right initially, and positive Y always moves from front to back as if you were looking FROM the positive Z direction.

The only command that defines an active configuration is "**connect**". You must have this command in your configuration. The "**connect**" command defines any location where another item can be added to the current item. Each connection must include a Connection Type identifier to define the type of connection the machine can take. This is typically an Arm connection type.

The commands that can change the coordinate system of the configuration are "**linearjoint**" and "**autojoint**". Take special care when you use either of these commands because each command transfers the origin of the configuration to the center of the joint. Keep in mind that the first "joint" command changes the axes of the coordinate system. What was the -Z direction now becomes the +X direction, and what was the +X direction now becomes the +Z direction. Y remains the same. These commands are usually used in pairs. The joints control the motion of the machine's components.

Connection Identifier Listing

ARM - This connection type specifies that the connection occurs directly to the machine arm. Although there are many possible connection types, PC-DMIS uses the ARM connection type in almost all machine configurations.

This is a typical Machine Code example:

```
ITEM:2000_20-12-18_ARM1 ARM
cadgeom 0 0 0 1 0 0 0 1 0 0 0 1 1 2000_20-12-18.draw
tablecenter 1345 1200 -2112 0 0 1
linearjoint 0 0 0 1 0 0 0 0 0 2690 x axis
cadgeom 0 0 0 1 0 0 0 0 1 1 0 0 2 2000_20-12-18.draw
linearjoint 0 0 0 -1 0 0 0 0 -1800 0 z axis
cadgeom 0 0 0 1 0 0 1 0 0 0 0 1 3 2000_20-12-18.draw
linearjoint 0 0 0 0 1 0 0 0 0 1200 y axis
cadgeom 0 0 0 0 1 0 1 0 0 0 1 0 4 2000_20-12-18.draw
connect 0 0 0 0 0 -1 ARM
```

Editing the tablesonly.dat File

The default tables are created and stored in a text file named tablesonly.dat. You can use the information in that file to create your own tables. For information on where this file is stored, see "Understanding Data Files" in the "Setting Your Preferences" chapter.

To edit tablesonly.dat, open it in a text editor and modify the data.

This example shows three tables. The first table has a width of 300 mm, a length of 200 mm, and a height of 50 mm.

```
[Tables]

Count=3

1=300,200,50

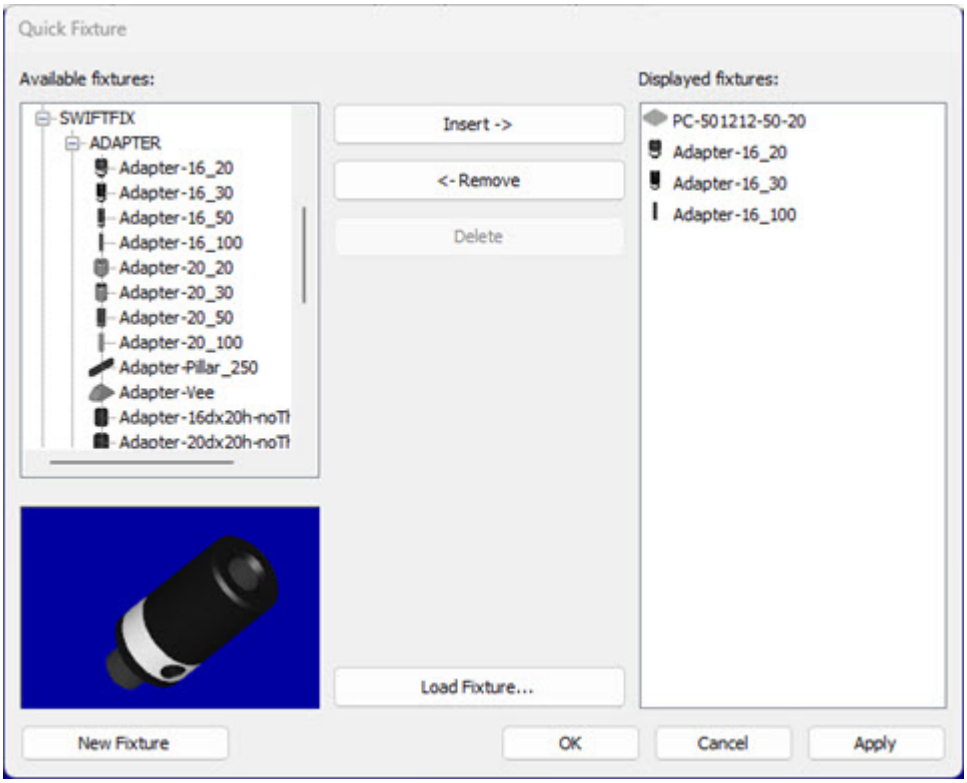
2=400,500,50

3=500,500,75
```

If you want to just have one table that matches your actual machine's dimensions, you can set `Count=1` , delete all but the first table, and then type your table's dimensions.

Inserting Quick Fixtures

Select **Insert | Hardware Definition | Quick Fixture** to display the **Quick Fixture** dialog box. You can use this dialog box to insert predefined or custom fixtures into the Graphic Display window.



Quick Fixture Dialog Box

This dialog box contains these options:

Available fixtures - Displays the fixtures that you can import into the Graphic Display window. These fixtures are stored in the "Models\QuickFix\" subfolder in the PC-DMIS installation directory. When you select a fixture, PC-DMIS displays a preview of the fixture in the preview pane below the list.

Displayed fixtures - Displays fixtures currently shown in the Graphic Display window. To reposition fixtures in the Graphic Display window, see "Using Quick Fixture Mode".

Insert - Moves the selected fixture from the **Available fixtures** list to the **Displayed fixtures** list, allowing the fixture to appear in the Graphic Display window.

Remove - Removes the selected fixture from the **Displayed fixtures** list.

Delete - After you add a custom fixture using the **New Fixture** option, a **User** section appears in the **Available fixtures** list. The **Delete** button is available when you select one of these custom fixtures from the **User** section. Click **Delete** to permanently remove the selected fixture from the list and the userquickfix.dat file.

Load Fixture - Loads a previously saved quick fixture (as a .qfxt extension) into the Graphic Display window. In the **Open** dialog box, select the fixture to load and click **Open**. The **Quick Fixture** dialog box displays the loaded fixture in the **Displayed fixtures** area. You can load only one .qfxt file for each measurement routine.

New fixture - Opens the **Open** dialog box, where you can browse to and select a fixture file. Click **Open** to add the selected file to the **Available fixtures** list. You can add any supported fixture file.

OK - Applies the current changes and closes the dialog box.

Apply - Applies the current changes without closing the dialog box.

When you select one or more Quick Fixture components in the **Quick Fixture** dialog box, the selected components are highlighted in red in the Graphic Display window.

In PC-DMIS Offline mode, if an animated machine has been added to the measurement routine, PC-DMIS inserts the new Quick Fixture components at the -X, -Y, -Z corner of the machine's work volume. Otherwise, PC-DMIS adds them at the origin.

Inserting and Removing Quick Fixtures

To insert a quick fixture into the Graphic Display window, follow these steps:

1. Select **Insert | Hardware Definition | Quick Fixture** to open the **Quick Fixture** dialog box.
2. Select the fixture that you want to add from the **Available fixtures** list. PC-DMIS displays a preview of the fixture in the preview pane.
3. Click **Insert**. The fixture name appears in the **Displayed fixtures** list, and the fixture model appears in the Graphic Display window.

   If an animated machine has been added to the measurement routine, PC-DMIS inserts the new Quick Fixture components at the -X, -Y, -Z corner of the machine work volume. Otherwise, PC-DMIS inserts them at the origin.

4. Click **OK**.

- If the machine table is empty, importing a base plate or CAD model automatically places it at the center of the table.
- If you insert a base plate before importing a CAD model, PC-DMIS places the CAD model at the center of the base plate.
- When you insert multiple fixtures, make sure they do not overlap.

To remove a quick fixture from the Graphic Display window, follow these steps:

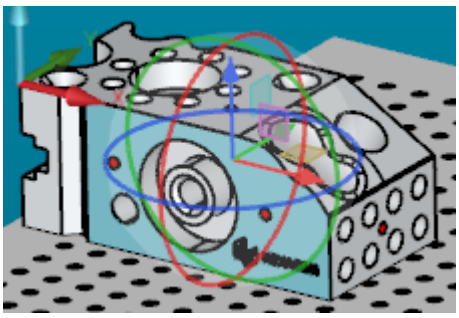
1. Select **Insert | Hardware Definition | Quick Fixture** to open the **Quick Fixture** dialog box.
2. Select one or more fixtures from the **Displayed fixtures** list. PC-DMIS highlights the selected fixtures in red in the Graphic Display window.
3. Click **Remove**. PC-DMIS removes the selected fixtures from the **Displayed fixtures** list and the Graphic Display window.
4. Click **OK**.

To reposition quick fixtures, see "Using Quick Fixture Mode".

Using Quick Fixture Mode

In **Quick Fixture Mode**, you can move, rotate, align, and attach fixture and CAD models in the Graphic Display window by using the Quick Fixture gizmo. To enter this mode, click the **Quick Fixture Mode** icon ( ) on the **Graphic Modes** toolbar.

When you select a fixture or CAD model, the Quick Fixture gizmo appears at the center of the selected object. The gizmo contains three axis arrows, three plane handles, and three rotation rings that you can use to move and rotate the selected object.



Quick Fixture gizmo

When you double-click a gizmo handle, the operation is based on the currently highlighted element.

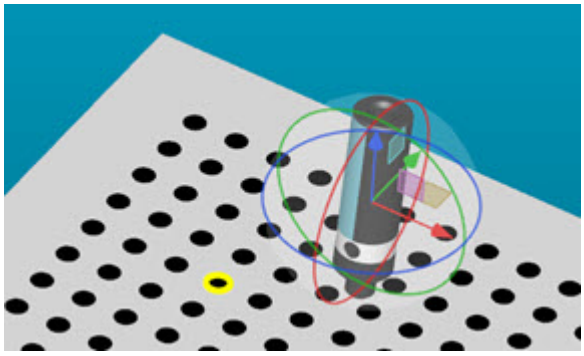
- If you highlight a rotation ring, the corresponding rotation operation (Level or Square) takes priority, even if the pointer is over an underlying axis.
- If you highlight a handle, the corresponding plane operation takes priority, even if it overlaps a single-axis handle.
- PC-DMIS uses the same hover-priority behavior for drag and double-click operations.

Attaching Fixtures

You can attach a fixture to a circle feature on another fixture or on the CAD model.

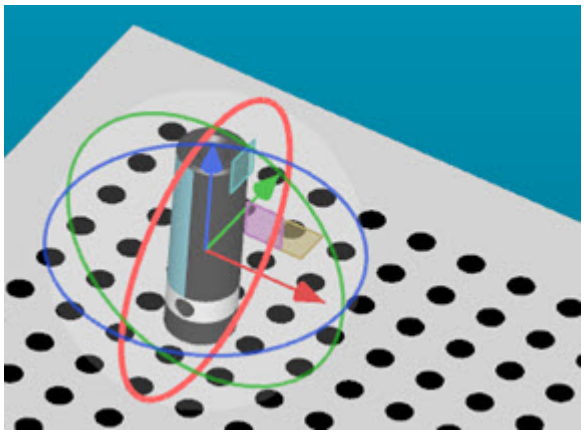
To attach a fixture:

1. Select a fixture.
2. Press and hold **Shift**.
3. Hover over the target circle until it is highlighted in yellow.



Example showing the selected fixture and highlighted circle.

4. Click the highlighted circle.



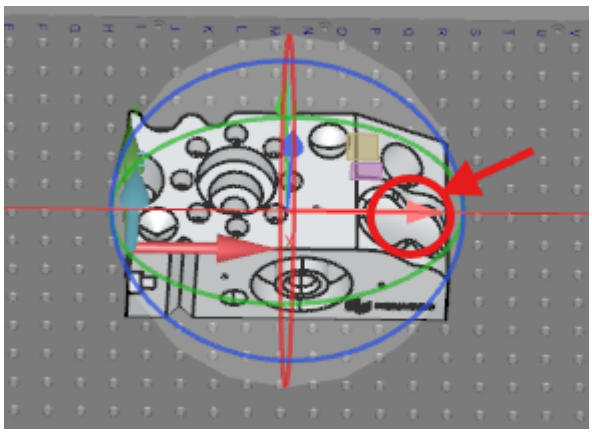
Example of a repositioned fixture attached to a circle feature.

PC-DMIS inserts the selected fixture into the hole.

Moving Objects

Move Along an Axis

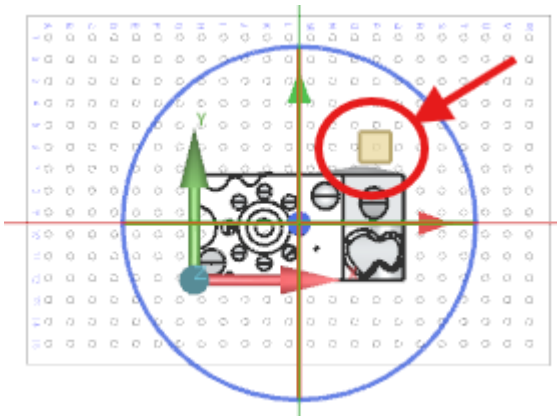
1. Select the fixture or CAD model.
2. Hover over an axis arrow until it is highlighted.



3. Click and drag the highlighted arrow to move the selected object along that axis.

Move Within a Plane

1. Select the fixture or CAD model.
2. Hover over a plane handle until it is highlighted.

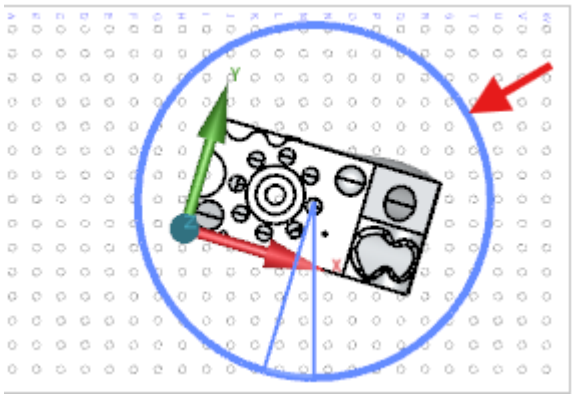


3. Click and drag the highlighted plane handle to move the selected object within the corresponding plane.

Rotating Objects

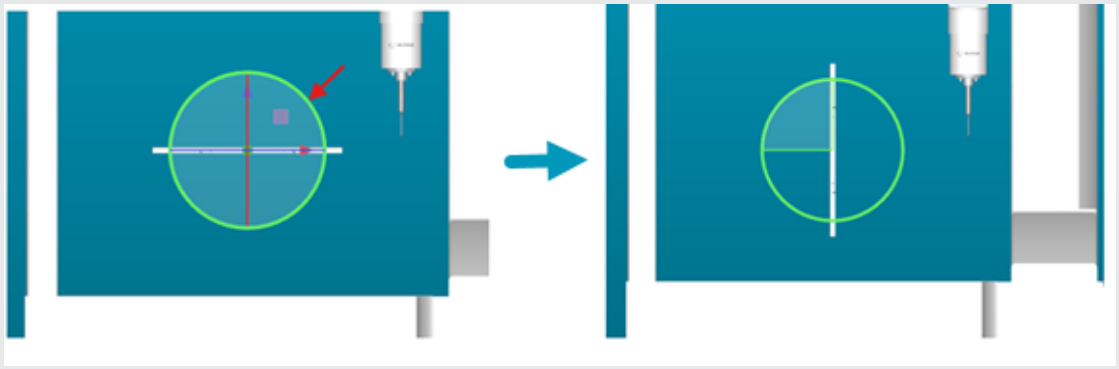
Rotate About an Axis

1. Select the fixture or CAD model.
2. Hover over a rotation ring until it is highlighted.



3. Click and drag the highlighted ring to rotate the selected object about the corresponding axis.

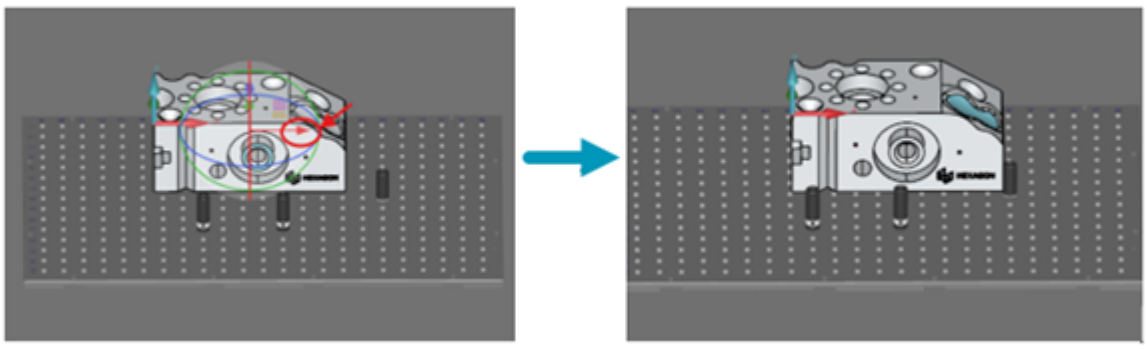
While dragging a rotation ring, press and hold **Shift** to snap the rotation to the nearest 90-degree position.



Dropping Objects

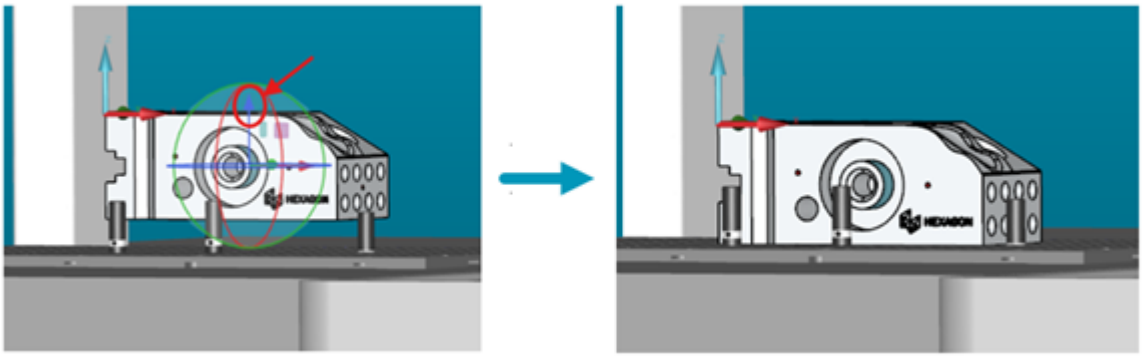
Drop Along an Axis in the Positive Direction

1. Select the fixture or CAD model.
2. Double-click an axis arrow to move the selected object in the positive direction until it contacts the nearest object.



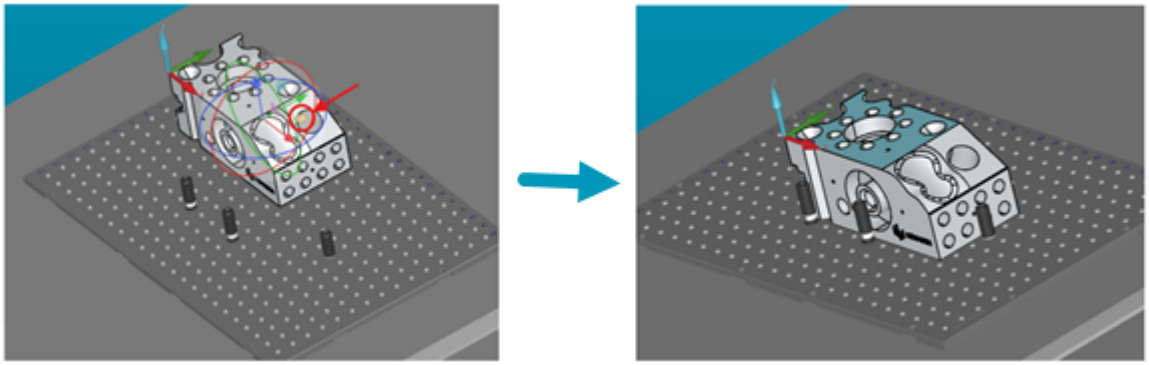
Drop Along an Axis in the Negative Direction

1. Select the fixture or CAD model.
2. Press and hold **Ctrl**, and then double-click an axis arrow to move the selected object in the negative direction until it contacts the nearest object.



Corner Drop

1. Select the fixture or CAD model.
2. Double-click a plane handle to move the selected object simultaneously along all three axes until it contacts the nearest object on each axis.



Corner drop uses the following collision detection logic:

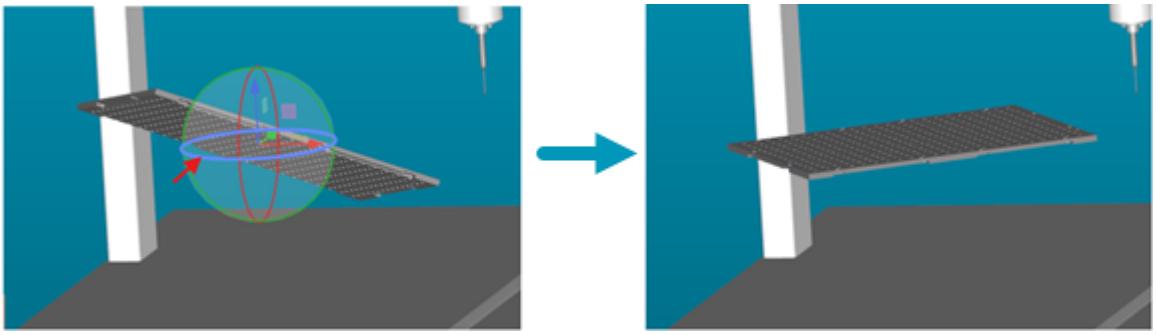
- For each axis, PC-DMIS first checks for collisions in both the positive and negative directions without moving the object.
- If collisions are detected in both directions, PC-DMIS moves the object toward the nearest collision.
- If a collision is detected in only one direction, PC-DMIS moves the object in that direction.
- If no collision is detected, PC-DMIS does not move the object along that axis.
- PC-DMIS processes each axis independently and sequentially.

Aligning Objects

Level

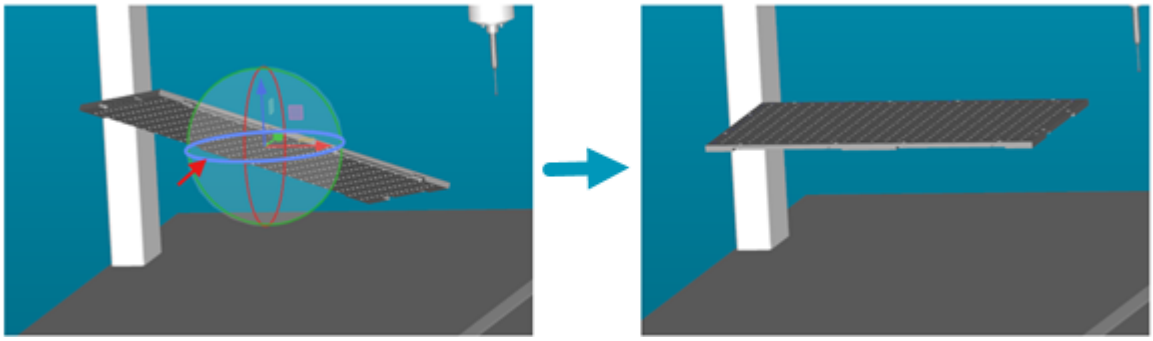
1. Select the fixture or CAD model.

2. Double-click a rotation ring to align the selected object's surface normal with the machine coordinate system.



Square

1. Select the fixture or CAD model.
2. Press and hold **Ctrl**, and then double-click a rotation ring to align the selected object's axes with the CAD coordinate system shown by the trihedron.



Adding Custom Fixtures

To add a custom fixture to the **Available fixtures** list:

1. Open the **Quick Fixture** dialog box (**Insert | Hardware Definition | Quick Fixture**).
2. Click **New Fixture**. In the **Open** dialog box, browse to and select a fixture model in a supported graphical format, and then click **Open**.
3. PC-DMIS adds the fixture to the **User** section of the **Available fixtures** list and is available for use in the current and future measurement routines.

Using Quick Fixtures Files

Using .DRAW Files

PC-DMIS stores quick fixture files with a .DRAW filename extension in the "Models\QuickFix\" sub-folder where you installed PC-DMIS.

In addition, PC-DMIS stores a definition of each quick fixture in a special data file (.dat filename extension) located in the directory where you installed PC-DMIS.

- If the quick fixture was originally shipped with PC-DMIS, it is stored in the *QuickFix.dat* file.
- If the quick fixture is a user-created fixture, its definition is stored in the *UserQuickFix.dat* file.

A typical quick fixture data file consists of two lines for each quick fixture, an **ITEM:** line and a **cadgeom** line. In a text editor, this file might look something like this:

```
ITEM:R20-501-SO RAYCO-STANDOFF
cadgeom 0 0 0 1 0 0 0 1 0 0 0 1 0 R20-501-SO.draw
ITEM:R20-5050-SO RAYCO-STANDOFF
cadgeom 0 0 0 1 0 0 0 1 0 0 0 1 0 R20-5050-SO.draw
ITEM:R20-7550-SO RAYCO-STANDOFF
cadgeom 0 0 0 1 0 0 0 1 0 0 0 1 0 R20-7550-SO.draw
ITEM:Adapter-16dx20h-noThread SWIFTFIX-ADAPTER
cadgeom 0 0 0 1 0 0 0 1 0 0 0 1 0 Adapter-16dx20h-noThread.draw
ITEM:Adapter-20dx20h-noThread SWIFTFIX-ADAPTER
cadgeom 0 0 0 1 0 0 0 1 0 0 0 1 0 Adapter-20dx20h-noThread.draw
ITEM:Adapter-16dx20h-withPin SWIFTFIX-ADAPTER
cadgeom 0 0 0 1 0 0 0 1 0 0 0 1 0 Adapter-16dx20h-withPin.draw
ITEM:Adapter-20dx20h-withPin SWIFTFIX-ADAPTER
cadgeom 0 0 0 1 0 0 0 1 0 0 0 1 0 Adapter-20dx20h-withPin.draw
ITEM:Adapter-Joint SWIFTFIX-ADAPTER
cadgeom 0 0 0 1 0 0 0 1 0 0 0 1 0 Adapter-Joint.draw
```

A sample QuickFix.Dat file.

To Use Custom Quick Fixture .DRAW Files from a Previous Installation

1. Close down PC-DMIS and open Windows Explorer.
2. Before you create new custom fixtures for your new installation, copy the .DRAW files from the "Models\QuickFix\" sub-folder of your previous installation, and paste them into the "Models\QuickFix\" sub-folder of your current PC-DMIS installation.
3. Copy the userquickfix.dat file from the directory of your previous installation, and paste it into the directory of your current PC-DMIS installation.
4. Restart PC-DMIS. The custom quick fixtures will appear in the **Quick Fixture** dialog box along with the fixtures supplied by your current PC-DMIS installation.

The .DRAW quick fixture files will not appear inside of the **Quick Fixture** dialog box unless the *userquickfix.dat* file contains the necessary definitions for the file. These definitions get added whenever you import your own custom IGES files as quick fixtures using the **Quick Fixture** dialog box. For information, see "Adding Custom Fixtures".

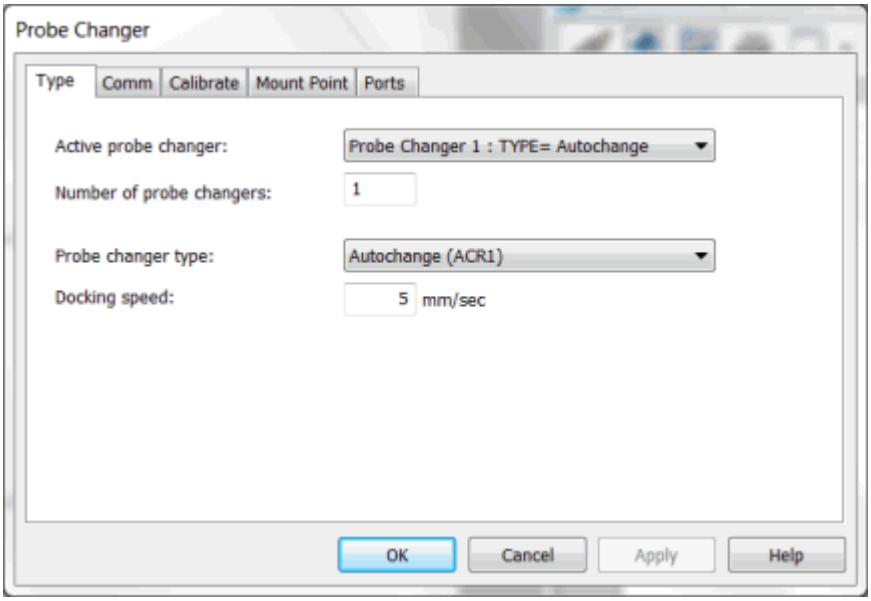
If you want to directly use the .DRAW files created by another user, but you don't want to overwrite your own quick fixtures by copying the other user's data file, you would need to use a text editor to merge the necessary **ITEM:** and **cadgeom** lines from the other user's data file into your data file.

Using .QFXT Files

You can also save and load fixture files as .QFXT files by using the **Save QuickFixture file** and **Load QuickFixture file** buttons on the **Quick Fixture** toolbar. For more information, see "Quick Fixture Toolbar".

Defining Probe Changers

Before you can begin to use your probe changer, you must select it in PC-DMIS, define its port locations, and set the options that you can use on it. To perform these tasks, select **Edit | Preferences | Probe Changer**. The **Probe Changer** dialog box opens:



Probe Changer Dialog Box

Initially, the **Probe Changer** dialog box displays only the **Type** tab. Some or all of the following tabs become available after you select your probe changer and click **Apply**:

Type - Use this tab to select and define the type of probe changer for your system.

Comm - Use this tab to define the serial port to use with the probe changer.

Calibrate - Use this tab to select the active tip to calibrate.

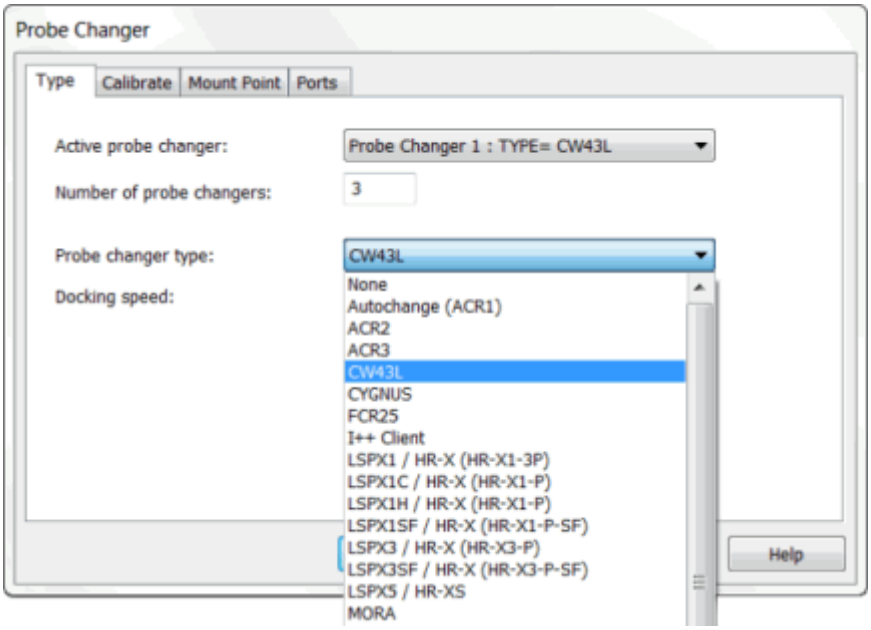
Mount Point - Use this tab to change the probe head wrist angle values and define a safe move location for the CMM to move to after each measurement cycle.

Ports - Use this tab to define the probe or stylus configuration for existing ports in the probe changer rack.

PC-DMIS supports various probe changer hardware, and terms are used by their respective manufacturers. "Slot", "port", and "garage" are used interchangeably. They all mean the location that holds the probe configuration.

Type Tab

Before you can begin the calibration process, you must select and define the type of probe changer for your system on the **Type** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**).



Probe Changer Dialog Box - Type Tab

Active probe changer

The **Active probe changer** list contains numbered items (Probe Changer 1, Probe Changer 2, Probe Changer 3, and other items) to which you can assign a probe changer and its values. The number of items that appears in the list depends on the value in the **Number of probe changers** box. Initially, PC-DMIS usually displays only Probe Changer 1. To add additional items to the list, increase the value in the **Number of probe changers** box.

PC-DMIS stores the probe changer type that you selected in the **Probe changer type** list, plus any other values, for the numbered item in the **Active probe changer** list.

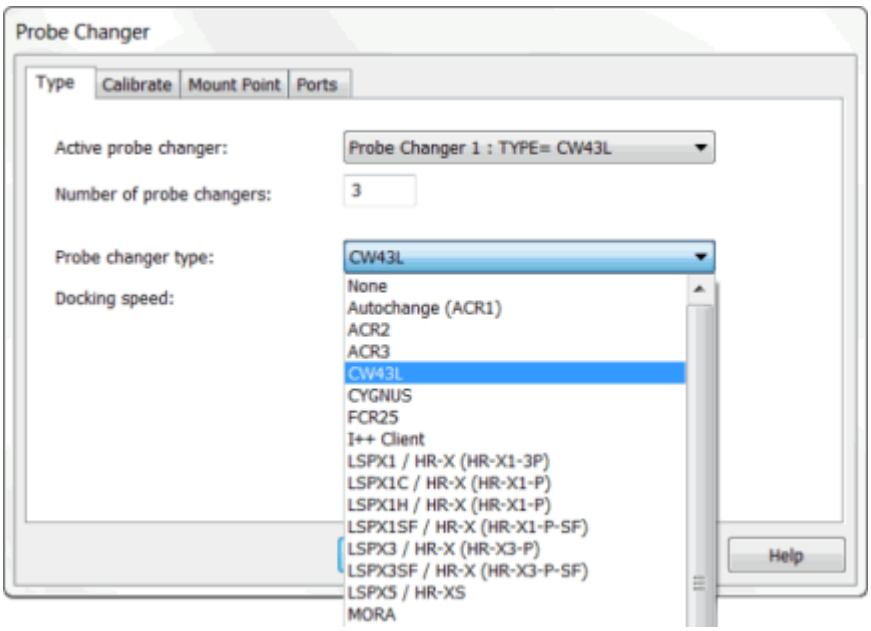
Number of probe changers

Type the number of different types of probe changers in the **Number of probe changers** box. The number that you enter becomes the number of available probe changers in the **Active probe changer** list.

If you type a smaller value in the **Number of probe changers** box, PC-DMIS removes all the probe changers after the probe changer in the new value position. If any of the probe changers to be removed have their type set, PC-DMIS prompts you to confirm their removal.

Probe changer type

The **Probe changer type** list contains the various probe changer types. For example:



CW43L Probe Changer Type

To select a probe changer:

1. Select the probe changer in the **Probe changer type** list.
2. Click **Apply** to make this probe changer active and load settings that apply to this probe changer.

Docking speed

You can change the docking speed to fine-tune the operation of the probe change cycle. To set the docking speed, type a new percentage value in the **Docking speed** box. The default value of 5% is appropriate for most machine configurations.

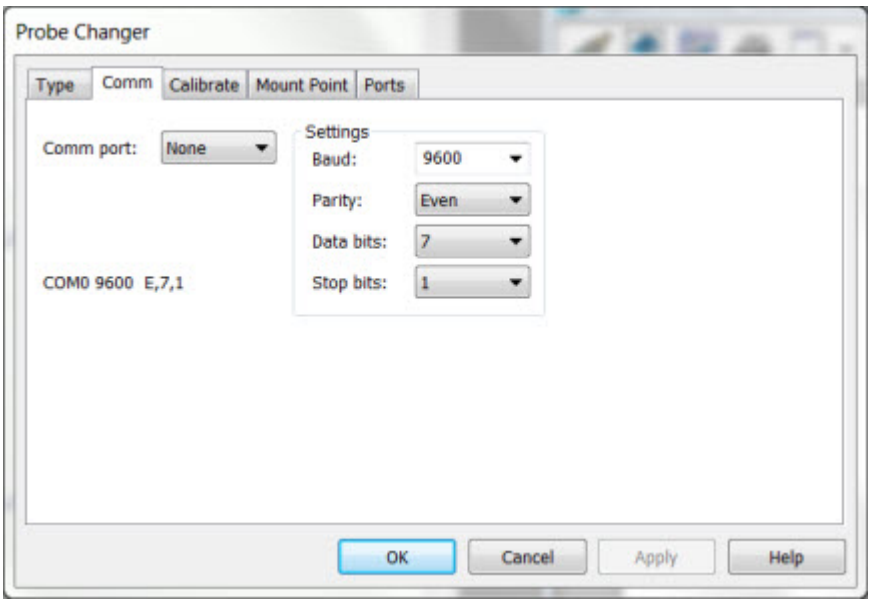
> The docking speed may not be available for some types of probe changers. The controller manages the probe change cycle when the **Docking speed** option is not available. For example, the controller manages the probe change cycle for the LSPX5, and other LSPX probe types. For these probe types, the controller controls the slow docking speed, and you cannot change it.

Apply button

To save your changes, click **Apply**.

Comm Tab

Some types of probe changers have a serial connection to the computer. Use the **Comm** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**) to choose your communications port (COM port) and modify your COM port settings. For information on your COM port settings, check the documentation that came with your computer hardware.

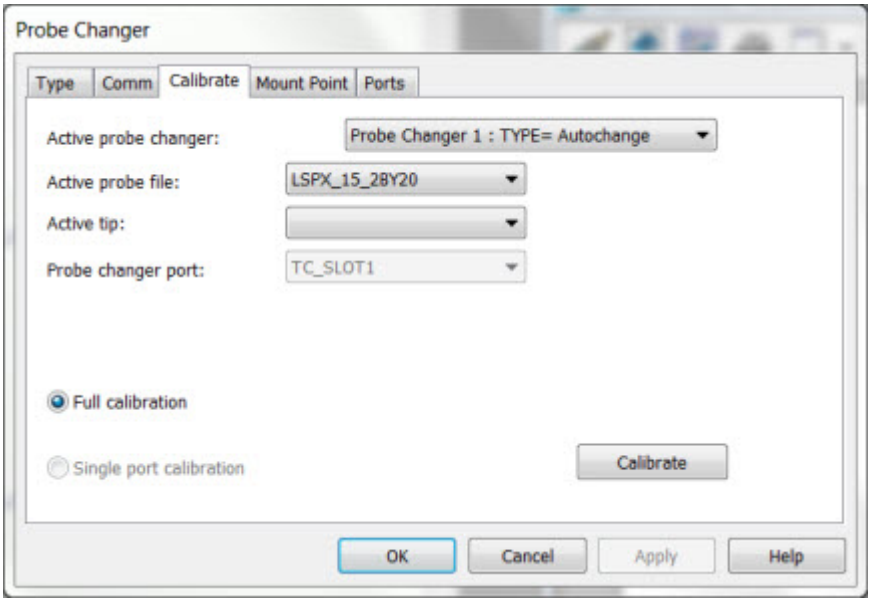


Probe Changer Dialog Box - Comm Tab

The **Comm** tab does appear if your probe changer does not have a serial connection.

Calibrate Tab

To open the **Calibrate** tab in the **Probe Changer** dialog box, select **Edit | Preferences | Probe Changer**.



Probe Changer Dialog Box - Calibrate Tab

Before you begin the calibration process, consider the following:

- You must choose the probe changer type from the **Type** tab.
- Before you start this process, verify that the stylus has been calibrated. For more information, see "Defining Probes" in the "Defining Hardware" chapter.

- The rack should be squared to one of the CMM's axes.

Generally, you should physically align probe changers along one of the machine’s axis. However, for the TP20, TP200, and SP600 Probe Changers, this isn't required. For these probe changers, the rack still needs to be level, but you can now rotate it so that the length of the rack is no longer aligned along a machine axis.

Active probe changer

From this list, select the probe changer to calibrate. For more information, see "Type Tab".

Active probe file

From this list, select a probe to use for the calibration process.

Active tip

From this list, choose a tip configuration for the probe that you selected.

Probe changer port

This list works in conjunction with the **Single port calibration** option. It enables you to choose a single port to calibrate. These dialog box items remain unavailable for selection until you define a probe changer that supports calibrating an individual port.

Full calibration

If you select the **Full Calibration** option, PC-DMIS measures the entire probe changer. This is the most often used method of calibration, and for some it is the only method that is available. It is recommended that the operator use the full calibration method.

Partial calibration

This option only calibrates a portion of the probe changer. This option only appears for the changer types that support it.

Single port calibration

Some probe changers, such as the ACR1, enable you to measure only a single port after a successful full calibration. The **Single port calibration** option only appears for the changer types that support it.

Calibrate Button

Before you can use your probe changer, you must define the changer's port locations through the appropriate probe changer calibration procedure. The following topics discuss the calibration processes for several probe changers. If you have a probe changer type that is different from the ones discussed, use the calibration process for the FCR25 Probe Changer as a guide. It should be similar enough for all supported types.

Calibrating the FCR25 Probe Changer

The calibration process for the Renishaw FCR25 Probe Changer represents the steps that you would take to prepare to use any of the probe changers that PC-DMIS supports. The process discussed here is specific to the FCR25 Probe Changer.

Two inserts are used with the FCR25 rack to accommodate different probe types: PA25-SH and PA25-20.

PA25-SH and PA25-20 Inserts

For example, the following image of an FCR25 Probe Changer shows three ports: two with inserts and one without (probes are also shown). The left port shows a PA25-SH insert, and the right port shows a PA25-20 insert. The middle port does not have an insert.

FCR25 Probe Changer inserts and probe types

> The FCR25 Probe Changer must be mounted on the machine table parallel to either the X or Y axis for successful calibration. The FCR25 Probe Changer can be mounted to your table with the MRS rack or the three and six port stand-alone racks. For mounting instructions, consult the documentation that came with your probe changer.

To calibrate your probe changer:

Step 1 - Select the FCR25 Probe Changer

To select the FCR25 Probe Changer:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **FCR25**.
3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.
4. In the **Active probe changer** list, select the item that represents the probe changer you are defining. If this is the first probe changer, it appears as **Probe Changer 1 : TYPE=None**.
5. In the **Number of probe changers** box, type the number of different types of probe changers.
6. In the **Docking speed** box, type a value. A value between 15-20% is appropriate for this machine configuration. You can adjust this value at any time to speed up or slow down the system.

   To avoid equipment damage due to excessive docking speed, gradually increase the **Docking speed** value.

7. Click **Apply** to apply any changes made for this probe changer, and then click **OK** to close the dialog box.

For details on controller configuration settings, see the documentation that came with your controller.

In the next step, you define the location your probe body moves to when you use the probe changer to switch probe components.

Step 2 - Define the Mount Point

The mount point for the FCR25 Probe Changer is the location in front of your probe changer where the machine moves to before it picks up or drops off a probe. You should determine a location that avoids collisions with the probe changer or part.

To define the mount point for your probe changer:

1. Select the **Mount Point** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**).
2. In the **Active probe changer** list, select **TYPE=FCR25**.
3. If necessary, alter the probe head wrist angle for both **A angle** and **B angle**. Typically, but not always, these values are 0 and 0, respectively. You need to use a

calibrated probe rotation that ensures the probe has the ability to move in and out of the probe rack during the necessary steps of the probe rack calibration procedure.

4. Use your jog box to manually move your machine to the desired mount point position.
5. Click the **Read Machine** button to populate the **X**, **Y**, and **Z** machine position values with the current position. You can also manually type these values.
6. To save your changes, click **Apply**.

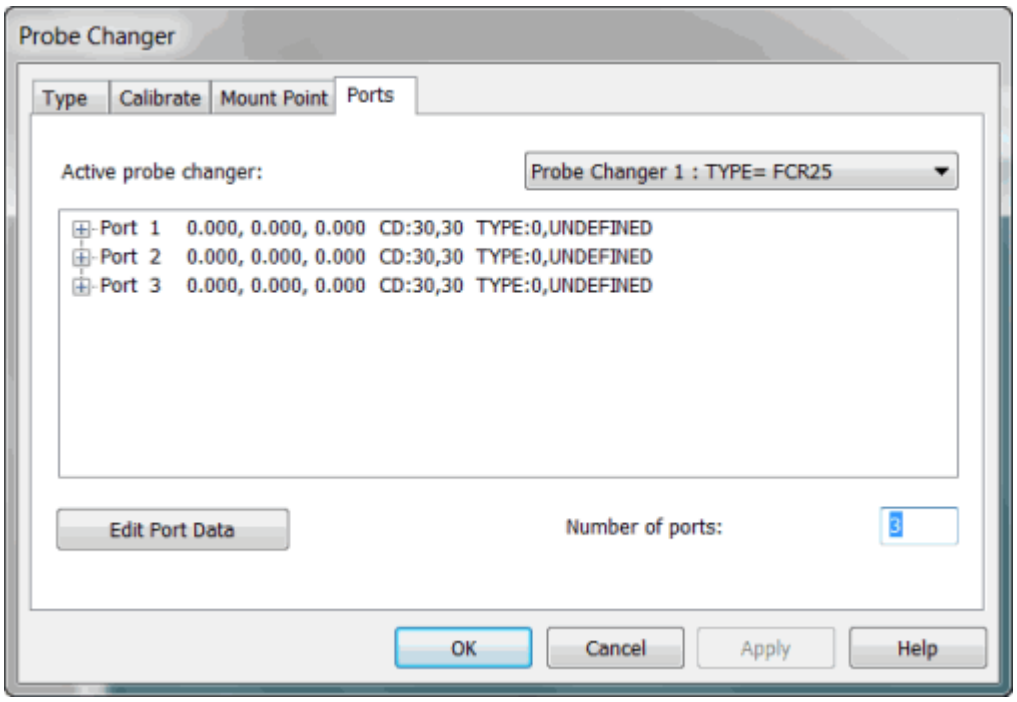
In the next step, you define the ports that your probe changes uses.

Step 3 - Define the Ports

The example described below has a PA25-SH insert in port 1(left), NO INSERT in port 2 (middle), and a PA25-20 insert in port 3 (right).

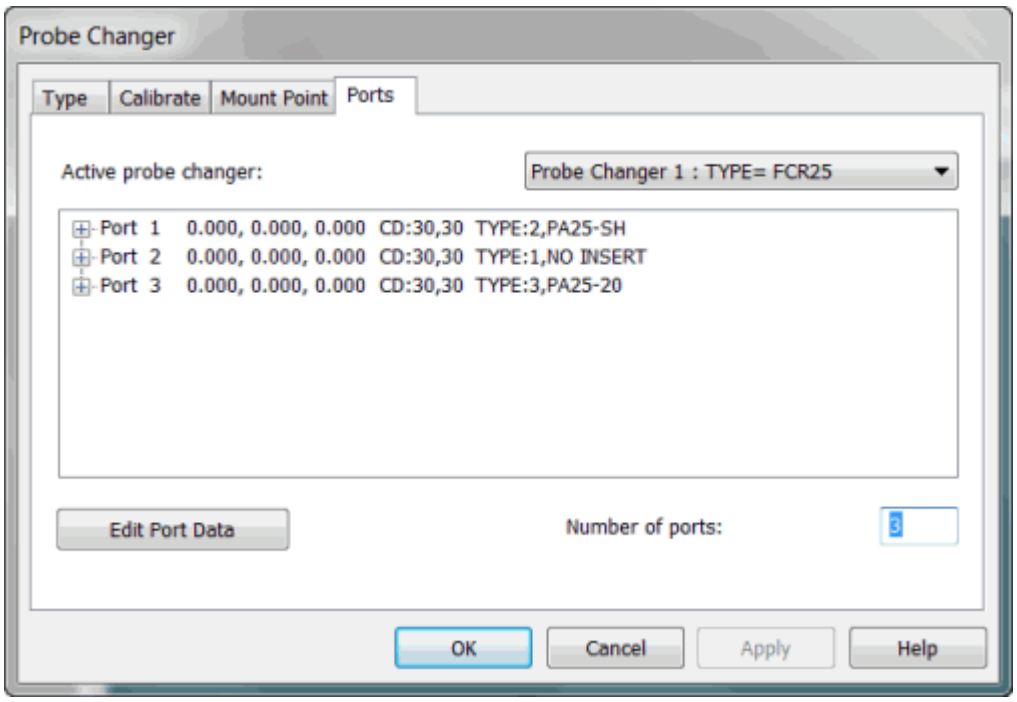
To define the ports of your FCR25 Probe Changer, do the following:

1. Select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**).
2. In the **Active probe changer** list, select **TYPE=FCR25**.
3. In the **Number of ports** box, in multiples of three, specify the number of ports for your FCR25 Probe Changer. PC-DMIS then lists the specified number of ports as "ports" (for example, port 1, port 2, port 3, and so forth). Until you define the ports, PC-DMIS lists the "port" entries as "UNDEFINED". You must define all of the ports in the rack before you start.



Ports tab with undefined ports.

4. Select a port from the list, and click **Edit Port Data**. The **Probe Changer Port Data** dialog box opens.
5. In the **Port type** list, select **NO INSERT**, **PA25-SH**, or **PA25-20**.
6. You may specify the **XYZ** values for the center position of the port or leave those values empty. In any case, PC-DMIS automatically populates these values upon successful calibration. See "Step 9 - Review Calibration Results".
7. To save the changes to the port data, click **OK**.
8. Repeat steps 4 through 6 for all ports in your changer.



Ports Tab

9. To save your changes, click **Apply**.

The next step prepares you to calibrate the probe changer.

Step 4 - Prepare the Probe Changer

The calibration process for the FCR25 Probe Changer may vary slightly depending on the types and locations of the inserts for each port. The process described here shows how PC-DMIS manages calibration for each port type.

Once you click the **Calibrate** button, the following message box appears:

PC-DMIS Message

Each FCR25 unit contains 3 ports. Different types of physical racks can hold varying numbers of FCR25 units. The current rack is configured to have a total of 3 ports, which means it should have 1 FCR25 units.

Please shim open all the lids and remove all modules and styli from the ports.

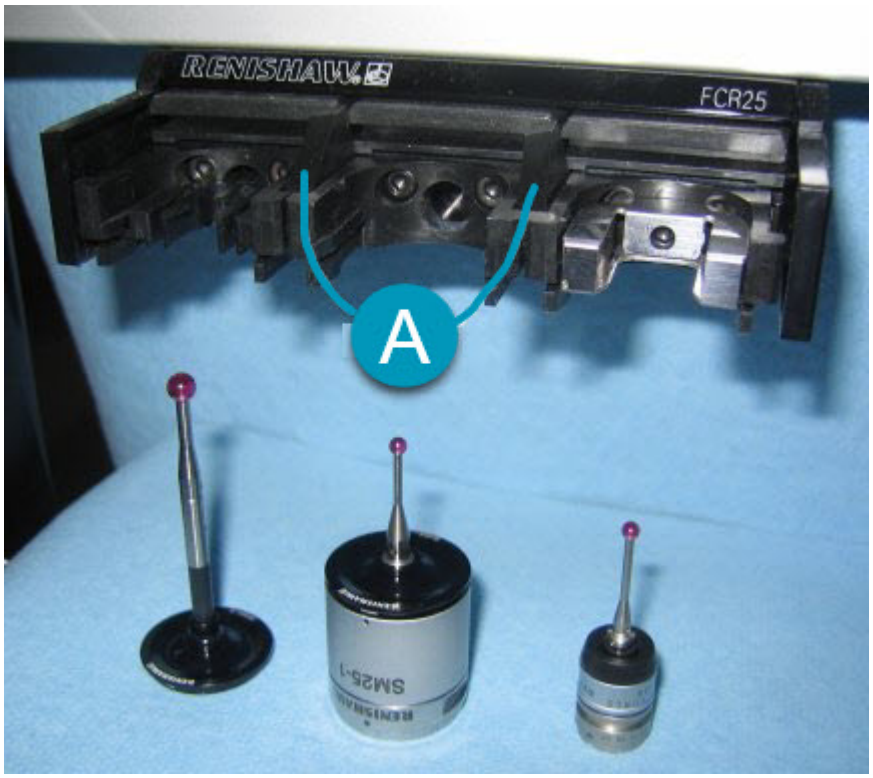
1. Read the instructions from the preceding prompt, and verify that you have the correct number of ports and FCR25 units (a unit is a set of three ports).

2. Open the lids to each port. Insert the shims, with the large ends of the shims toward the back of the ports to hold them open.

   A "shim" is a tapered piece of plastic that fits in between two ports to hold their lids open. The picture below shows a close-up view of a shim between ports 2 and 3, holding their lids open. Without a shim, the lids are shut, as you can see in port 1.

Shim holding the lids open on two ports

3. With the lids open, remove all of the modules and styli by sliding them forward and out of the ports, as shown below:



(A) - Shims

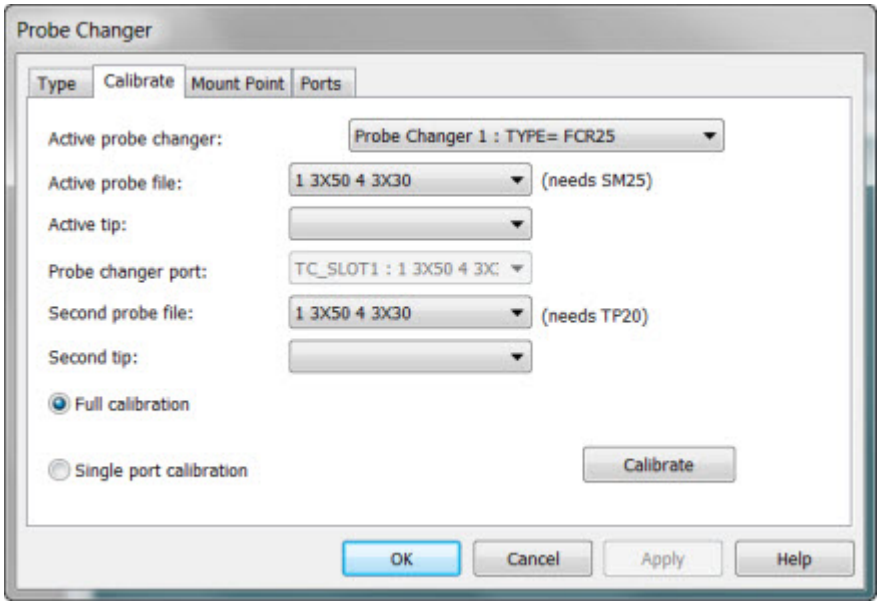
4. When you are ready to measure port 1, click **OK**.

The next step starts the calibration process.

Step 5 - Begin Calibration

Before you start the calibration process, you must specify or verify the probes to use in the calibration of your FCR25 Probe Changer.

1. Select the Calibrate tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Calibrate Tab

2. In the **Active probe changer** list, select **TYPE=FCR25**.
3. Determine the type of calibration. Select one of the following:
   - To calibrate one port, select the **Single port calibration** option. If you select the single port calibration, you must also select the needed port from the **Probe changer port** list.
   - To calibrate all FCR25 ports, select the **Full calibration** option. This documentation describes the **Full calibration** option.
4. In the **Active probe file** list, select the currently attached probe that defines the current probe configuration.
5. In the **Active tip** list, select the current tip.
6. If any ports require a secondary probe file to pick up that type of stylus, select the required probe file that defines the secondary probe configuration from the **Second probe file** list. Then select the needed tip from the **Second Tip** list. For example, a PA25-20 insert would require you to specify something like the SO25TP20_3 to accommodate the size of stylus used with the insert.
7. When you are ready to begin the calibration, click **Calibrate**.

In the next step, PC-DMIS measures port 1.

Step 6 - Measure Port 1/PA25-SH Insert

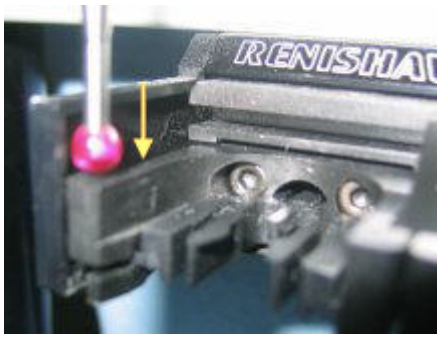
For the FCR25 Probe Changer, PC-DMIS prompts you through the process of measuring port 1 (the left-most port) through a series of message boxes. Follow the prompts and take the needed hits as directed in the instructions for each hit.

1. Hit 1 on top surface:

PC-DMIS Message

Please take a hit on the top face of the front left corner for port 1 (which is local port 1 on FCR25 unit number 1).

Use your machine's jog box to measure the first hit on the top surface of port 1 as shown in the image below:



First hit on the top surface of port 1

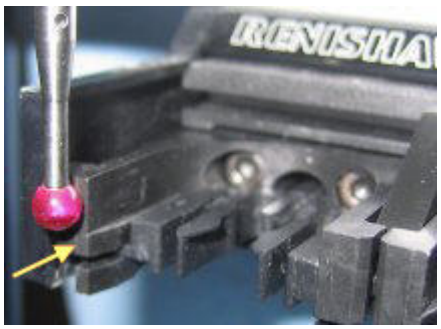
When you click **OK**, you are prompted to take the hit with the **Execution** dialog box.

2. Hit 2 on the front surface:

PC-DMIS Message

Please take a hit on the front face of the front left corner for port 1 (which is local port 1 on FCR25 unit number 1).

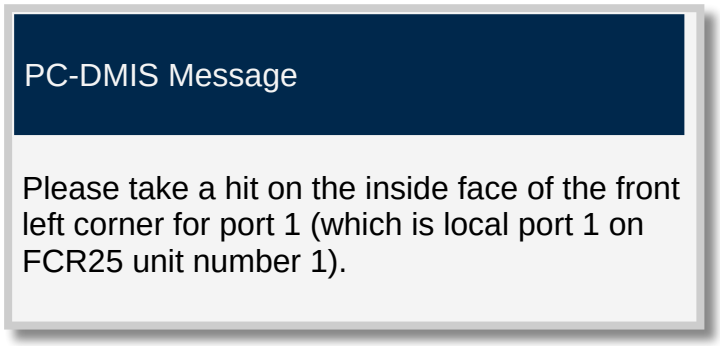
Use your machine's jog box to measure the second hit on the front surface of port 1, as shown in the image below:



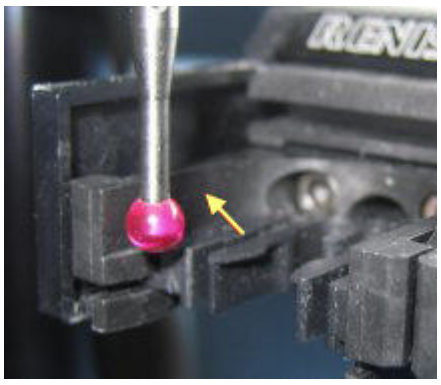
Second hit on the front surface of port 1

When you click **OK**, you are prompted to take the hit with the **Execution** dialog box.

3. Hit 3 on the inside surface:



Use your machine's jog box to measure the third hit on the inside surface of port 1 as shown in the image below:



Third hit on the inside surface of port 1

When you click **OK**, you are prompted to take the hit with the **Execution** dialog box.

This set of three hits establishes the location for the tool changer. These three hits would be the same if the port didn't have an insert. If you used a PA25-20 insert in this port, the hits would be taken on the insert in a similar fashion.

You are then asked to complete a few steps through the following message box:

PC-DMIS Message

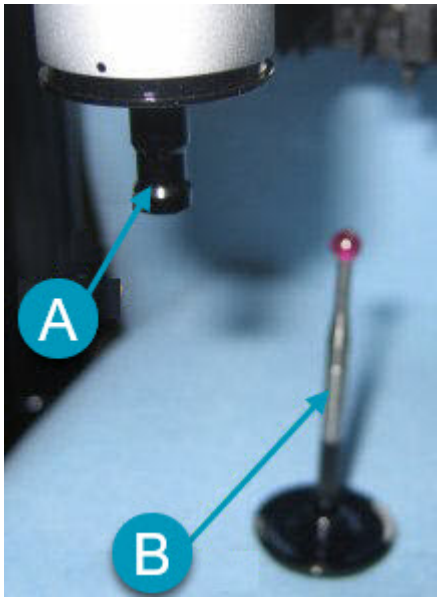
Please do the following steps in the indicated order.

1. Remove the current SH-1/2/3 stylus.
2. Attach the SHSP (Stylus Holder Setting Piece).
3. Jog the probe to a safe location with a clear line of approach to the port(s) being calibrated.
4. Then click **OK**.

After you click **OK** the machine will begin DCC measurement.

Complete the instructions in the message box:

1. Remove the specified stylus (in this case, the SH-1/2/3 stylus).
2. Attach the SHSP as shown in the image below:



WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

Attach the SHSP
(A) - SHSP
(B) - SH-1/2/3

> Whenever the instructions direct that you should jog the probe to a "safe location" or a location "with a clear line of approach", you should move the probe to a position that is in front of and slightly above the rack.

3. When you have completed these steps, click **OK** to begin DCC measurement.

> **WARNING:** When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

- PC-DMIS automatically measures the three hits with the SHSP that were previously taken with the SH-1/2/3 stylus.
- It also takes a hit on the opposite inside face.
- This completes the measurement of port 1.

In the next step, you measure port 3.

Step 7 - Measure Port 3 / PA25-20 Insert

Before PC-DMIS can measure port 3 (the right-most port) for the FCR25 Probe Changer, you must first change the probe to the probe file you specified for the **Second Probe File** in step 5.

1. When prompted, remove the current module, and add the TM25-20 module to the end of the probe body. The image below shows the TM25-20 module and TP20 type stylus after this change:

TM25-20 module and TP20 type stylus

> Changing probes may not be necessary depending on your FCR25 Probe Changer configuration. For example, if there are no inserts in any of the ports, then this probe change may not be necessary. The change specified in this step is only required to accommodate the calibration of port 3 with the PA25-20 insert.

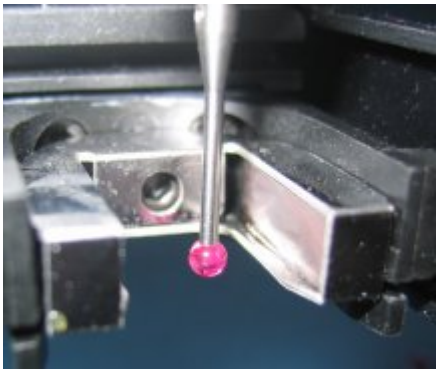
2. After you change the probe, click **OK**. PC-DMIS displays the following prompt:

> PC-DMIS Message
>
> Please jog the probe to a safe location with a clear line of approach to the port(s) being calibrated, then click OK.
>
> When you click OK the machine will begin DCC operation.

3. After you move the probe to a safe location, click **OK** to begin DCC measurement of the insert in port 3.

> **WARNING:** When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

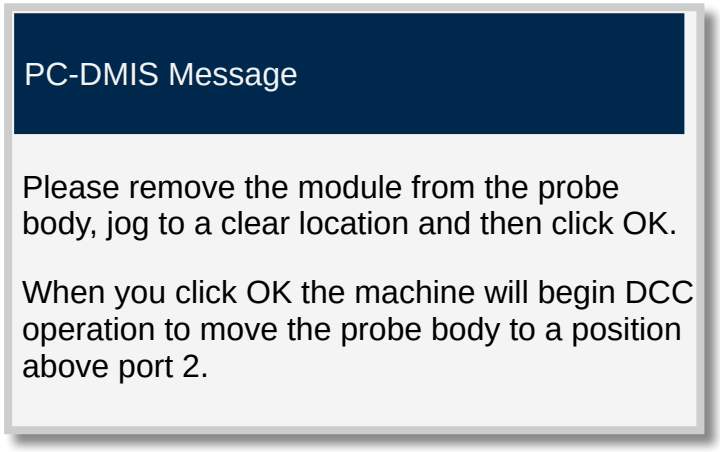
The following images show the probe taking measurements. PC-DMIS automatically takes hits to determine the location of the insert.



In the next step, you measure port 2.

Step 8 - Measure Port 2 / No Insert

1. Before you measure port 2 for the FCR25 Probe Changer, PC-DMIS prompts you to remove the module that PC-DMIS used for the measurement of port 3:



2. Once you have removed the module and moved the probe to a safe location, click **OK** to continue the process.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

PC-DMIS moves the probe body to a position that is centered above port 2 as shown in the image below. (The image also shows the module that PC-DMIS expects you to add in the next prompt.)

Position centered above port 2

The procedure for measuring port 2 would be used for all ports if you didn't have an insert in any of the ports. The ports would also be measured in a different order (port 1 first, followed by port 2, and then port 3).

PC-DMIS Message

Place the desired module into the port and slowly lower the probe body towards the module while being careful not to collide with the port.

Continue lowering until the module jumps upwards slightly due to the magnetic attraction. Observe to see if the module jumps straight up (indicates good alignment) or tilts (indicates poor alignment).

Reposition and repeat as necessary until satisfied with the alignment, then click OK.

3. Follow the prompt to place the module into the port. Then, slowly lower the probe body towards the module until the magnetic attraction causes the module to jump up towards the probe body. If you have a poor alignment, use the jog box to reposition the probe body, and repeat this process until you get a good alignment.

   The following images show the process described above.

   - Slowly lowering the probe body:

   - Module jumps upward for a good alignment:

- Module tilted for a poor alignment:

4. When you have established a good alignment, click **OK**. The following prompt appears:

PC-DMIS Message
Slowly lower the probe body onto the module. IMMEDIATELY stop when the LED on the probe head illuminates and then click OK. When you click OK the machine will begin a small DCC movement to finish seating the probe body into the module.

The image below shows the probe body that has been lowered just before the LED is lit:

5. Notice the slight gap between the probe body and the SM25-2 module. From this point, continue to lower the probe body and stop when the LED is lit. This does not close the gap completely. To finish the process, click **OK**.

   WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

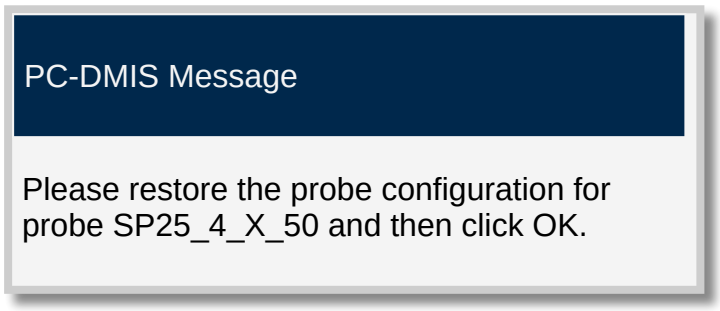
   At this point, the probe body automatically moves down the rest of the way to seat the probe module and close the gap. The following prompt appears:

   PC-DMIS Message

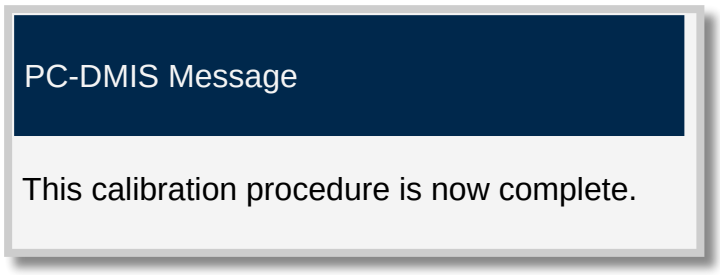
   Moving in only the one axis (as much as possible) please move the probe clear from the port and then click OK.

6. Move the probe straight out from the port to a position in front of the port as shown in the following image:

7. Click **OK**. This completes the measurement of port 2. PC-DMIS then prompts you to set the configuration back to the original probe configuration:



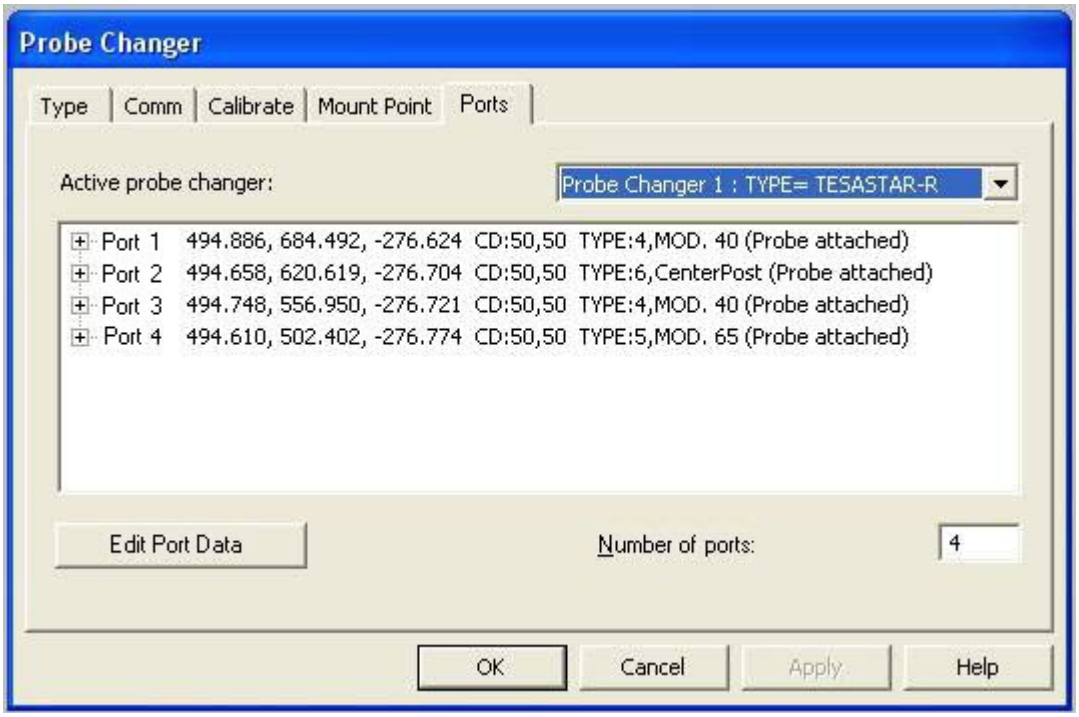
8. If needed, remove the current module, and add the modules and tips that make up the requested probe file. When you are done, click **OK**. The following prompt appears:



This step completes the calibration of the FCR25 Probe Changer. The next step describes how to review your calibration.

Step 9 - Review the Calibration Results

1. When the calibration of the FCR25 Probe Changer is complete, select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). This tab displays the calibration information for the location of each calibrated port. For example:



Probe Changer dialog box - Ports tab with calibration results

2. When you view the results, look for the following. Any significant deviations from these expectations may be due to a bad hit.
    - The probe changer must be aligned parallel to either the X or the Y axis of the CMM.
    - The X and Y values should show equal spacing between ports (roughly 40 mm apart).
    - The Z values should be nearly identical, since the ports are all at the same height.

How a `LOADPROBE` command works with the probe changer:

1. During the execution of a measurement routine, the probe entities that you added to each port are automatically picked up from the port whenever PC-DMIS executes a `LOADPROBE` command for that probe.
2. Before it picks it up, the probe body moves to the mount point and then into the empty port to drop off the current probe.
3. The rack's keys rotate to the release position. The current probe remains in the port, while the probe body lifts away to detach.
4. The probe body moves over the load position above the port containing the probe.
5. The probe body moves down onto the new probe. The keys rotate again to automatically engage the new module.
6. The probe body moves back out of the port and over to the rack’s mount point.

7. The CMM continues to measure the part with the newly-loaded probe.

Calibrating the ACR1 Probe Changer

This section describes how to define and calibrate the ACR1 Probe Changer.

No inserts are used for any of the port positions. However, if you intend to use probe extensions in any of the ports, you must define them as part of the port type before you begin.

ACR1 probe changer showing two different probe extensions in ports 7 and 8.

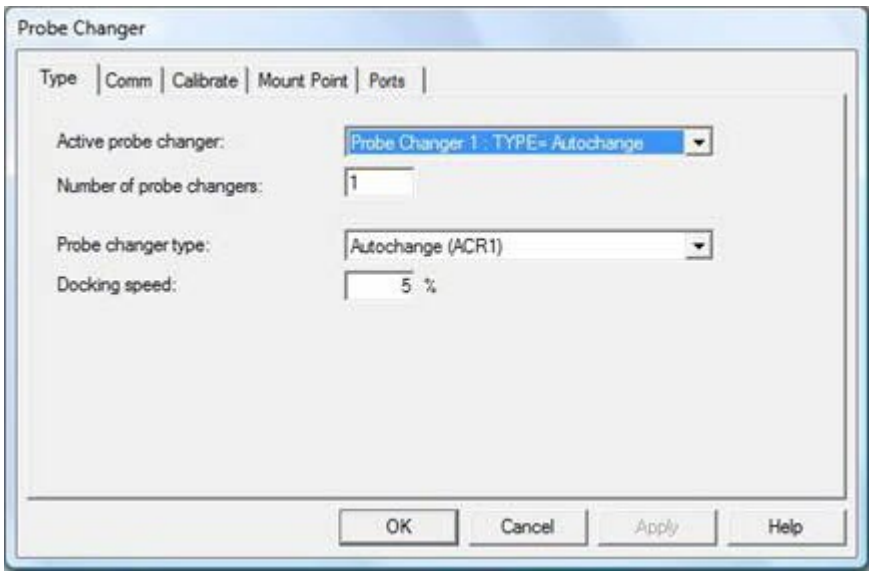
> The ACR1 Probe Changer MUST BE mounted on the machine table parallel to either the X or Y axis for successful calibration. For mounting instructions, consult the documentation that came with your probe changer.

To calibrate your probe changer:

Step 1 - Select the ACR1 Probe Changer

To select the ACR1 Probe Changer:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **Autochange (ACR1)**:



Probe Changer Dialog Box - Type Tab

3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.

4. In the **Active probe changer** list, select the item that represents the probe changer you are defining. If this is the first probe changer, it appears as **Probe Changer 1 : TYPE=None**.

5. In the **Number of probe changers** box, type the number of different types of probe changers.

6. In the **Docking speed** box, type a value. A value between 15-20% is appropriate for this machine configuration. You can adjust this value at any time to speed up or slow down the system.

   To avoid equipment damage due to excessive docking speed, gradually increase the **Docking speed** value.

7. Click **Apply** to apply any changes made for this probe changer, and then click **OK** to close the dialog box.

For details on controller configuration settings, see the documentation that came with your controller.

In the next step, you define the communications port.

Step 2 - Define the Communications Port

You can use the ACR1 Probe Changer in one of two modes:

- Host mode - In this mode, the rack controller connects to a communications port on the computer via a cable. All of the functions are based on signals between the two devices. The probe changer needs to connect to a serial communications port if you use it in host mode. You need to identify this communications (Comm) port before calibration can begin.

  If you use host mode, follow the steps below.

- Stand-alone mode - In this mode, there is no direct communications with the computer or PC-DMIS. This means that all rack functions are based on timing. The probe changer relies on timing to do a change cycle (to deposit and collect hardware from the probe changer). Respective modes are configured with the dip switches on the rear of the rack controller(s). They are covered in the Renishaw documentation or in the prints for the specific CMM configuration and are not covered here.

  If you use stand-alone mode, skip to "Step 3 - Define the Mount Point".

To define the communications port:

1. Select the **Comm** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**).

2. In the **Comm port** box, select port **2** (typically if you use Host mode) or **None** (if you use Stand-alone mode). The setting depends on the machine's configuration.

Probe Changer Dialog Box - Comm Tab

3. Unless otherwise indicated, use the following default settings:

   Baud: 9600

   Parity: Even

   Data bits: 7

   Stop bits: 1

4. Click **Apply** and then **OK** to close the dialog box.

5. Restart PC-DMIS to force the new port settings to be read.

> If you change the port settings, you must restart PC-DMIS. Otherwise, the system may not work properly.

6. Once PC-DMIS restarts, select **Edit | Preferences | Probe Changer** to open the **Probe Changer** dialog box.

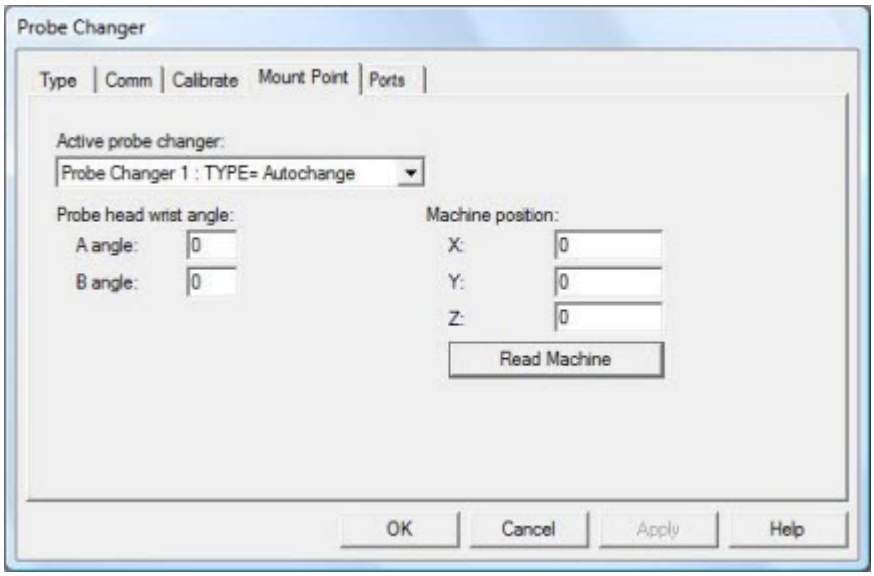
In the next step, you define the location of the probe body when you use the probe changer to switch probe components.

Step 3 - Define the Mount Point

The mount point for the ACR1 Probe Changer is the location in front of the probe changer where the machine moves to before it picks up or drops off a probe. You should determine a location that avoids collision with the probe changer or part.

To define the mount point for your probe changer:

1. Select the **Mount Point** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Mount Point Tab

2. In the **Active probe changer** list, select **TYPE=ACR1**.

3. If necessary, alter the probe head wrist angle for both **A angle** and **B angle**. Typically, but not always, these values are 0 and 0, respectively. You need to use a calibrated probe rotation that ensures the probe can move in and out of the probe rack during the necessary steps of the probe rack calibration procedure.

4. Use your jog box to manually move your machine to the desired mount point position.
5. Click the **Read Machine** button to populate the **X**, **Y**, and **Z** machine position values with the current position. You can also manually type these values.
6. To save your changes, click **Apply**.

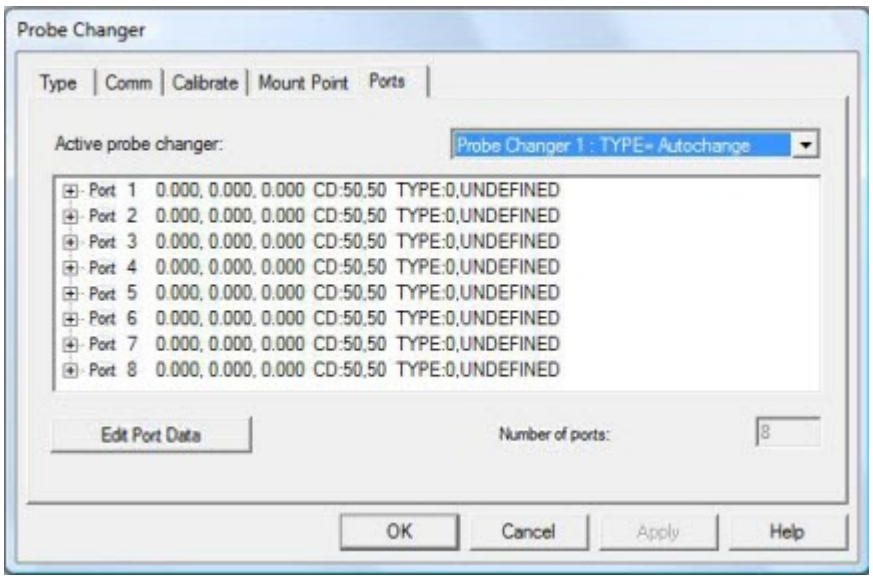
In the next step, you define the ports that your probe changer uses.

Step 4 - Define the Ports

The example described below has a probe extension in port 7 and port 8. When you use a probe extension such as these, you must identify and define it prior to calibration.

To define the ports of your ACR1 Probe Changer, do the following:

1. Select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). When you first identify the probe changer, the list shows all of the ports as UNDEFINED:



Example showing the undefined ports on the Ports tab of the Probe Changer dialog box.

You must define all of the ports in the probe changer before you start.

2. In the **Active probe changer** list, select **TYPE= Autochange**.

3. Select a port in the list, and click **Edit Port Data**. The **Probe Changer Port Data** dialog box appears:

Probe Changer Port Data Dialog Box - Port type Option

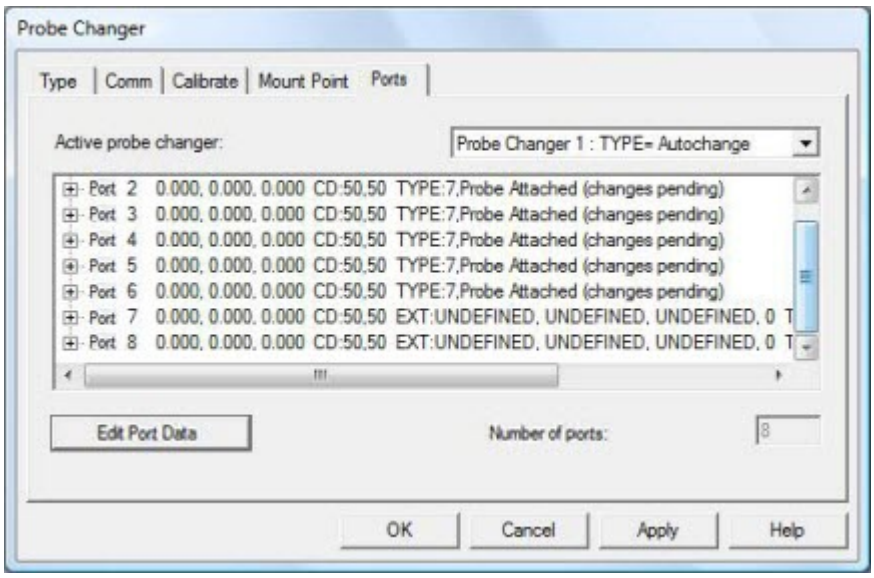
4. For each port, you need to classify its contents as either "Probe Attached" or "Extension Only". In the **Port type** list, select the appropriate option:

   - Probe Attached - Only probe bodies are in the ports, or the port is empty.
   - Extension Only - The port contains a probe extension (Renishaw PEM Autojoint to Autojoint Extension Bar, commonly called PEM). The PEM is available in various lengths, but the length is not significant at this point.

5. You can specify the **XYZ** values for the center position of the port, or leave those values empty. In any case, PC-DMIS automatically populates these values upon successful calibration. See "Step 10 - Review the Calibration Results".

6. To save your changes to the port data and close the **Probe Changer Port Data** dialog box, click **OK**. Repeat steps 4 and 5 for all ports in your probe changer.

   In the example below, ports 1 through 6 have been defined as containing only a probe body. Ports 7 and 8 are identified as each holding a PEM probe extension. It is not necessary that they be in adjacent ports; this is for illustration purposes only.



Example showing the defined ports on the Ports tab of the Probe Changer dialog box.

7. To save your changes, click **Apply**.

You are now ready to begin calibration. The next step starts the calibration process.

Step 5 - Prepare for Calibration

The calibration process for the ACR1 Probe Changer may vary slightly depending on the types and locations of the inserts for each port. The process described here shows how PC-DMIS manages calibration for each port type.

Once you click the **Calibrate** button, the following message box appears:

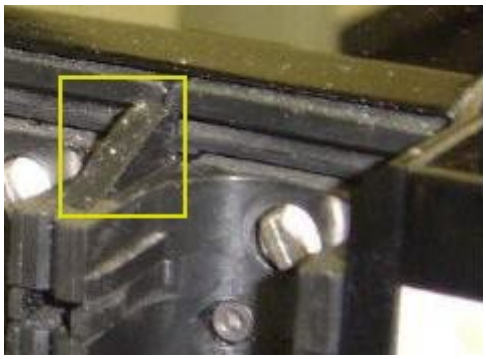
PC-DMIS Message

Please click OK, then shim open all the probe changer lids and remove all probes from the rack before proceeding with any measurement.

Note: You can safely ignore any cycle or lock errors that might occur on the rack status indicator lights during this calibration.

1. Read and follow the instructions from each prompt.
2. Open the lids to each port. Insert the shims, with the large ends of the shims toward the back of the ports to hold them open.

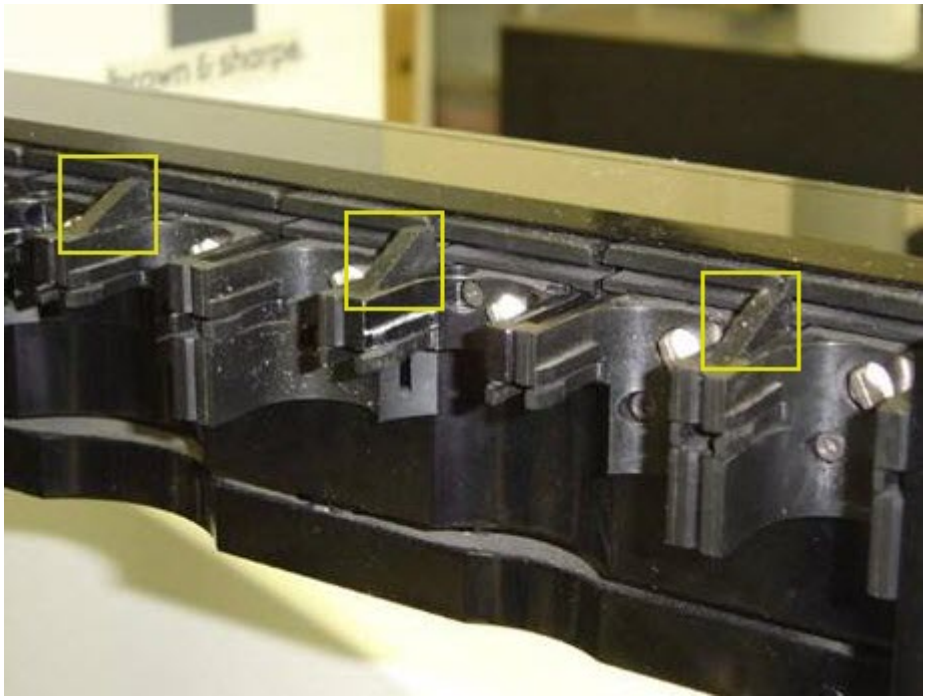
A "shim" is a tapered piece of plastic that fits in between two ports to hold their lids open. The picture below shows a close-up view of shims between multiple adjacent ports, holding open their lids.



Example showing shims between multiple adjacent ports.

Without a shim, the lids will shut.

3. With the lids open, remove all of the modules and styli by sliding them forward and out of the ports, as shown below:



Example showing the ACR1 probe changer with empty ports held open using shims.

4. When you are ready to measure port 1, click **OK**.

In the next step, you measure port 1.

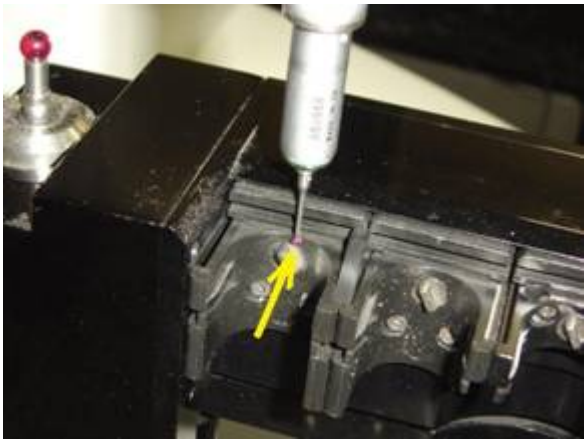
Step 6 - Measure Port 1

For the ACR1 Probe Changer, PC-DMIS prompts you through the process of measuring port 1 (the left-most port) through a series of message boxes. Follow the prompts and take the needed hits as directed in the instructions for each hit.

PC-DMIS Message

Please take a hit in the back of the circle for port 1. The hit should be taken in the middle just above the metal key.

Use your machine's jog box to measure the first hit on the back (arc) surface of port 1 as shown in the image below:



Example showing the back surface of port 1.

When you click **OK**, you are prompted to take the hit with the **Execution** dialog box.

In the next step, you measure port 8.

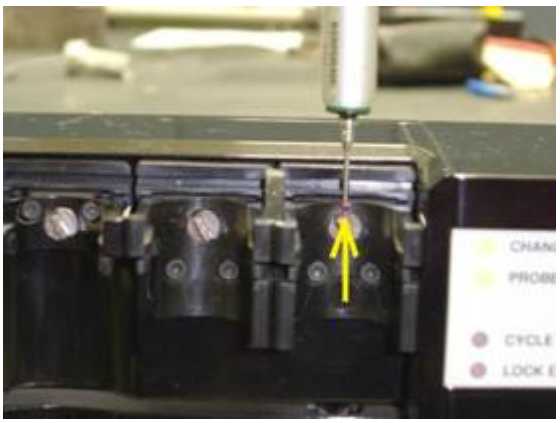
Step 7 - Measure Port 8

For the ACR1 Probe Changer, PC-DMIS prompts you through the process of measuring port 8 (the right-most port) through a series of message boxes. Follow the prompts and take the needed hits as directed in the instructions for each hit.

PC-DMIS Message

Please take a hit in the back of the circle for port 8. The hit should be taken in the middle just above the metal key.

Use your machine's jog box to measure the second hit on the back (arc) surface of port 8 as shown in the image below:



Example showing the back (arc) surface of port 8.

When you click **OK**, you are prompted to take the hit with the **Execution** dialog box.

This set of two hits establishes the location for the probe changer and would be the same if port 8 didn't have an extension.

At this point, the system goes into DCC Mode and measures a series of hits on all ports. It starts at port 8 and progresses down to port 1.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

After the DCC measurement of the ports, the next step measures the datum sphere.

Step 8 - Measure the Datum Sphere

You are now asked to complete a few steps for the ACR1 Probe Changer through the following message boxes:

PC-DMIS Message

Please jog to a clear location then click OK. If you have a moveable wrist it will then rotate to the A/B angles defined on the Mount Point tab.

Follow the instructions for this message and then click **OK**.

PC-DMIS Message

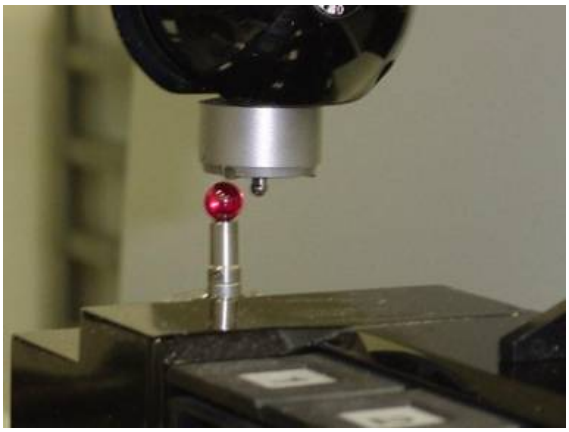
Please remove the shims and close all the probe changer lids. Then release the auto joint adapter and take 1 hit on the bottom of the auto joint with the probe changer datum sphere. Be careful to avoid the small pins and holes and take the hit on a flat area.

After you complete this point the auto joint diameter will be measured in DCC.

Follow the instructions for this message and then click **OK**.

At this point, a message displays in the **Machine commands** list in the **Execution** dialog box. It instructs you to take a hit with the stylus on top of the datum sphere (inverted probe stylus) on the left end of the probe changer.

Follow the instructions in the dialog box, remove the probe, and then take one hit on the datum sphere.



When you have completed these steps, click **OK** to begin DCC measurement.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

PC-DMIS automatically lowers the Autojoint extension to the side of the datum sphere. It then proceeds to take four hits in DCC Mode on the outside diameter of the Autojoint extension.

In the next step, you measure the datum sphere with PEM extension(s).

Step 9 - Measure the Datum Sphere with PEM Extension(s) (optional)

This example for the ACR1 Probe Changer uses two Autojoint extensions (PEM modules) in ports 7 and 8.

WARNING: At different times throughout this procedure, the machine moves in DCC mode. When this happens, to avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

The system displays this message:

PC-DMIS Message

Please attach only the extension to be used in port 7. When you click OK if you have a wrist it may rotate (if needed) to allow for any rotation of the bottom joint. When prompted then take 1 hit on the bottom of the auto joint with the probe changer datum sphere. Be careful to avoid the small pins and holes and take the hit on a flat area.

After you complete this point the auto joint diameter will be measured in DCC.

If you use PEM (extensions), it is necessary to also take a manual hit at the bottom of each one as shown in the picture below.

Example showing the manual hit at the bottom of each PEM.

When you have completed these steps, click **OK**. DCC measurement begins.

PC-DMIS Message

Please attach only the extension to be used in port 8. When you click OK if you have a wrist it may rotate (if needed) to allow for any rotation of the bottom joint. When prompted then take 1 hit on the bottom of the auto joint with the probe changer datum sphere. Be careful to avoid the small pins and holes and take the hit on a flat area.

After you complete this point the auto joint diameter will be measured in DCC.

The picture below shows the manual hit being taken with the 50 mm PEM identified as being stored in port 8.

When you have completed these steps, click **OK**. DCC measurement begins.

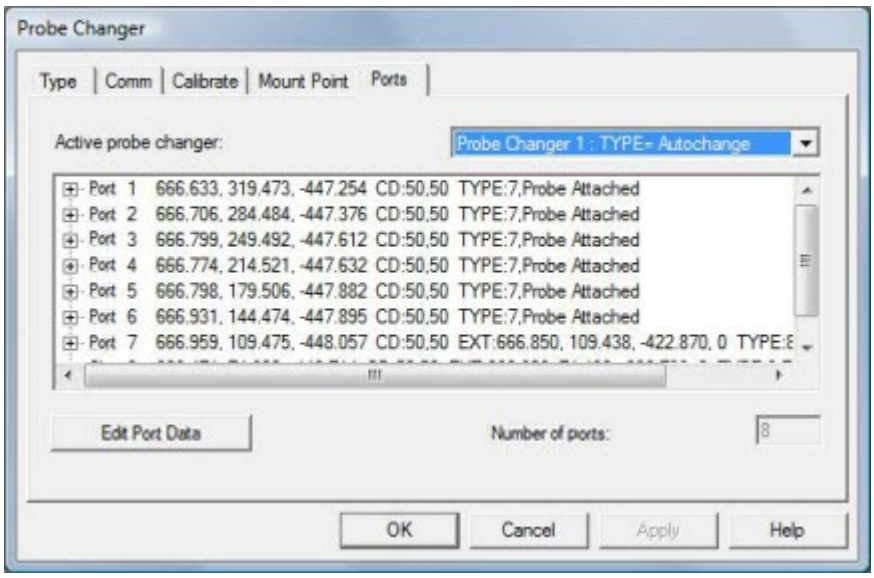
PC-DMIS Message

All measurement is now complete. Please reconnect the probe used to measure the ports and then click OK.

This completes the calibration of the ACR1 Probe Changer. The next step describes how to review your calibration.

Step 10 - Review the Calibration Results

1. When the calibration of the ACR1 Probe Changer is complete, select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). This tab displays the calibration information for the location of each calibrated port. For example:



Example showing the calibration results on the Ports tab of the Probe Changer dialog box.

2. When you view the results, look for the following. Any significant deviations from these expectations may be due to a bad hit.

    - The position and spacing of the ports. For example, the ACR1 rack defined in this calibration process is aligned parallel to the Y axis of the CMM.
    - The X values of the ports should be, within reason, nearly identical since all of the ports are co-linear.
    - Similarly, the Z values should also be nearly identical, since the ports are all at the same height.
    - The Y values should be equally spaced (roughly 35 mm apart).

The results during measurement routine execution are:

1. During measurement routine execution, probe entities that are added to each of the ports are automatically picked up from that location whenever PC-DMIS executes a `LOADPROBE` command for that probe.
2. The probe body moves to the mount point and then into the port, which pushes the lid backwards.
3. The key mechanism automatically turns to disengage/engage, loads the new module, and continues to measure.

Calibrating the ACR3 Probe Changer

The calibration process for the Renishaw ACR3 Probe Changer represents the steps that you would take to prepare to use any of the probe changers that PC-DMIS supports. The process discussed here is specific to the ACR3 Probe Changer.

No inserts are used for any of the port positions. However, if you intend to use probe extensions in any of the ports, you must define them as part of the port type before you begin.

Renishaw ACR3 Probe Changer rack

This probe changer MUST BE mounted on the machine table parallel to either the X or Y axis for successful calibration. For mounting instructions, consult the documentation that came with your probe changer.

Caution about Adaptors with an HP-L laser

You can use angular adapters with an HP-L laser in an ACR3 probe calibration. These adaptors let you use an HP-L laser at orientations that you cannot get with a standard build.

You must place the angular adapters in the same probe changer as the required probe build describes. For example, if you have an angular adapter and an HP-L laser, both components must be in the same probe changer. If you don't do this, a crash will occur that may destroy your sensor.

Be aware that once the machine picks up the angular adapter, PC DMIS does not move the rack back to the unlocked position if the HP-L is in another probe changer.

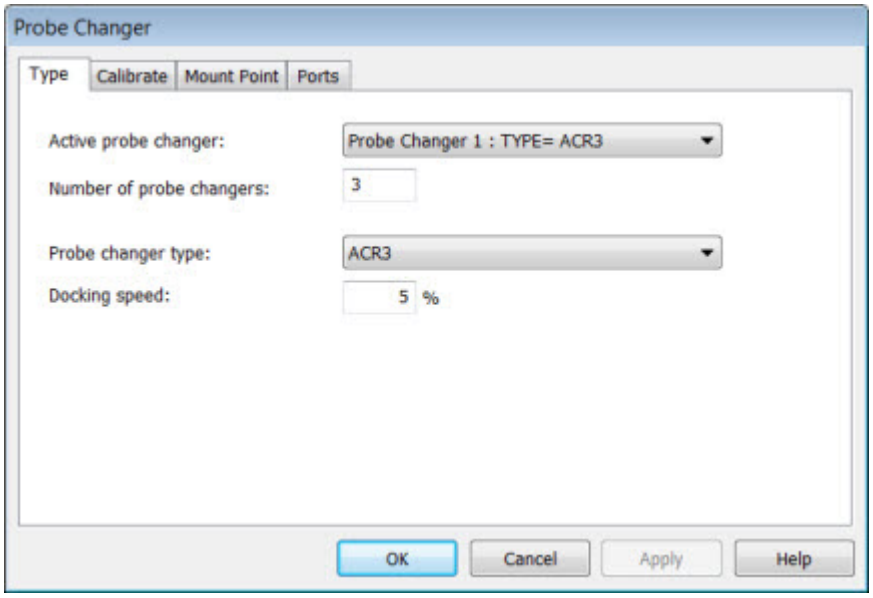
To calibrate your probe changer:

WARNING: At different times throughout this procedure, the machine moves in DCC mode. When this happens, to avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

Step 1 - Select the ACR3 Probe Changer

To select the ACR3 Probe Changer:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **ACR3**:



Probe Changer Dialog Box - Type Tab

3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.
4. In the **Active probe changer** list, select the item that represents the probe changer you are defining. If this is the first probe changer, it appears as **Probe Changer 1 : TYPE=None**.
5. In the **Number of probe changers** box, type the number of different types of probe changers.
6. In the **Docking speed** box, type a value. A value between 15-20% is appropriate for this machine configuration. You can adjust this value any time to speed up or slow down the system.

> To avoid equipment damage due to excessive docking speed, gradually increase the **Docking speed** value.

7. Click **Apply** to apply any changes made for this probe changer, and then click **OK** to close the dialog box.

> For details on controller configuration settings, see the documentation that came with your controller.

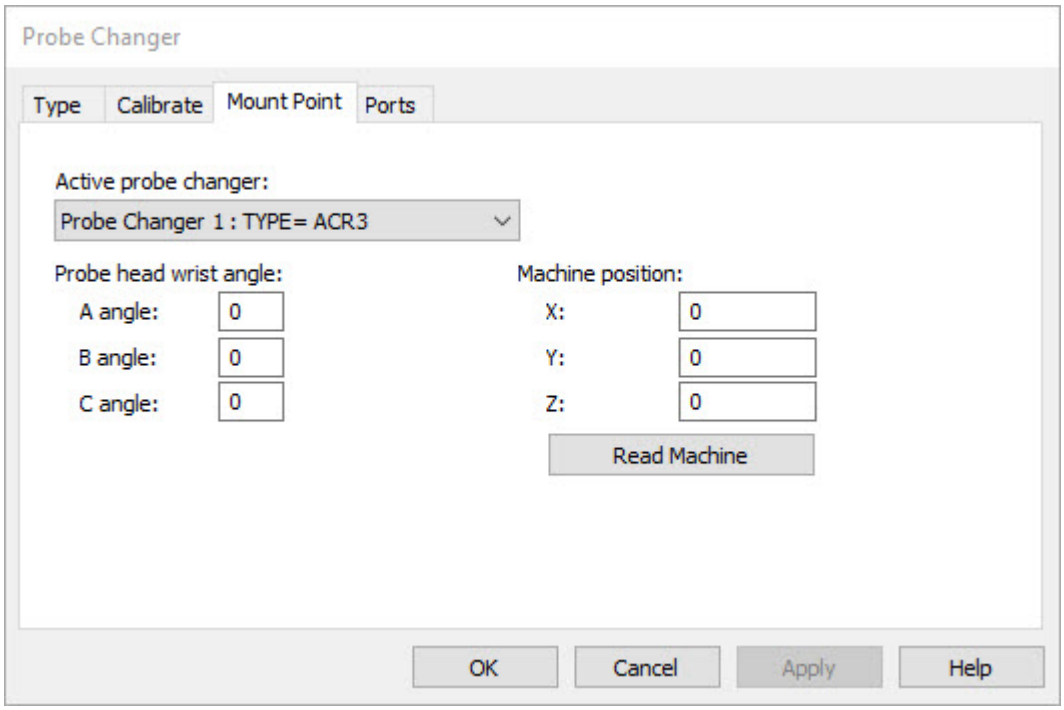
In the next step, you define the location of the probe body when you use the probe changer to switch probe components.

Step 2 - Define the Mount Point

The mount point for the ACR3 Probe Changer is the location in front of your probe changer where the machine moves to before it picks up or drops off a probe. You should determine a location that avoids collision with the probe changer or part.

To define the mount point for your probe changer:

1. From the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Mount Point** tab.



Probe Changer Dialog Box - Mount Point Tab

2. From the **Active probe changer** list, select **TYPE=ACR3**.

3. If necessary, alter the probe head wrist angles for **A angle**, **B angle**, and **C angle**. These values are required when you change probes in the probe changer. If an angle is not available in the probe head, the value for that angle should be 0 (zero). Before calibration, you need to set these values because part of the calibration procedure includes rotation of the probe head to these angles. You need to use a calibrated probe rotation that ensures the probe has the ability to move in and out of the probe changer during the necessary steps of the probe changer calibration procedure. After calibration, if you change the angles, PC-DMIS displays a warning message to inform you that recalibration is needed.

4. Use your jog box to manually move your machine to the desired mount point position.

5. Click the **Read Machine** button to populate the **X**, **Y**, and **Z** machine position values with the current position. You can also manually type these values.

6. Click **Apply** to save your changes.

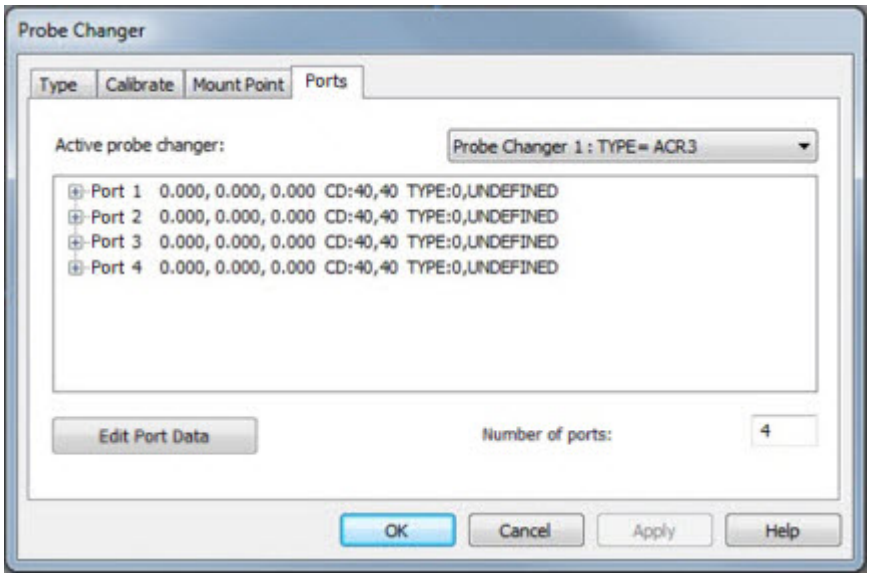
In the next step, you define the ports.

Step 3 - Define the Ports

The example described below has a probe extension in port 7 and port 8. When you use a probe extension such as these, you must identify and define it prior to calibration.

To define the ports of your ACR3 Probe Changer, do the following:

1. Select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). When the probe changer is first identified, the list shows all of the ports as UNDEFINED:

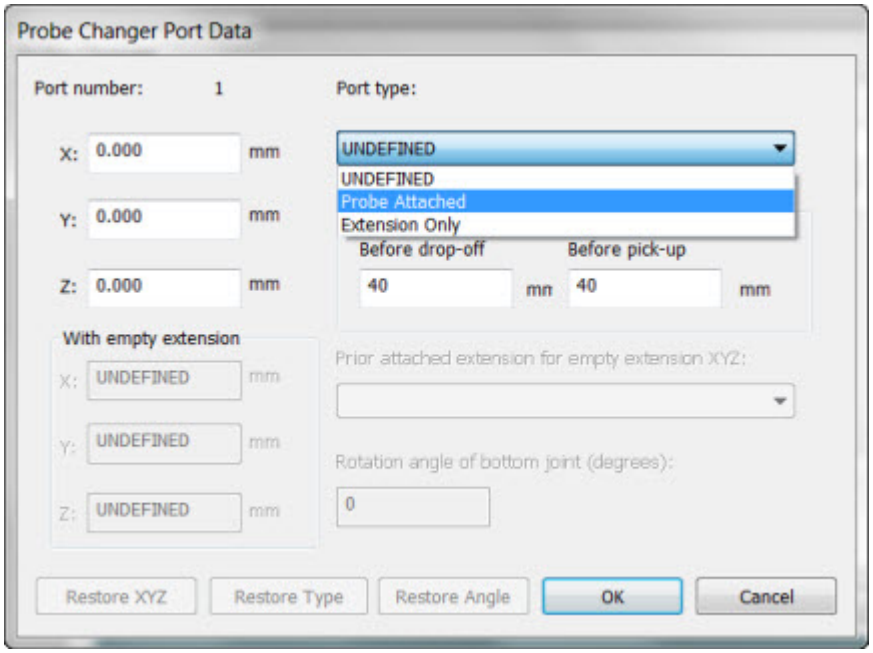


Example of the Ports tab with undefined ports.

   You must define all of the ports in the probe changer before you start.

2. In the **Active probe changer** list, select **TYPE= ACR3**.

3. Select a port in the list, and click **Edit Port Data**. The **Probe Changer Port Data** dialog box appears:



Probe Changer Port Data Dialog Box - Port type List

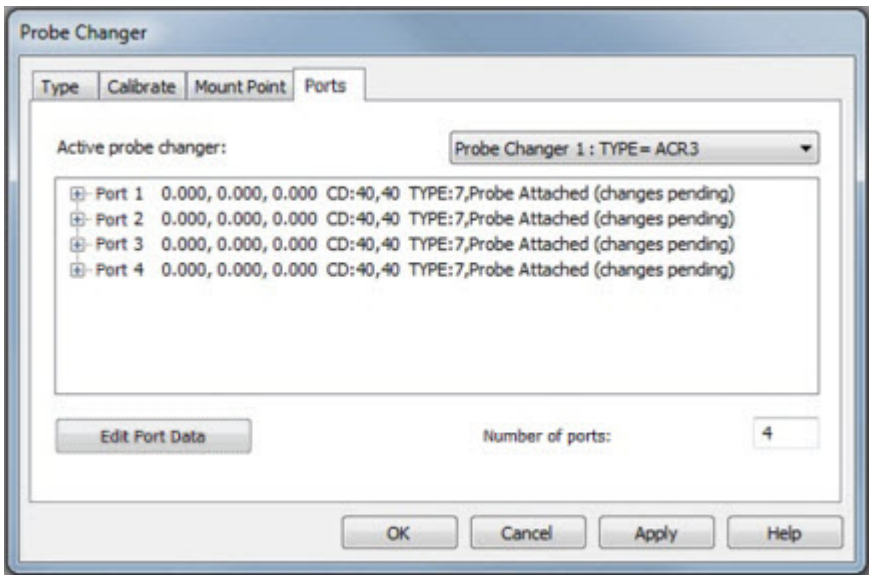
4. For each port, you need to classify its contents as either "Probe Attached" or "Extension Only". In the **Port type** list, select the appropriate option:

   - Probe Attached - Only probe bodies are in the ports, or the port is empty.
   - Extension Only - The port contains a probe extension (Renishaw PEM Autojoint to Autojoint Extension Bar, commonly called PEM). The PEM is available in various lengths, but the length is not significant at this point.

5. You can specify the **XYZ** values for the center position of the port, or leave those values empty. In any case, PC-DMIS automatically populates these values upon successful calibration. See "Step 12 - Review the Calibration Results".

6. To save your changes to the port data and close the **Probe Changer Port Data** dialog box, click **OK**. Repeat steps 4 and 5 for all ports in your probe changer.

   In the example below, ports 1 through 4 have been defined as containing only a probe body:



Example of the Ports tab showing the defined ports.

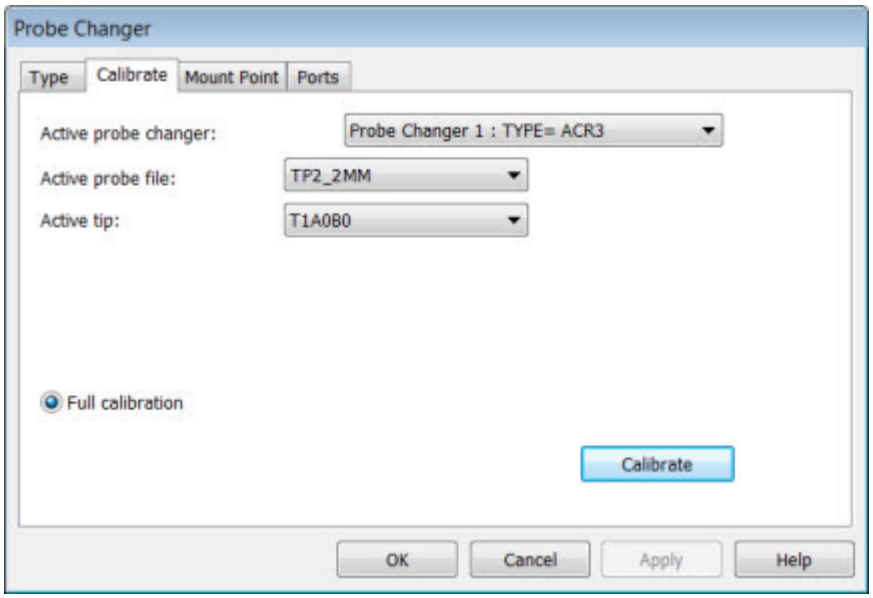
7. To save your changes, click **Apply**.

The next step starts the calibration process.

Step 4 - Prepare for Calibration

To start the calibration process for the ACR3 Probe Changer:

1. Select the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):

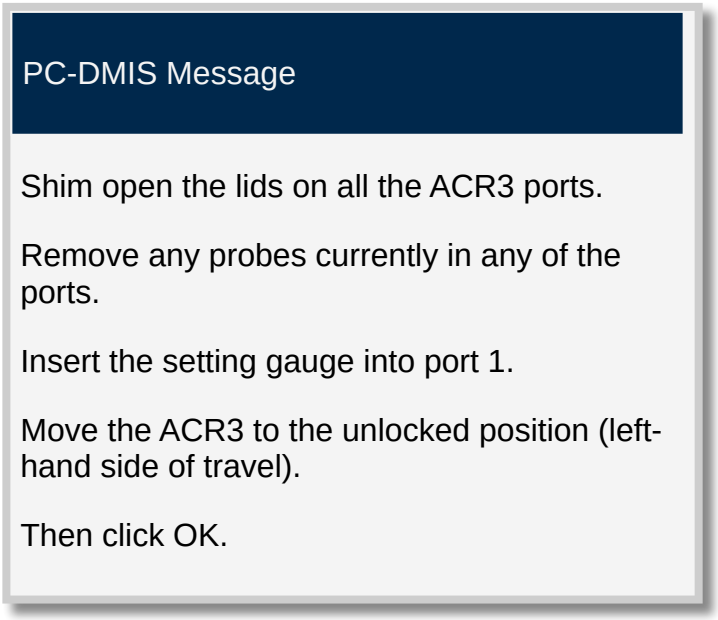


Probe Changer Dialog Box - Calibrate Tab

2. In the **Active probe changer** list, select **Probe Changer 1: TYPE=ACR3**.
3. The entry in the **Active probe file** list defaults to the current measurement routine setting. If this is not what is to be used for the probe changer calibration, select the proper probe.

4. The entry in the **Active tip** list defaults to the current measurement routine setting. If this is not what is to be used for the probe changer calibration, select the tip ID to be used for calibration. This is usually **T1A0B0**.

5. Click **Calibrate**. The following message box appears:



6. Read and follow the instructions from each prompt.

7. Hold the lids open by pushing them all the way back and inserting a shim before and/or after each port.

   A "shim" is a tapered piece of plastic that fits in between two ports to hold their lids open. The picture below shows a close-up view of shims between multiple adjacent ports, holding open their lids:

Example showing shims between multiple adjacent ports.

Without a shim, the lids will shut.

8. With the lids open, remove all of the modules and styli by sliding them forward and out of the ports, as shown below:

Example showing the ACR3 probe changer with empty ports held open using shims.

9. When you are ready to take the first measurement, click **OK**.

In the next step, you take the first manual hit.

Step 5 - Take the First Manual Hit

When you start the calibration process for the ACR3 Probe Changer, a series of message boxes prompt you to record two positions and measure two manual hits. Three are required to fully define the orientation of this probe changer in the machine's XY plane.

The probe changer MUST BE ALIGNED parallel to either the X or Y axis. The manual hits locate the probe changer in the machine space. Follow the prompts and take the needed hits as directed in the instructions for each hit.

Renishaw provides a setting gauge with the probe changer. Take the first manual hit on the top face of the setting gauge that is inserted into port 1. Use the setting gauge to take hits on port 1 without having to use the probe body.

Example of a setting gauge.

The prompt for the first manual hit on the top face is:

PC-DMIS Message

Unlock the quick connect joint and remove the probe assembly.

After the probe is removed, use the jog box to move the autojoint above the central port of the setting gauge in port 1.

Slowly lower the probe head so that the autojoint just contacts the top face of the setting gauge which may be used as a feeler gauge as needed. Be careful not to move the position of the ACR3 during this process.

When in position, click OK.

PC-DMIS prompt for the first manual hit.

1. Use your machine's jog box to position the Autojoint directly on the top face of the setting gauge, as shown below:

Example showing the Autojoint positioned directly on top of the setting gauge.

2. When you are ready to take the first measurement, click **OK** with the probe in position.

In the next step, you take the second manual hit.

Step 6 - Take the Second Manual Hit

For the ACR3 Probe Changer, take the second hit with the Autojoint positioned directly in front of the setting gauge. The prompt for the second manual hit on the front edge of the setting gauge is:

PC-DMIS Message

Raise the probehead so that the autojoint is clear of the setting gauge.

Move the probehead so that the external surface of the autojoint is touching the front edge of the setting gauge.

Again be careful not to move the position of the ACR3 during this process.

When in position, click OK.

PC-DMIS prompt for the second manual hit.

1. Use your machine's jog box to position the probe directly in front of (and against) the setting gauge, as shown below:

Example showing the second manual hit.

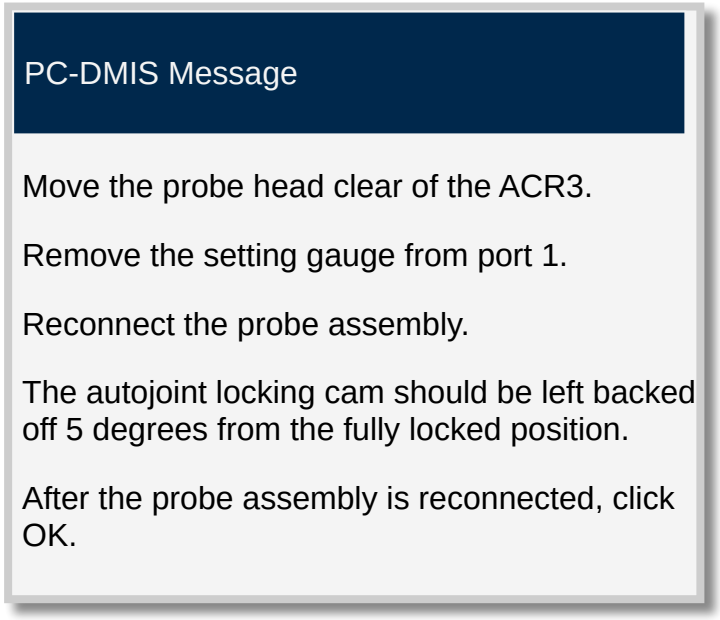
2. When you are ready to take the second measurement, click **OK** with the probe in this position.

In the next step, you remove the setting gauge and reconnect the probe assembly to the Autojoint.

Step 7 - Remove the Setting Gauge and Reconnect the Probe Assembly

For the ACR3 Probe Changer, after you have used the setting gauge to take the first (top face) hit and second (front edge) hit, do the following:

1. Remove the setting gauge from port 1 when you are prompted, as shown below:



PC-DMIS prompt to remove the setting gauge.

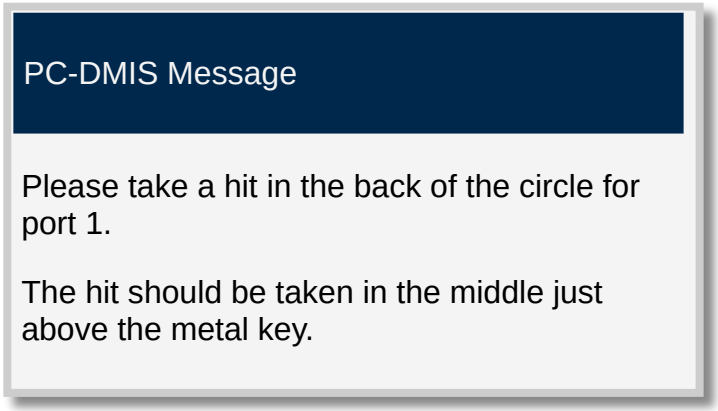
2. Reconnect the probe assembly to the Autojoint to prepare for the remaining calibration as the message instructs.

3. After you have reconnected the probe assembly, click **OK**.

In the next step, you take the first manual probe hit.

Step 8 - Take the First Manual Probe Hit

For the ACR3 Probe Changer, this is the first of two hits that you need to take to locate the probe changer. You will take the first hit in the XY plane inside the back of port 1 (just above the metal key). The prompt for the first manual probe hit is:



PC-DMIS prompt for the first manual probe hit.

1. When you are ready to take the first measurement, click **OK**.

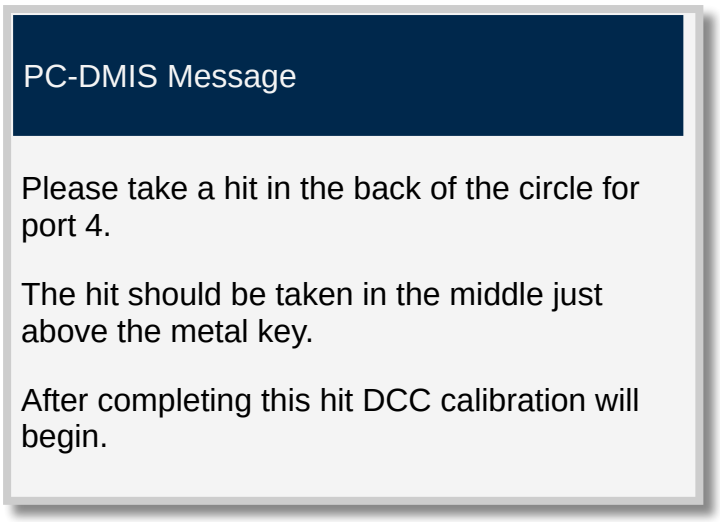
2. Use your machine's jog box to measure the first probe hit inside the back of port 1, as shown below.

Example showing the first probe hit inside the back of port 1.

In the next step, you take the second manual probe hit.

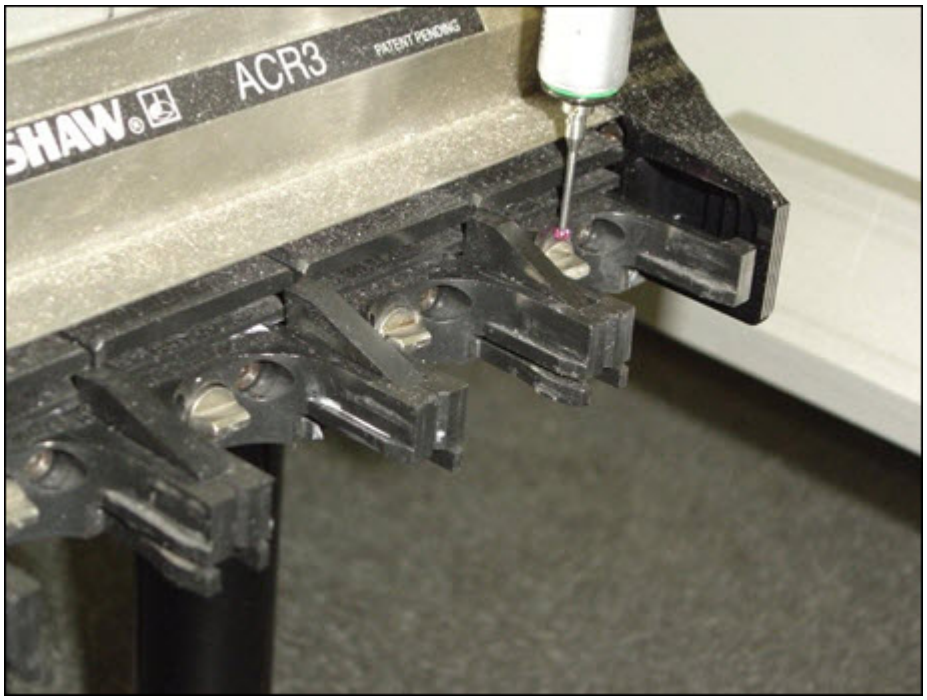
Step 9 - Take the Second Manual Probe Hit

For the ACR3 Probe Changer, this is the second of two hits that you need to take to locate the probe changer. You will take the second hit in the XY plane inside the back of port 4 (just above the metal key). The prompt for the second manual probe hit is:



PC-DMIS prompt for the second manual probe hit.

1. When you are ready to take the second measurement, click **OK**.
2. Use your machine's jog box to measure the second probe hit inside the back of port 4, as shown below:



Example showing the second manual probe hit inside the back of port 4.

This set of two manual probe hits establishes the location and orientation for the ACR3 Probe Changer.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

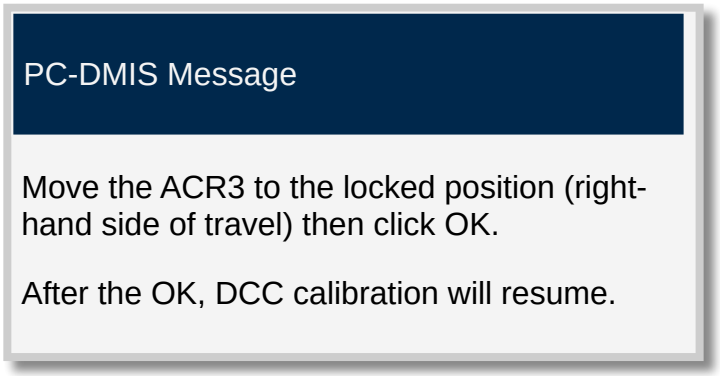
At this point, the system goes into DCC Mode and measures a series of hits that are required to accurately locate and orient the probe changer.

In the next step, you slide the ACR3 probe rack to the right side of its travel range.

Step 10 - Slide the Probe Rack to the Right Side of its Travel Range

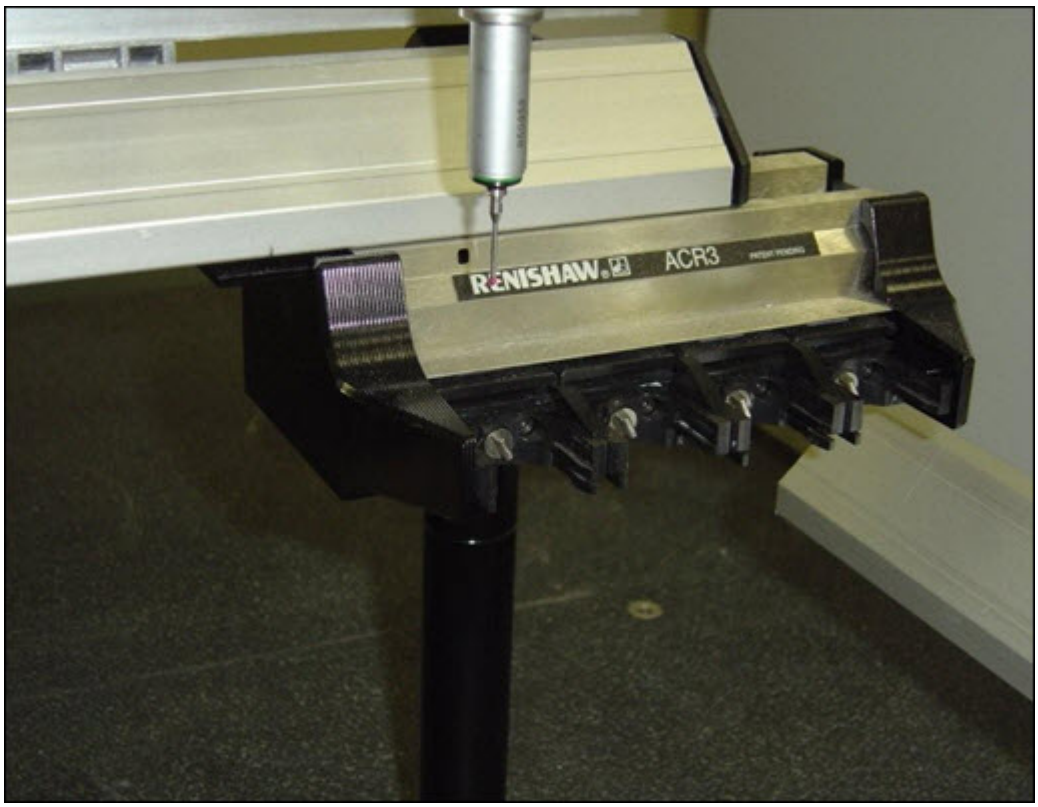
To continue with the calibration process for the ACR3 Probe Changer, you need to reposition the ACR3 probe changer to the right side of its travel range (the "locked" position.) The keys should now be oriented at approximately the 11 o'clock position.

The prompt for the locked position is:



PC-DMIS prompt to move the ACR3 to the locked position.

1. Manually slide the ACR3 probe changer to the right side of its travel range by pushing it along the FCR rail, as shown below:



Example showing the ACR3 probe changer at the right side of its travel range.

2. When the probe changer is correctly positioned, click **OK** to continue the calibration process.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

In the next step, you move the probe head into port 4.

Step 11 - Move the Probe Head into Port 4

For the ACR3 Probe Changer, you must follow additional procedures after the DCC measurement is done. This process includes steps to visually align the probe changer through a sight hole.

The prompt for moving the probe head is:

PC-DMIS Message
Move the ACR3 so that port 4 is directly behind the autojoint on the probe head. Slowly move the probe head directly back into the docked position in port 4. Try to move only along the one axis if possible.

When in position, Click OK

PC-DMIS prompt to move the probe head into port 4.

The prompt for aligning the probe changer through a sight hole is:

PC-DMIS Message

Slowly move the probe head along the direction of + or - ACR3 travel as needed until the alignment circle is centered in the alignment window above port 1.

For more information about the alignment circle and alignment window please refer to the ACR3 manual.

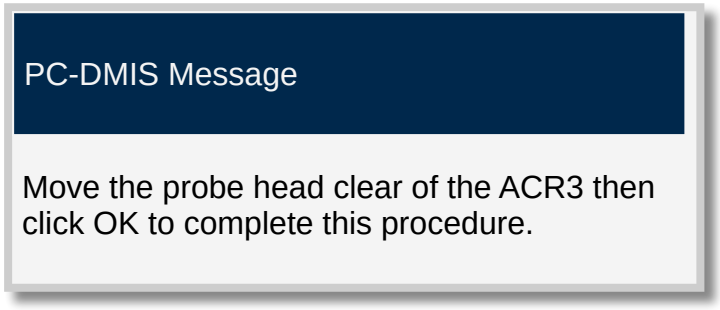
When in position, click OK

PC-DMIS prompt to align the probe changer.

1. Use your machine's jog box to slowly move the probe changer to the left or right until the square sight hole aligns with the round hole underneath, as shown below:

Example showing the visual alignment of the probe changer.

2. Once this is done, click **OK** at the last prompt, as shown below:



PC-DMIS prompt to move the probe head clear of the ACR3.

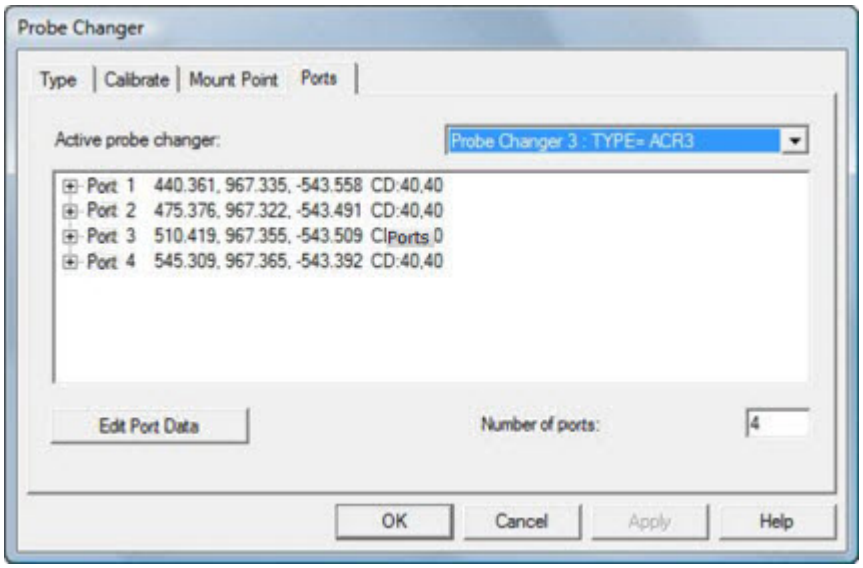
The ACR3 calibration is now complete.

3. Move the probe out and away from the probe changer's port 4 position. Return the probe changer to its right-most side of travel.

In the next step, you review the calibration results.

Step 12 - Review the Calibration Results

1. When the calibration of the ACR3 Probe Changer is complete, select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). This tab displays the calibration information for the location of each calibrated port. For example:



Example showing the calibration results on the Ports tab of the Probe Changer dialog box.

2. When you view the results, look for the following. Any significant deviations from these expectations may be due to a bad hit.

   - This probe changer MUST BE aligned parallel to either the X or Y axis of the CMM. This means that in one of these axes, there should be little or no change between ports.
   - In the other (X/Y) axis, you should see only the distance between the ports (roughly 35 mm).

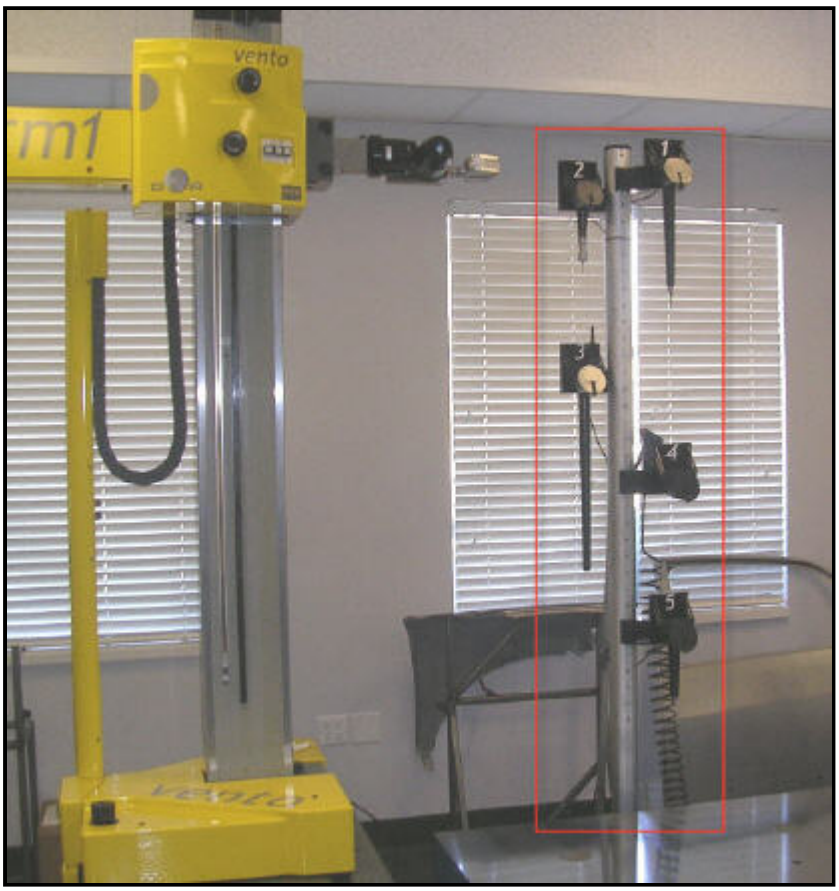
- The Z values should be nearly identical, since the ports are all at the same height.

The results during measurement routine execution are:

1. During measurement routine execution, probe entities that are added to each port are automatically picked up from that location whenever PC-DMIS executes a LOADPROBE command for that probe.
2. The probe body moves to the mount point and then into the port to drop off the current probe, which pushes the lid backwards.
3. The machine DCC movement slides the rack from the right to the left side of travel, turning the key in the process to unlock the probe from the wrist.
4. The probe then moves out from the port and into a different port to load the next probe. At this point, the DCC movement slides from the left to the right to lock this probe onto the wrist.
5. Finally, the probe travels out of the port and to the probe changer’s mount point.
6. From there, it continues to measure.

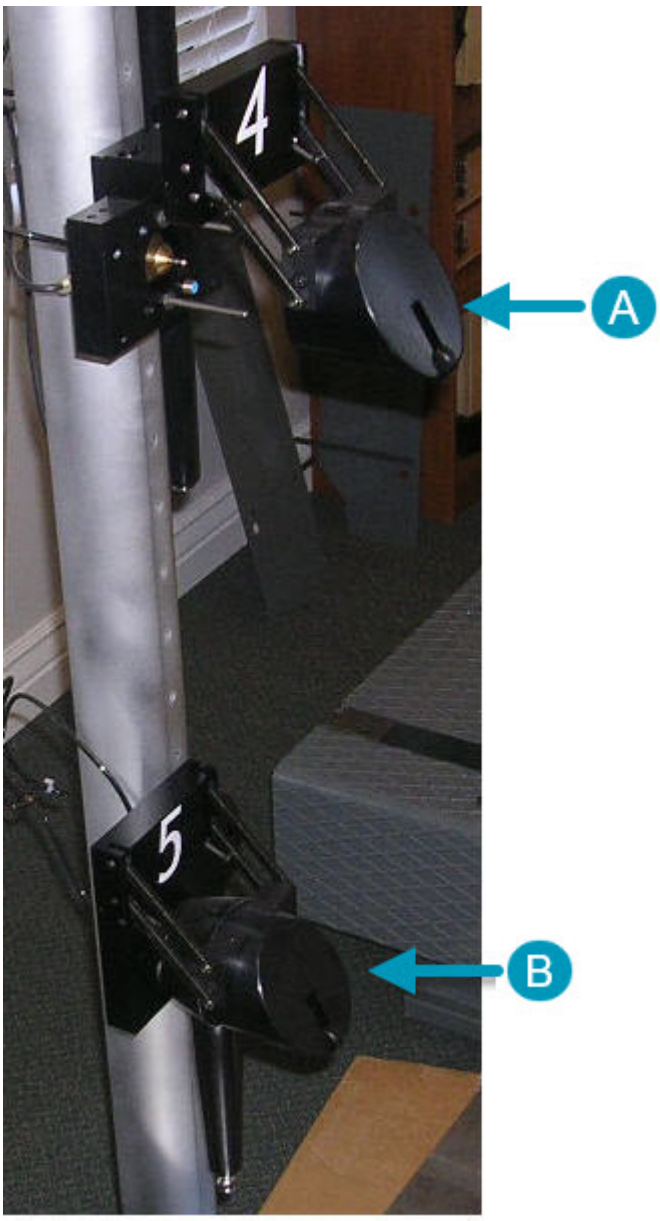
Calibrating the CW43 Probe Changer

This topic describes how to calibrate the CW43L Probe Changer.



Vertical CW43 Probe Changer with Five Ports

The CW43 Probe Changer can hold two different kinds of ports: normal ports and three-axis ports (ports that hold probes that can rotate in three axes).



A *- Port 4 shows a three-axis port.*
B *- Port 5 shows a normal port.*

The CW43L Probe Changer calibration procedure requires you to perform the calibration using a probe with the wrist map in order to properly calculate the port locations. Once you calibrate the probe changer, you can then use it to change probes regardless of whether or not they actually use the wrist map.

Before you start the calibration process, ensure that the installation personnel have mechanically aligned all of the ports so that the front face and the top of the ports are parallel to the movement of the machine's ram. If the ports are not properly aligned in this fashion, problems can occur during a probe change operation.

Step 1 - Select the CW43 Probe Changer

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **CW43L**.
3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.
4. In the **Number of probe changers** box, type the number of different types of probe changers. Generally, this is **1**.

   The **Active probe changer** list now reads: **Probe Changer 1 : Type= CW43L**.

Step 2 - Define the Ports

In this step, define the number of ports for your probe changer as well as the hardware held in each port.

1. Select the **Ports** tab.
2. In the **Number of ports** box, specify the number of ports used on your probe changer.
3. Click **Apply**.
4. Expand each port in the list, and define the probe file names that correspond to the hardware (probe or extension) that each port holds. You can do this now or any time after this point.
5. Click **Apply** when you are finished.

Getting Around Three-Axis Ports

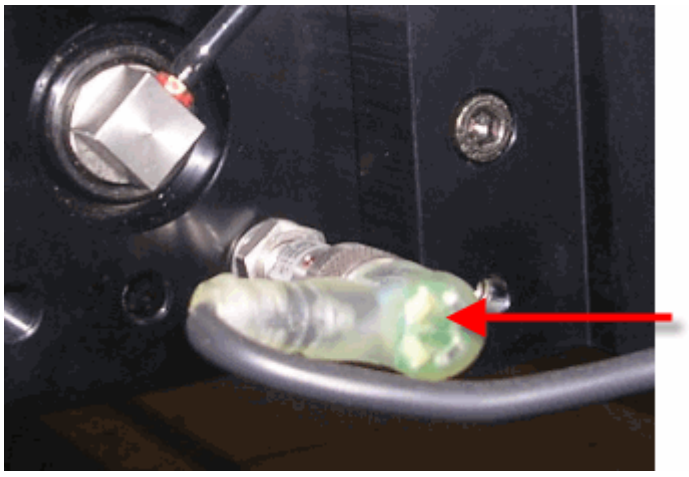
If you have a three-axis port, notice that it sticks out from the rack more than the normal ports. This may cause clearance problems when performing a probe change operation. To help avoid crashing into these ports, we recommend that you install this type of port on the ends of the probe changer: either on the top or the bottom on a vertical probe changer or on the left or right sides of a horizontal probe changer. If you cannot do this due to space constraints in your environment, modify the default clearance distance that the probe uses when moving to and from the different ports. You can do this by accessing the PC-DMIS Settings Editor and modifying the `TCRackClearance` or `TCRack3AxisClearance` entry in the next step.

- `TCRackClearance` - This entry is the clearance distance in front of a normal port. It has a default value of 150 mm.
- `TCRack3AxisClearance` - This entry is the clearance distance in front of a three-axis port. It has a default value of 300 mm.

Step 3 - Define the Three-Axis Port and Change Clearance Distances

You only need to perform this step if you have a three-axis port (a port capable of storing a three-axis probe). If not, go to the next step. You can perform this step later, but it is recommended that you do it now. This step essentially tells PC-DMIS which port is the three-axis port and whether or not you intend to perform load or unload operations automatically for that port.

1. Click **OK** to close the **Probe Changer** dialog box.
2. Exit the PC-DMIS application.
3. Launch the PC-DMIS Settings Editor.
4. Navigate to the **Leitz** section.
5. Select the `CW43LThirdAxisTCSlot` or `CW43LThirdAxisTCVerticalSlot` entry according to the port type mounted on the tool changer. The `CW43LThirdAxisTCSlot` entry is used for the old port type, where the third axis lies horizontally. The `CW43LThirdAxisTCVerticalSlot` entry is used for the new port type, where the third axis lies vertically. By default, these entries have a value of -1, which means that a three-axis port is not available on the probe changer.
    - If you plan to *manually* load and unload the three-axis probe from the port yourself, you should set this value to **0**.
    - If you plan to have PC-DMIS *automatically* load and unload the probe, you should set this value to the port number that holds the three-axis probe.
6. Ensure that the `CW43LTTest3AxisSlotTC` entry is set to **True**. There are two LED lights in a magnetic relay located on the back of a three-axis port: a green light and an amber light. The green light means that the port relay has power. The amber light is only illuminated if the three-axis joint is physically located in the port. A **True** value for this entry checks for the amber light and is an indication to the CMM controller that it is safe to apply the 24 volt DC motor power to the three-axis joint.



Solenoid Connection with Green and Amber LED Lights

> During a probe changer operation, NEVER attempt to *manually change* the three-axis probe while the green LED light on the top of the three axis joint is illuminated. An illuminated green LED light signifies that motor power (+24V DC) is present. If a probe change is done while there is motor power, it could cause a voltage spike that would damage the third axis motor. The same is possible for other voltage signals (+5V DC, +12V DC, and so on) needed for items that may attach to the third axis (NC100 video probe, and so forth). This applies only when the joint is connected to the probe head.

7. If needed, you can also modify the clearance distances for the `TCRackClearance` and `TCRack3AxisClearance` entries. You should only need to do this if your three-axis port could not be placed on the ends of the rack.
8. If you need to change the third-axis angle position when the probe is inside the port, set the desired value for the `CW43LTThirdAxisSlotAngle` entry. The default value is -1. If the value is -1, the angle value is the default value (according to the port type). You can set a value in these ranges:
   - 0 to 180
   - 0 to -180
9. If needed, modify the port cover lift direction in the `CW43LThirdAxisTCLeftToRightLift` entry. To determine the value, stand in front of the probe changer port and check the direction.
   - If the port cover lift direction is from left to right, set the value to **True** (this is the default value).
   - If the port cover lift direction is from right to left, set the value to **False**.

> PC-DMIS uses the value that you set for the `CW43LThirdAxisTCLeftToRightLift` entry only when the value for the `CW43LThirdAxisTCVerticalSlot` entry is not set to **-1**.

10. Save any changes and then close PC-DMIS Settings Editor.
11. Restart PC-DMIS and reload your measurement routine.
12. Select **Edit | Preferences | Probe Changer** to open the **Probe Changer** dialog box.

Step 4 - Prepare for Calibration

This step defines the probe file and tip angle to use during the calibration process.

1. Select the **Calibrate** tab.

2. In the **Active probe file** list, select the probe to use.

3. In the **Active tip** list, select the tip angle to use. The tip angle you use depends on your specific machine. This tip angle is used throughout the entire calibration process.

Step 5 - Begin Calibration

In this step, you need to decide whether to calibrate a single port in the probe changer or calibrate all of the ports, and then start the calibration procedure.

1. Decide the type of calibration to perform: either **Single port calibration** or **Full calibration**.

    - If you selected **Single port calibration**, the **Probe changer port** list becomes available for selection. In the **Probe changer** list, select the single probe to calibrate.

    - If you selected **Full calibration**, PC-DMIS calibrates all the available ports on your probe changer, starting with the first port and moving sequentially through all the ports.

2. Click the **Calibrate** button. PC-DMIS prompts if it is OK to rotate to the previously defined probe angle.

3. Click **OK**. The probe rotates to the defined angle, and a message box appears prompting you to take three hits.

Step 6 - Calibrate by Taking Three Hits

In this step, the probe is manually moved to take three hits, one on three different faces of each port being calibrated. For a full calibration, hits on the first defined port are taken and then move sequentially to the second port, and so on until the last. For a single port calibration, only hits on the one port being calibrated are made.

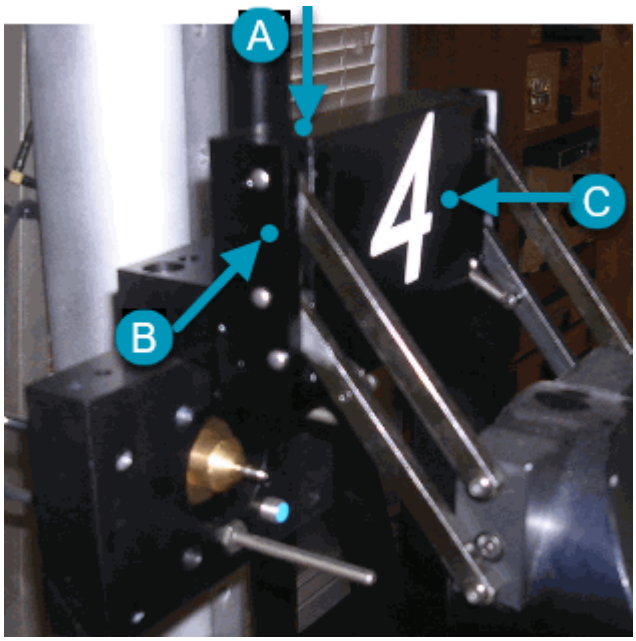
For a vertical probe changer:

- Take the first hit anywhere on the *top* of the top of the port. Press **Done**.

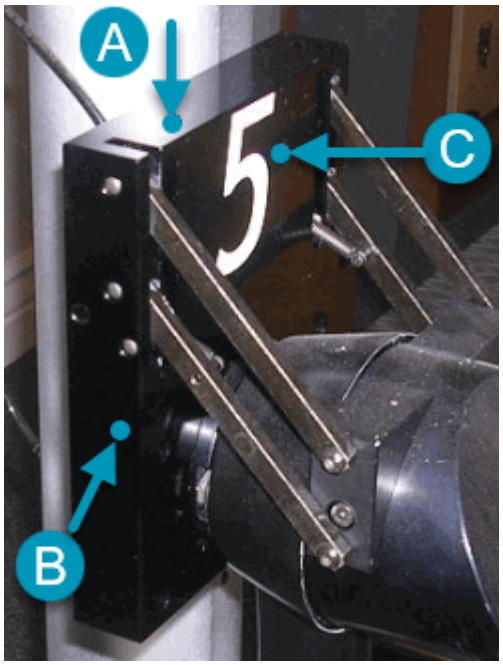
- Take the second hit anywhere on the *side* of the port *nearest the ram* of the machine. Press **Done**.

- Take the third hit anywhere on the *front face* of the port. (If this is the three-axis port, take the hit on the face to which the hinges of the port cover are attached.) Press **Done**.

Examples of taking three hits on a vertical probe changer. The following two pictures provide examples of the surfaces where the three hits should be taken for both a three-axis probe port and a normal probe port.



Three-axis probe port on a vertical rack



Normal probe port on a vertical rack

A - First hit on the top surface
B - Second hit on the side closest to the ram (depending on where your CMM ram is located, this could be on the other side)
C - Third hit on the front face

For a horizontal probe changer:

- Take the first hit anywhere on the *top* of the top of the port. Press **Done**.
- Take the second hit anywhere on *either side* of the port. Press **Done**.

- Take the third hit anywhere on the *front face* of the port. (If this is the 3 axis port, take the hit on the face to which the hinges of the port cover are attached.) Press **Done**.

Step 7 - Define a Mount Point

In this step, you define a safe location and probe head angle in front of the rack where the CMM is able to reach all the ports. This is called the "mount point".

The mount point location is NOT the same thing as the distance in front of the probe changer as defined by the `TCRackClearance` and `TCRack3AxisClearance` entries.

1. Select the **Mount Point** tab.
2. In the **Probe head wrist angle** boxes, use the **A angle** and **B angle** boxes to define the probe head angle to use when the probe head is at the mount point location.
3. Use the jog box to manually move the probe to where you want your mount point, and then click the **Read Machine** button. PC-DMIS pulls in the XYZ location from the CMM.
4. Click **Apply** and then **OK**.

You are now done with the calibration of the CW43 Probe Changer. You can now perform probe changes.

Remember, during a probe changer operation, NEVER attempt to manually change a three axis probe while the green LED light on the top of the three axis joint is lit. This applies only when the joint is connected to the probe head.

Calibrating the HR-MP (used with TM or THD) Probe Changer

This section describes how to calibrate the HR-MP (used with TM or THD) Probe Changer. The process discussed here is specific to the HR-MP (used with TM or THD) Probe Changer.

You can calibrate the probe changer in the following ways::

- When you calibrate the probe changer for the first time, you need to take manual hits.
- When the probe changer is removed and mounted at the same location, you can select to calibrate the probe changer in DCC Mode without taking manual hits.
- When the probe changer is removed and relocated on the CMM table, you can follow the same steps when you calibrate for the first time.

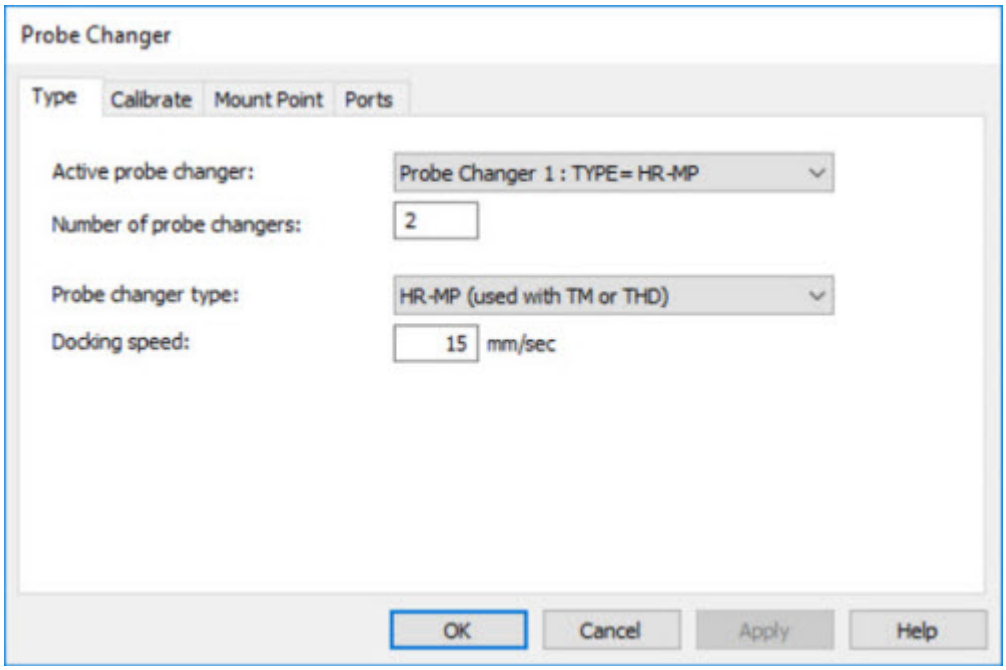
- The calibration of a single port is available in DCC Mode or Manual Mode.

To calibrate your probe changer:

Step 1 - Select the HR-MP (used with TM or THD) Probe Changer

To select the HR-MP (used with TM or THD) Probe Changer, follow these steps:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **HR-MP (used with TM or THD)**.



Probe Changer Dialog Box - Type Tab

3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.
4. In the **Active probe changer** list, select the list item that represents the probe changer that you want to define. If this is the first probe changer, it appears as **Probe Changer 1: TYPE=None**.
5. In the **Number of probe changers** box, specify the number of probe changers that you want to define.
6. In the **Docking speed** box, type a value. A value between 10-20 mm/sec is appropriate for this machine configuration. You can adjust this value at any time to speed up or slow down the system.

> To avoid equipment damage due to excessive docking speed, gradually increase the **Docking speed** value.

7. Click **Apply** to apply any changes made for this probe changer, and then click **OK** to close the dialog box.

> For details on controller configuration settings, see the documentation that came with your controller.

In the next step, you define the location your probe body moves to when using the probe changer to switch probe components.

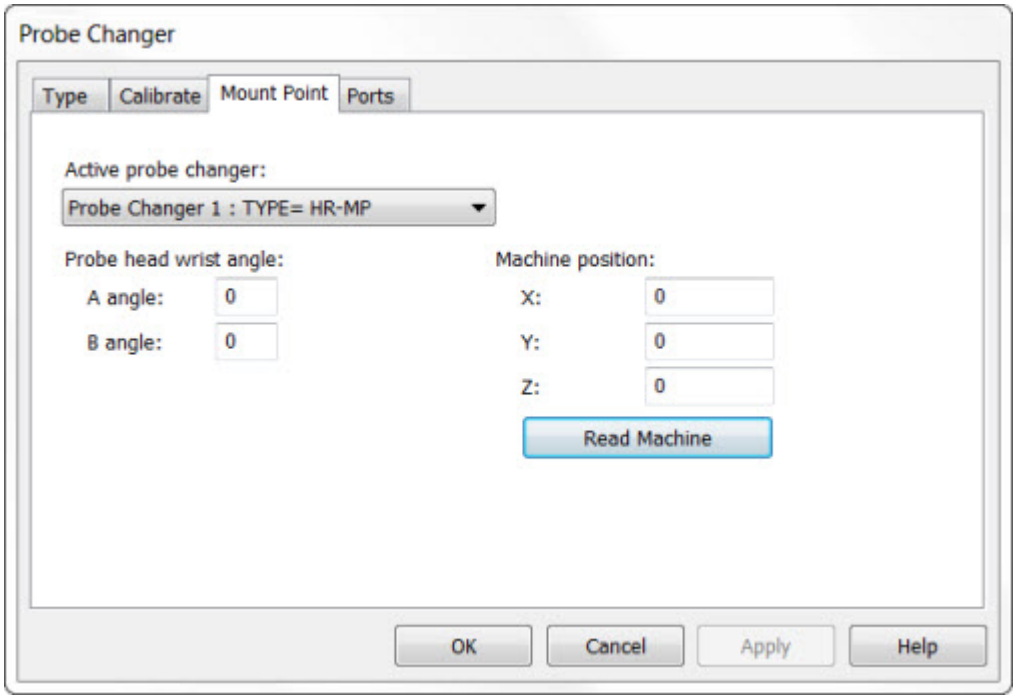
Step 2 - Define the Mount Point

The probe changer mount point is the location in front of the probe changer where the machine moves to before it picks up or drops off a probe. You should pick a location that avoids collisions with the probe changer, the part, clamps, or any other object in the workspace.

To define the mount point for your probe changer, follow these steps:

1. Select the **Mount Point** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**).

2. In the **Active probe changer** list, select **TYPE=HR-MP**:



Probe Changer Dialog Box - Mount Point Tab

3. If necessary, alter the probe head wrist angle for both **A angle** and **B angle**. Often, but not always, these values are both 0 (zero). You need to use a calibrated probe rotation that ensures that the probe has the ability to move in and out of the probe rack during the necessary steps of the probe rack calibration procedure.

4. Use your jog box to manually move your machine to the desired mount point position.
5. Click the **Read Machine** button to populate the **X**, **Y**, and **Z** machine position values with the current position. You can also type these values.
6. To save your changes, click **Apply**.

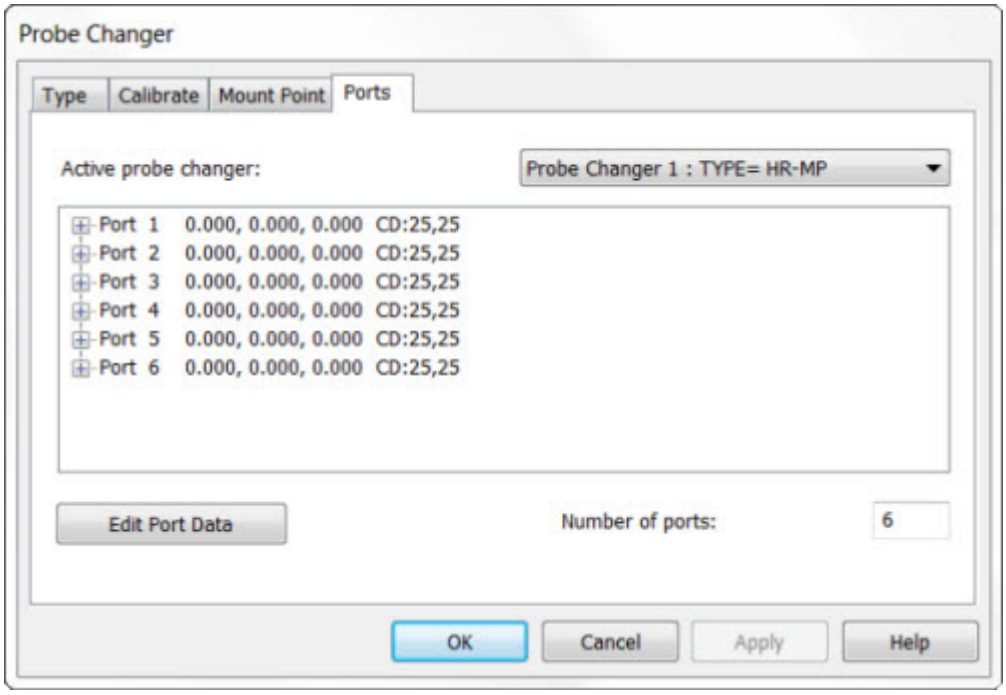
In the next step, you define the ports.

Step 3 - Define the Ports

The final step prior to rack calibration is to define the ports on the rack that you are calibrating.

To define the ports for your HR-MP (used with TM or THD) Probe Changer, follow these steps:

1. Select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**).
2. In the **Active probe changer** list, select **TYPE=HR-MP**:



Probe Changer Dialog Box - Ports Tab

3. In the **Number of ports** box, type the number of ports on your probe changer.
4. To save your changes, click **Apply**.

You are now ready to begin calibration. The next step starts the calibration process.

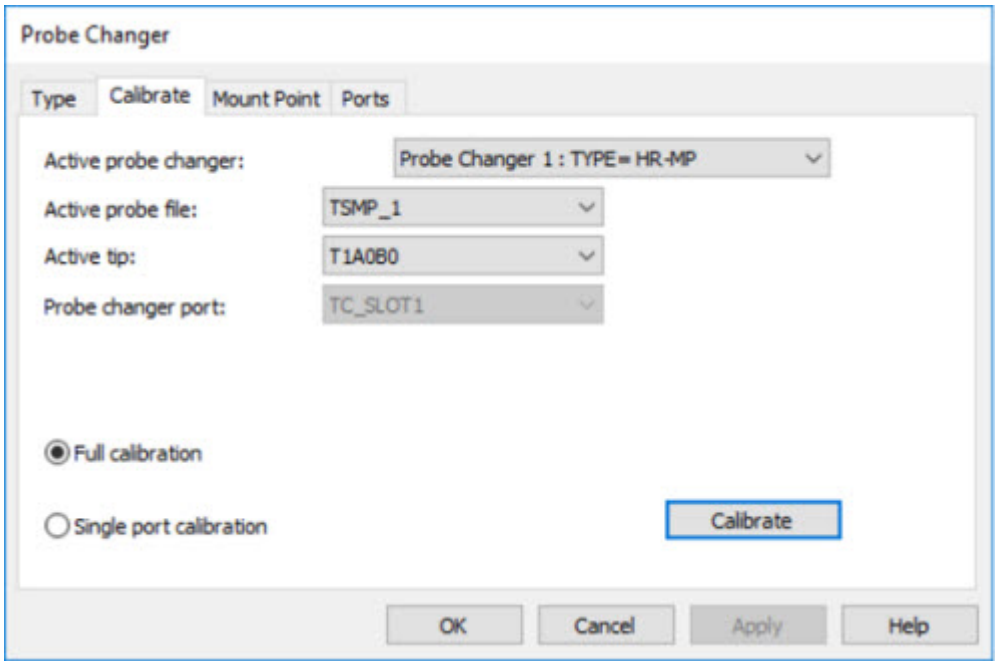
Step 4 - Prepare for Calibration

This step starts the calibration process for the HR-MP (used with TM or THD) Probe Changer.

To start the calibration process, follow these steps:

1. Select the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**).

2. In the **Active probe changer** list, select **Probe Changer 1: TYPE=HR-MP**:

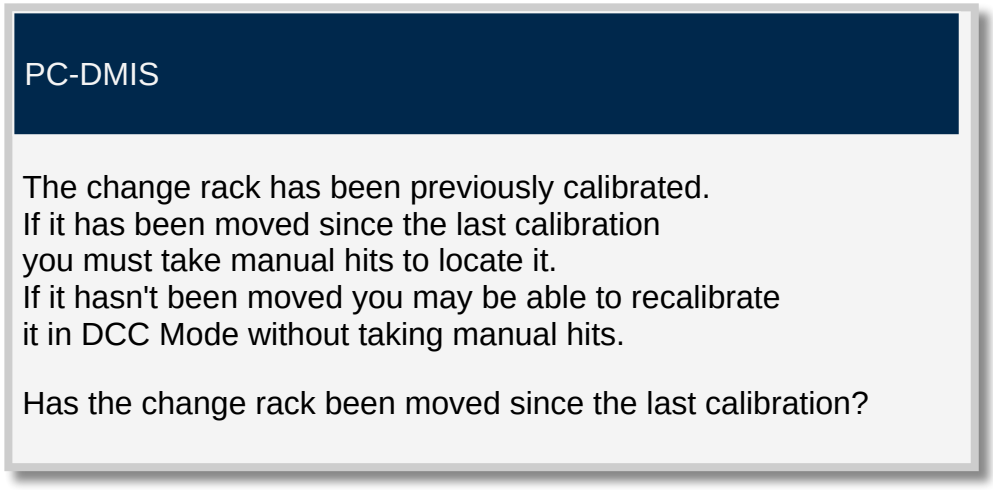


Probe Changer Dialog Box - Calibrate Tab

3. The entry in the **Active probe file** list defaults to the current measurement routine setting. If this is not what is to be used for the rack calibration, select the proper probe.

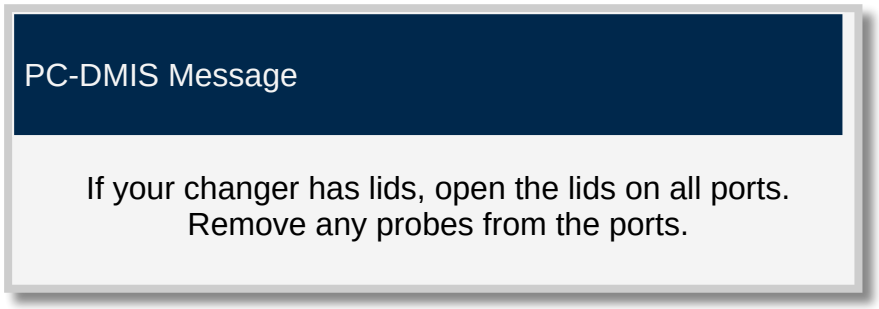
4. The entry in the **Active tip** list defaults to the current measurement routine setting. If this is not what is to be used for the rack calibration, select the tip ID to be used for calibration. This is usually **T1A0B0**.

5. Click **Calibrate**. The following message box appears:



6. If you are calibrating the probe changer for the first time after installation, or if you want to move the probe changer to a new location, click **Yes**. If you have removed and mounted the probe changer at the same location, click **No**. If you click **Yes**, PC-DMIS prompts you to take manual hits. If you click **No**, the probe changer calibration starts in DCC Mode.

7. If you click **Yes**, the following message appears:



8. Open all lids. To open the lid or lids, push them all the way back.

9. With the lid or lids open, remove all of the modules or styli by sliding them forward and out of the ports.

10. Empty the ports of all probes.

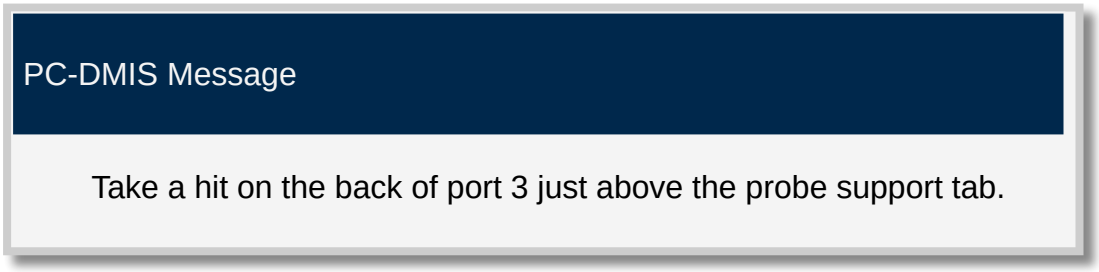
11. When you are ready to take the first measurement, click **OK**.

In the next step, you take the manual hits.

Step 5 - Take the Manual Hits

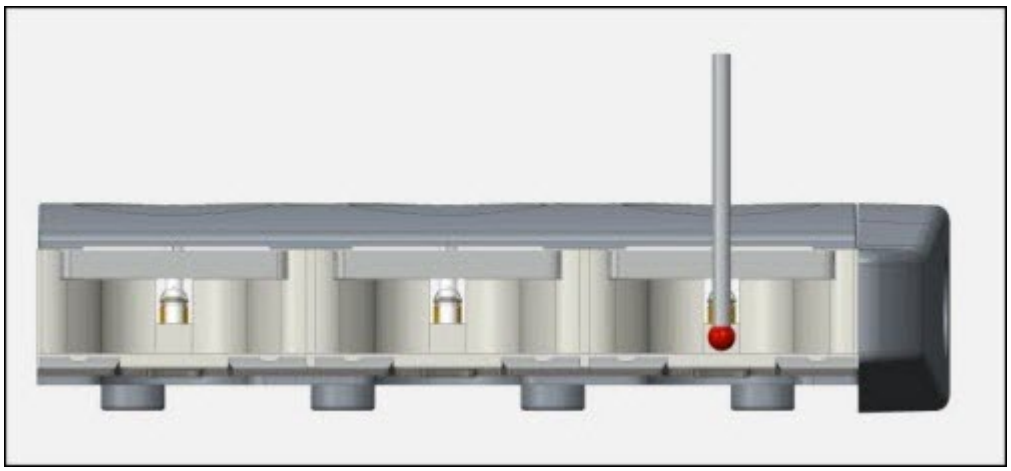
PC-DMIS moves you through the process of measuring four manual hits through a series of message boxes. You will take the first hit for the HR-MP (used with TM or THD) Probe Changer on the back surface of the last port (for example, port 3).

The following message prompts you to open all the lids and take the first hit:

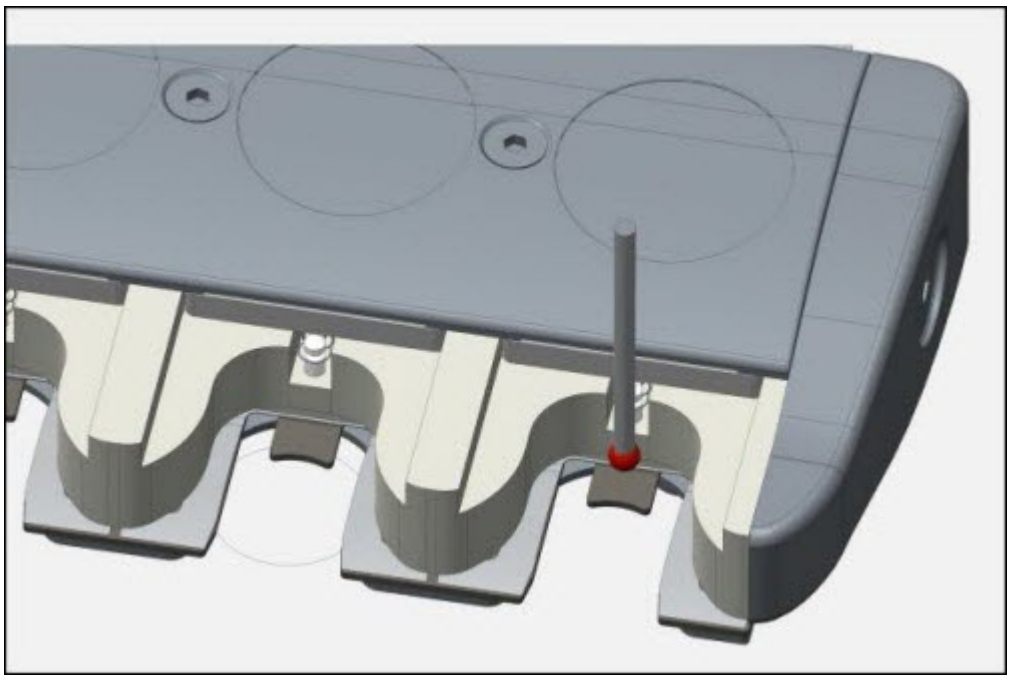


1. When you are ready to take the first measurement, click **OK**.

2. Use your machine's jog box to take the first manual hit on the back surface of port 3 and just above the probe support tab, as shown below:



View of the first hit on the back surface of port 3



View of the first hit on the back surface of port 3 and above the probe support tab

3. Repeat the step 1 and 2 as prompted for all the ports.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

In the next step, you take the manual hit on the top of the probe support tab.

Step 6 - Take the Manual Hit on Top of the Probe Support Tab

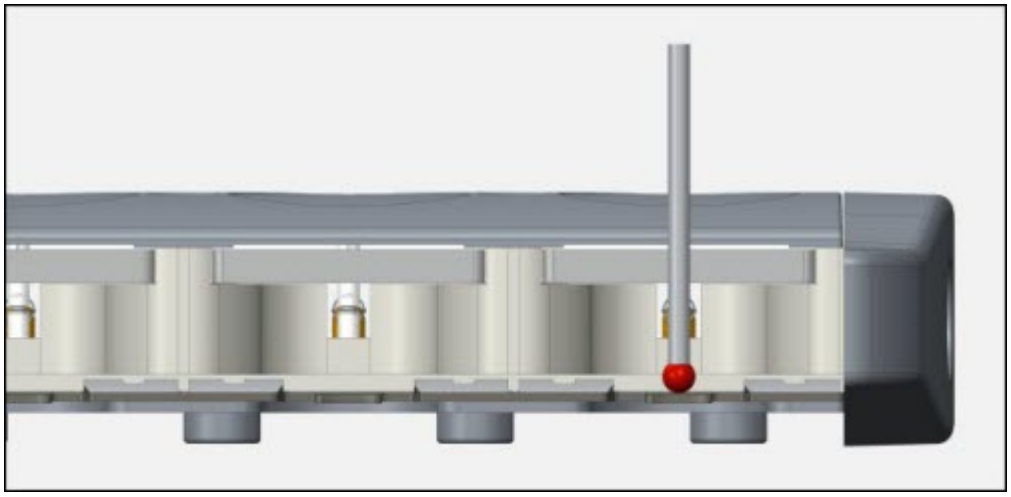
When the following message box appears, you will take the manual hit for the HR-MP (used with TM or THD) Probe Changer on the top of the probe support tab in port 1.

PC-DMIS Message

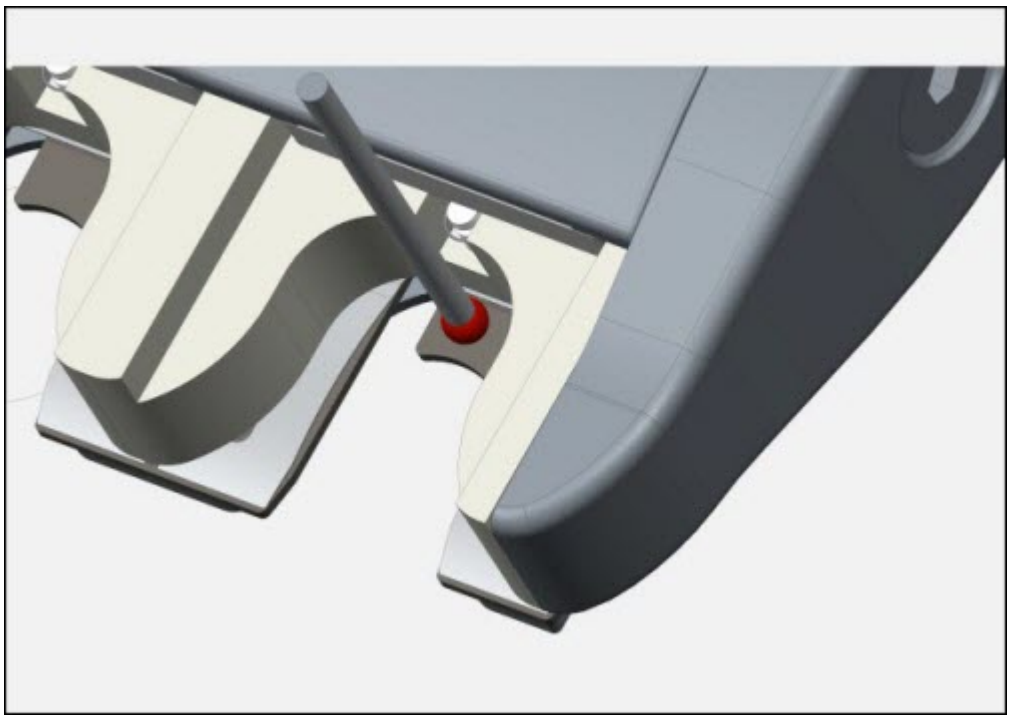
Take a hit on top of the probe support tab in the back of port 1.

After completing the hit, DCC motion will begin
for the rest of the measurement.

1. When you are ready to take the hit, click **OK**.
2. Use your machine's jog box to measure the hit on the top surface of the probe support tab in the back of the port:



View of the fourth hit on the top surface of the probe support tab



View of the fourth hit on the top surface of the probe support tab in the back of the port

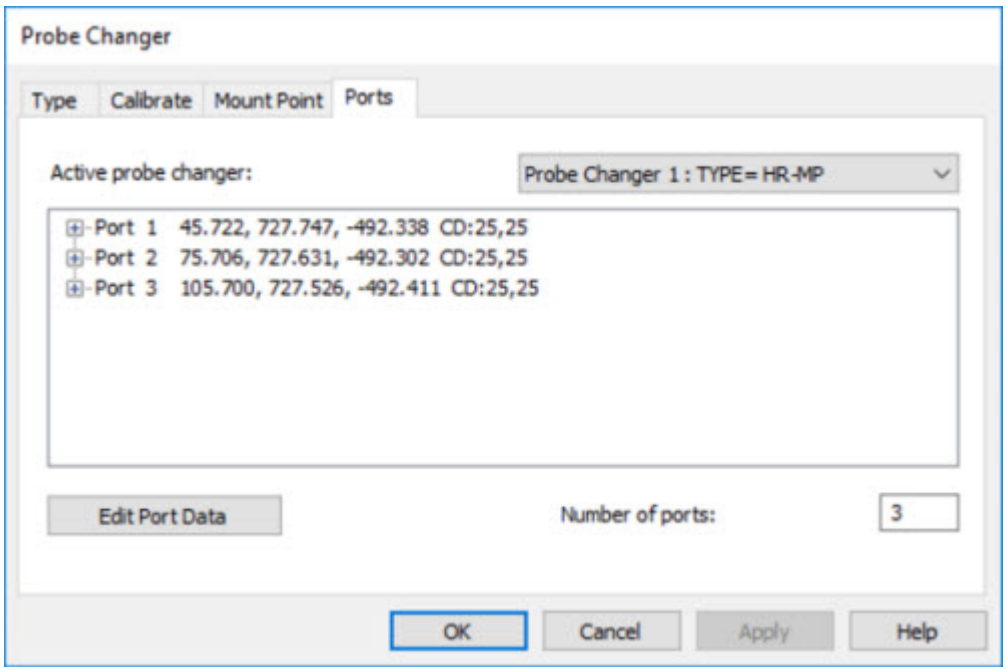
> **WARNING:** When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

3. Click **OK**. The system goes into DCC Mode and measures a series of hits required to accurately locate and orient the rack.

In the next step, you review the calibration results.

Step 7 - Review the Calibration Results

1. When the calibration of the HR-MP (used with TM or THD) Probe Changer is complete, select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). This tab displays the calibration information for the location of each calibrated port. For example:



Ports tab of Probe Changer dialog box showing the calibration results.

2. When you view the results, look for the following. Any significant deviations from these expectations may be due to a bad hit.
    - This rack is not necessarily aligned parallel to any axis of the CMM.
    - The Z values should be nearly identical since the ports are all at the same height.

The results during measurement routine execution are:

1. The probe entities that are added to each of the ports are automatically picked up from that location whenever PC-DMIS executes a `LOADPROBE` command for that probe.
2. The probe body moves to the mount point and then into the "unload" port (the port that used to contain the currently-used probe entity) to drop off the current probe. The current "puck", a conical piece of hardware that connects to the bottom of the probe body, is held in place by the rack while the probe body lifts away to detach.
3. From there, the probe moves over to the next "load" position. The magnetic connection automatically engages to load the new module.
4. The probe then moves back to the rack's mount point.
5. From there, it continues to measure.

Next, you can choose to recalibrate all ports in DCC Mode, or recalibrate a single port.

Recalibrate the Ports

After you complete a full calibration of the HR-MP (used with TM or THD) Probe Changer, you can choose to recalibrate all ports in DCC Mode, or recalibrate a single port.

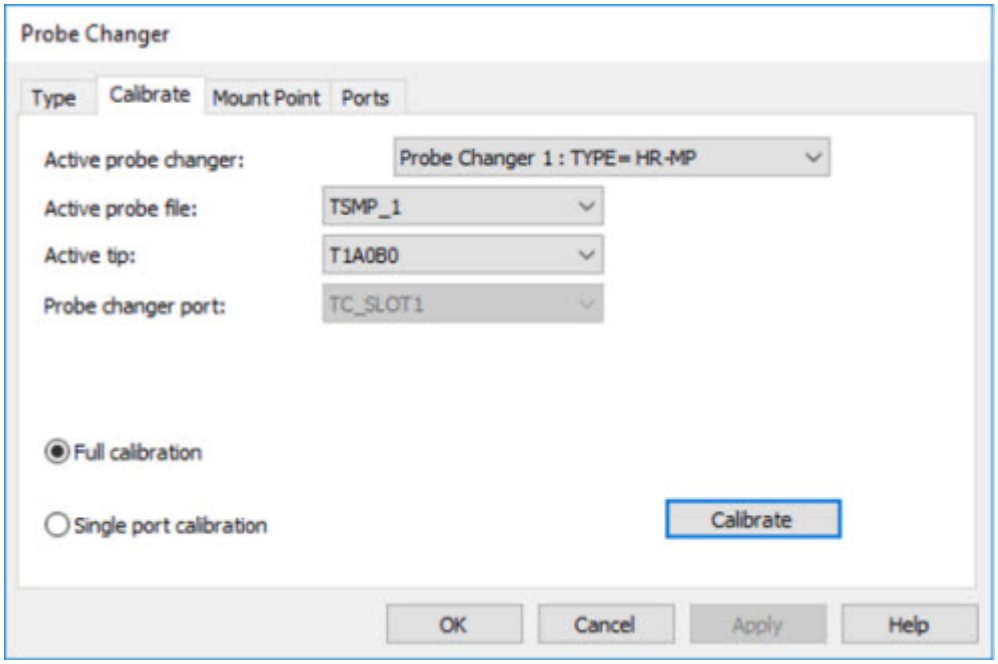
WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

Recalibrating All Ports in DCC Mode

If you have removed and mounted the probe changer at the same location, you will be able to recalibrate in DCC Mode.

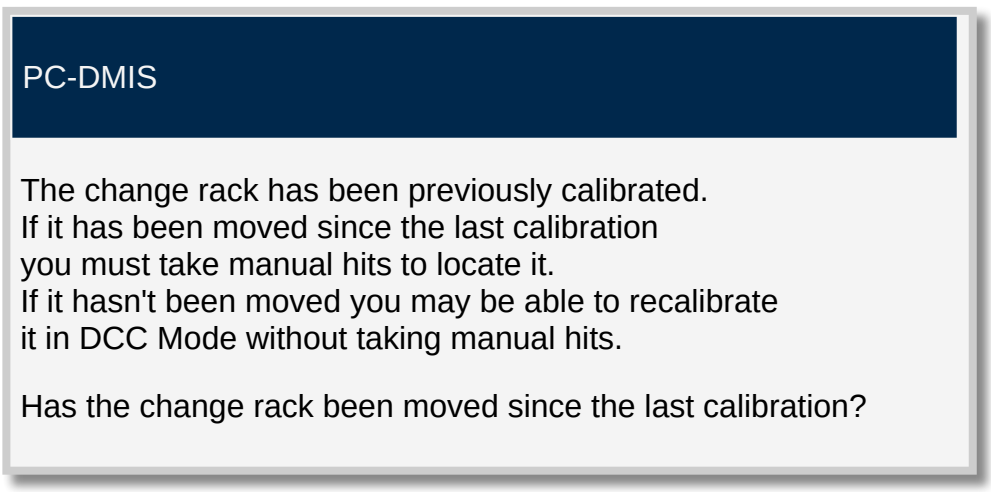
To recalibrate all ports in DCC Mode, follow these steps:

1. Select the **Full calibration** option on the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). (If you did not complete a full calibration, the option is not available.)

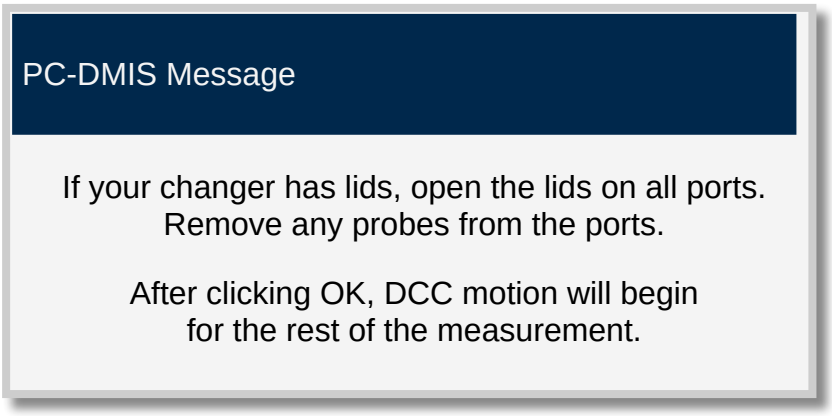


Probe Changer Dialog Box - Calibrate Tab

2. To begin the calibration, click **Calibrate**. A message prompts you if the change rack has been moved since the last calibration:



3. Click **No**. The following message appears:

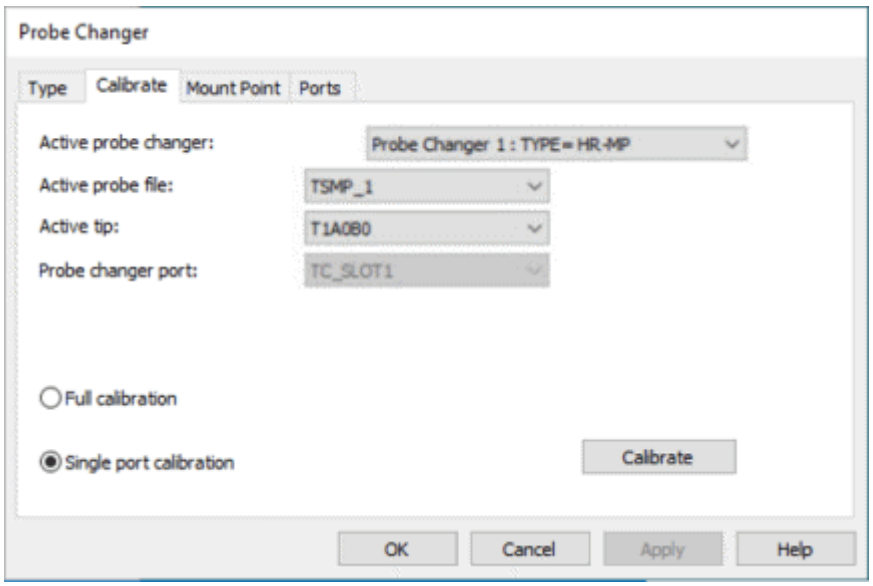


4. Open all lids. To open the lid or lids, push them all the way back.
5. With the lid or lids open, remove all of the modules or styli by sliding them forward and out of the ports.
6. Empty the ports of all probes.
7. Click **OK**. The system goes into DCC Mode and measures a series of hits required to accurately locate and orient the rack.

Recalibrating a Single Port

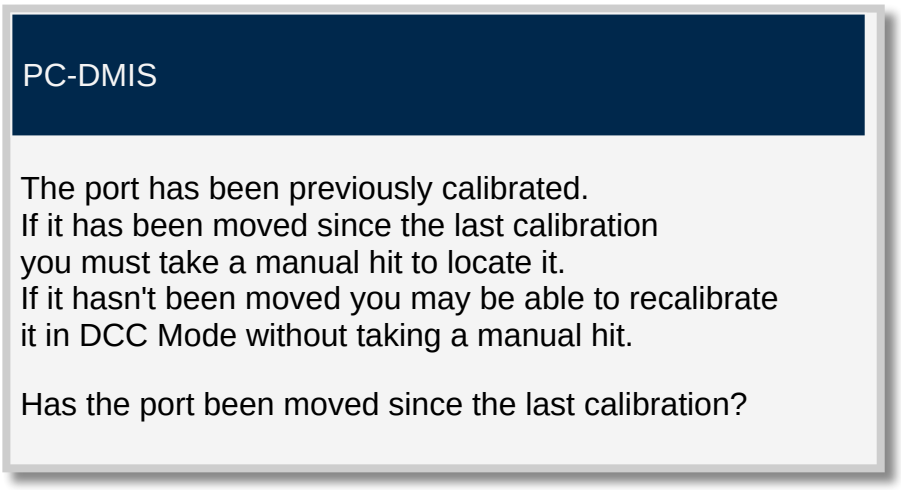
To recalibrate a single port, follow these steps:

1. Select the **Single port calibration** option on the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). (If you did not complete a full calibration, the option is not available.)
2. When you select the **Single port calibration** option, the **Probe changer port** list becomes available. Select the port that you want to calibrate. For example:



Probe Changer Dialog Box - Calibrate Tab

3. To begin the calibration, click **Calibrate**. A message prompts you to take a hit on the top left surface of the port that you selected:



4. Click **No**. The following message appears:

   a. Open the lid. To open the lid, push it all the way back.

   b. With the lid open, remove the module or styli by sliding it forward and out of the port.

   c. Empty the port of its probe.

   d. Click **OK**. The system goes into DCC Mode and measures the hit.

Calibrating the HR-MS or HR-X1 Probe Changer

This section describes how to calibrate the HR-MS or HR-X1 Probe Changer. The process discussed here is specific to the HR-MS and HR-X1 Probe Changer.

You can calibrate the probe changer in the following ways:

- When you calibrate the probe changer for the first time, you need to take manual hits.

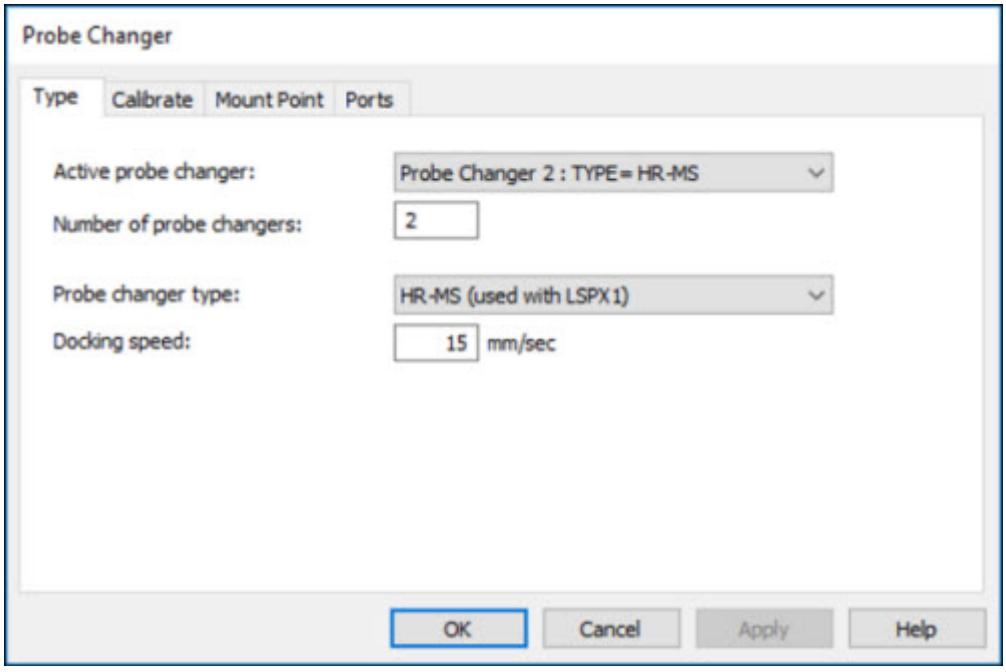
- When the probe changer is removed and mounted at the same location, you can select to calibrate the probe changer in DCC Mode without taking manual hits.
- When the probe changer is removed and relocated on the CMM table, you can follow the same steps when you calibrate for the first time.
- The calibration of a single port is available in DCC Mode or Manual Mode.

To calibrate your probe changer:

Step 1 - Select the HR-MS or HR-X1 Probe Changer

To select the HR-MS or HR-X1 Probe Changer, follow these steps:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **HR-MS** or **HR-X1**:



Probe Changer Dialog Box - Type Tab

3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.
4. In the **Active probe changer** list, select the list item that represents the probe changer that you want to define. If this is the first probe changer, it appears as **Probe Changer 1: TYPE=None**.
5. In the **Number of probe changers** box, specify the number of probe changers that you want to define.
6. In the **Docking speed** box, type a value. A value between 10-20 mm/sec is appropriate for this machine configuration. You can adjust this value at any time to speed up or slow down the system.

> To avoid equipment damage due to excessive docking speed, gradually increase the **Docking speed** value.

7. Click **Apply** to apply any changes made for this probe changer, and then click **OK** to close the dialog box.

> For details on controller configuration settings, see the documentation that came with your controller.

In the next step, you define the location your probe body moves to when using the probe changer to switch probe components.

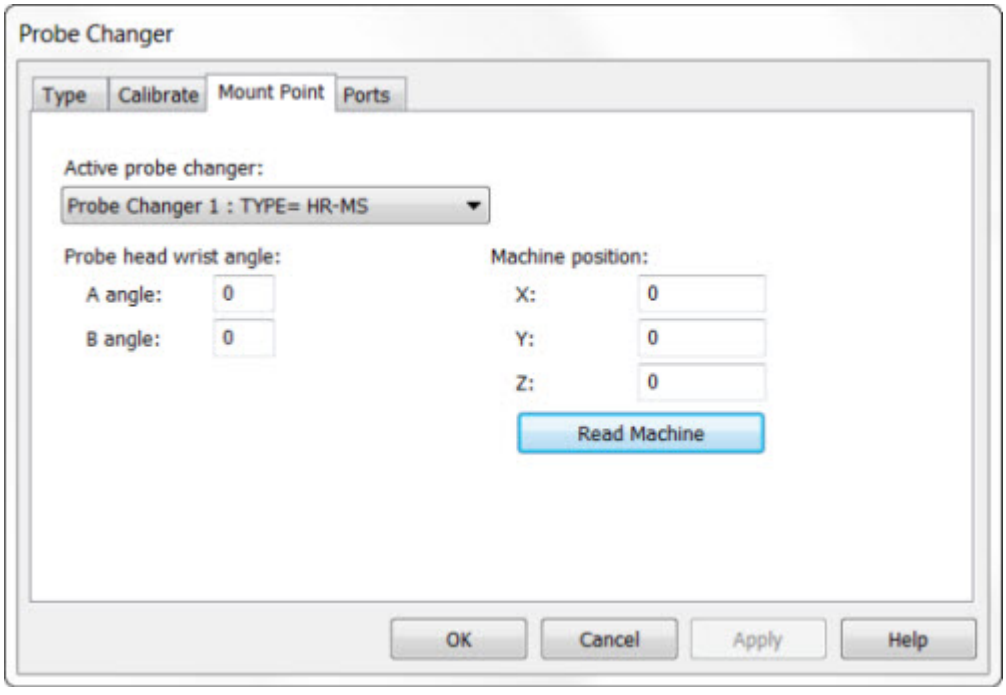
Step 2 - Define the Mount Point

The probe changer mount point is the location in front of the probe changer where the machine moves to before it picks up or drops off a probe. You should pick a location that avoids collisions with the probe changer, the part, clamps, or any other object in the workspace.

To define the mount point for your probe changer, follow these steps:

1. Select the **Mount Point** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**).

2. Depending on which probe changer you are calibrating, in the **Active probe changer** list, select **TYPE=HR-MS** or **TYPE=HR-X1**:



Probe Changer Dialog Box - Mount Point Tab

3. If necessary, alter the probe head wrist angle for both **A angle** and **B angle**. Often, but not always, these values are both 0 (zero). You need to use a calibrated probe rotation that ensures that the probe can move in and out of the probe rack during the necessary steps of the probe rack calibration procedure.
4. Use your jog box to manually move your machine to the desired mount point position.
5. Click the **Read Machine** button to populate the **X**, **Y**, and **Z** machine position values with the current position. You can also type these values.
6. To save your changes, click **Apply**.

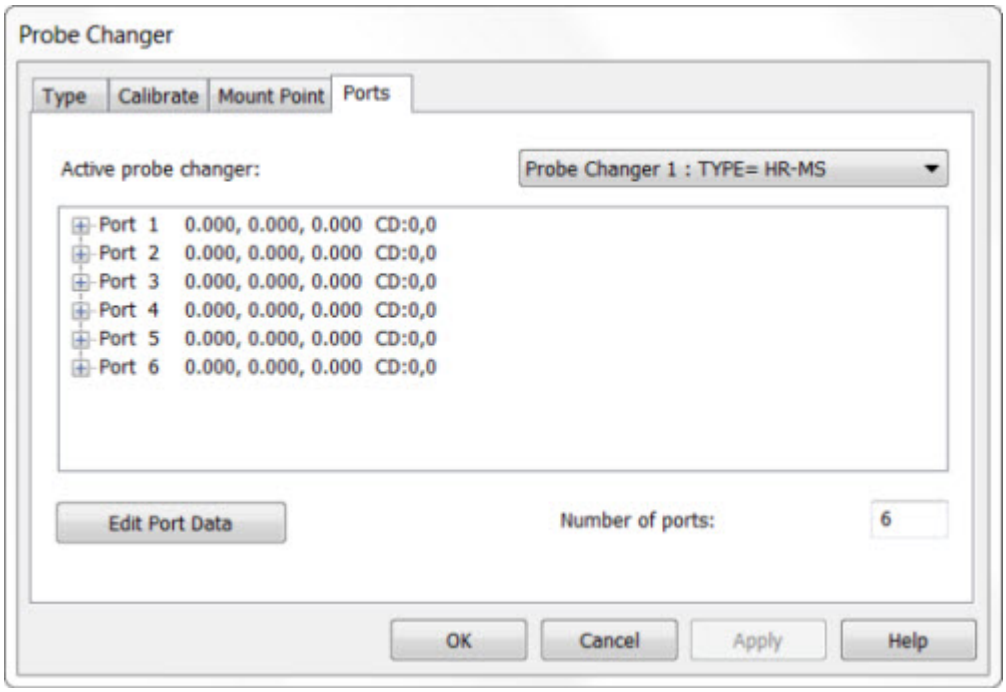
In the next step, you define the ports.

Step 3 - Define the Ports

The final step prior to rack calibration is to define the ports on the rack that you are calibrating.

To define the ports for your HR-MS or HR-X1 Probe Changer, follow these steps:

1. Select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**).
2. In the **Active probe changer** list, select **TYPE=HR-MS** or **TYPE=HR-X1**:



Probe Changer Dialog Box - Ports Tab

3. In the **Number of ports** box, type the number of ports on your probe changer.
4. To save your changes, click **Apply**.

You are now ready to begin calibration. The next step starts the calibration process.

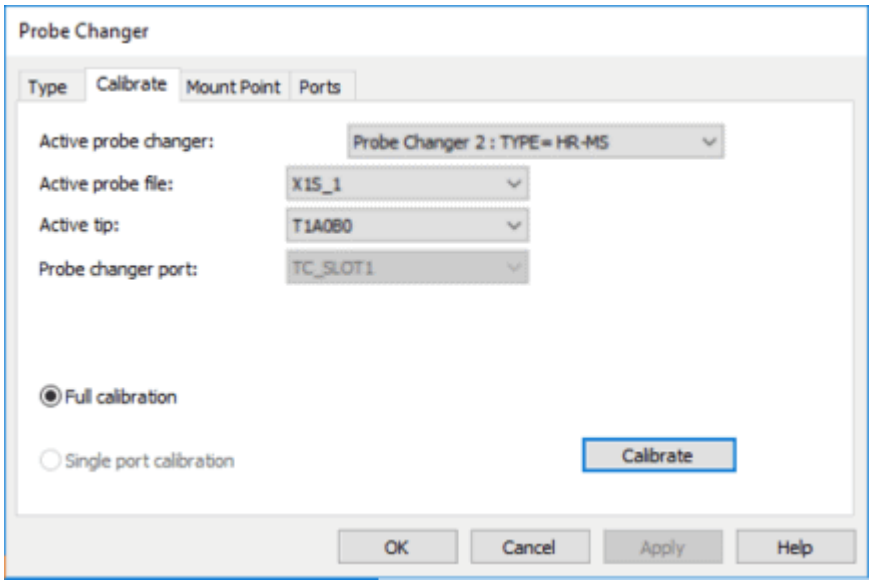
Step 4 - Prepare for Calibration

This step starts the calibration process for the HR-MS or HR-X1 Probe Changer.

To start the calibration process, follow these steps:

1. Select the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**).

2. Depending on which probe changer you are calibrating, in the **Active probe changer** list, select **Probe Changer 1: TYPE=HR-MS** or **TYPE=HR-X1**:



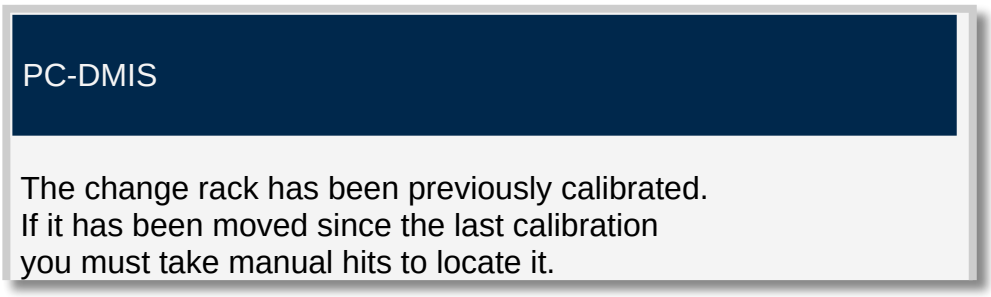
Probe Changer Dialog Box - Calibrate Tab

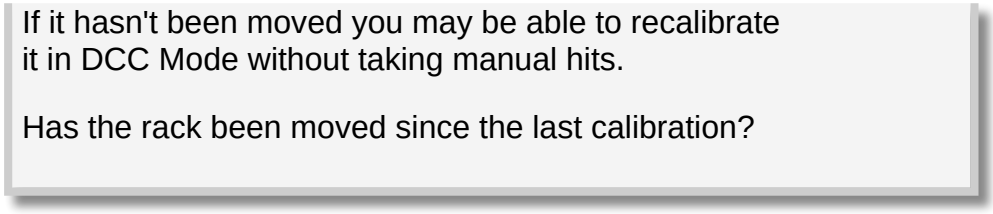
3. The entry in the **Active probe file** list defaults to the current measurement routine setting. If this is not the correct probe for the rack calibration, select it from the list.

4. The entry in the **Active tip** list defaults to the current measurement routine setting. If this is not the correct tip for the rack calibration, select the correct tip ID from the list. This is usually the tip corresponding to the angles defined on the **Mount Point** tab in Step 2.

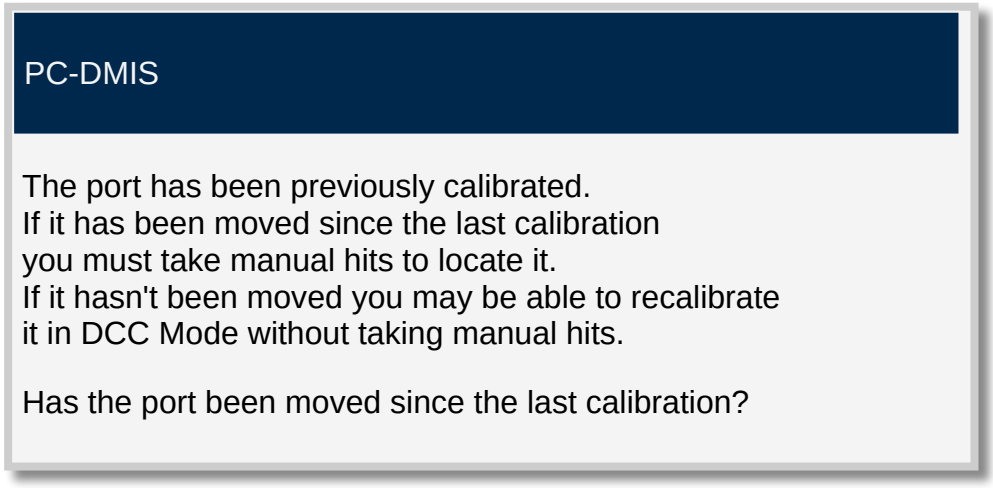
5. Click **Calibrate**. For a full calibration using manual hits, PC-DMIS shows one of the following messages:

   For full calibration:

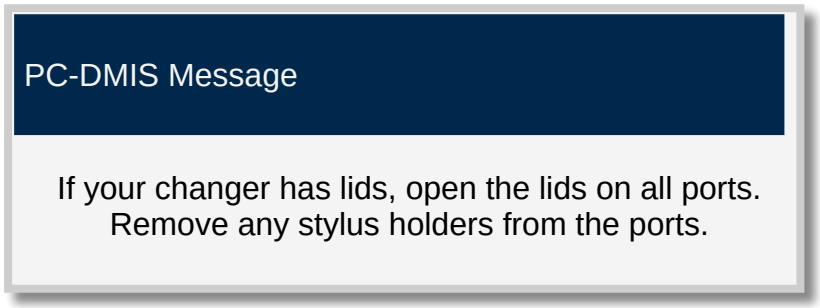




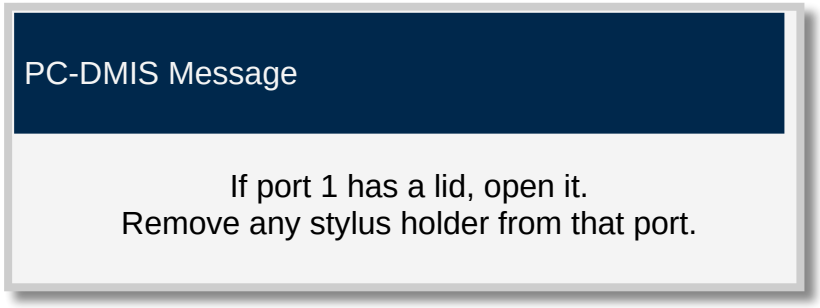
For single-port calibration:



If you click **Yes** on this message, PC-DMIS shows the following message for a full calibration:



If this is a single port calibration, PC-DMIS shows a similar message:



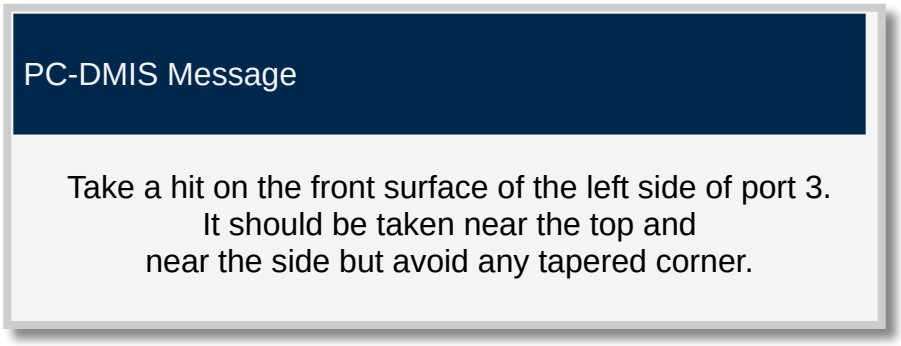
6. Remove the requested modules or styli by sliding them forward and out of the stylus holder.
7. When you are ready to take the first measurement, click **OK**.

In the next step, you take the first manual hit.

Step 5 - Take the Manual Hits

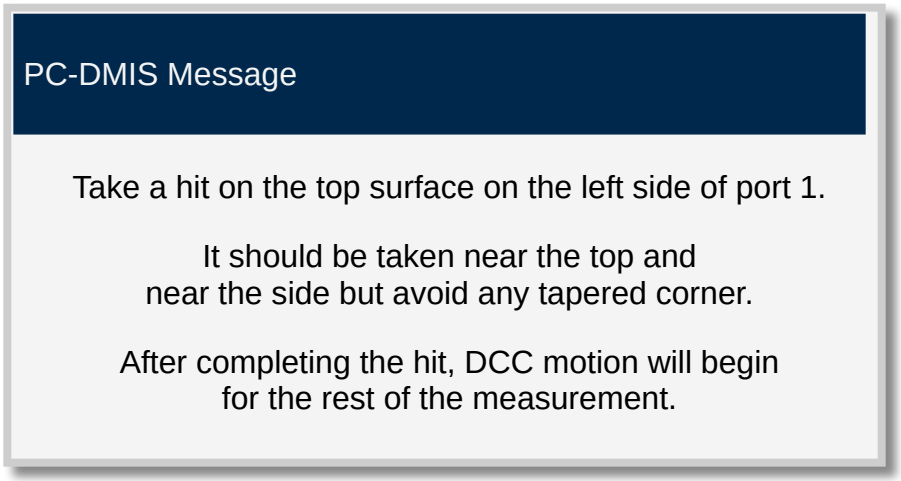
PC-DMIS moves you through the process of measuring the manual hits through a series of message boxes. The number of hits depends on how many ports the probe changer has. For the full calibration, the software requires a single manual hit on the front surface on the left side of each port starting with the last port and ending with the first port. When you complete the manual hits on the front surface of the left side of each port, the software prompts for a final hit on the top of port 1.

If your probe changer has three ports, the prompt for the first hit is:



1. When you are ready to begin, click **OK**.
2. Use your machine's jog box to take each manual hit in the location that the software prompts you.

When you complete all the front surface, left side hits, PC-DMIS prompts you one last time to take a top hit on the left side of the first port:

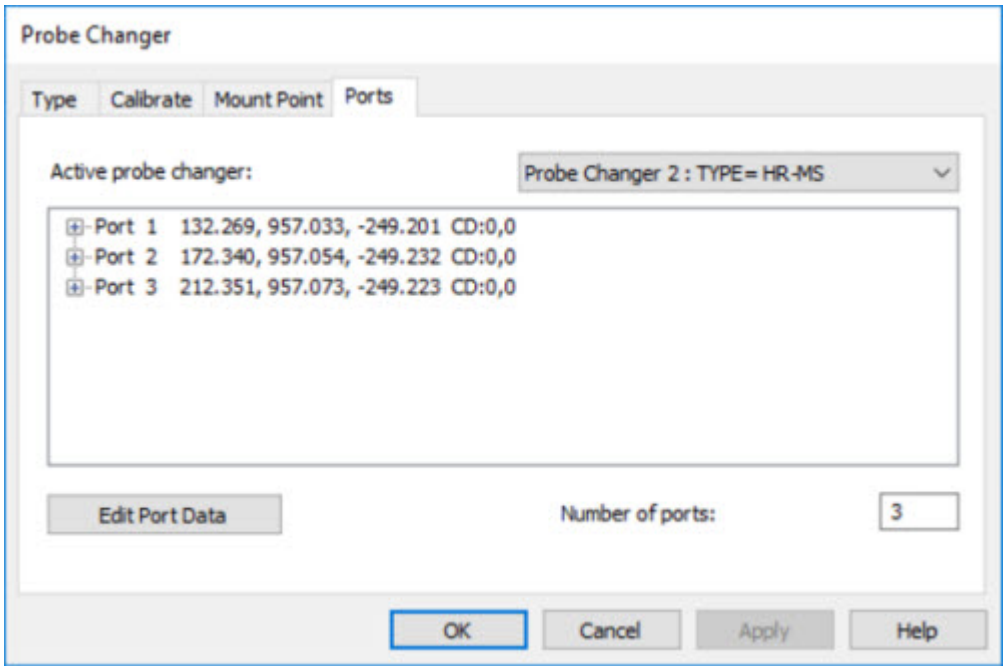


WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

In the next step, you review the calibration results.

Step 6 - Review the Calibration Results

1. When the calibration is complete, select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). This tab displays the calibration information for the location of each calibrated port. For example:



Probe Changer dialog box - Ports tab with calibration results

2. When you view the results, look for the following. Any significant deviations from these expectations may be due to a bad hit.

   - This rack is not necessarily aligned parallel to any axis of the CMM.
   - The Z values should be nearly identical since the ports are all at the same height.

Recalibrate the Ports

After you complete a full calibration of the HR-MS or HR-X1 Probe Changer, you can choose to recalibrate all ports in DCC Mode or recalibrate a single port.

Recalibrating All Ports in DCC Mode

Recalibrating a Single Port

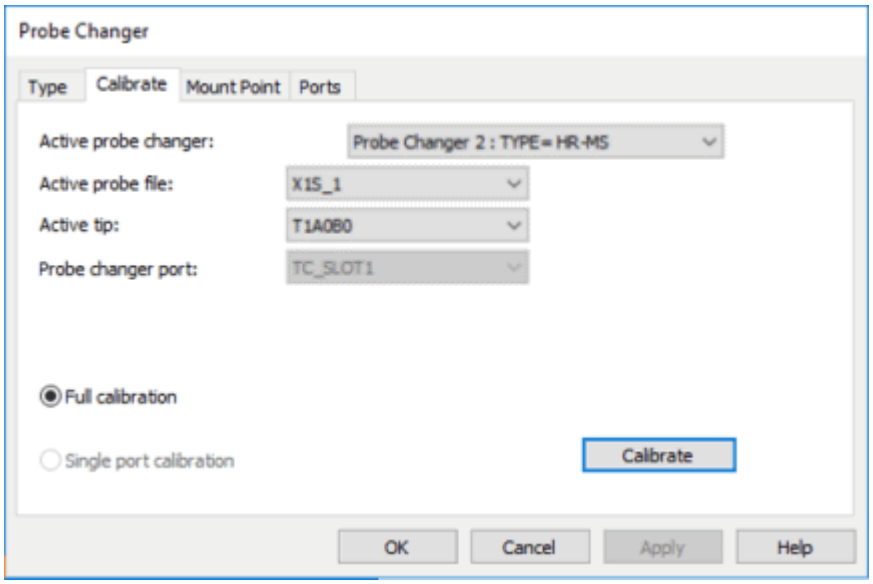
WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

Recalibrating All Ports in DCC Mode

If you have removed and mounted the probe changer at the same location, you will be able to recalibrate in DCC Mode.

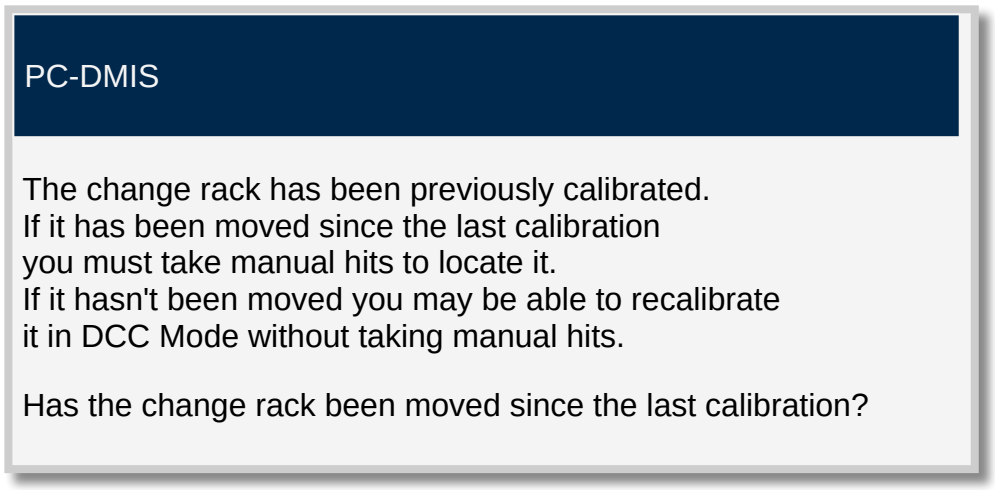
To recalibrate all ports in DCC Mode, follow these steps:

1. Select the **Full calibration** option on the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). (If you did not complete a full calibration, the option is not available.)

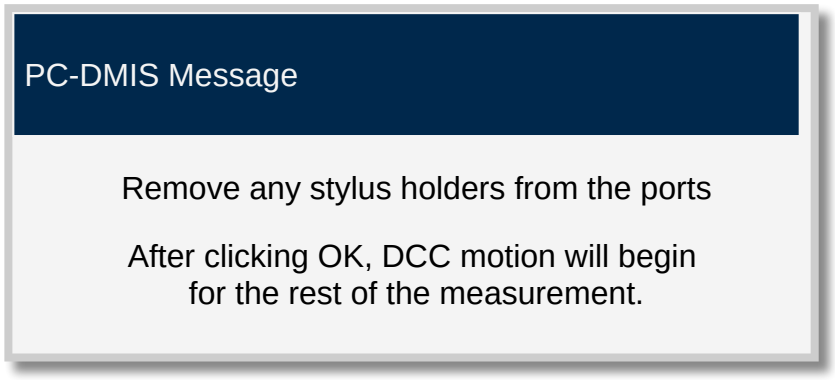


Probe Changer Dialog Box - Calibrate Tab

2. To begin the calibration, click **Calibrate**. A message prompts you if the change rack has been moved since the last calibration:



3. Click **No**. The following message appears:

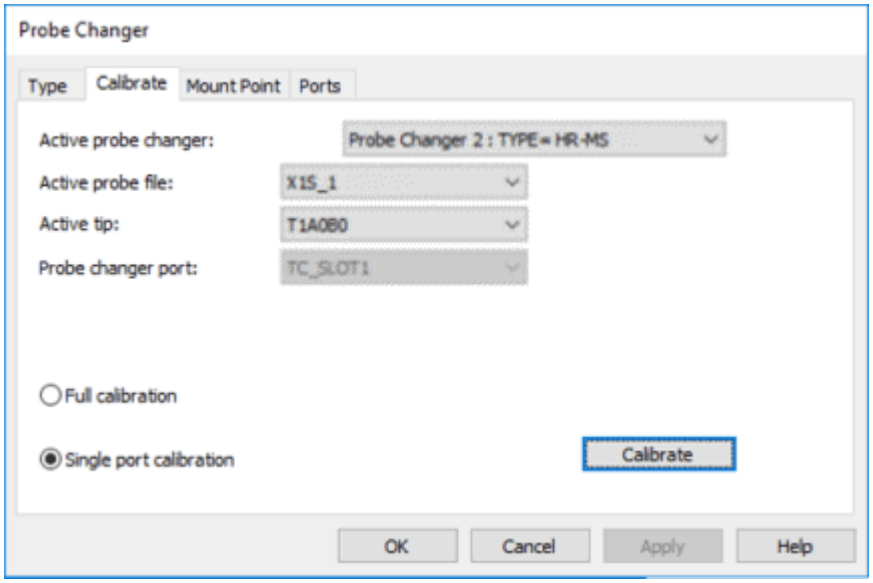


4. Open all lids. To open the lid or lids, push them all the way back.
5. With the lid or lids open, remove the requested modules or styli by sliding them forward and out of the stylus holder.
6. Click **OK**. The system goes into DCC Mode and measures a series of hits required to accurately locate and orient the rack.

Recalibrating a Single Port

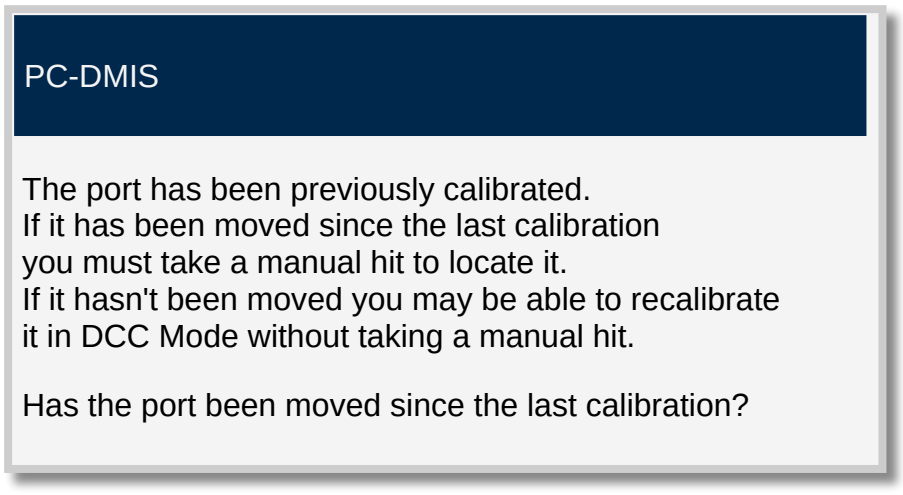
To recalibrate a single port, follow these steps:

1. Select the **Single port calibration** option on the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). (If you did not complete a full calibration, the option is not available.)
2. When you select the **Single port calibration** option, the **Probe changer port** list becomes available. Select the port that you want to calibrate. For example:

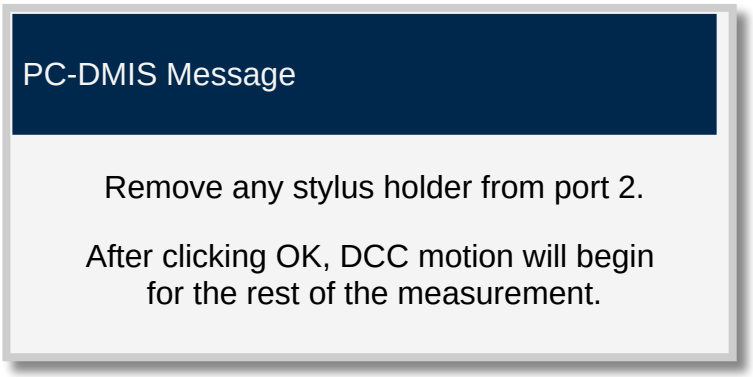


Probe Changer Dialog Box - Calibrate Tab

3. To begin the calibration, click **Calibrate**. A message prompts you to take a hit on the top left surface of the port that you selected:



4. Click **No**. The following message appears:



5. Open the lid. To open the lid, push it all the way back.
6. With the lid or lids open, remove the requested modules or styli by sliding them forward and out of the stylus holder.
7. Click **OK**. The system goes into DCC Mode to complete the measurement.

Defining the I++ Client Probe Changer

You can assign all of the probes that are available for DCC tool changes by the I++ server to the one port that is available for the I++ Client Probe Changer. When loading one of those probes, a request to load it is sent to the I++ server. The I++ server performs the actual change.

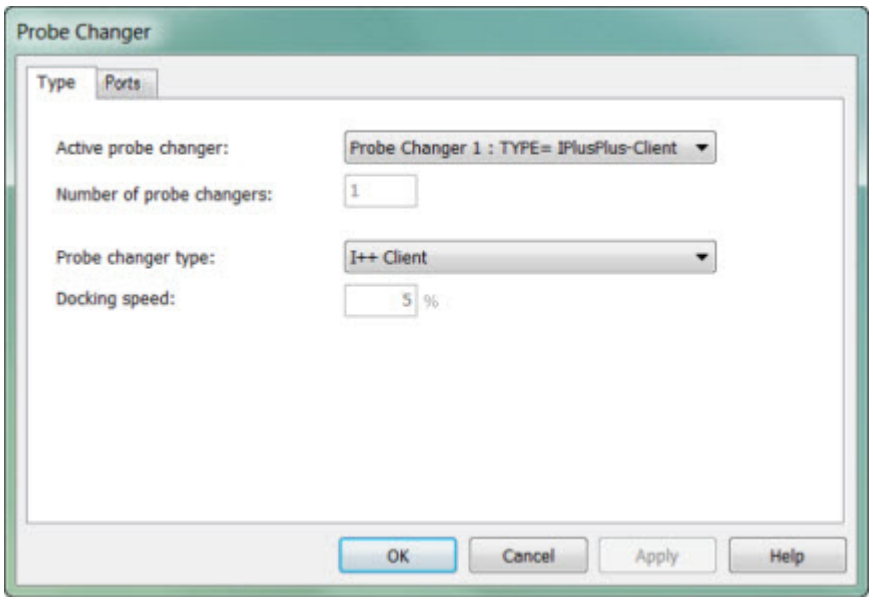
The I++ Client Probe Changer cannot have multiples, and you cannot combine it with other types.

To define the I++ Client Probe Changer:

Step 1 - Select the I++ Client Probe Changer

To select the I++ Client Probe Changer:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **I++ Client**:



Probe Changer Dialog Box - Type Tab

3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.
4. In the **Active probe changer** box, select **TYPE=IPlusPlus-Client**.
5. Ensure that the value of "1" appears in the **Number of probe changers** box.
6. Note that you cannot change the value that appears in the **Docking speed** box.
7. Click **Apply** to apply any changes made for this probe changer, and then click **OK** to close the dialog box.

For details on controller configuration settings, see the documentation that came with your controller.

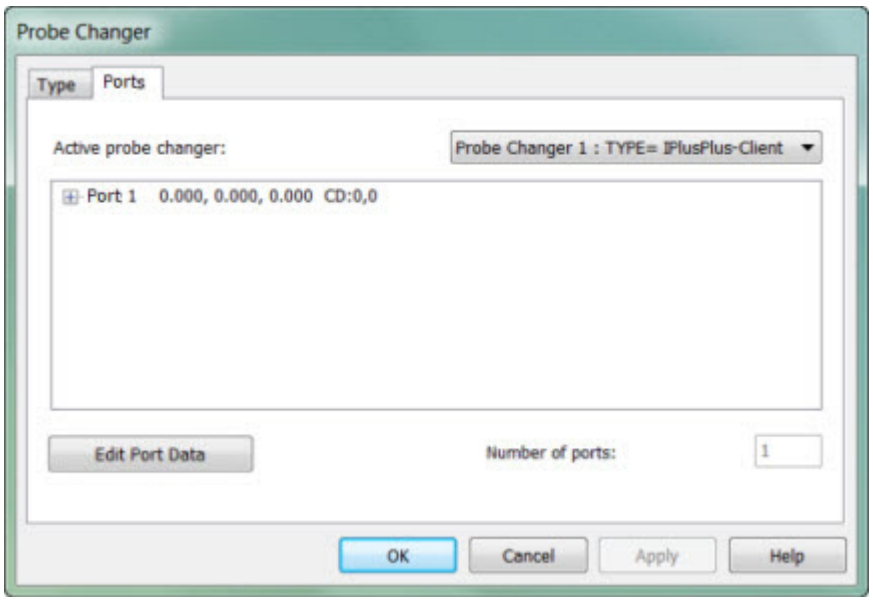
In the next step, you assign the probes to the port.

Step 2 - Assign the Probes to the Port

The **Ports** tab for the I++ Client Probe Changer has only one port. You can assign probes to this port, or remove them. You cannot edit the port's data or change the number of ports.

To assign the probes:

1. Select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Ports Tab

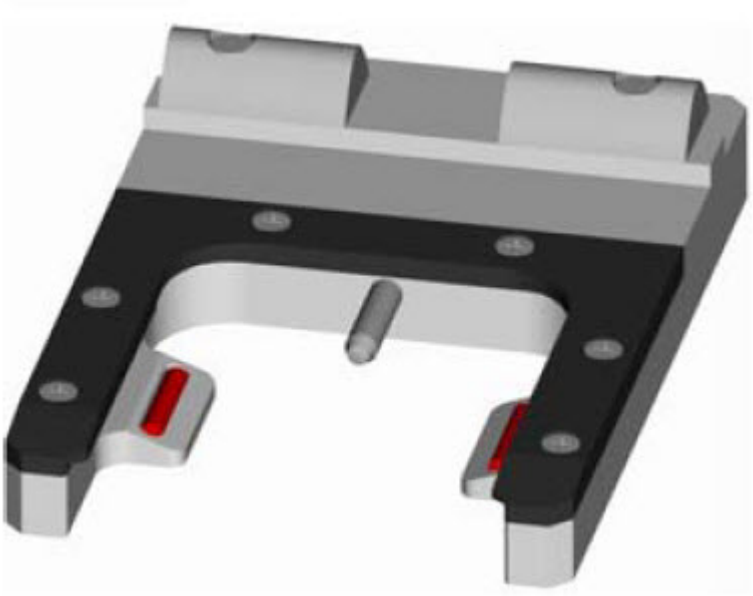
2. Expand the list beside port 1 to open the list of assigned probes.
3. Add the probes that are available for changes by the I++ server. If the I++ server configuration changes, you should update this list by adding any newly available probes and removing any that are no longer available.
4. To save your changes, click **Apply**.

Calibrating the LSPX3 / HR-X (HR-X3-P) Probe Changer

The HR-X3-P and HR-X3-P-SF style ports have considerably different physical constructions and have different dimensional offsets. You cannot mix-and-match these port styles.

The calibration process for the LSPX3 / HR-X (HR-X3-P) probe changer represents the steps that you would take to prepare to use any of the probe changers that PC-DMIS supports. The process discussed here is specific to the LSPX3 / HR-X (HR-X3-P) probe changer.

No inserts or extensions are used for any of the port positions.



Leitz LSPX3 / HR-X (HR-X3-P) probe changer

You must mount the rack in a horizontal orientation that your sensor can match.

The LSPX3 / HR-X (HR-X3-P) probe changer DOES NOT need to be mounted on the machine table parallel to either the X or Y axis. However, it must be oriented at an angle which matches an available wrist angle for loading and unloading. For mounting instructions, consult the documentation that came with your probe changer.

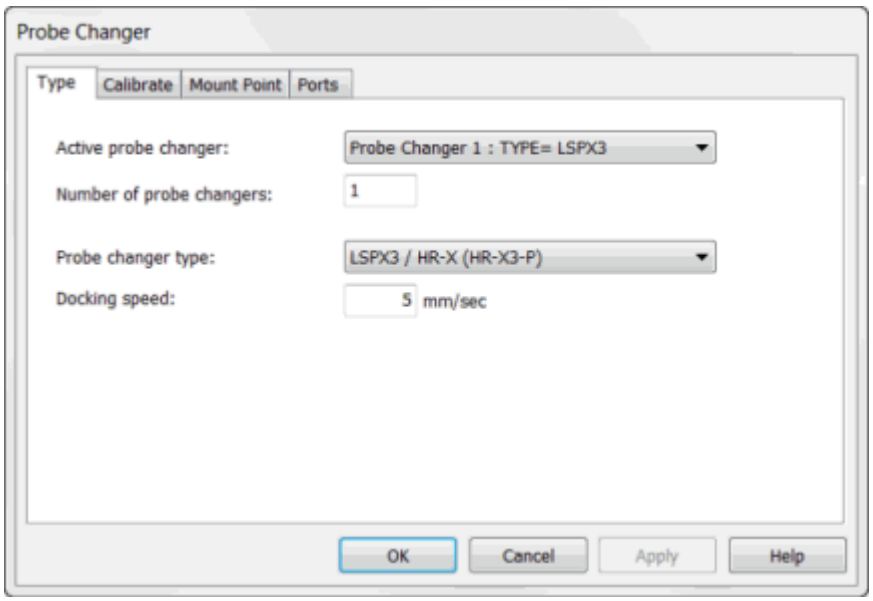
If you use X3T style probes, you need to define the A/B wrist angles that are appropriate to the orientation of the probe changer. This is not required for X3C style probes. For X3C style probes, the rigid mounting of the probe head to the CMM Ram constrains the physical orientation of the probe changer.

To calibrate your probe changer:

Step 1 - Select the LSPX3 / HR-X (HR-X3-P) Probe Changer

To select the LSPX3 / HR-X (HR-X3-P) probe changer:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **LSPX3 / HR-X (HR-X3-P)**.



Probe Changer Dialog Box - Type Tab

3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.

4. In the **Active probe changer** list, select the list item that represents the probe changer that you want to define. If this is the first probe changer, it appears as **Probe Changer : TYPE= None**.

5. In the **Number of probe changers** box, specify the number of probe changers that you want to define.

6. In the **Docking speed** box, type a value. A value between 10-20 mm/sec is appropriate for this machine configuration. You can adjust this value at any time to speed up or slow down the system.

   To avoid equipment damage due to excessive docking speed, gradually increase the **Docking speed** value.

7. Click **Apply** to apply any changes made for this probe changer, and then click **OK** to close the dialog box.

   For details on controller configuration settings, see the documentation that came with your controller.

Next Step

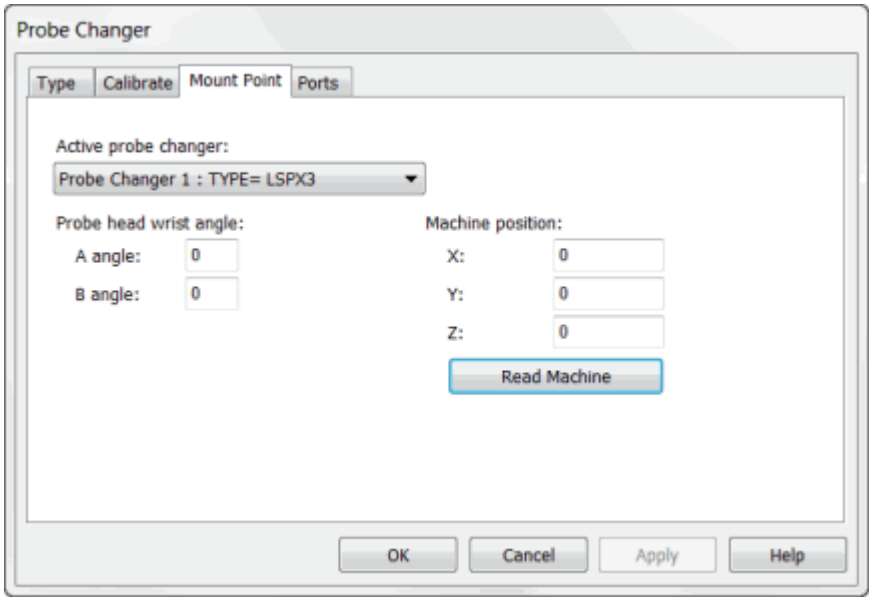
In the next step, you define the location your probe body moves to when using the probe changer to switch probe components.

Step 2 - Define the Mount Point

The mount point for the LSPX3 / HR-X (HR-X3-P) probe changer is the location in front of the probe changer that the machine moves to before it picks up or drops off a probe. This should be a location that avoids collisions with the probe changer or part.

To define the mount point for your probe changer:

1. Select the **Mount Point** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**).



Probe Changer Dialog Box - Mount Point Tab

2. In the **Active probe changer** list, select **TYPE=LSPX3**.
3. If necessary, alter the probe head wrist angle for both **A angle** and **B angle**. Often, but not always, these values are both 0. You need to use a calibrated probe rotation that ensures that the probe has the ability to move in and out of the probe changer during the necessary steps of the probe rack calibration procedure.
4. Use your jog box to manually move your machine to the desired mount point position.
5. Click the **Read Machine** button to populate the **X**, **Y**, and **Z** machine position values with the current position. You can also type these values.
6. To save your changes, click **Apply**.

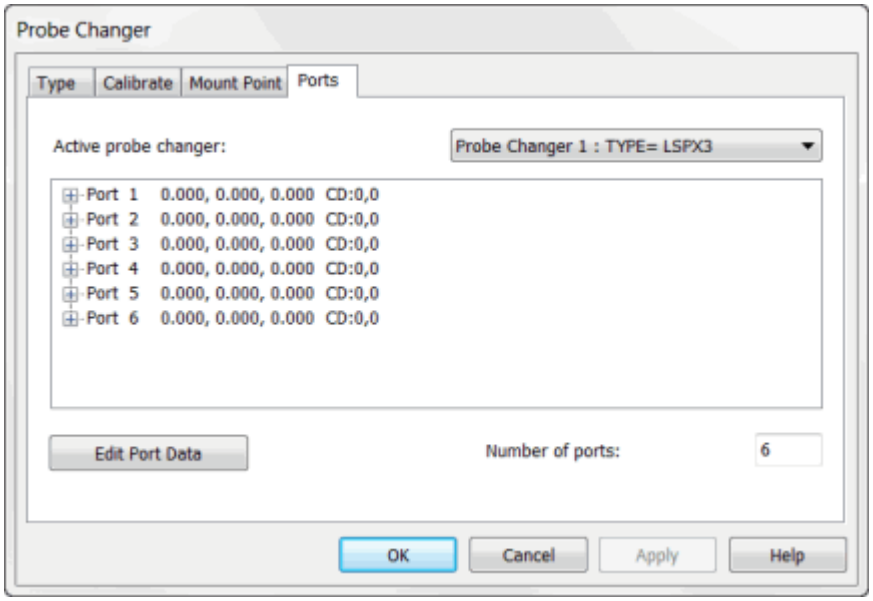
In the next step, you define the number of ports.

Step 3 - Define the Number of Ports

The final step prior to LSPX3 / HR-X (HR-X3-P) probe changer calibration is to define the number of ports.

To define the number of ports:

1. Select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**).



Probe Changer Dialog Box - Ports Tab

2. In the **Active probe changer** list, select **Probe Changer : TYPE= LSPX3**.
3. In the **Number of ports** box, type the number of ports that the probe changer has.
4. To save your changes, click **Apply**.

You are now ready to begin calibration. The next step starts the calibration process.

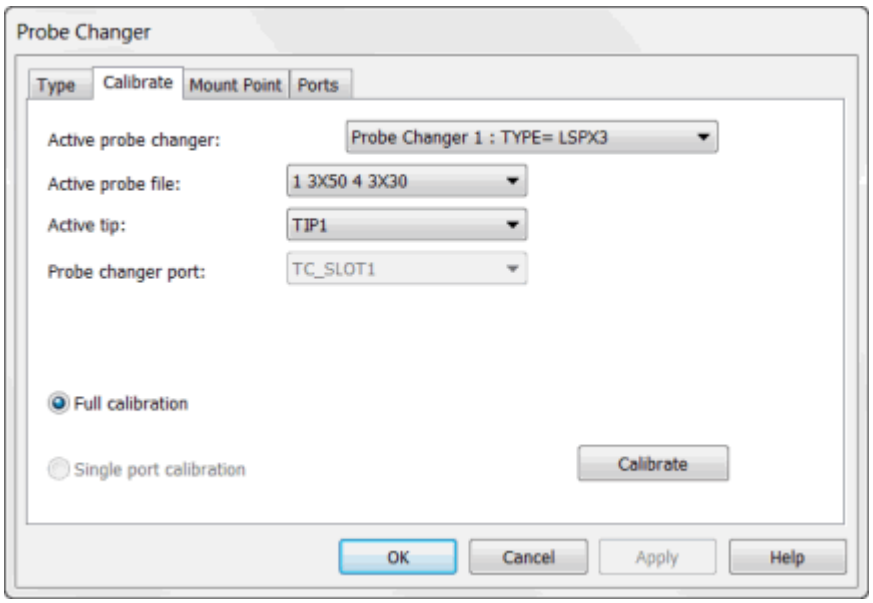
Step 4 - Prepare for Calibration

This step starts the calibration process for the LSPX3 / HR-X (HR-X3-P) probe changer.

You may use a straight-down 5 x 50 mm stylus tip.

To start the calibration process:

1. Select the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**).



Probe Changer Dialog Box - Calibrate Tab

2. In the **Active probe changer** list, select **Probe Changer : TYPE= LSPX3**.
3. The entry in the **Active probe file** list defaults to the current measurement routine setting. If this is not what you will use for the probe changer calibration, select the proper probe.
4. The entry in the **Active tip** list defaults to the current measurement routine setting. If this is not what you will use for the probe changer calibration, select the tip ID to use for calibration. This is usually **TIP1**.
5. Empty the ports of all probes.
6. Click **Calibrate**.
7. When you are ready to take the first measurement, click **OK**.

In the next step, you take the first manual hit.

Step 5 - Take the First Manual Hit

When you start the calibration procedure for the LSPX3 / HR-X (HR-X3-P) probe changer, PC-DMIS shows you a sequence of message boxes that step you through a series of manual hits. You first take one hit on the overhang of the collet, and then three hits on each port. These hits fully define the orientation of the probe changer in the machine's XY plane. You do not need to align the probe changer to any single axis, as the manual hits identify any rotation involved. Follow the prompts and take the needed hits as directed in the instructions for each hit.

You take the first hit on top of the clamp for port 1, using the overhang of the collet near the probe pin. The prompt for the first hit on port 1 is:

PC-DMIS Message

Please take a hit on top of the clamp for port 1 using the overhang of the collet near the probe pin

PC-DMIS prompt to take the first manual hit on port 1.

You must take a hit on the top of the first port, using the overhang of the collet. The image below shows the overhang of the collet:

Location of first hit for port 1 on overhang of collet

1. When you are ready to take the first measurement, click **OK**.
2. Use your machine's jog box to take the first manual hit as instructed by PC-DMIS.

In the next step, you define the location of the first port.

Step 6 - Define the Location of the First Port

In this step for the LSPX3 / HR-X (HR-X3-P) probe changer, you define the location of the first port. This message appears:

PC-DMIS Message

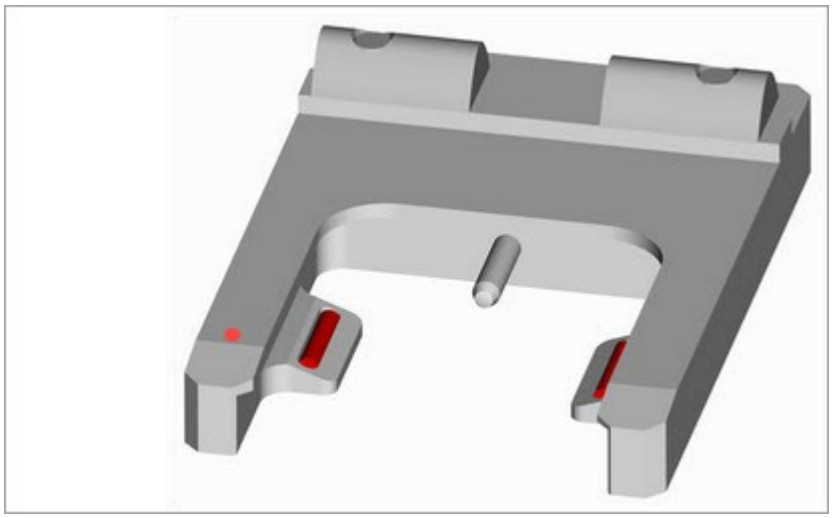
From the viewpoint of facing the front of the probe changer, please use the probe tip to take one hit on the top of the port, then one hit on the external left edge of the port and finally one hit on the external front edge of the port for port 1

PC-DMIS prompt to define the location of the first port.

To take the hits, click **OK**. To abandon the calibration, click **Cancel**.

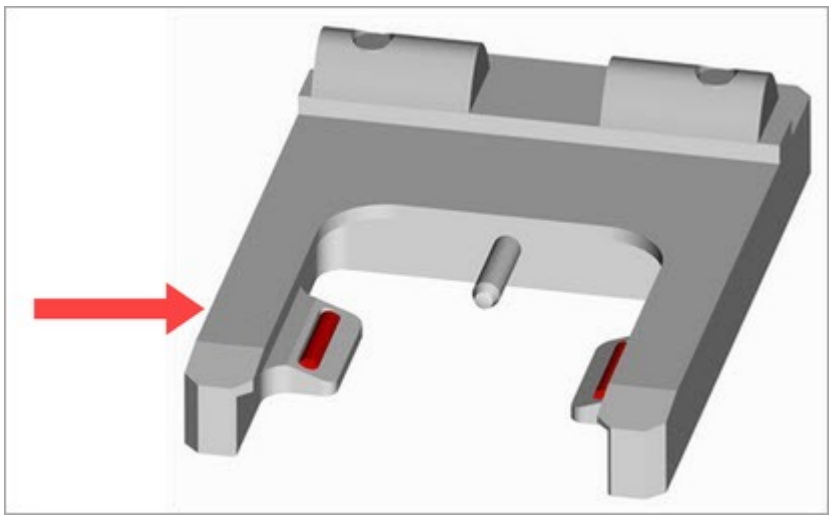
You must take three hits:

1. Take the first hit on the top of the port. The image below shows the location:



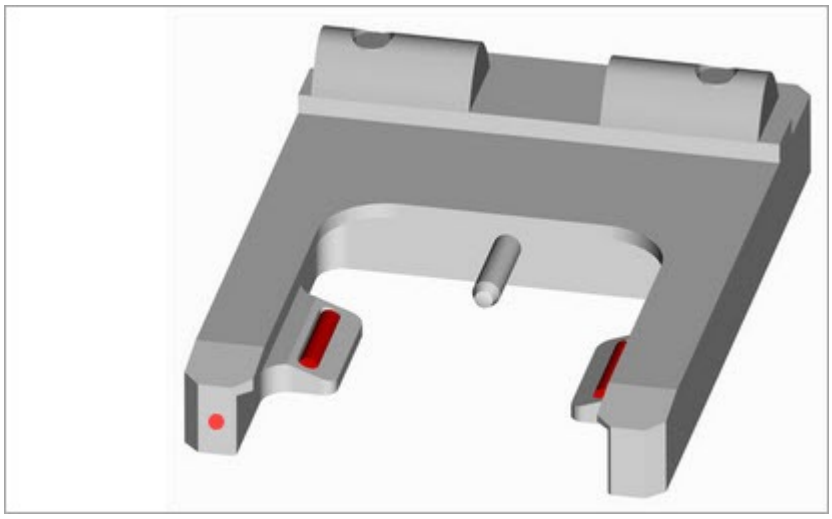
Example showing the first hit on the top of the port.

2. Take the second hit on the external left edge of the port. This face is turned away from you in the image below, so the arrow shows where it is:



Example showing the second hit on the external left edge of the port.

3. Take the third hit on the external front edge of the port. The image below shows the location:



Example showing the third hit on the external front edge of the port.

In the next step, you define the location of the second port and all subsequent ports.

Step 7 - Define the Location of the Second Port

In this step for the LSPX3 / HR-X (HR-X3-P) probe changer, you define the location of the second port and all subsequent ports that are available on your probe changer. This message appears:

PC-DMIS Message

From the viewpoint of facing the front of the probe changer, please use the probe tip to take one hit on the top of the port, then one hit on the external left edge of the port and finally one

hit on the external front edge of the port for port 2

PC-DMIS prompt to define the location of the second port.

To define the locations of the second port and all subsequent ports, follow the procedure described in Step 6 - Define the Location of the First Port. PC-DMIS prompts you for each port in turn, and these hits establish the location of every port.

To take the hits, click **OK**. To abandon the calibration, click **Cancel**.

You take all of these hits in manual mode with your machine's jog box.

In the next step, you review the calibration results.

Step 8 - Review the Calibration Results

1. When the calibration of the LSPX3 / HR-X (HR-X3-P) probe changer is complete, select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). This tab displays the calibration information for the location of each calibrated port.

2. When you view the results, look for the following.

   - This probe changer is not necessarily aligned parallel to any axis of the CMM.
   - The Z values should be nearly identical since the ports are all at the same height.

   Any significant deviations from these expectations may be due to a bad hit.

The results during measurement routine execution are:

1. The probe entities that are added to each of the ports are automatically picked up from that location whenever PC-DMIS executes a `LOADPROBE` command for that probe.

2. The probe body moves to the mount point and then into the "unload" port (the port that used to contain the currently used probe entity) to drop off the current probe. The current "puck", a conical piece of hardware that connects to the bottom of the probe body, is held in place by the probe changer while the probe body lifts away to detach.

3. From there, the probe moves over to the next "load" position. The magnetic connection automatically engages to load the new module.

4. The probe then moves back to the probe changer's mount point and from there, it continues to measure.

In the next step, you can choose to recalibrate individual ports.

Step 9 - Recalibrate Individual Ports

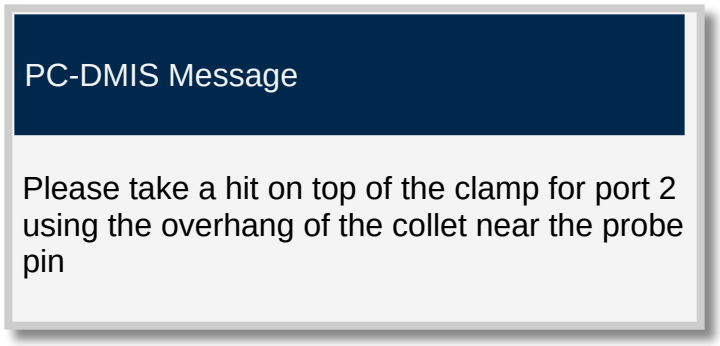
After you complete a full calibration of the LSPX3 / HR-X (HR-X3-P) probe changer, if you suspect there's an issue with the calibration results of a port, you can choose to recalibrate individual ports.

1. Select the **Single port calibration** option on the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). This option is only available after you complete a full calibration.

2. When you select the **Single port calibration** option, the **Probe changer port** list becomes available. Select the port that you want to calibrate.

3. Remove any probe or stylus holder from the port that you selected.

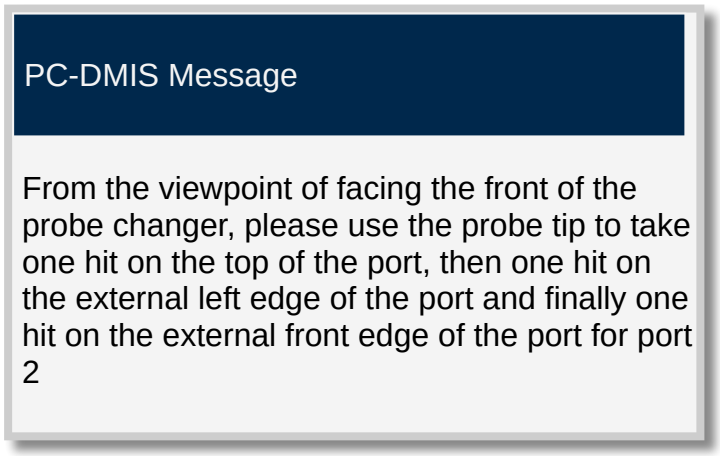
4. To begin the calibration, click **Calibrate**. PC-DMIS prompts you to take a hit on the overhang of the collet for the port that you selected. For example, for port 2:



PC-DMIS prompt to take a hit on the overhang of the collet for port 2.

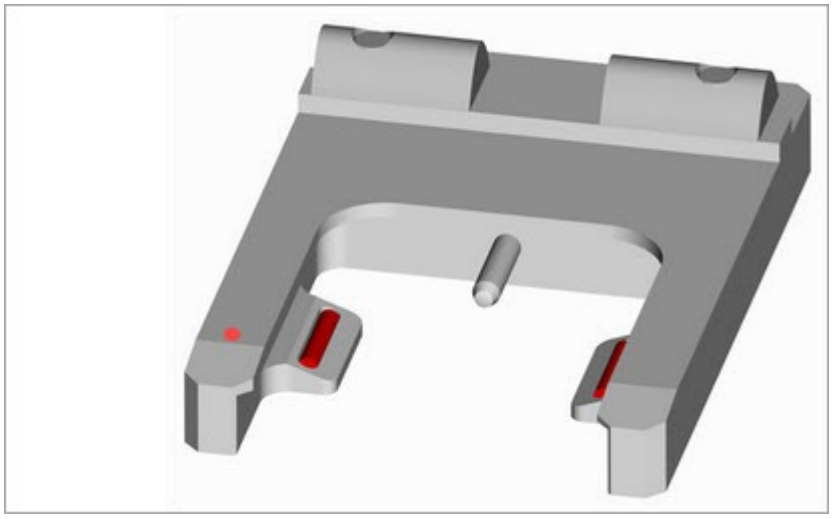
Location of the hit on the overhang of the collet.

5. PC-DMIS then prompts you to take three hits on the port that you selected. For example, for port 2:



PC-DMIS prompt to define the location of port 2.

6. Click **OK**, and then take the three hits in the order that PC-DMIS prompts for them, as described in Step 6 - Define the Location of the First Port: one hit on the top of the port, one hit on the external left edge, and one hit on the external front edge.



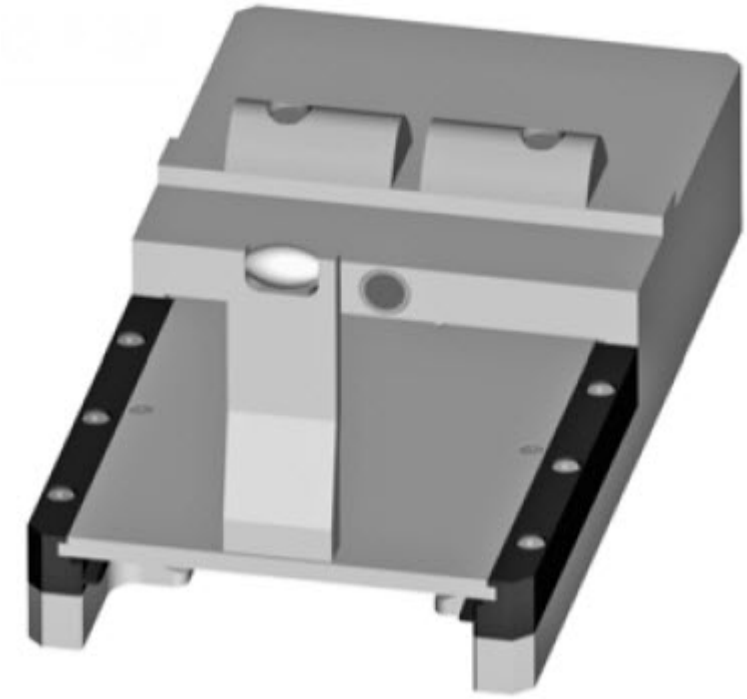
Example showing the first hit on the top of the port.

Calibrating the LSPX3SF / HR-X (HR-X3-P-SF) Probe Changer

The HR-X3-P and HR-X3-P-SF style ports have considerably different physical constructions and have different dimensional offsets. You cannot mix-and-match these port styles.

The calibration process for the LSPX3SF / HR-X (HR-X3-P-SF) probe changer represents the steps that you would take to prepare to use any of the probe changers that PC-DMIS supports. The process discussed here is specific to the LSPX3SF / HR-X (HR-X3-P-SF) probe changer.

No inserts or extensions are used for any of the port positions.



Leitz LSPX3SF / HR-X (HR-X3-P-SF) probe changer

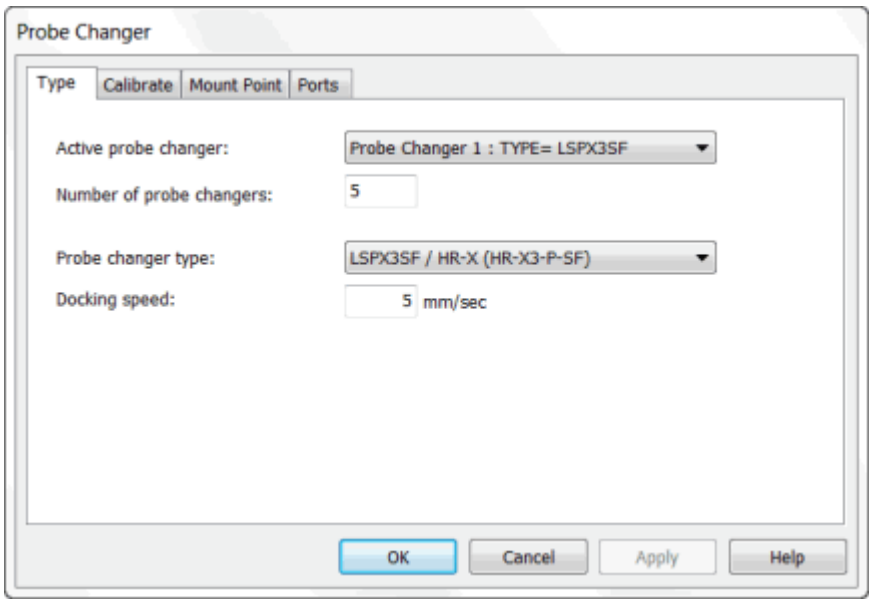
> **!** The LSPX3SF / HR-X (HR-X3-P-SF) stylus changer DOES NOT need to be mounted on the machine table parallel to either the X or Y axis. However, it must be oriented at an angle which matches an available wrist angle for loading and unloading. For mounting instructions, consult the documentation that came with your probe changer.

To calibrate your probe changer:

Step 1 - Select the LSPX3SF / HR-X (HR-X3-P-SF) Probe Changer

To select the LSPX3SF / HR-X (HR-X3-P-SF) probe changer:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **LSPX3SF / HR-X (HR-X3-P-SF)**:



Probe Changer Dialog Box - Type Tab

3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.

4. In the **Active probe changer** list, select the list item that represents the probe changer that you want to define. If this is the first probe changer, it appears as **Probe Changer : TYPE= None**.

5. In the **Number of probe changers** box, specify the number of probe changers that you want to define.

6. In the **Docking speed** box, type a value. A value between 10-20 mm/sec is appropriate for this machine configuration. You can adjust this value at any time to speed up or slow down the system.

   To avoid equipment damage due to excessive docking speed, gradually increase the **Docking speed** value.

7. Click **Apply** to apply any changes made for this probe changer, and then click **OK** to close the dialog box.

For details on controller configuration settings, see the documentation that came with your controller.

Next Step

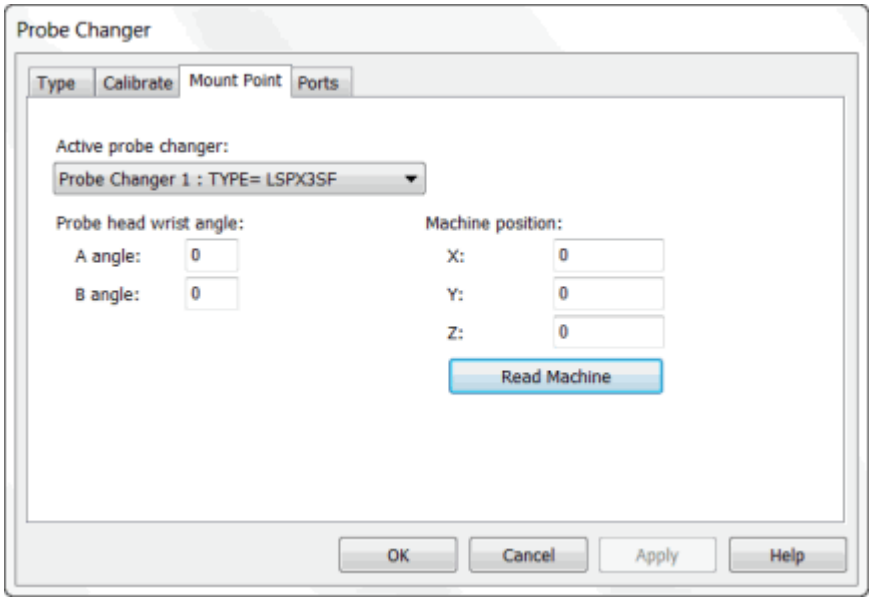
In the next step, you define the location your probe body moves to when using the probe changer to switch probe components.

Step 2 - Define the Mount Point

The mount point for the LSPX3SF / HR-X (HR-X3-P-SF) probe changer is the location in front of the probe changer that the machine moves to before it picks up or drops off a probe. This should be a location that avoids collisions with the probe changer or part.

To define the mount point for your probe changer:

1. Select the **Mount Point** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**).



Probe Changer Dialog Box - Mount Point Tab

2. In the **Active probe changer** list, select **TYPE=LSPX3SF**.
3. If necessary, alter the probe head wrist angle for both **A angle** and **B angle**. Often, but not always, these values are both 0. You need to use a calibrated probe rotation that ensures that the probe has the ability to move in and out of the probe changer during the necessary steps of the probe rack calibration procedure.
4. Use your jog box to manually move your machine to the desired mount point position.
5. Click the **Read Machine** button to populate the **X**, **Y**, and **Z** machine position values with the current position. You can also type these values.
6. To save your changes, click **Apply**.

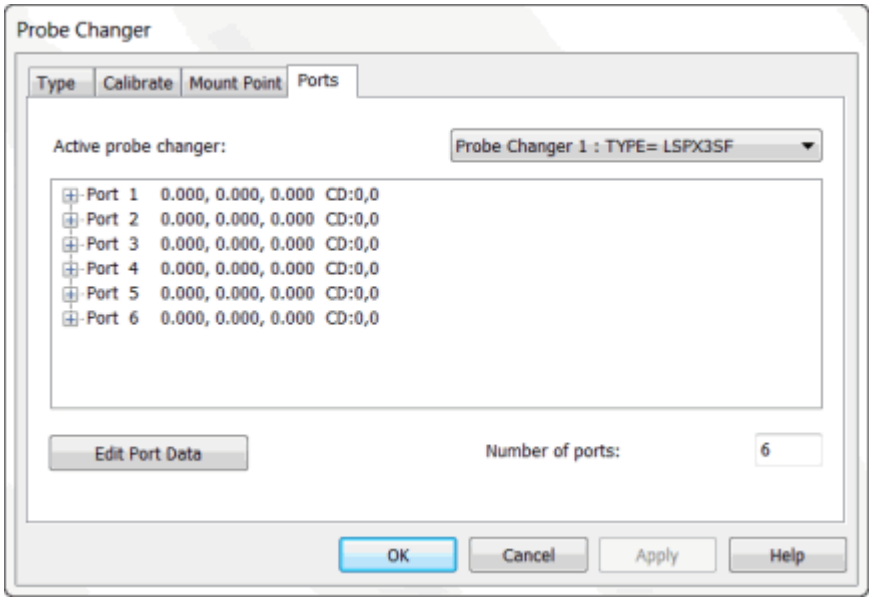
In the next step, you define the number of ports.

Step 3 - Define the Number of Ports

The final step prior to probe changer calibration is to define the number of ports.

To define the number of ports:

1. Select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Ports Tab

2. In the **Active probe changer** list, select **Probe Changer : TYPE= LSPX3SF.**
3. In the **Number of ports** box, type the number of ports that the probe changer has.
4. To save your changes, click **Apply**.

You are now ready to begin calibration. The next step starts the calibration process.

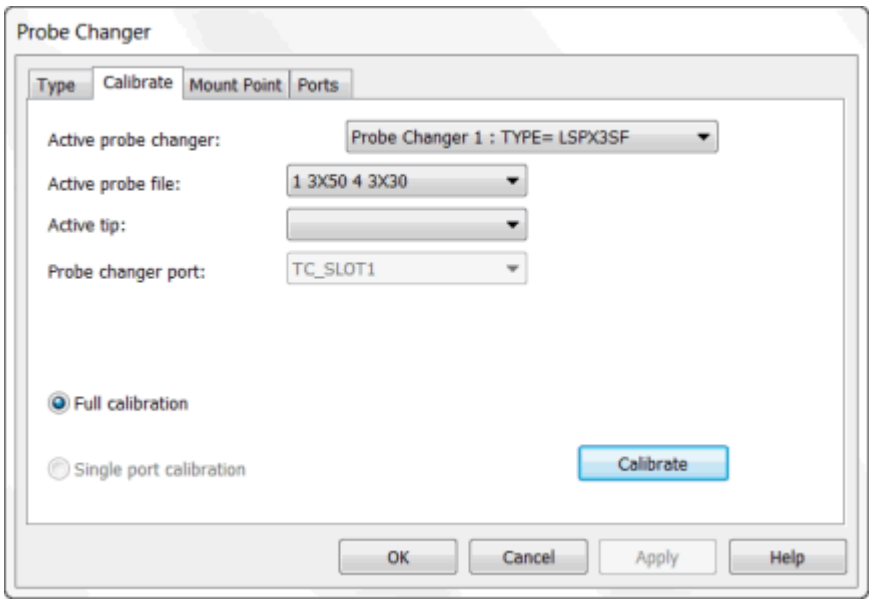
Step 4 - Prepare for Calibration

This step starts the calibration process for the LSPX3SF / HR-X (HR-X3-P-SF) probe changer.

You may use a straight-down 5 x 50 mm stylus tip.

To start the calibration process:

1. Select the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**).



Probe Changer Dialog Box - Calibrate Tab

2. In the **Active probe changer** list, select **Probe Changer : TYPE= LSPX3SF**.
3. The entry in the **Active probe file** list defaults to the current measurement routine setting. If this is not what is to be used for the probe changer calibration, select the proper probe.
4. The entry in the **Active tip** list defaults to the current measurement routine setting. If this is not what you will use for the probe changer calibration, select the tip ID to use for calibration. This is usually **TIP1**.
5. Empty the ports of all probes.
6. Click **Calibrate**.
7. When you are ready to take the first measurement, click **OK**.

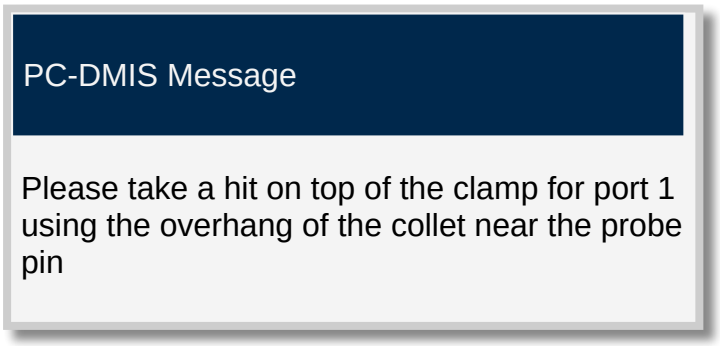
In the next step, you take the first manual hit.

Step 5 - Take the First Manual Hit

When you start the calibration procedure for the LSPX3SF / HR-X (HR-X3-P-SF) probe changer, PC-DMIS shows you a sequence of message boxes that step you through a series of manual hits. You first take one hit on the overhang of the collet, and then three hits on each port. These hits fully define the orientation of the probe changer in the machine's XY plane. You do not need to align the probe changer to any single axis, as the manual hits identify any rotation involved. Follow the prompts and take the needed hits as directed in the instructions for each hit.

> **!** On the SF style ports, you need to slide the port covers back out of the way prior to beginning the alignment hits.

You take the first hit on top of the clamp for port 1, using the overhang of the collet near the probe pin. The prompt for the first hit on port 1 is:



PC-DMIS prompt to take the first manual hit on port 1.

You must take a hit on the top of the first port, using the overhang of the collet. The image below shows the overhang of the collet:

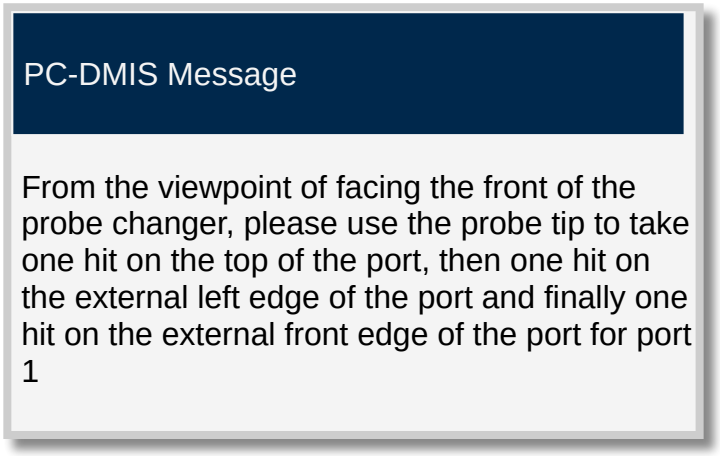
Location of first hit for port 1 on overhang of collet

1. When you are ready to take the first measurement, click **OK**.
2. Use your machine's jog box to take the first manual hit as instructed by PC-DMIS.

In the next step, you define the location of the first port.

Step 6 - Define the Location of the First Port

In this step for the LSPX3SF / HR-X (HR-X3-P-SF) probe changer, you define the location of the first port. This message appears:



PC-DMIS prompt to define the location of the first port.

To take the hits, click **OK**. To abandon the calibration, click **Cancel**.

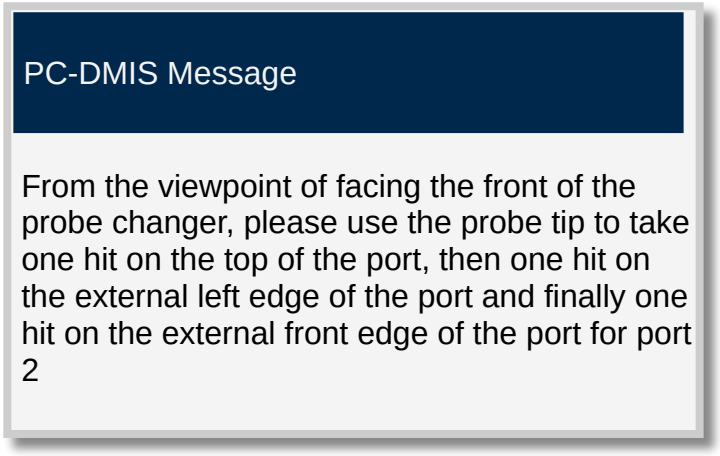
You must take three hits:

1. Take the first hit on the top of the port.
2. Take the second hit on the external left edge of the port, on the outer face of the left side.
3. Take the third hit on the external front edge of the port.

In the next step, you define the location of the second port and all subsequent ports.

Step 7 - Define the Location of the Second Port

In this step for the LSPX3SF / HR-X (HR-X3-P-SF) probe changer, you define the location of the second port and all subsequent ports that are available on your probe changer. This message appears:



PC-DMIS prompt to define the location of the second port.

To define the locations of the second port and all subsequent ports, follow the procedure described in Step 6 - Define the Location of the First Port. PC-DMIS prompts you for each port in turn, and these hits establish the location of every port.

To take the hits, click **OK**. To abandon the calibration, click **Cancel**.

You take all of these hits in manual mode with your machine's jog box.

In the next step, you review the calibration results.

Step 8 - Review the Calibration Results

1. When the calibration of the LSPX3SF / HR-X (HR-X3-P-SF) probe changer is complete, select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). This tab displays the calibration information for the location of each calibrated port.

2. When you view the results, look for the following.

    - This probe changer is not necessarily aligned parallel to any axis of the CMM.
    - The Z values should be nearly identical since the ports are all at the same height.

      Any significant deviations from these expectations may be due to a bad hit.

The results during measurement routine execution are:

1. The probe entities that are added to each of the ports are automatically picked up from that location whenever PC-DMIS executes a `LOADPROBE` command for that probe.

2. The probe body moves to the mount point and then into the "unload" port (the port that used to contain the currently used probe entity) to drop off the current probe. The current "puck", a conical piece of hardware that connects to the bottom of the probe body, is held in place by the probe changer while the probe body lifts away to detach.

3. From there, the probe moves over to the next "load" position. The magnetic connection automatically engages to load the new module.

4. The probe then moves back to the probe changer’s mount point.

5. From there, it continues to measure.

In the next step, you can choose to recalibrate individual ports.

Step 9 - Recalibrate Individual Ports

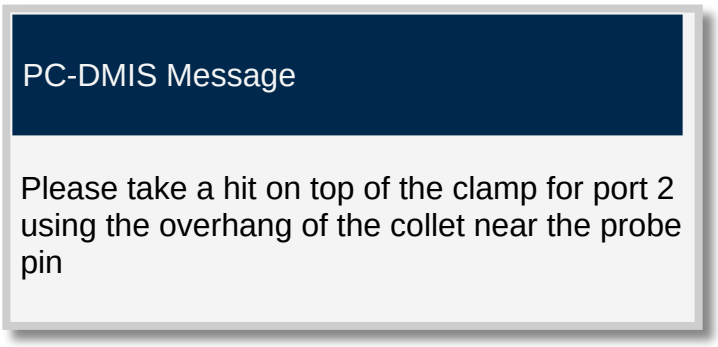
After you complete a full calibration of the LSPX3SF / HR-X (HR-X3-P-SF) probe changer, if you suspect there's an issue with the calibration results of a port, you can choose to recalibrate individual ports.

1. Select the **Single port calibration** option on the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). (If you did not complete a full calibration, the option is not available.)

2. When you select the **Single port calibration** option, the **Probe changer port** list becomes available. Select the port that you want to calibrate.

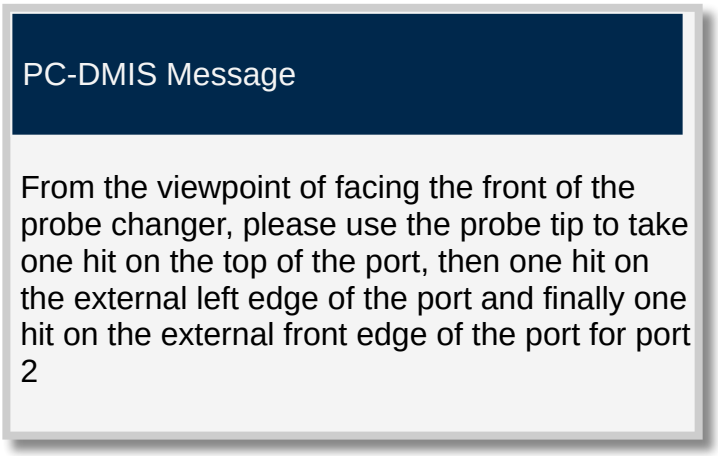
3. Remove any probe or stylus holder from the port that you selected.

4. To begin the calibration, click **Calibrate**. PC-DMIS prompts you to take a hit on the overhang of the collet for the port that you selected. For example, for port 2:



PC-DMIS prompt to take a hit on the overhang of the collet for port 2.

5. PC-DMIS then prompts you to take three hits on the port that you selected. For example, for port 2:



PC-DMIS prompt to define the location of port 2.

6. Click **OK**, and then take the three hits in the order that PC-DMIS prompts for them, as described in Step 6 - Define the Location of the First Port: one hit on the top of the port, one hit on the external left edge, and one hit on the external front edge.

Calibrating the LSPX5 / HR-XS Probe Changer

The calibration process for the LSPX5 / HR-XS probe changer represents the steps that you would take to prepare to use any of the probe changers that PC-DMIS supports. The process discussed here is specific to the LSPX5 / HR-XS Probe Changer.

This probe changer MUST BE mounted on the machine table parallel to either the X or Y axis for successful calibration. For mounting instructions, consult the documentation that came with your probe changer.

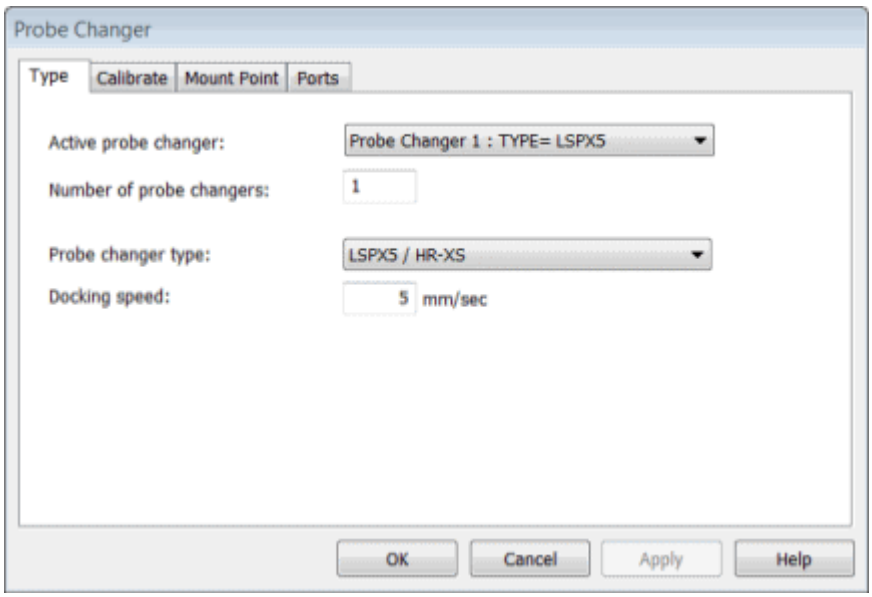
LSPX5 / HR-XS Probe Changer

To calibrate your probe changer:

Step 1 - Select the LSPX5 / HR-XS Probe Changer

To select the LSPX5 / HR-XS Probe Changer:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **LSPX5 / HR-XS**:



Probe Changer Dialog Box - Type Tab

3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.

4. In the **Active probe changer** list, select the list item that represents the probe changer that you want to define. If this is the first probe changer, it appears as **Probe Changer 1: TYPE=None**.

5. In the **Number of probe changers** box, specify the number of probe changers that you want to define.

6. In the **Docking speed** box, type a value. A value between 10-20 mm/sec is appropriate for this machine configuration. You can adjust this value at any time to speed up or slow down the system.

   > To avoid equipment damage due to excessive docking speed, gradually increase the **Docking speed** value.

7. Click **Apply** to apply any changes made for this probe changer, and then click **OK** to close the dialog box.

> For details on controller configuration settings, see the documentation that came with your controller.

In the next step, you define the mount point.

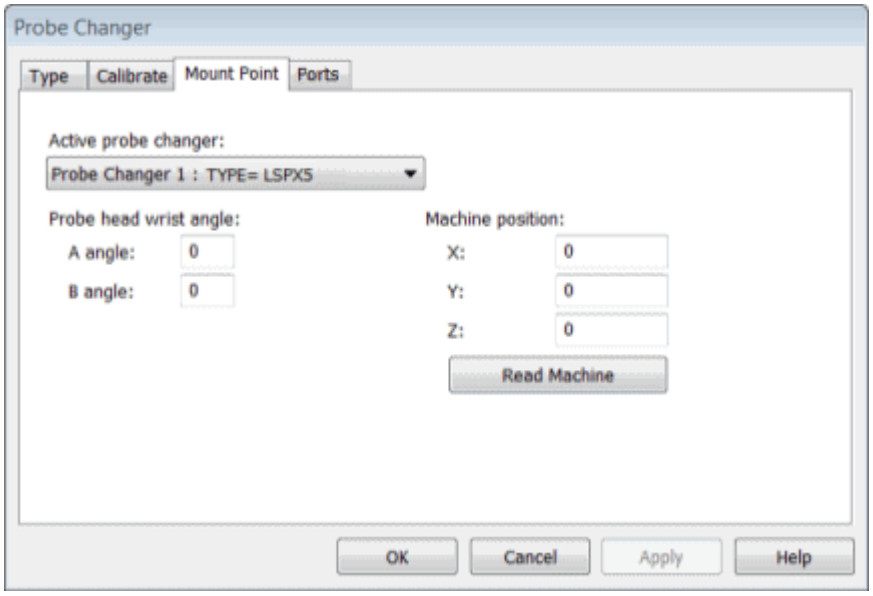
Step 2 - Define the Mount Point

The probe changer mount point is the location in front of the probe changer where the machine moves to before it picks up or drops off a probe. You should pick a location that

avoids collisions with the probe changer, the part, clamps, or any other object in the workspace.

To define the mount point for your probe changer, follow these steps:

1. Select the **Mount Point** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Mount Point Tab

2. In the **Active probe changer** list, select **TYPE=LSPX5**.
3. Alter the probe head wrist angle for both **A angle** and **B angle** to 0. (This is a fixed head and cannot be mounted on a wrist.)
4. Use your jog box to manually move your machine to the desired mount point position.
5. Click the **Read Machine** button to populate the **X**, **Y**, and **Z** machine position values with the current position. You can also type these values.
6. To save your changes, click **Apply**.

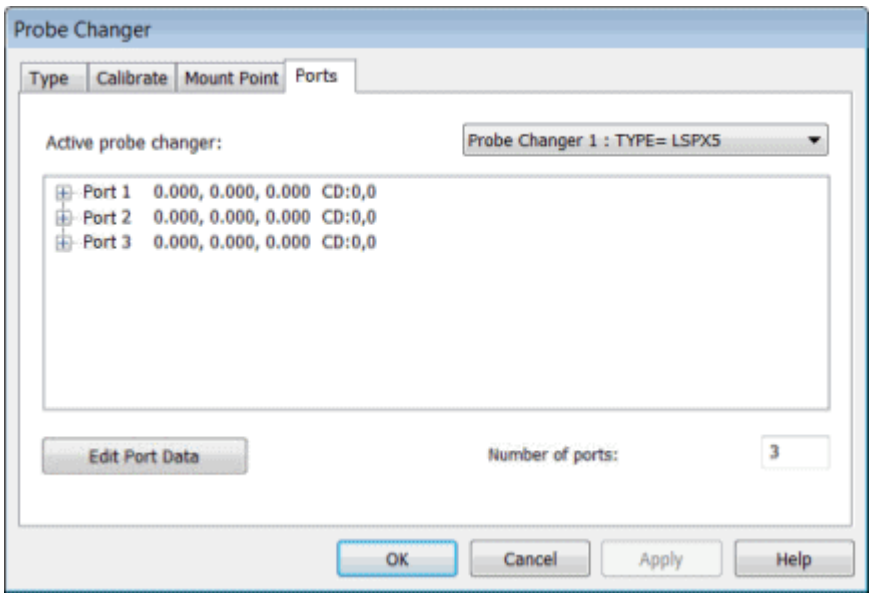
In the next step, you define the ports.

Step 3 - Define the Ports

The final step prior to rack calibration of the LSPX5 / HR-XS Probe Changer is to define the ports on the rack that you are calibrating.

To define the ports, do the following:

1. Select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Ports Tab

2. In the **Active probe changer** list, select **TYPE=LSPX5**.
3. In the **Number of ports** box, type the number of ports on your probe changer.
4. To save your changes, click **Apply**.

You are now ready to begin calibration. The next step starts the calibration process.

Step 4 - Prepare for Calibration

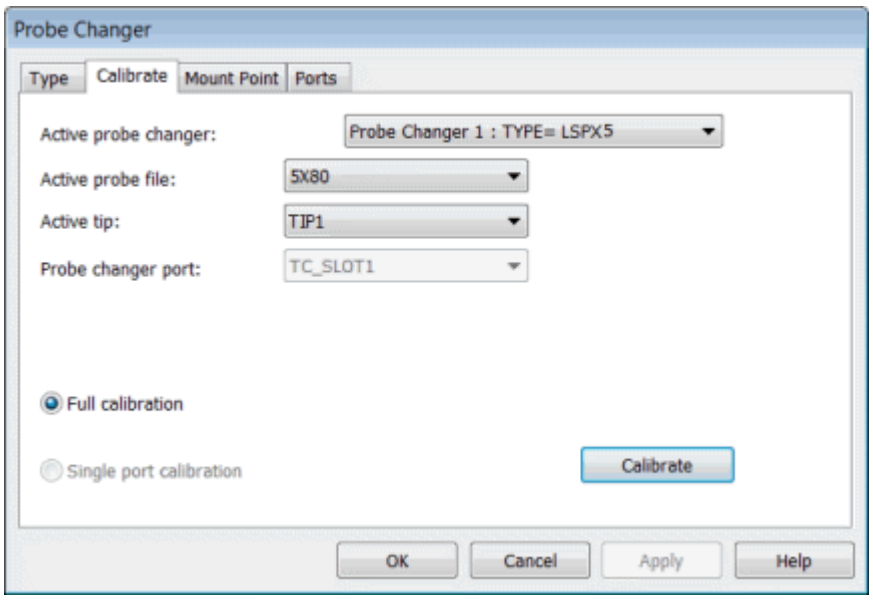
This step starts the calibration process for the LSPX5 / HR-XS probe changer.

The calibration process does not need any specific probe tip. However, a sturdy probe tip is recommended. Typically, a 5 x 60 mm tip is used.

Calibrate with a straight tip that points down with no cubes or any other joints.

To begin the calibration process, do the following:

1. Select the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



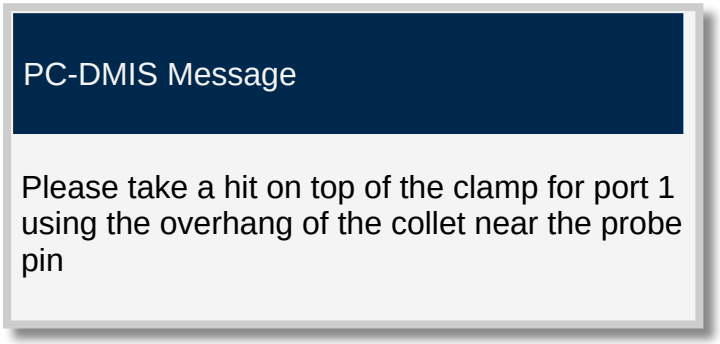
Probe Changer Dialog Box - Calibrate Tab

2. In the **Active probe changer** list, select **Probe Changer 1: TYPE=LSPX5**.
3. The entry in the **Active probe file** list defaults to the current measurement routine setting. If this is not what is to be used for the rack calibration, select the proper probe.
4. The entry in the **Active tip** list defaults to the current measurement routine setting. If this is not what is to be used for the rack calibration, select the tip ID to be used for calibration. This is usually **TIP1**.
5. To begin, click **Calibrate**.

In the next step, you take a point with the over-hang of the collet.

Step 5 - Take a Point with the Overhang of the Collet

For the LSPX5 / HR-XS Probe Changer, the prompt to take a point on the overhang of the collet is:

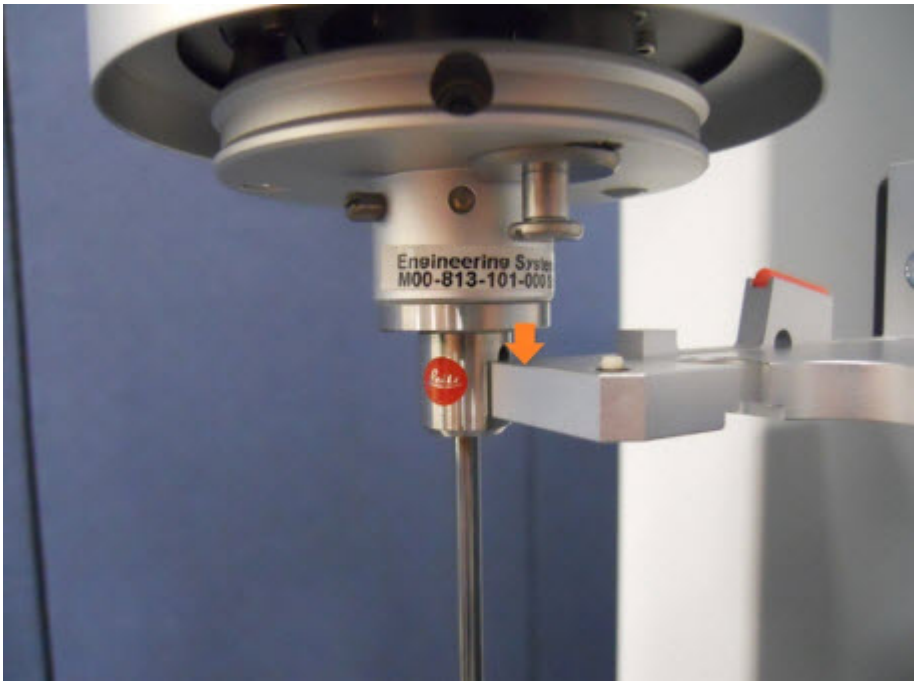


PC-DMIS prompt to take a hit on top of the clamp for port 1.

You must take a hit on the top of the first port, using the overhang of the collet. The image below shows the overhang of the collet:

Overhang of the collet

The image below shows how to take a point with the overhang:

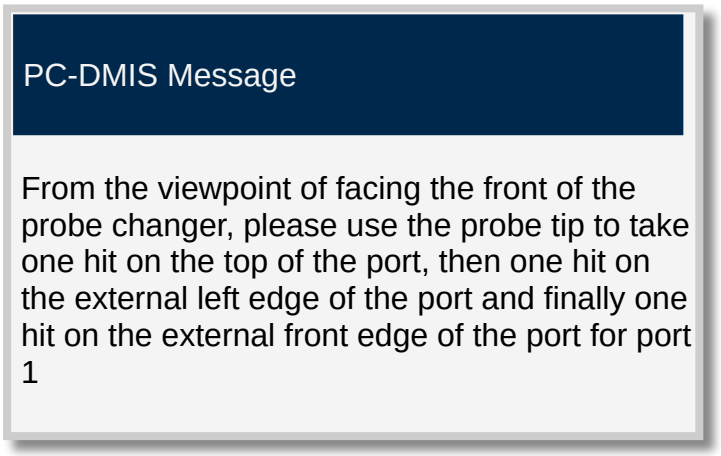


One point with the overhang of the collet

In the next step, you define the location of the first port.

Step 6 - Define the Location of the First Port

In this step for the LSPX5 / HR-XS Probe Changer, you define the location of the first port. This message appears:

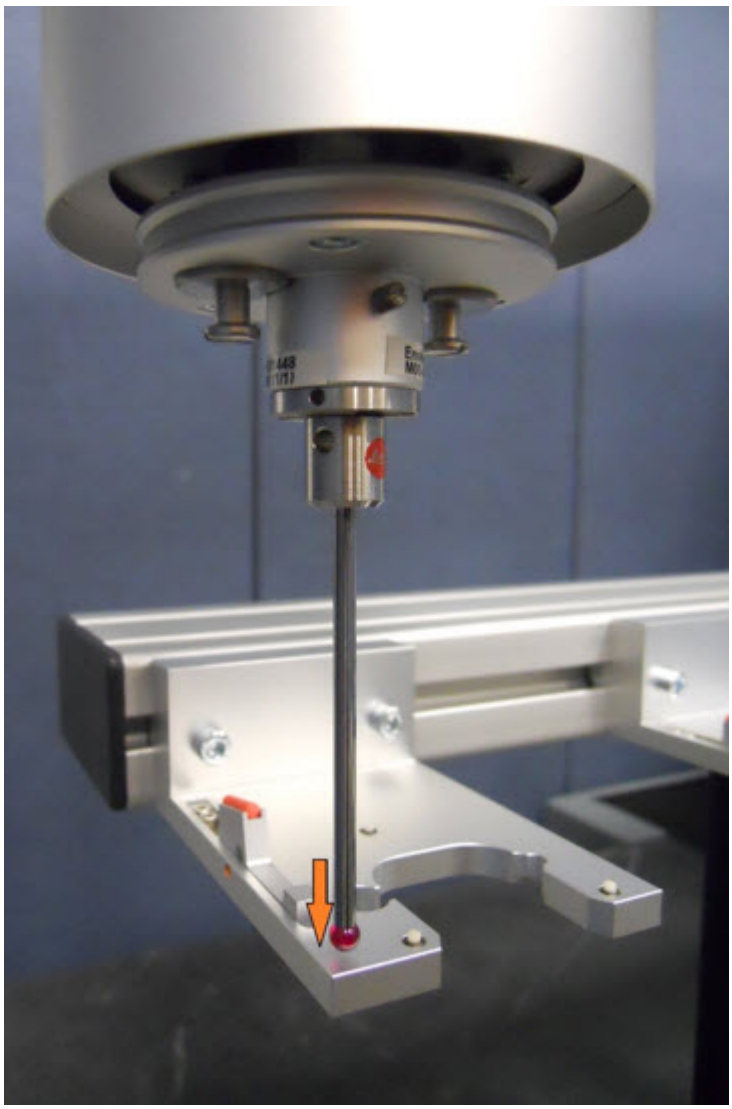


PC-DMIS prompt to define the location of the first port.

To take the hits, click **OK**. To abandon the calibration, click **Cancel**.

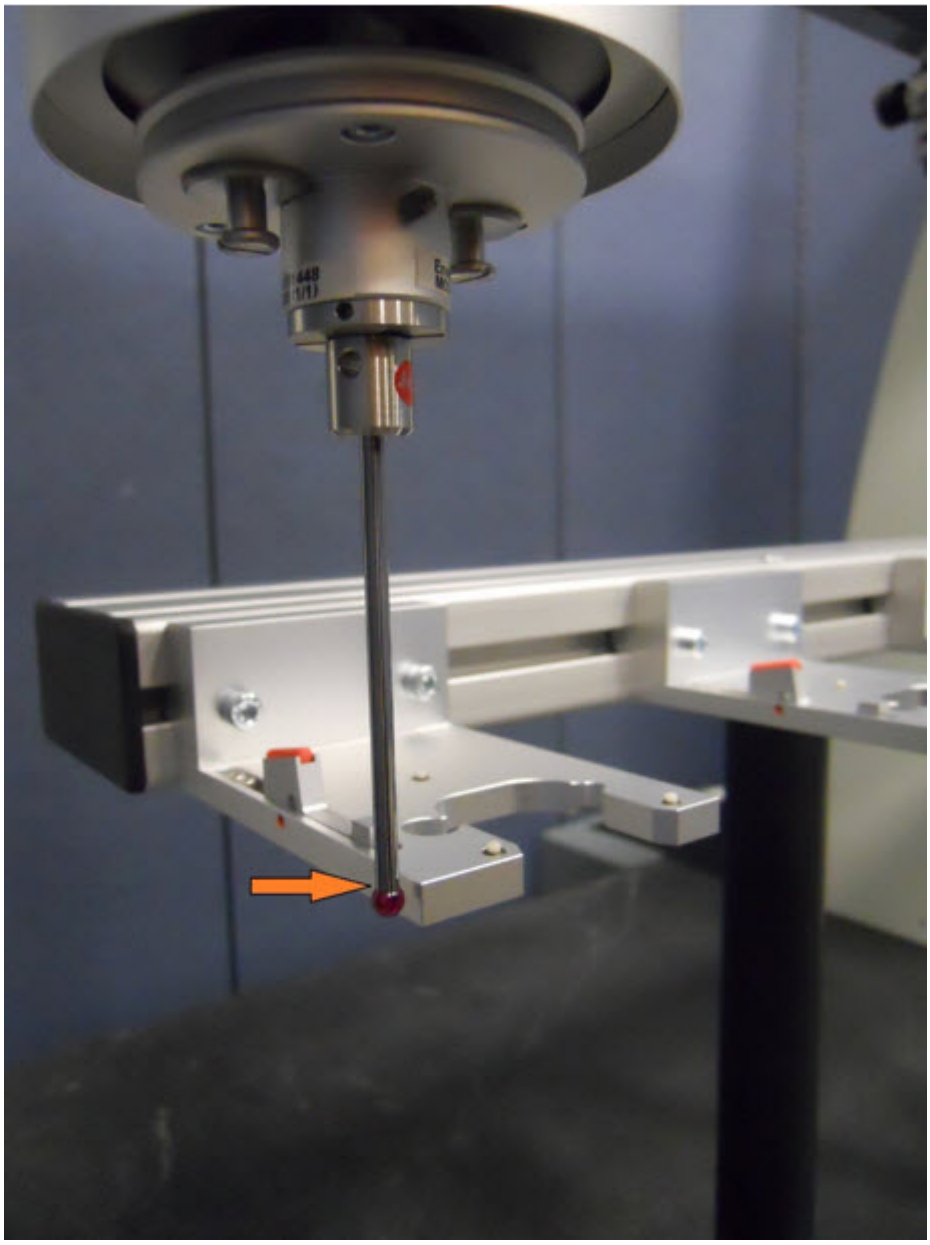
You must take three hits:

1. Take the first hit on the top of the port to define its location. The image below shows the location:



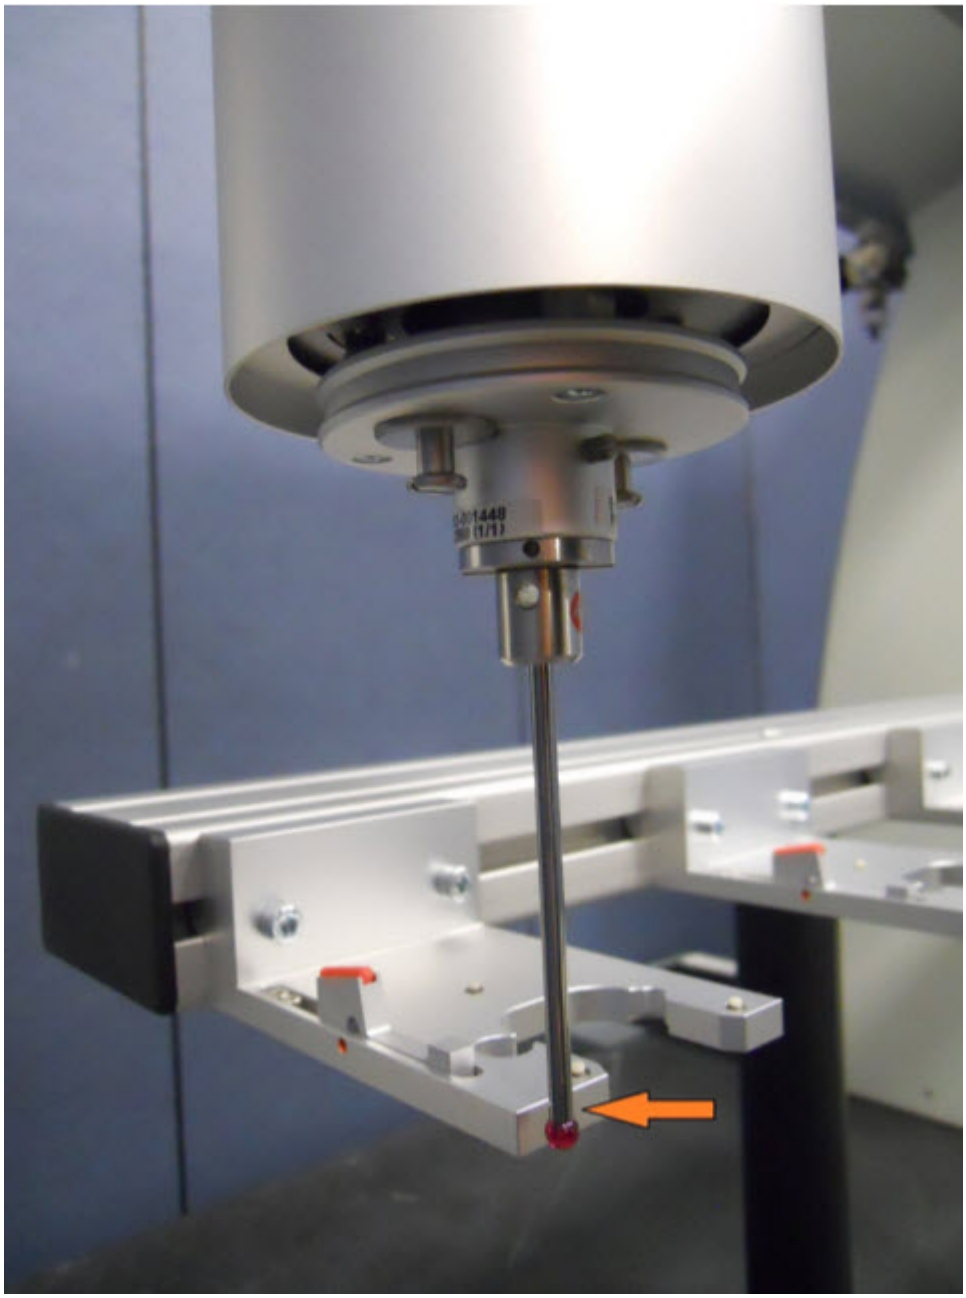
Example showing the first hit on top of the port.

2. Take the second hit on the left of the port to define its location. The image below shows the location:



Example showing the second hit on the left side of the port.

3. Take the third hit on the front of the port to define its location. The image below shows the location:



Example showing the third hit in front of the port.

In the next step, you define the location of the second port and all subsequent ports.

Step 7 - Define the Location of the Second Port

In this step for the LSPX5 / HR-XS Probe Changer, you define the location of the second port and all subsequent ports that are available on your probe changer. This message appears:

PC-DMIS Message

From the viewpoint of facing the front of the probe changer, please use the probe tip to take one hit on the top of the port, then one hit on

the external left edge of the port and finally one hit on the external front edge of the port for port 2

PC-DMIS prompt to define the location of the second port.

To take the hits, click **OK**. To abandon the calibration, click **Cancel**.

To define the locations of the second port and all subsequent ports, follow the procedure described in Step 6 - Define the Location of the First Port.

You have now completed the probe changer calibration process.

Calibrating the SCP600 Probe Changer

These topics describe how to define and calibrate the SP600 Probe Changer.

Inserts or extensions are not used for any of the port positions.

A Renishaw SCP600 Stylus Change Rack

The SCP600 Probe Changer MUST BE mounted on the machine table parallel to either the X or Y axis. The stylus must be greater than 40 mm so the puck and body of the probe clear the stylus wrench used to hold the port open. For mounting instructions, consult the documentation that came with your probe changer.

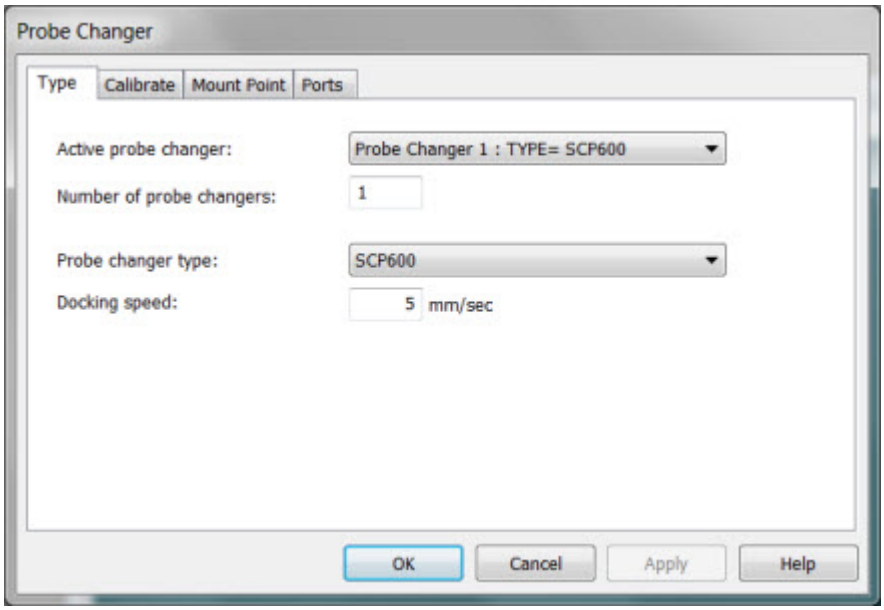
To calibrate your probe changer:

Step 1 - Select the SCP600 Probe Changer

To select the SCP600 Probe Changer:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.

2. In the **Probe changer type** list, select **SCP600**:



Probe Changer Dialog Box - Type Tab

3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.

4. In the **Active probe changer** list, select the list item that represents the probe changer to define. If this is the first probe changer, this shows **Probe Changer 1: TYPE=None**.

5. In the **Number of probe changers** box, specify the number of different types of probe changers.

6. In the **Docking speed** box, type a value. A value between 10-20 mm/sec is appropriate for this machine configuration. You can adjust this value at any time to speed up or slow down the system.

> To avoid equipment damage due to excessive docking speed, gradually increase the **Docking speed** value.

7. Click **Apply** to apply any changes made for this probe changer, and then click **OK** to close the dialog box.

> For details on controller configuration settings, see the documentation that came with your controller.

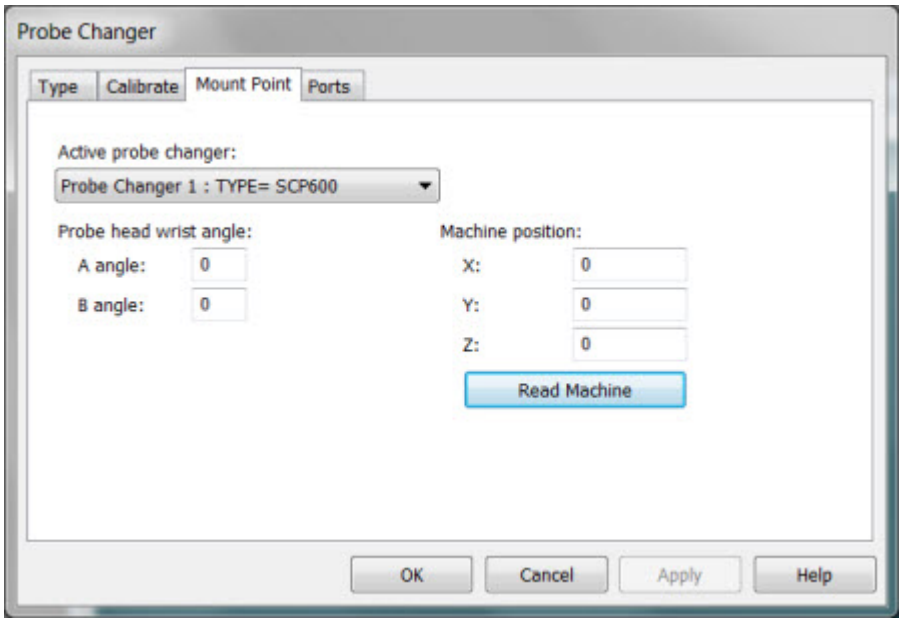
In the next step, you define the location your probe body moves to when using the probe changer to switch probe components.

Step 2 - Define the Mount Point

The probe changer mount point is the location in front of the probe changer where the machine moves to before it picks up or drops off a probe. You should pick a location that avoids collisions with the probe changer, the part, clamps, or any other object in the workspace.

To define the mount point for your probe changer, follow these steps:

1. Select the **Mount Point** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Mount Point Tab

2. In the **Active Probe Changer** list, select **TYPE=SCP600**.
3. If necessary, alter the probe head wrist angle for both **A angle** and **B angle**. Typically, but not always, these values are both 0 (zero). You need to use a calibrated probe rotation to ensure the probe has the ability to move in and out of the probe changer during the necessary steps of the probe rack calibration procedure.
4. Use your jog box to manually move your machine to the desired mount point position.
5. Click the **Read Machine** button to populate the **X**, **Y**, and **Z Machine Position** values with the current position. You may also manually type these values.
6. To save your changes, click **Apply**.

In the next step, you define the ports.

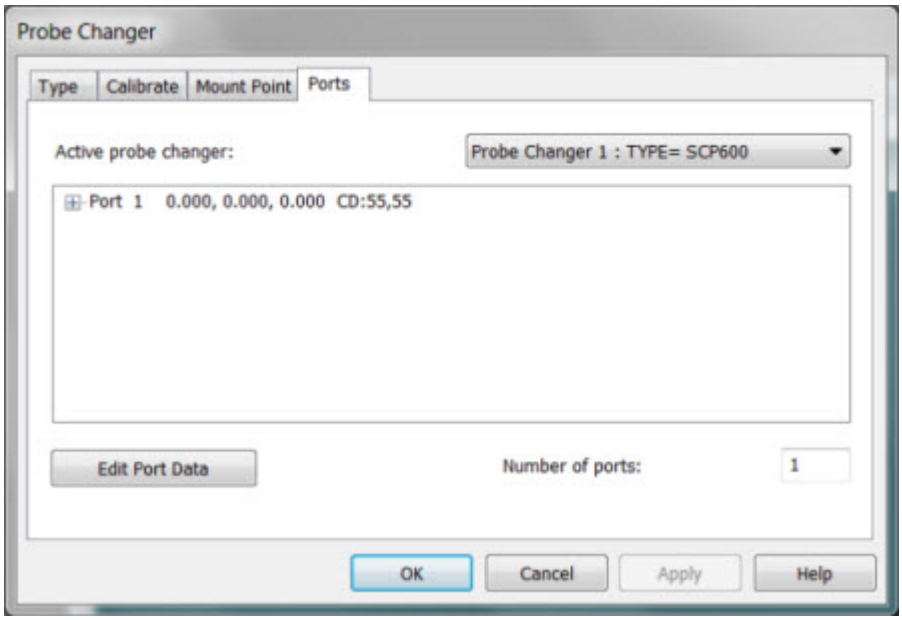
Step 3 - Define the Ports

The SCP600 is a single port rack. You can make use of any quantity of racks acting independently. You can also assemble them to form a multi-port rack of any quantity. This requires that you position them tightly against one another so that there is no space between them.

Regardless of how many rack pieces you use, you must define and calibrate them individually. However you choose to use them, you must first enter the number of ports in the **Ports** tab before calibration begins.

To define the ports for your SCP600 Probe Changer, do the following:

1. Select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Ports Tab

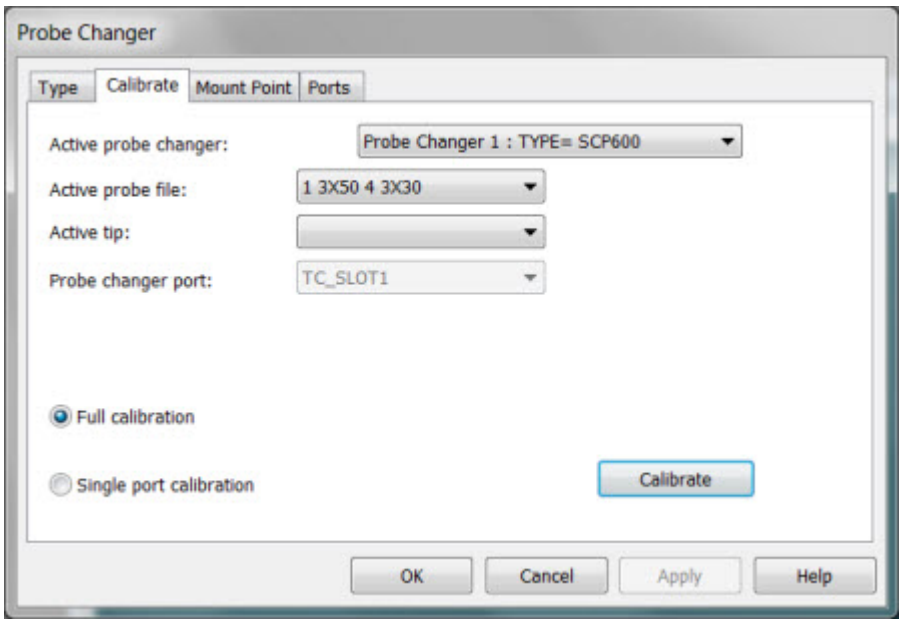
2. In the **Active Probe Changer** list, select **TYPE=SCP600**.
3. In the **Number of ports** box, type the number of ports on your probe changer.
4. To save your changes, click **Apply**.

You are now ready to begin calibration. The next step starts the calibration process.

Step 4 - Prepare for Calibration

To begin the calibration process for the SCP600 Probe Changer:

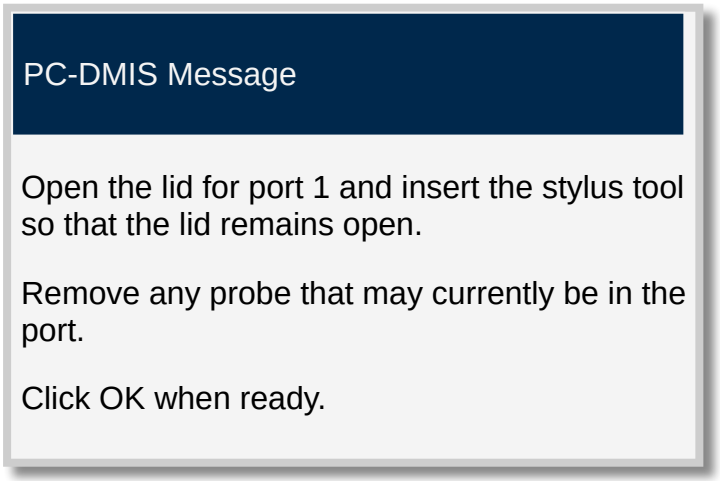
1. Select the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



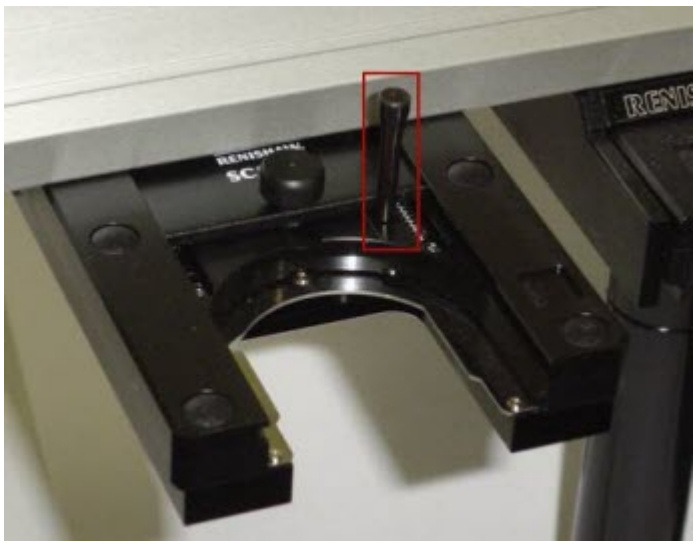
Probe Changer Dialog Box - Calibrate Tab

2. In the **Active probe changer** list, select **Probe Changer 1: TYPE=SCP600**.
3. In the **Active tip** list, select the tip ID to use for calibration. This is usually **T1A0B0**.
4. Click the **Calibrate** button.

Once you click **Calibrate**, the following message box appears:



1. To open the lid or lids, push them all the way back and insert a metallic pin (called a stylus wrench) into the hole in the top of the port near the back right corner. This hole is located to the side of the spring on the right when facing the rack.
2. With the lid or lids open, remove any modules or styli by sliding them forward and out of the ports.



Example of the SCP600 probe changer with an empty port held open by the stylus wrench.

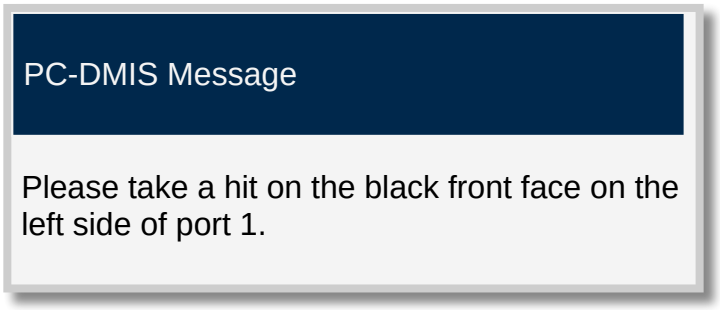
3. When you are ready to take the first measurement, click **OK**.

In the next step, you take the first manual hit.

Step 5 - Take the First Manual Hit

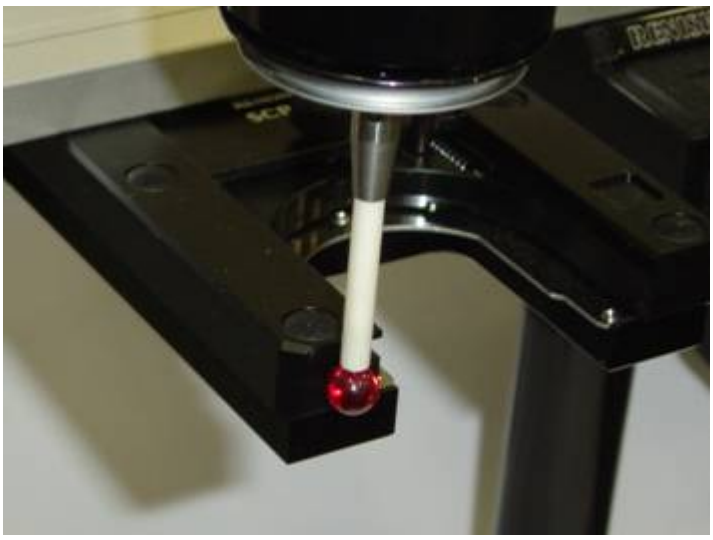
For the SCP600 Probe Changer, a series of message boxes prompts you through the process of measuring two manual hits. Two hits are required to define the location of this rack in the machine's workspace. Follow the prompts and take the needed hits as directed in the instructions for each hit.

You will take the first manual hit in the XY plane on the vertical face in front of the rack on the left side of the port. The prompt is:



PC-DMIS prompt for the first manual hit.

Use your machine's jog box to measure the first hit on the front face of the port, to the left of the opening:



In the next step, you take the second manual hit.

Step 6 - Take the Second Manual Hit

For the SCP600 Probe Changer, you will take the second manual hit in the Z direction, on the horizontal face on top of the rack to the left of the open port.

The prompt for the second hit on the top is:

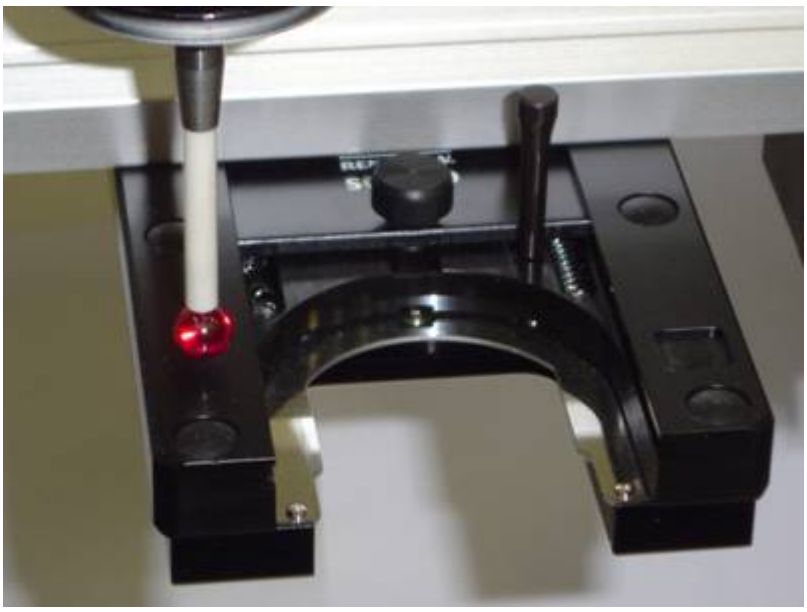
PC-DMIS Message

Please take a hit on the black top face on the left side of port 1.

The hit should be on the left portion and not inside a recessed circle.

After completing this hit, DCC calibration will begin to complete the measurement of this port.

Use your machine's jog box to measure the second hit on the top, flat, plastic surface of the port, left of the opening:

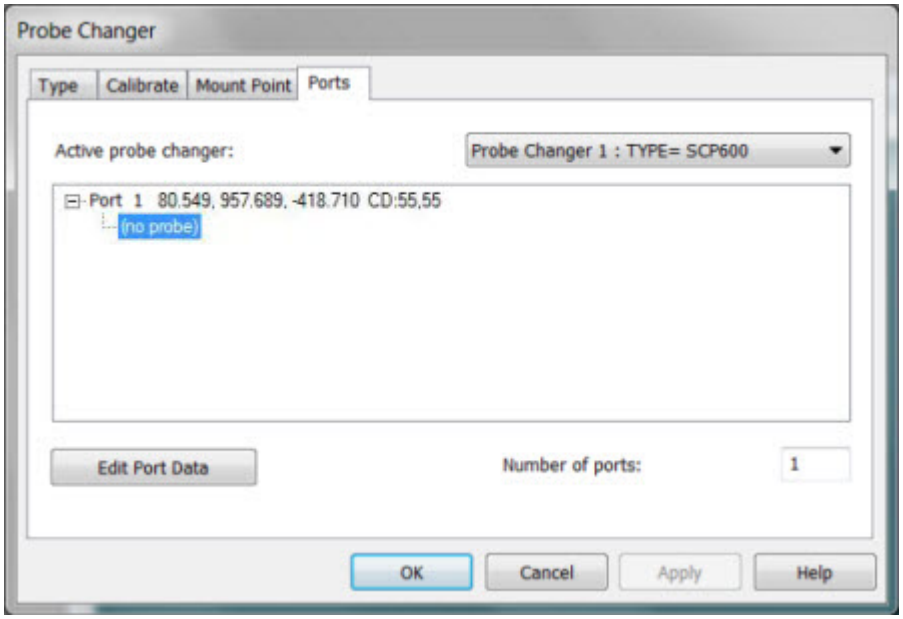


WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

In the next step, you review the calibration results.

Step 7 - Review the Calibration Results

1. When the calibration of the SCP600 Probe Changer is complete, select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). This tab displays the calibration information for the location of each calibrated port. For example:



Probe Changer dialog box - Ports tab with calibration results

2. When you view the results, look for the following. Some things to watch for are the position of the rack and the spacing of the ports. Any significant deviations from these expectations may be due to a bad hit.
    - This rack must be aligned parallel to the X or Y axis of the CMM.
    - When using multiple ports as one rack, the X and Y values should show equal spacing between ports, roughly 85 mm apart.
    - The Z values should be nearly identical, since the ports are all at the same height.

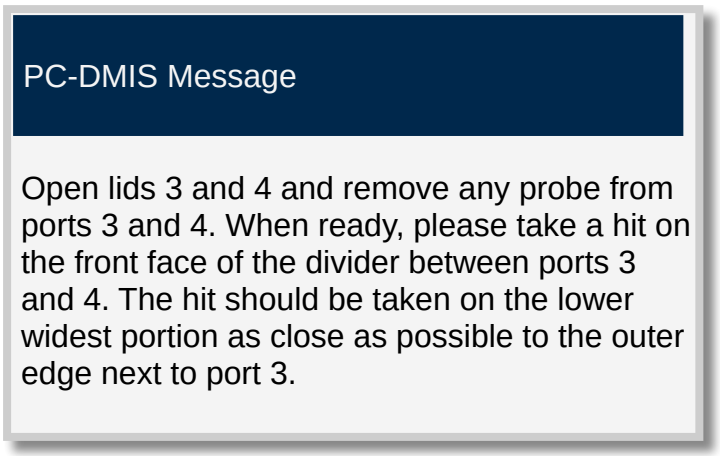
The results during measurement routine execution are:

1. The probe entities that are added to each of the ports are automatically picked up from that location whenever PC-DMIS executes a `LOADPROBE` command for that probe.
2. The probe body moves to the mount point and then into the "unload" port (the port that used to contain the currently-used probe entity), which pushes the lid backwards. The current "puck", a black and conical piece of hardware that connects to the bottom of the probe body, is held in place by the rack while the probe body lifts away to detach.
3. From there, the probe moves over to the next "load" position. The magnetic connection automatically engages to load the new module.
4. It then moves back to the rack’s mount point.
5. From there, it continues to measure.

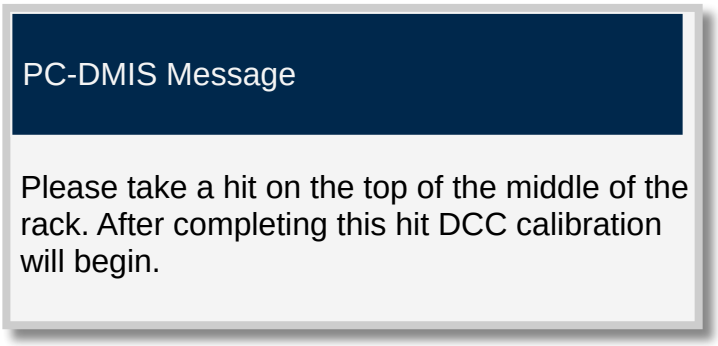
Calibrating the SCR200 Probe Changer

This topic describes how to calibrate the SCR200 Probe Changer.

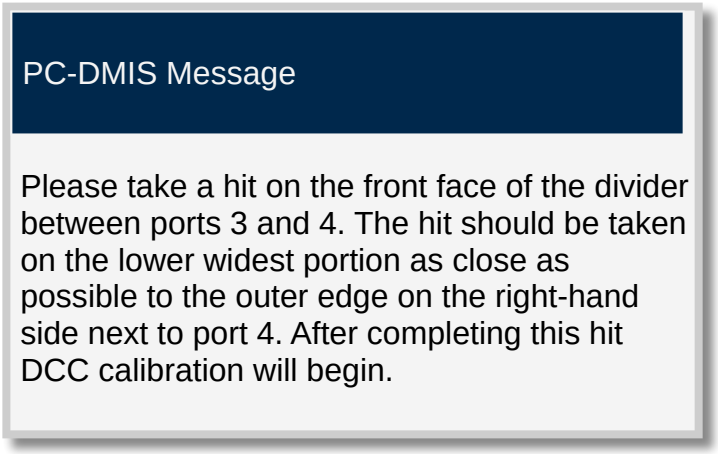
When you click the **Calibrate** button on the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), the first prompt appears:



1. Open lids 3 and 4. Remove any probes from those ports.
2. Click **OK**.
3. Take one hit on the front face of the probe changer's center post. A second prompt appears and asks you to take the second hit:



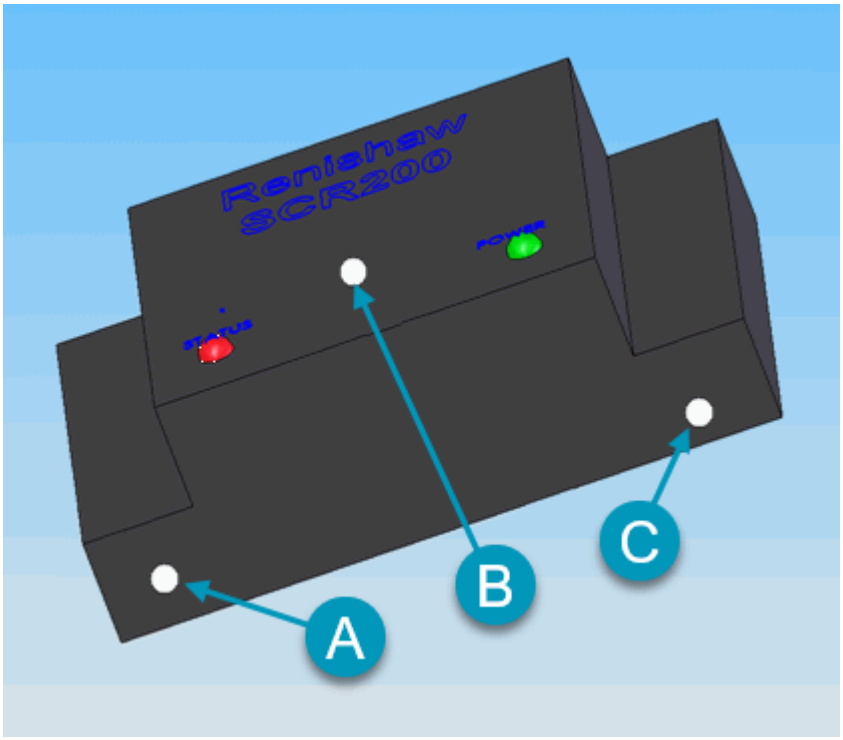
4. Click **OK**.
5. Take the second manual hit on the top of the center post. A third prompt appears and asks you to take the final hit:



6. Click **OK**.
7. Take the third manual hit again on the front face of the center post.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

- You should have taken all three hits similar to shown here:



A - 1st Manual Hit (in front of center post)

B - 2nd Manual Hit (on top of center post)

C - 3rd Manual Hit (in front of center post)

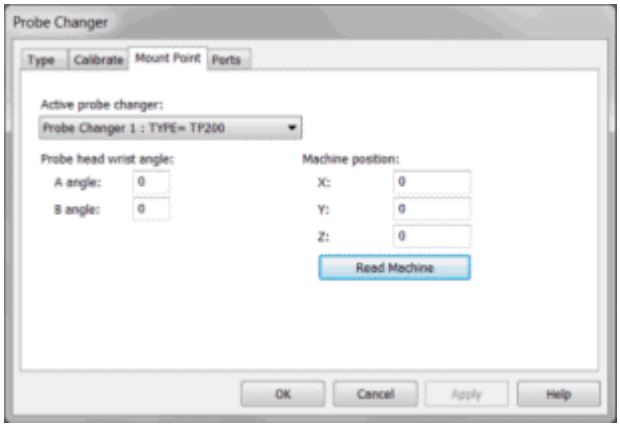
- PC-DMIS takes the remaining hits in DCC Mode:

  1 hit each on the left and right inside sides of port 3.

  1 hit each on the left and right inside sides of port 4.

After the calibration, the **Probe Changer** dialog box appears.

1. Select the **Mount Point** tab:

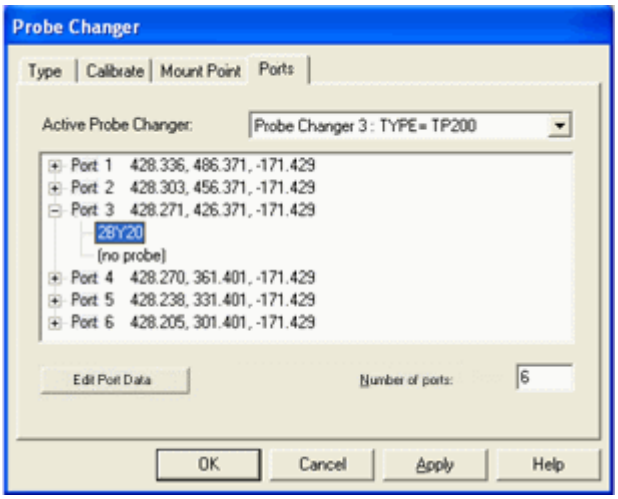


Probe Changer Dialog Box - Mount Point Tab

2. Confirm the wrist angle for the change cycle by typing in the angle in the **A Angle** and **B Angle** boxes.

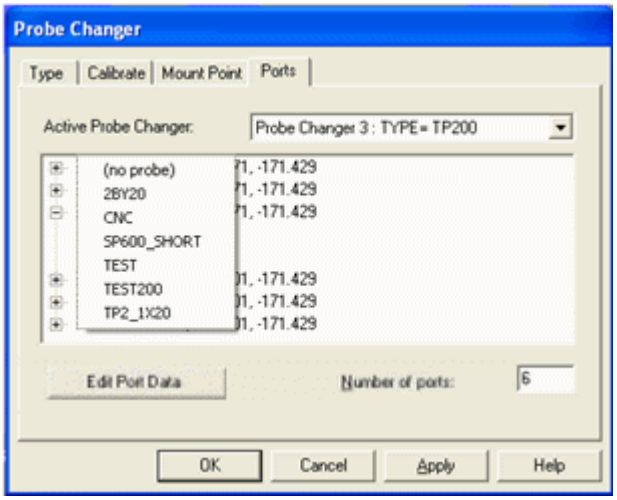
3. Specify the rack's safe position (a position where probes can be swapped in and out safely) in machine coordinates. You can type this manually into the **X**, **Y**, and **Z** boxes in the **Machine Position** area, or click the **Read Machine** button.

4. Select the **Ports** tab:



Probe Changer Dialog Box - Ports Tab

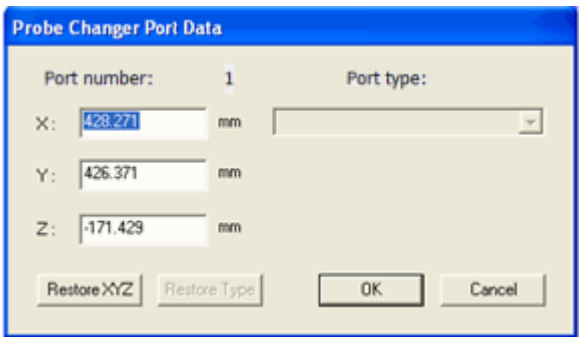
5. To define the contents of each port in the rack, expand the plus sign **(+)** for each port and then double-click the **(no probe)** item. A list of available probes appears. For example:



List of available probes

6. Select the probe file to add to the current port.

7. If necessary, adjust the port position. Select the port's position and then click the **Edit Port Data** button. The **Probe Changer Port Data** dialog box appears. For example:



Probe Changer Port Data Dialog Box

8. Modify the **X**, **Y**, **Z** position of the port.
9. Click **OK** to close the **Probe Changer Port Data** dialog box.
10. Click **OK** to close the **Probe Changer** dialog box.

Calibrating the Senmation Probe Changer

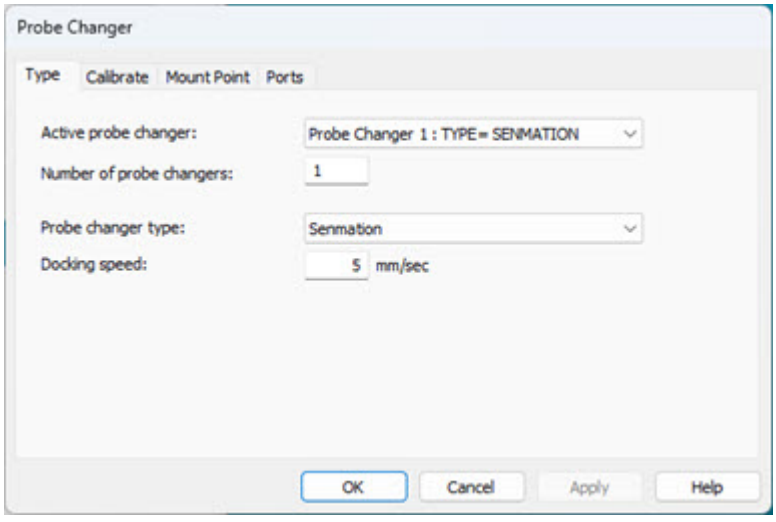
The calibration process for the Senmation probe changer represents the steps that you would take to prepare to use any of the probe changers that PC-DMIS supports. The process discussed here is specific to the Senmation probe changer.

To calibrate your probe changer:

Step 1 - Select the Senmation Probe Changer

To select the Senmation probe changer:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **Senmation**:



Probe Changer Dialog Box - Type Tab

3. Click **Apply** to make the probe changer active and load the settings that are relevant to it. Other tabs become visible after you click **Apply**.

4. In the **Active probe changer** list, select the probe changer that you want to define. If this is the first probe changer, it appears as **Probe Changer 1: TYPE=None**.
5. In the **Number of probe changers** box, specify the number of probe changers that you want to define.
6. In the **Docking speed** box, type a value. A value between 10 and 20 mm/sec is appropriate for this machine configuration. You can adjust this value at any time to increase or decrease the docking speed. For the first replacement attempt, use a reduced speed to help protect the machine. After you finish testing, you can return to the regular speed.

   To avoid equipment damage due to excessive docking speed, gradually increase the **Docking speed** value.

7. Click **Apply** to apply your changes, and then click **OK** to close the dialog box.

For details on controller configuration settings, see the documentation that came with your controller.

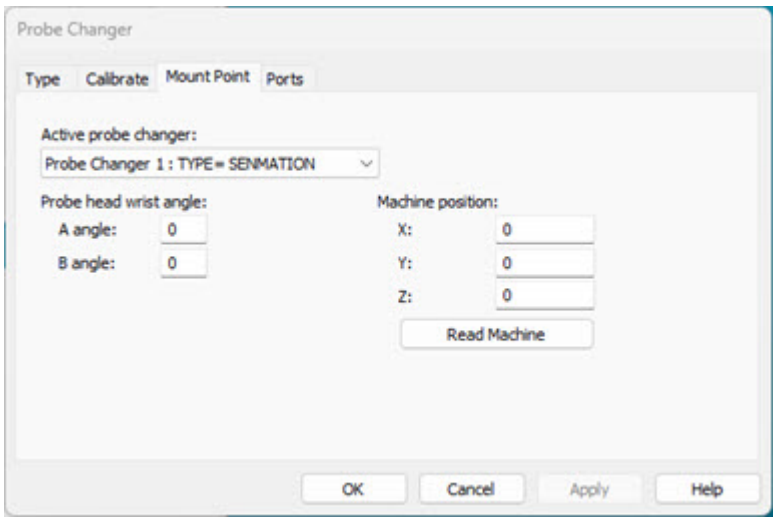
In the next step, you define the mount point.

Step 2 - Define the Mount Point

The probe changer mount point is the location in front of the probe changer where the machine moves to before it picks up or drops off a probe. You should pick a location that avoids collisions with the probe changer, the part, clamps, or any other object in the workspace.

To define the mount point for your probe changer, follow these steps:

1. Select the **Mount Point** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Mount Point Tab

2. In the **Active probe changer** list, select **TYPE=SENMATION**.
3. Rotate the probe head wrist to a suitable **A angle** and **B angle**.
4. Use the jog box to manually move the machine to the desired mount point position.
5. Click the **Read Machine** button to populate the **X**, **Y**, and **Z** machine position values with the current position. You can also enter these values manually.
6. To save your changes, click **Apply**.

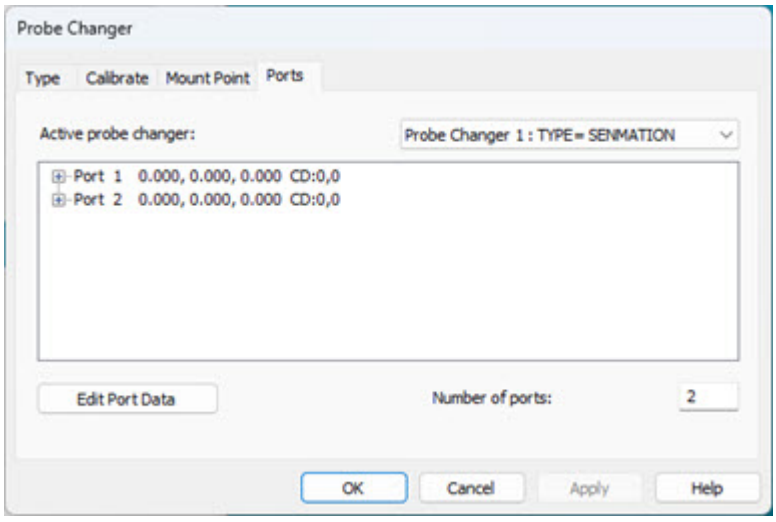
In the next step, you define the ports.

Step 3 - Define the Ports

Before calibrating the rack, define the number of ports on the probe changer.

To define the ports, do the following:

1. Select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Ports Tab

2. In the **Active probe changer** list, select **TYPE=SENMATION**.
3. In the **Number of ports** box, type the number of ports on your probe changer.
4. To save your changes, click **Apply**.

You are now ready to prepare the probe changer for calibration. The next step describes how to select the probe and tip to use for calibration.

Step 4 - Prepare for Calibration

This step describes how to prepare the Senmation probe changer for calibration.

In this version, you can calibrate the Senmation change rack only with a rotary probe head. Use a 3 x 50 mm or 5 x 50 mm tip for calibration.

Use a straight tip that points down and has no cubes or other joints.

Before you calibrate the change rack, you must calibrate the following probe angles so that PC-DMIS can calculate accurate probe head offset distances and ensure safe probe exchange: A0B0, A0B90, A0B-90, A0B180, A45B0, A90B0, A90B90, A90B180. If any of these angles are not calibrated, PC-DMIS displays a message similar to the following:

PC-DMIS

In order to calibrate senmation tool changer, you need to use a probe with the following calibrated tip angles:

T1A0B0

T1A45B0

T1A90B0

T1A90B90

T1A90B180

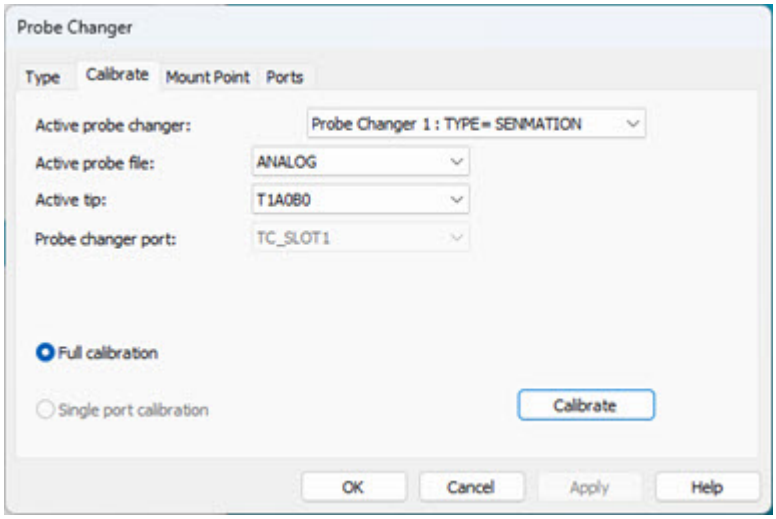
T1A0B90

T1A0B-90

T1A0B180

To begin the calibration process, do the following:

1. Select the Calibrate tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Calibrate Tab

2. In the **Active probe changer** list, select **Probe Changer 1: TYPE=SENMATION**.
3. The **Active probe file** list defaults to the probe file specified in the current measurement routine. A rotary probe head is required for calibration.
4. The **Active tip** list defaults to the tip specified in the current measurement routine. One calibrated tip is required.
5. Click **Calibrate** to begin the calibration process.

Orient the change rack as level as possible and aligned with the machine beam direction to help ensure safe probe exchange.

In the next step, take the required manual hits.

Step 5 - Take the Manual Hits

When you click the **Calibrate** button on the Calibrate tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), a series of message boxes guides you through the process of taking manual hits. The number of manual hits required depends on the number of ports in the probe changer.

For example, a two-port rack requires five manual hits to fully define the rack's orientation. Follow the prompts and take the required hits.

The first prompt appears:

PC-DMIS Message

From the viewpoint of facing the front of the probe changer, please use the probe tip to take one hit on the front of the locating block of port 1.

1. Take the first manual hit on the front of the locating block of port 1. (The first port is the leftmost port; take the manual hits in this order.) A second prompt appears:

   PC-DMIS Message

   From the viewpoint of facing the front of the probe changer, please use the probe tip to take one hit on the front of the locating block of port 2.

2. Take the second manual hit on the front of the locating block of port 2. A third prompt appears:

   PC-DMIS Message

   From the viewpoint of facing the front of the probe changer, please use the probe tip to take one hit on the top of the locating block of port 1.

3. Take the third manual hit on the top of the locating block of port 1. A fourth prompt appears:

   PC-DMIS Message

   From the viewpoint of facing the front of the probe changer, please use the probe tip to take one hit on the left of the locating block of port 1.

4. Take the fourth manual hit on the left of the locating block of port 1. A fifth prompt appears:

   PC-DMIS Message

   From the viewpoint of facing the front of the probe changer, please use the probe tip to take one hit on the left of the locating block of port 2.

5. Take the fifth manual hit on the left of the locating block of port 2.

6. After you finish taking the manual hits, move the probe head to a safe position near the first port. Automatic calibration then begins.

If a collision occurs during automatic calibration, open the Settings Editor application and adjust the approach and prehit distances. For more details, see the `TCSenmationDccPrehitSENMATION`, `TCSenmationDccLeftApproachSENMATION`, and `TCSenmationDccRightApproachSENMATION` entries in the "Option" topic of the PC-DMIS Settings Editor documentation.

You have now completed the probe changer calibration process.

Calibrating the SP600 Probe Changer

These topics describe how to define and calibrate the SP600 Probe Changer.

There are no inserts or extensions used for any of the port positions.

A Renishaw SP600 Stylus Change Rack (SCR600)

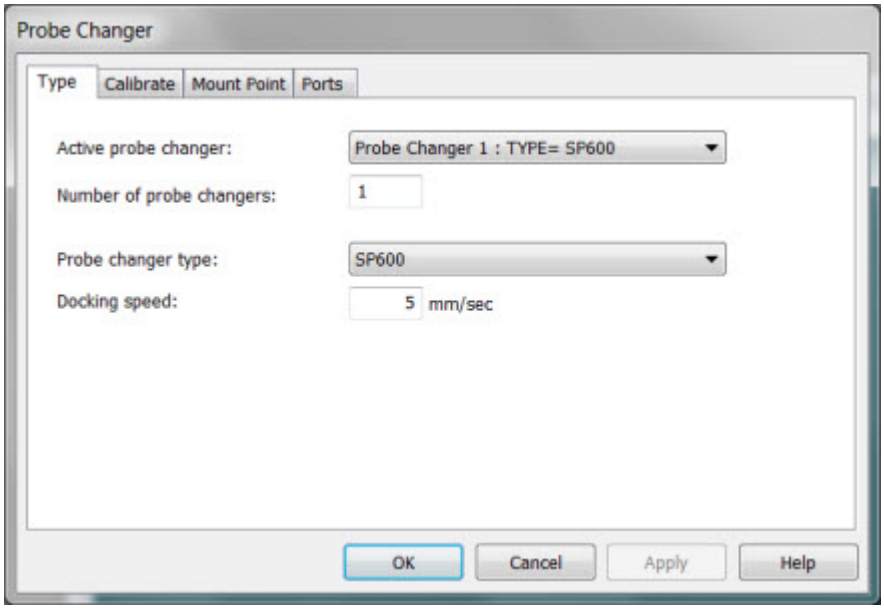
The SP600 Probe Changer DOES NOT need to be mounted on the machine table parallel to either the X or Y axis. For mounting instructions, consult the documentation that came with your probe changer.

To calibrate your probe changer:

Step 1 - Select the SP600 Probe Changer

To select the SP600 Probe Changer:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **SP600**:



Probe Changer Dialog Box - Type Tab

3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.
4. In the **Active probe changer** box, select the list item that represents the probe changer to define. If this is the first probe changer, it appears as **Probe Changer 1: TYPE=None**.
5. In the **Number of probe changers** box, specify the number of different types of probe changers.
6. In the **Docking speed** box, type a value. A value between 10-20 mm/sec is appropriate for this machine configuration. You can adjust this value at any time to speed up or slow down the system.

To avoid equipment damage due to excessive docking speed, gradually increase the **Docking speed** value.

7. Click **Apply** to apply any changes made for this probe changer, and then click **OK** to close the dialog box.

For details on controller configuration settings, see the documentation that came with your controller.

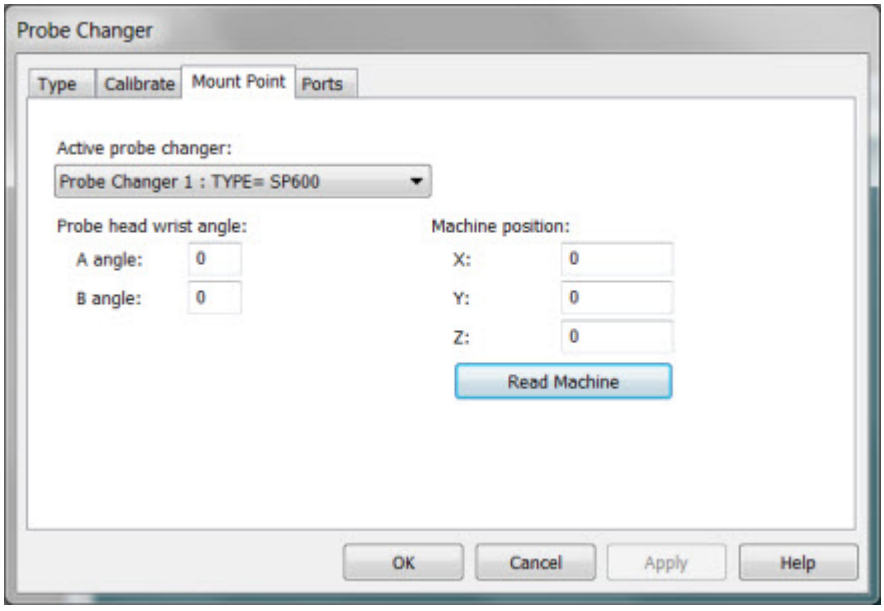
In the next step, you define the location your probe body moves to when using the probe changer to switch probe components.

Step 2 - Define the Mount Point

The mount point for your SP600 Probe Changer is the location in front of your probe changer where the machine moves to before it picks up or drops off a probe. You should determine a location that avoids collisions with the probe changer or part.

To define the mount point for your probe changer:

1. Select the **Mount Point** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Mount Point Tab

2. In the **Active probe changer** list, select **TYPE=SP600**.

3. If necessary, alter the probe head wrist angle for both **A angle** and **B angle**. Typically, but not always, these values are 0 and 0, respectively. You need to use a

calibrated probe rotation that ensures the probe has the ability to move in and out of the probe rack during the necessary steps of the probe rack calibration procedure.

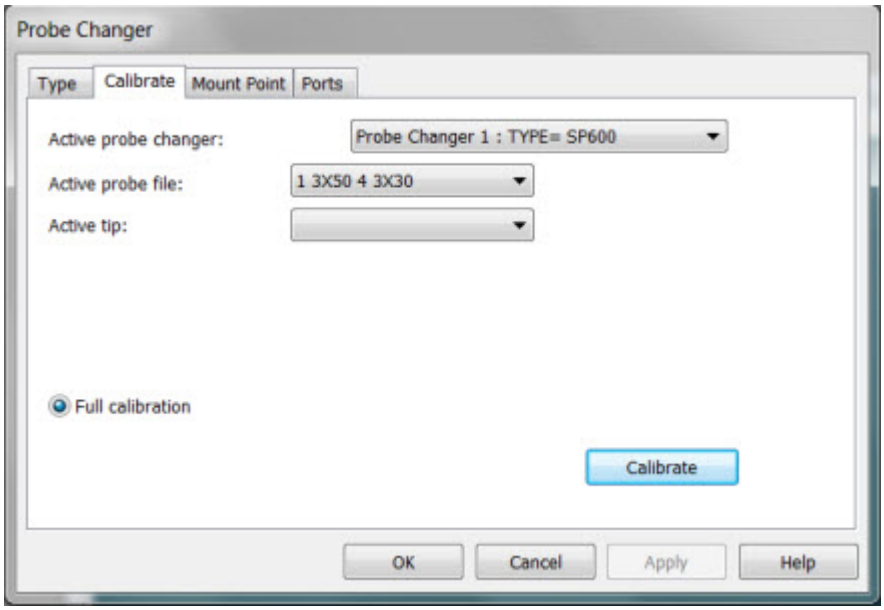
4. Use your jog box to manually move your machine to the desired mount point position.
5. Click the **Read Machine** button to populate the **X**, **Y**, and **Z Machine position** values with the current position. You may also manually type these values.
6. To save your changes, click **Apply**.

You are now ready to begin calibration. The next step starts the calibration process.

Step 3 - Prepare for Calibration

To begin the calibration procedure for the SP600 Probe Changer:

1. Select the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Calibrate Tab

2. In the **Active probe changer** list, select **TYPE=SP600**.
3. In the **Active tip** list, select the tip ID to be used for calibration. This is usually **T1A0B0**.
4. Click the **Calibrate** button.

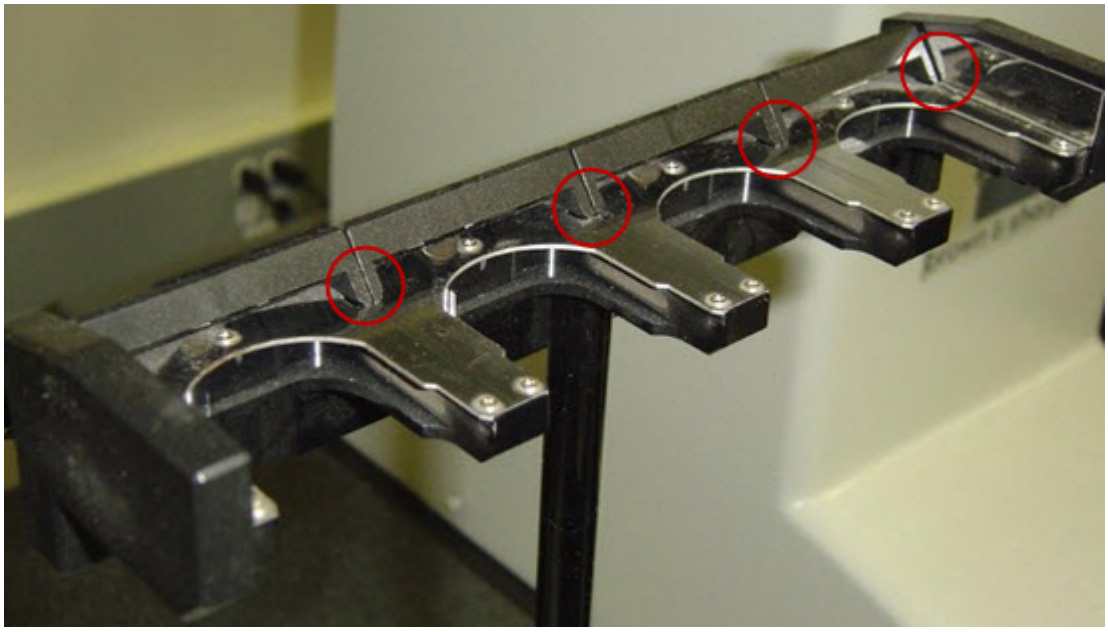
Once you click **Calibrate**, the following message box appears:

PC-DMIS Message

Open all lids and remove any probe from port 1.

When ready, please take a hit in the center of the vertical face between ports 1 and 2.

1. To open all the lids, push them all the way back and down. Plastic extensions on each side of the lid slide into corresponding holes in the rack surface to keep the lids open.
2. With the lids open, remove all of the modules and styli by sliding them forward and out of the ports.



SP600 Probe Changer showing empty ports held open by plastic extensions on each side of the port cover that slide into corresponding holes in the rack surface (indicated by the red circles)

3. When you are ready to take the first measurement, click **OK**.

In the next step, you take the first manual hit.

Step 4 - Take the First Manual Hit

PC-DMIS moves you through the process of measuring three manual hits through a series of message boxes. Three hits are required to fully define the orientation of this rack in the machine's XY plane. It is not necessary to align the rack to any single axis, as the manual hits identify any rotation involved. Follow the prompts and take the needed hits as directed in the instructions for each hit.

The first manual hit is taken in the XY plane, on the vertical face in front of the rack between port 1 and port 2.

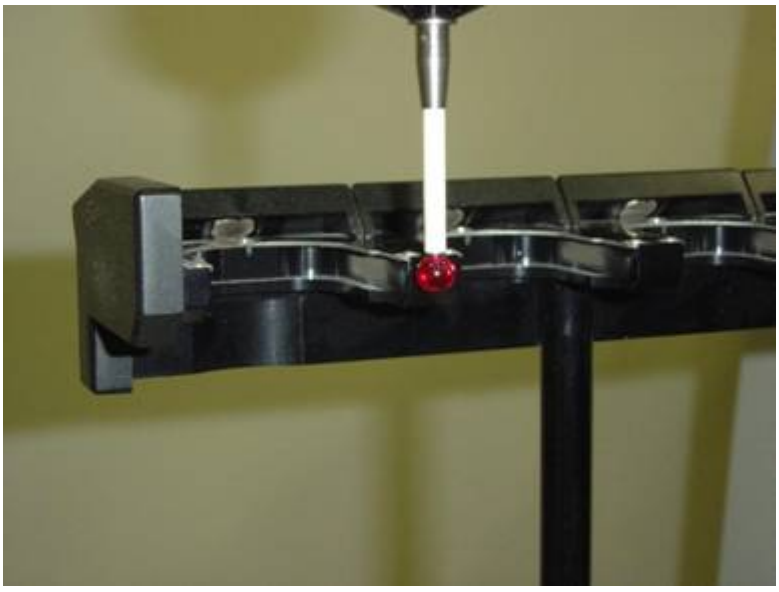
The prompt for the first hit on the front face is:

PC-DMIS Message

Open all lids and remove any probe from port 1.

When ready, please take a hit in the center of the vertical face between ports 1 and 2.

Use your machine's jog box to measure the first hit on the front face between port 1 and port 2.



In the next step, you take the second manual hit.

Step 5 - Take the Second Manual Hit

For the SP600 Probe Changer, you will take the second manual hit in the Z direction, on the horizontal face on top of the rack between port 2 and port 3.

The prompt for the second hit on the top is:

PC-DMIS Message

Please take a hit on top of the metallic docking plate in the middle between ports 2 and 3.

Use your machine's jog box to measure the second hit on the top metal surface between port 2 and port 3.

In the next step, you take the third manual hit.

Step 6 - Take the Third Manual Hit

For the SP600 Probe Changer, you will take the third and final manual hit in the XY plane, on the vertical face in front of the rack between port 3 and port 4.

The prompt for the third hit in front is:

PC-DMIS Message

Please take a hit in the center of the vertical face between ports 3 and 4. After completing this hit, DCC calibration will begin.

Use your machine's jog box to measure the third hit on the front vertical surface, between port 3 and port 4 as shown below.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

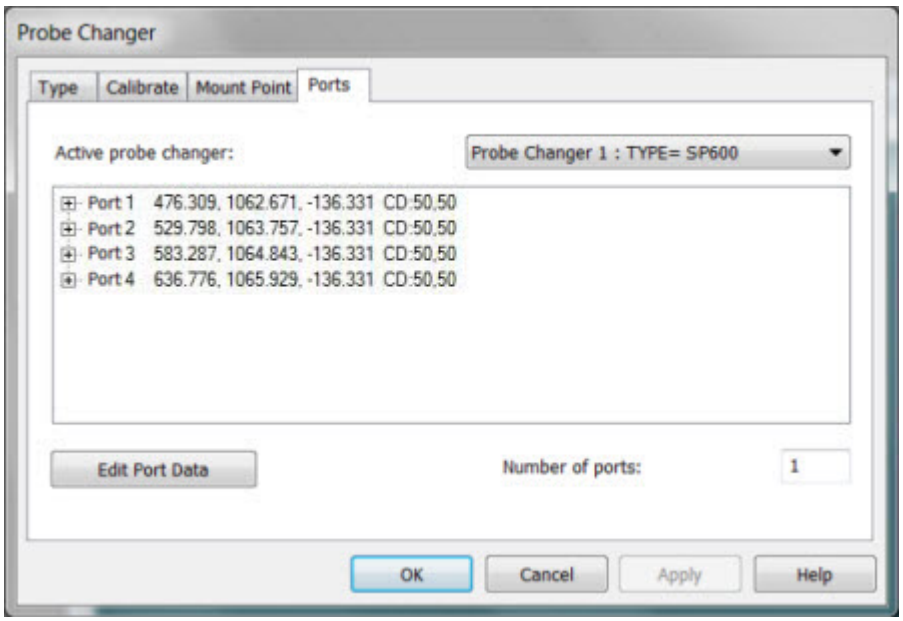
This set of two hits establishes the location and orientation for the tool changer.

At this point, the system goes into DCC Mode and measures a series of hits required to accurately locate and orient the rack.

In the next step, you review the calibration results.

Step 7 - Review the Calibration Results

1. For the SP600 Probe Changer, once the DCC measuring finishes, select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). This tab displays the calibration information for the location of each calibrated port. For example:



Probe Changer dialog box - Ports tab with calibration results

2. When you view the results, look for the following. Some things to watch for are the position of the rack and the spacing of the ports. Any significant deviations from these expectations may be due to a bad hit.

    - This rack is not necessarily aligned parallel to any axis of the CMM.
    - However, the X and Y values should show equal spacing between ports, roughly 53.5 mm apart.
    - Similarly, the Z values should be nearly identical, since the ports are all at the same height.

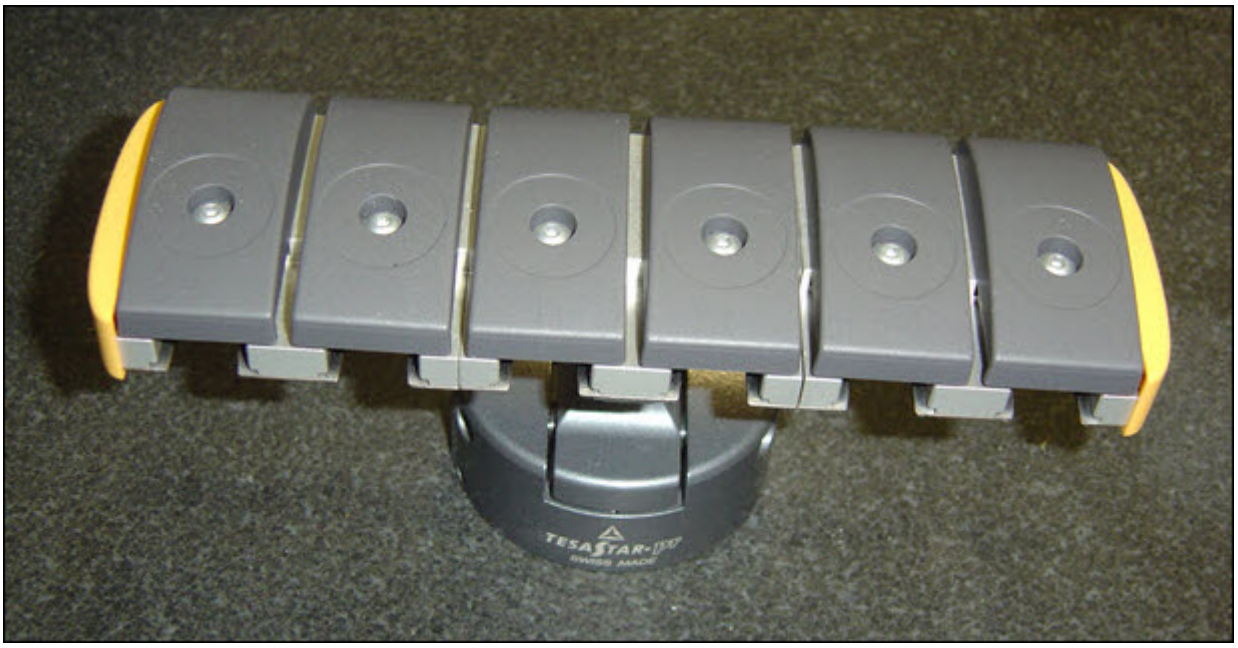
The results during measurement routine execution are:

1. Probe entities that are added to each of the ports are automatically picked up from that location whenever PC-DMIS executes a `LOADPROBE` command for that probe.
2. The probe body moves to the mount point and then into the "unload" port (the port that used to contain the currently used probe entity), which pushes the lid backwards. The current "puck", a black conical piece of hardware that connects to the bottom of the probe body, is held in place by the rack while the probe body lifts away to detach.
3. From there, the probe moves over to the next "load" position. The magnetic connection automatically engages to load the new module.
4. It then moves back to the rack’s mount point.
5. From there, it continues to measure.

Calibrating the TESASTAR-PR / HR-P Probe Changer

The calibration process for the TESASTAR-PR / HR-P Probe Changer represents the steps that you would take to prepare to use any of the probe changers that PC-DMIS supports. The process discussed here is specific to the TESASTAR-PR / HR-P Probe Changer.

Inserts or extensions are not used for any of the port positions.



TESASTAR-PR / HR-P Probe Changer rack

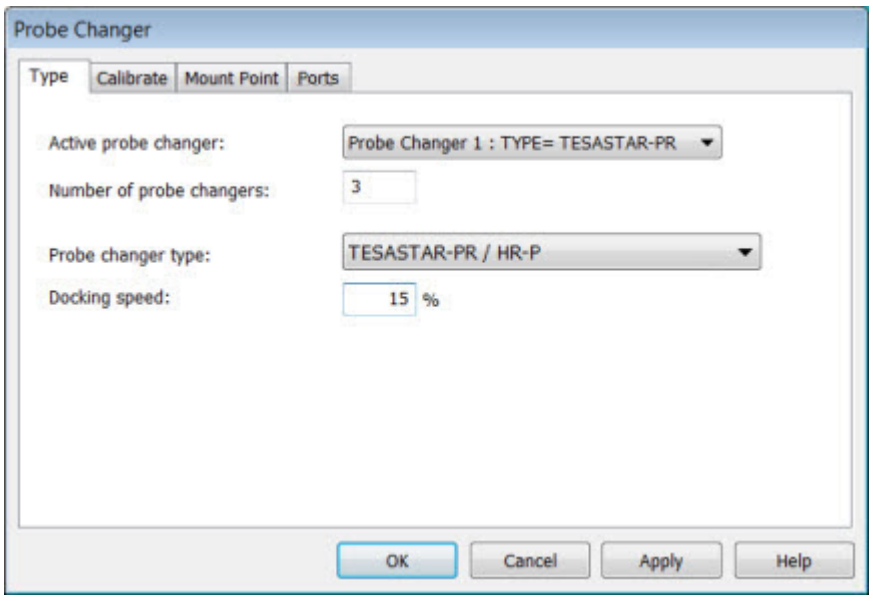
> This probe changer MUST be mounted on the machine table parallel to a machine axis, such as the X or Y axis. For mounting instructions, consult the documentation that came with your probe changer.

To calibrate your probe changer:

Step 1 - Select the TESASTAR-PR / HR-P Probe Changer

To select the TESASTAR-PR / HR-P Probe Changer:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **TESASTAR-PR / HR-P**:



Probe Changer Dialog Box - Type Tab

3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.

4. In the **Active probe changer** box, select the list item that represents the probe changer you want to define. If this is the first probe changer, it appears as **Probe Changer 1: TYPE=None**.

5. In the **Number of probe changers** box, specify the number of probe changers that you want to define.

6. In the **Docking speed** box, type a value. A value between 15-20% is appropriate for this machine configuration. You can adjust this value at any time to speed up or slow down the system.

   To avoid equipment damage due to excessive docking speed, gradually increase the **Docking speed** value.

7. Click **Apply** to apply any changes made for this probe changer, and then click **OK** to close the dialog box.

For details on controller configuration settings, see the documentation that came with your controller.

In the next step, you define the mount point and wrist angles for your system.

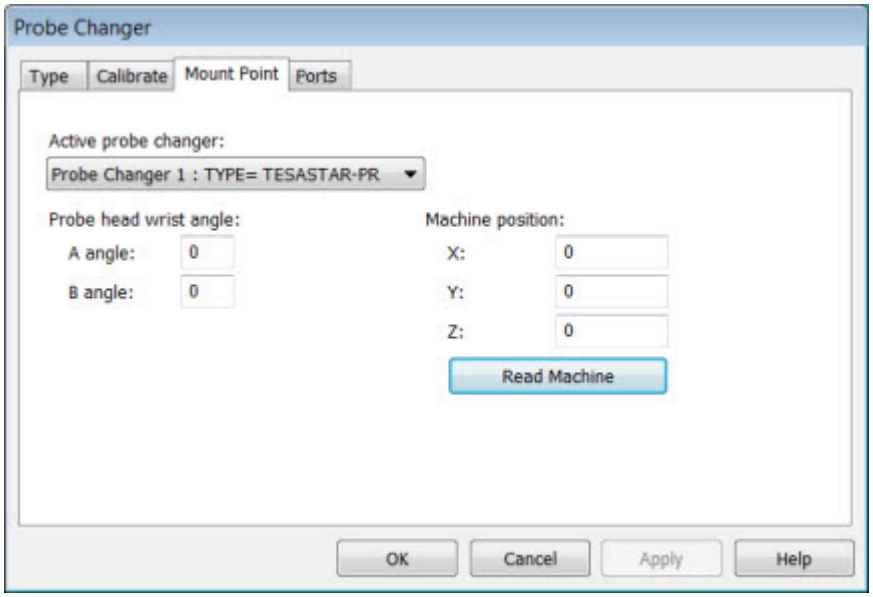
Step 2 - Define the Mount Point and Wrist Angle

The probe changer mount point is the location in front of the probe changer where the machine moves to before it picks up or drops off a probe. You should pick a location that

avoids collisions with the probe changer, the part, clamps, or any other object in the workspace.

To define the mount point for your probe changer, follow these steps:

1. Select the **Mount Point** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Mount Point Tab

2. In the **Active probe changer** list, select **TYPE=TESASTAR-PR**.
3. If necessary, alter the probe head wrist angle for both **A angle** and **B angle**. Often, but not always, these values are both 0 (zero). You need to use a calibrated probe rotation to ensure the probe has the ability to move in and out of the probe changer during the necessary steps of the probe rack calibration procedure.
4. Use your machine's jog box to manually move your machine to the desired mount point position.
5. Click the **Read Machine** button to populate the **X**, **Y**, and **Z Machine position** values with the current position. You can also manually type these values.
6. To save your changes, click **Apply**.

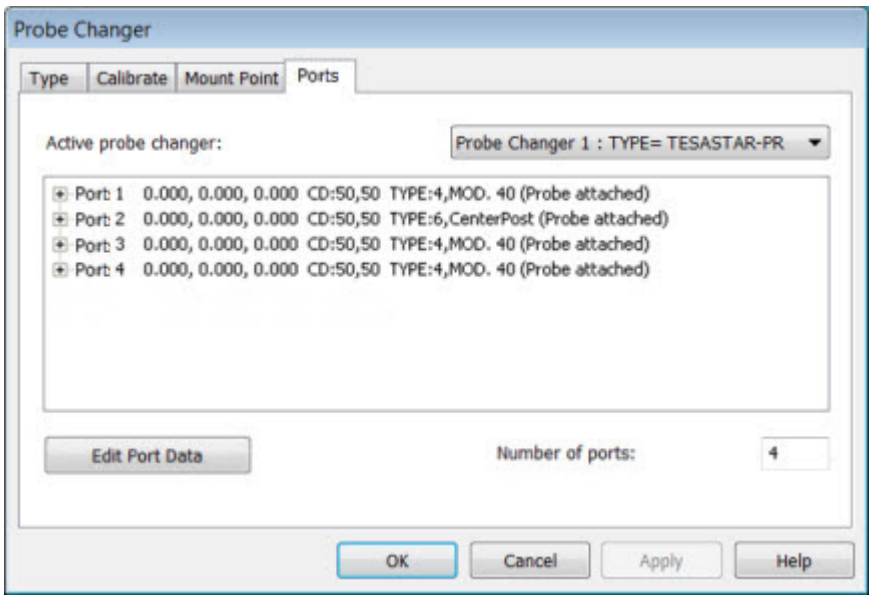
In the next step, you define the ports for your system.

Step 3 - Define the Ports

The final step prior to the actual calibration of the TESASTAR-PR / HR-P Probe Changer is to define the ports on the probe changer.

To define the ports, do the following:

1. Select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Ports Tab

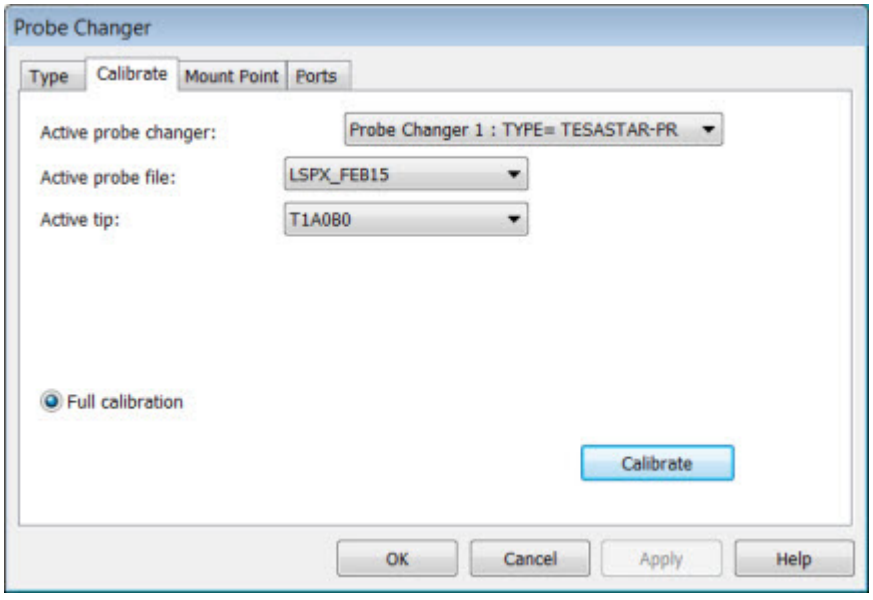
2. In the **Active probe changer** list, select **TYPE=TESASTAR-PR**.
3. In the **Number of ports** box, type the number of ports that you want to define. This should match the number of physical ports on the probe changer.
4. To save your changes, click **Apply**.

The next step starts the calibration process.

Step 4 - Prepare for Calibration

To begin the calibration process for the TESASTAR-PR / HR-P Probe Changer:

1. Select the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Calibrate Tab

2. Click the **Calibrate** button. If the proper probe assembly is not currently loaded, the following message appears:

   If this is the case, it is necessary to load the proper probe components and start the calibration again.

3. The **Active probe file** and **Active tip** items both default to the current measurement routine settings. If needed, change these to the probe and tip that you intend to use for the probe changer calibration.

4. Open the lids on each port by sliding them back until they click into place.

   PC-DMIS prompt to open the port lids before calibration.

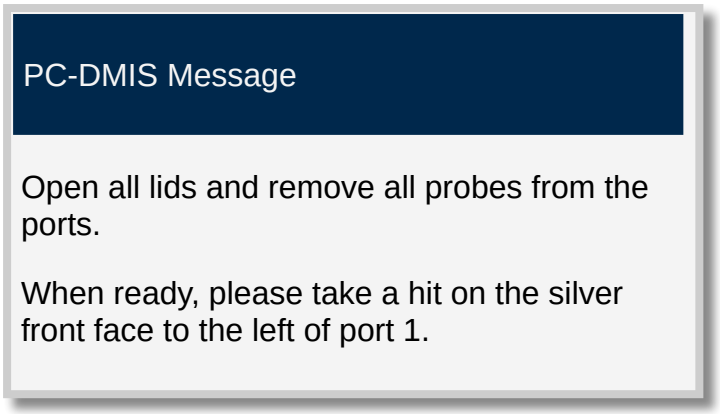
   Example showing the open port lids before calibration.

In the next step, you take the first manual hit.

Step 5 - Take the First Manual Hit

Once you start the calibration procedure for the TESASTAR-PR / HR-P Probe Changer, the ports must be emptied of all probes. You will take the first hit on the front face to the left of the first port.

PC-DMIS prompts you through the process of measuring the manual hits through a series of message boxes. The following message prompts you to open all the lids and take the first hit:

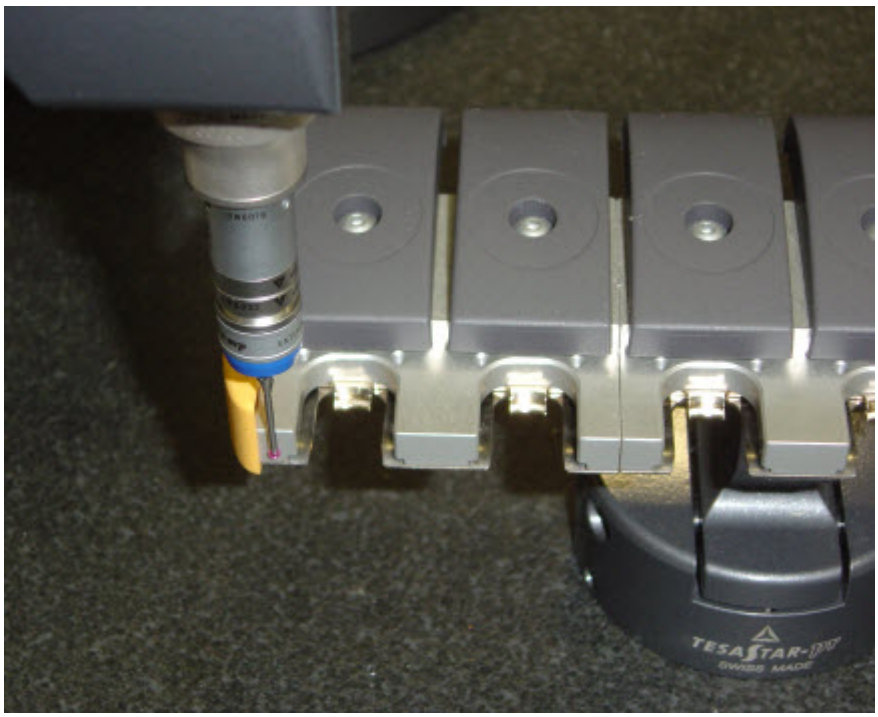


Prompt for the first manual hit in the front face, left of port 1

1. When you are ready to take the first measurement, click **OK**.
2. Remove all of the modules and styli by sliding them forward and out of the ports.

   Three hits are required to fully define the orientation of this rack in the machine’s XY plane. It is not necessary to align the rack to any single axis, as the manual hits will identify any rotation involved. Follow the prompts and take the needed hits as directed in the instructions for each hit.

   The first manual hit is taken in the XY plane, on the vertical face in the back of port #1.
3. Use your machine's jog box to measure the first hit on the front face to the left of port #1.

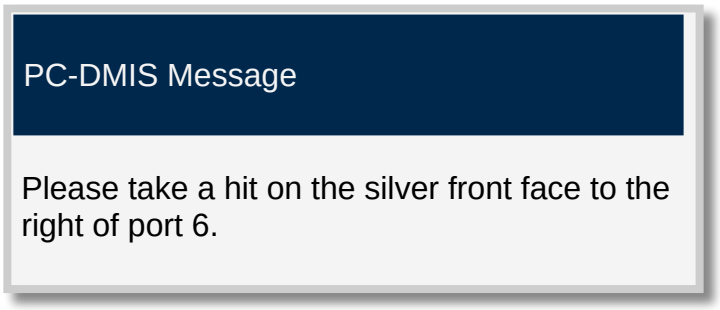


Location of first manual hit during calibration

In the next step, you take the second manual hit.

Step 6 - Take the Second Manual Hit

You will take the second manual hit for the TESASTAR-PR / HR-P Probe Changer on the front face to the right of the last port. Once the first manual hit is completed, the following message box appears:



Prompt for the second manual hit inside the last port

Use your machine's jog box to measure the second hit on the front surface to the right of the last port.

Location of second manual hit during calibration

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

After it takes this hit on the back of the last port, PC-DMIS drives in DCC Mode and takes some additional measurements working backwards from the last port towards the first port. When this is complete, it positions the probe above the rack and provides instructions to proceed.

In the next step, you take the third manual hit.

Step 7 - Take the Third Manual Hit

You will take the third manual hit for the TESASTAR-PR / HR-P Probe Changer on the top surface to the right of the last port. Once you complete the second manual hit, the following message box appears:

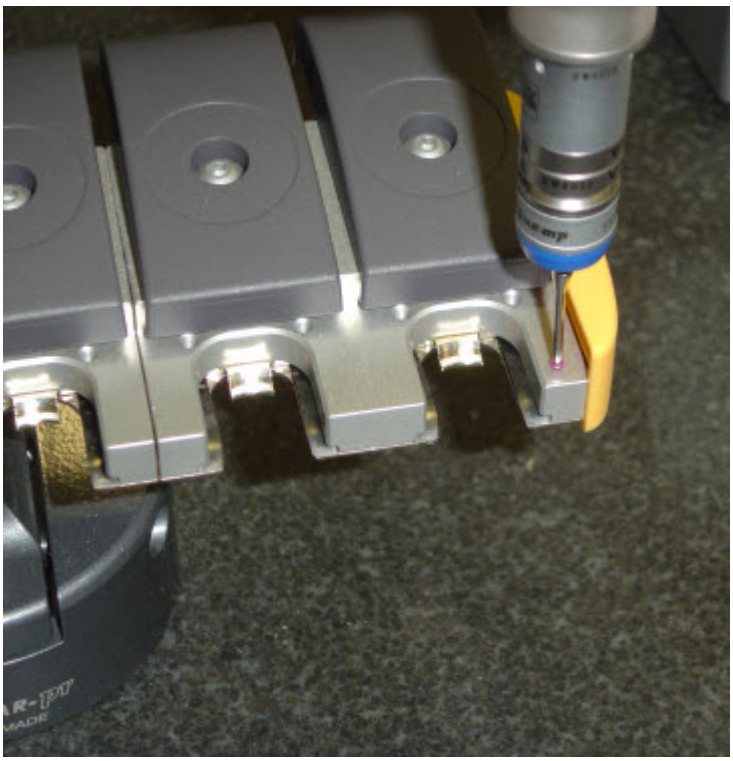
PC-DMIS Message

Please take a hit on top on the silver surface to the right of port 6.

After completing this hit, DCC calibration will begin

Prompt for the third manual hit on the top to the right of the last port

Use your machine's jog box to measure the third hit on the top surface to the right of the last port.



Location of third manual hit during calibration

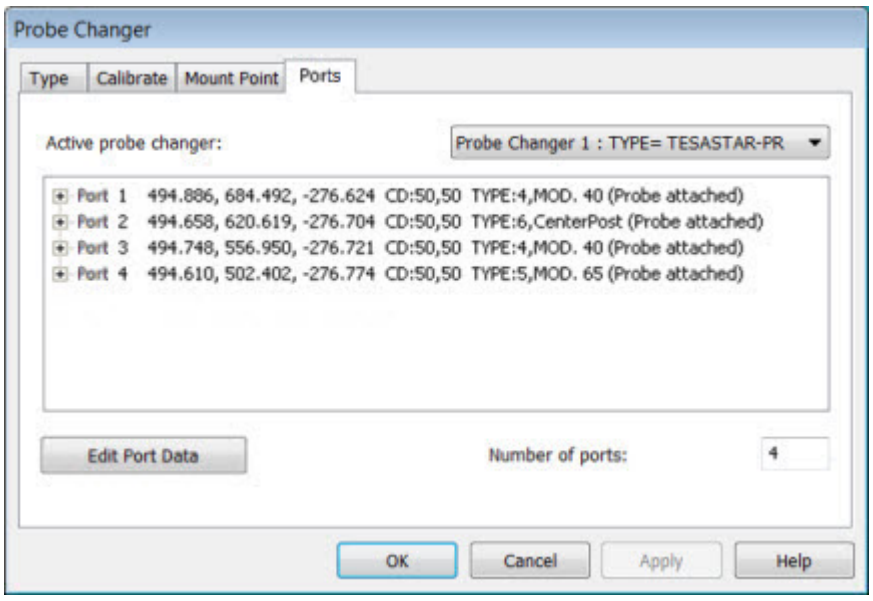
WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

After it takes this hit on the back of the last port, PC-DMIS drives in DCC Mode and takes some additional measurements. It works backwards from the last port towards the first port. When this is complete, the **Calibrate** tab appears.

The next step is to review the calibration results after DCC calibration is complete.

Step 8 - Review the Calibration Results

1. When the calibration of the TESASTAR-PR / HR-P Probe Changer is complete, select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). The calibration information now exists for the location of each calibrated port. For example:



Probe Changer dialog box - Ports tab with calibration results

2. When you view the results, look for the following. Any significant deviations from these expectations may be due to a bad hit.

    - This rack is not necessarily aligned parallel to any axis of the CMM. However, the X and Y values should show equal spacing between ports (roughly 30 mm apart).
    - The Z values should be nearly identical since the ports are all at the same height.

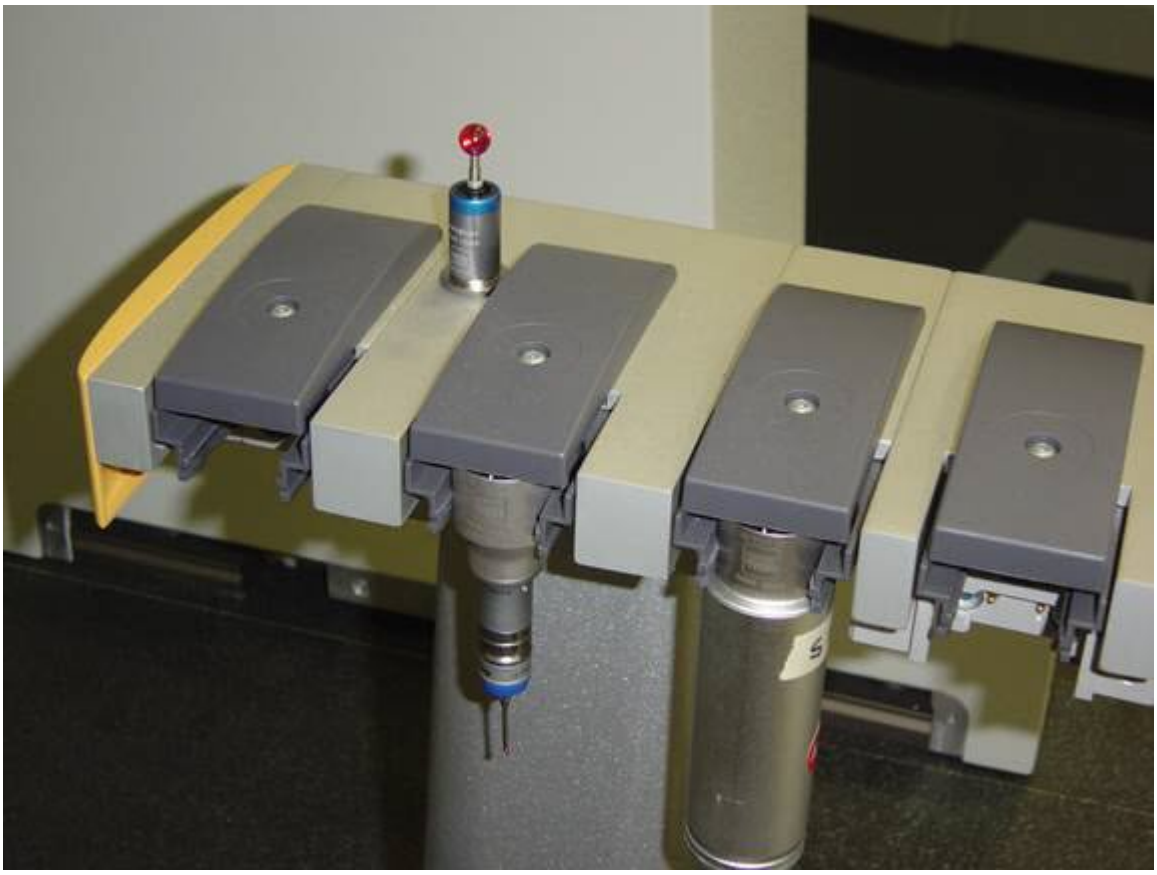
The results during measurement routine execution are:

1. Probe entities that are added to each of the ports are automatically picked up from that location whenever PC-DMIS executes a `LOADPROBE` command for that probe.
2. The probe body moves to the mount point and then into the "unload" port to drop off the current probe.
3. The current probe remains in the port while the probe body lifts away to detach.
4. From there, the probe moves over to the next "load" position and down onto the new probe. This automatically engages the new module.
5. It then moves back out of the port and over to the rack’s mount point.
6. From there, it continues to measure.

Calibrating the TESASTAR-R / HR-R Probe Changer

While this calibration process is specific to the TESASTAR-R / HR-R Probe Changer, it is similar to the steps required for any probe changer that PC-DMIS supports.

This documentation expects that you are positioning the probe changer so that the center post of the probe changer is vertical to the CMM table with the ports parallel to the CMM table:

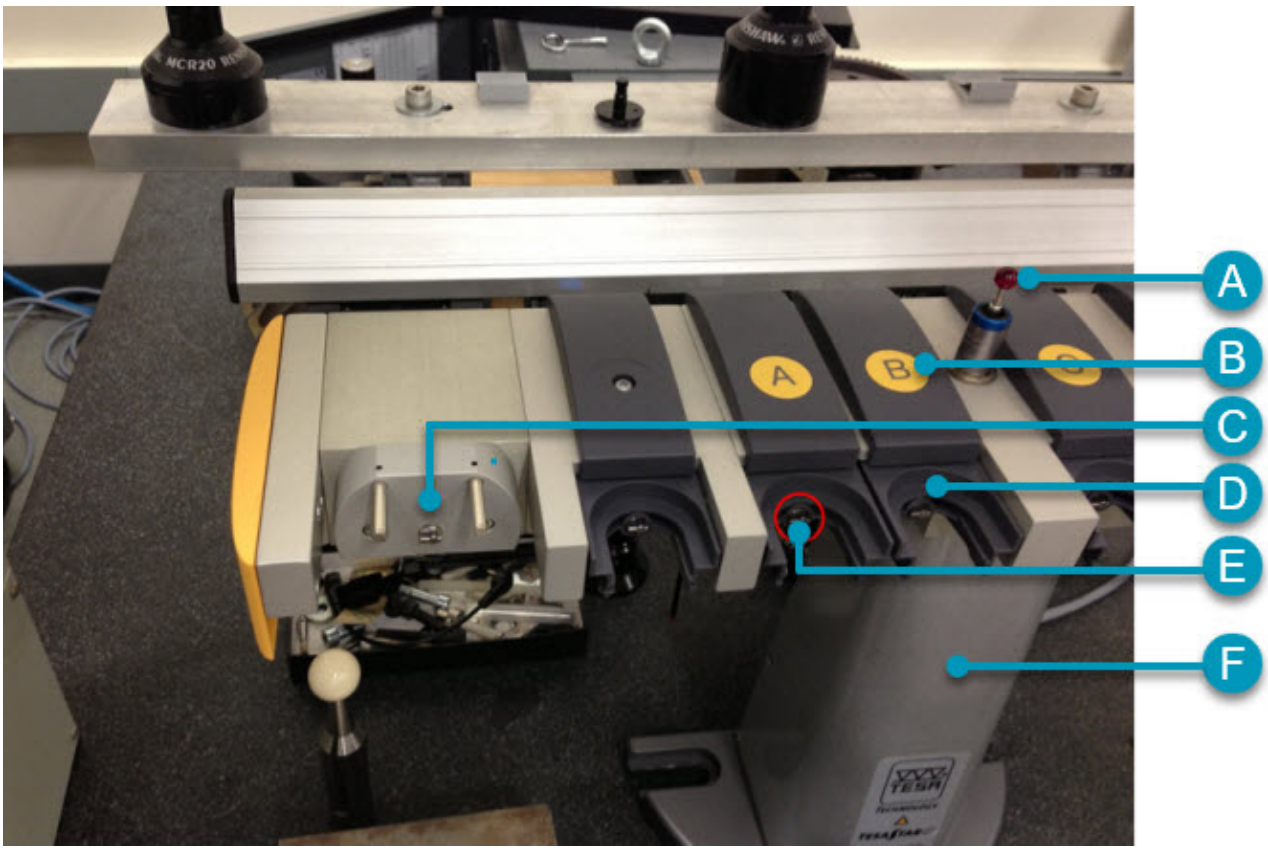


TESASTAR-R / HR-R Probe Changer

This probe changer MUST be mounted on the machine table parallel to a machine axis, such as the X or Y axis. For mounting instructions, consult the documentation that came with your probe changer.

You should mount all HD ports on the end of the tool changer rack. If you would like to mount the HD ports in the middle of the rack, you must set the `UseTCVerticalClearanceForHD_TESASTAR-R` entry to True in the PC-DMIS Settings Editor. This will allow the wrist to move up during tool changes to avoid the HD ports. For more information, see the PC-DMIS Settings Editor documentation.

Probe Changer Components



TESASTAR-R / HR-R Probe Changer components:
***A** - Datum Sphere*
***B** - Lid/Cover*
***C** - HD Port*
***D** - Port*
***E** - Key*
***F** - Center Post*

Wrist Types

The procedure for calibrating the TESASTAR-R / HR-R Probe Changer varies depending on the type of wrist. This documentation defines the wrists as follows:

- HD wrist with an HDKJ extension:

- Wrist:

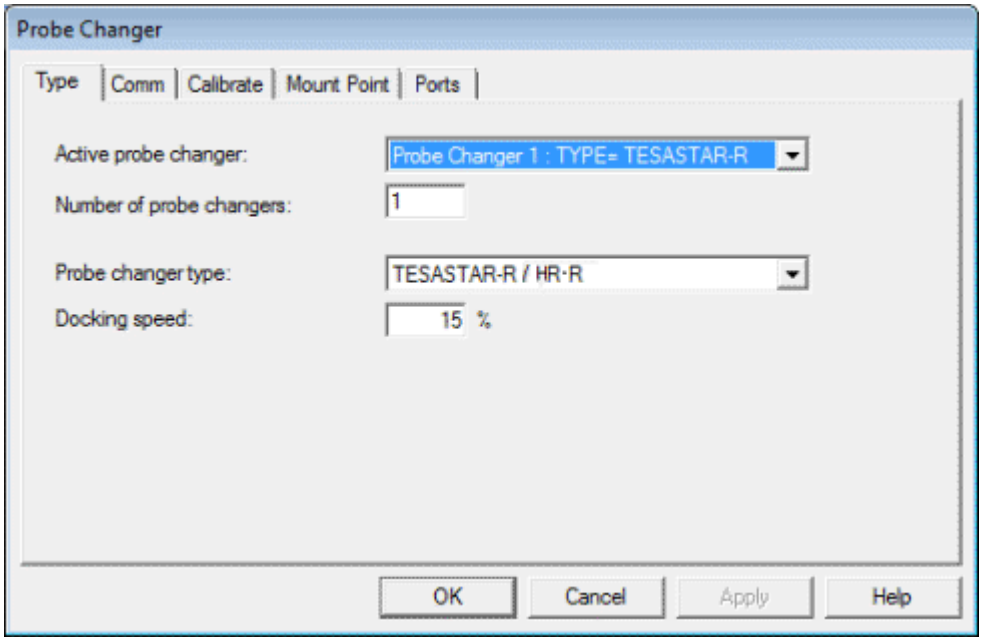
Calibration

To calibrate your probe changer:

Step 1 - Select the TESASTAR-R / HR-R Probe Changer

To select the TESASTAR-R / HR-R Probe Changer:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **TESASTAR-R / HR-R**:



Probe Changer Dialog Box - Type Tab

3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.
4. In the **Active probe changer** box, select the list item that represents the probe changer you want to define. If this is the first probe changer, this shows **Probe Changer 1: TYPE=None**.
5. In the **Number of probe changers** box, specify the number of probe changers that you want to define.
6. In the **Docking speed** box, type a value. A value between 15-20% is appropriate for this machine configuration. You can adjust this value at any time to speed up or slow down the system.

> To avoid equipment damage due to excessive docking speed, gradually increase the **Docking speed** value.

7. Click **Apply** to apply any changes made for this probe changer, and then click **OK** to close the dialog box.

For details on controller configuration settings, see the documentation that came with your controller.

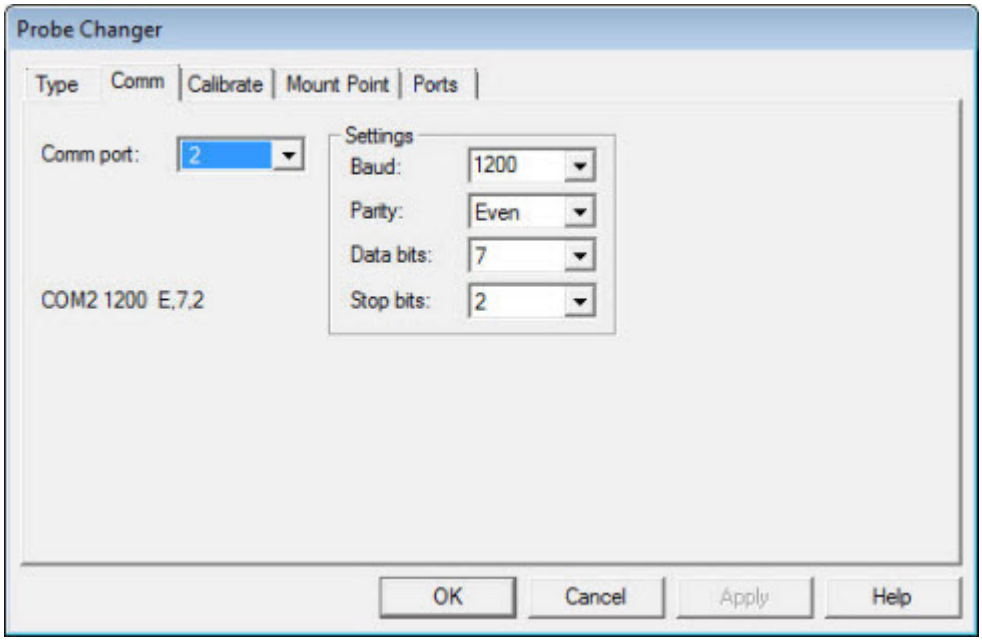
In the next step, you define the communications port.

Step 2 - Define the Communications Port

You must enable communications with the TESASTAR-R / HR-R Probe Changer before you can use it to calibrate it or automatically change probes.

To define the communications port:

1. Select the **Comm** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Comm Tab

2. For specific settings to use, refer to the documentation on the probe changer itself and then fill in the information on the **Comm** tab.
3. Click **Apply** and then **OK**.
4. Close and restart PC-DMIS to initialize these new parameters and enable PC-DMIS to communicate with the probe changer.

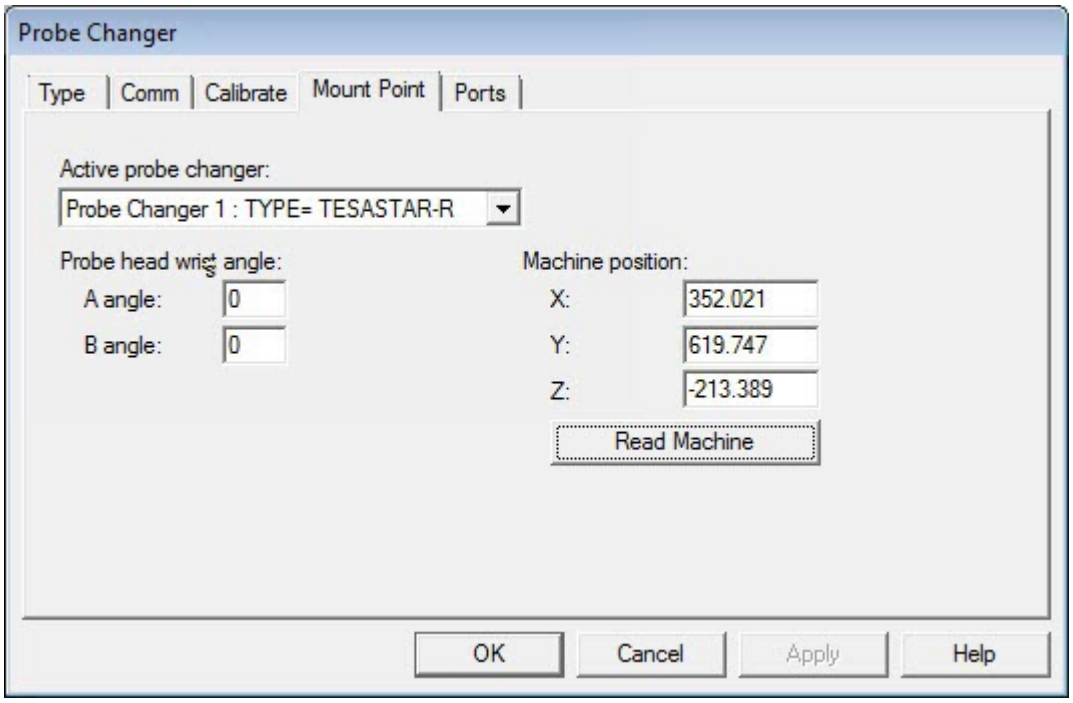
In the next step, you define the mount point and wrist angles for your system.

Step 3 - Define the Mount Point and Wrist Angle

The probe changer mount point is the location in front of the probe changer where the machine moves to before it picks up or drops off a probe. You should pick a location that avoids collisions with the probe changer, the part, clamps, or any other object in the workspace.

To define the mount point for your probe changer, follow these steps:

1. Select the **Mount Point** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Mount Point Tab

2. In the **Active probe changer** list, select **TYPE=TESASTAR-R**.

3. If necessary, alter the probe head wrist angle for both **A angle** and **B angle**. Often, but not always, these values are both 0 (zero). You need to use the wrist angles that align the key port on the joint on the probe component with the key blade in the back of the port that turns the key to lock/unlock the joint.

   HD joints and regular joints both contain keys that have to be locked/unlocked. When assembled together, the key on the HD joint and the key on the regular joint are normally 180 degrees opposite of each other.

   - If your rack has HD ports, the wrist angles used should be the ones that align the key on the HD joint with the back of the port.
   - If your rack does NOT have HD ports, the wrist angles should be the ones that align the key on the regular joint with the back of the port.

4. Use your jog box to manually move your machine to the desired mount point position.

5. Click the **Read Machine** button to populate the **X**, **Y**, and **Z Machine position** values with the current position. You can also manually type these values.

6. To save your changes, click **Apply**.

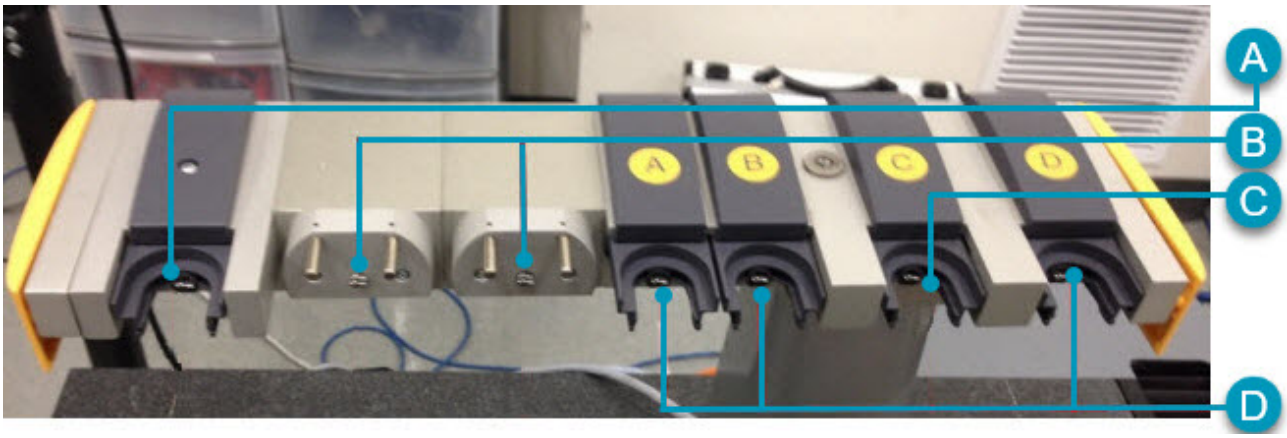
It is important that you correctly set the mount point angles before calibrating.

In the next step, you define the ports for your system.

Step 4 - Define the Ports

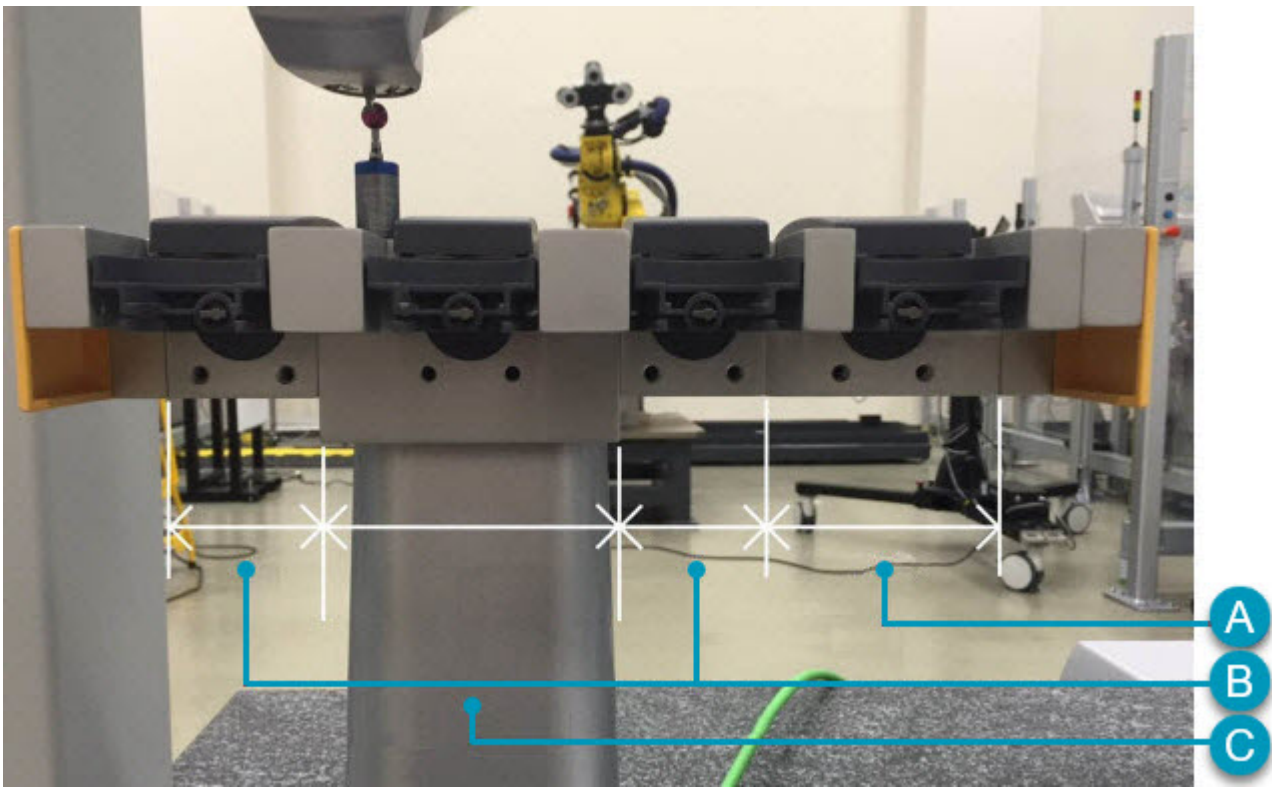
The final step prior to the actual calibration of the TESASTAR-R / HR-R Probe Changer is to define the number and configuration of the ports on the probe changer. For an example of how to define ports, see "Example of Defining Ports" at the end of this topic.

The TESASTAR-R / HR-R rack has four types of ports:



Types of ports:
***A** - MOD .65: Has a circular port*
***B** - HD: Has a port with two pins for changing the HD components*
***C** - Center Post: Has a circular port and is mounted on the probe changer post*
***D** - MOD .40: Has a circular port*

Another image of the ports on the TESASTAR-R / HR-R rack appears below:

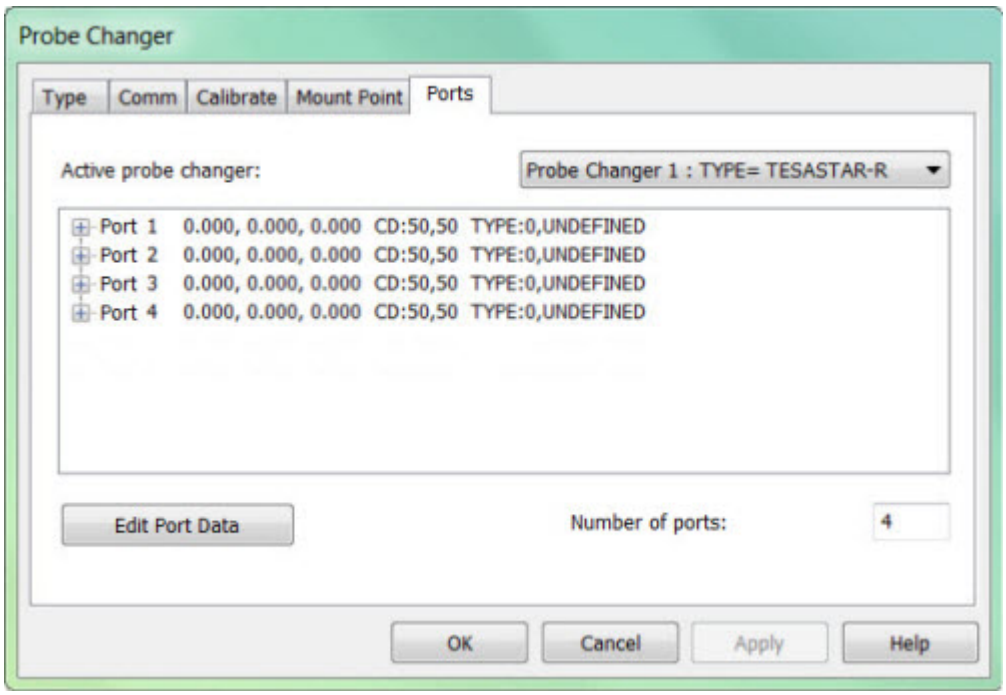


Types of ports:
***A** - MOD .65*
***B** - MOD .40*
***C** - Center Post*

TKJ extension-only ports have an extension-only location associated with each empty HD extension.

Defining the Number of Ports

1. Select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):

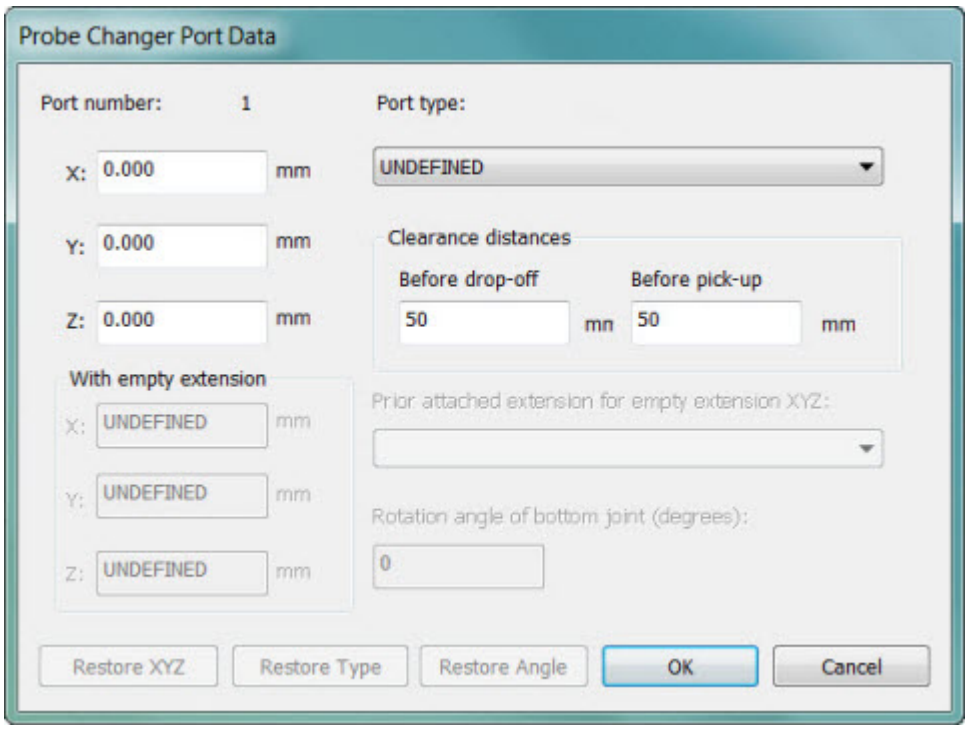


Probe Changer dialog box with undefined ports

2. In the **Active probe changer** list, select **TYPE=TESASTAR-R**.
3. In the **Number of ports** box, type the number of ports that you want to define. This should match the number of physical ports on the probe changer.
4. Click **Apply** to store this parameter.

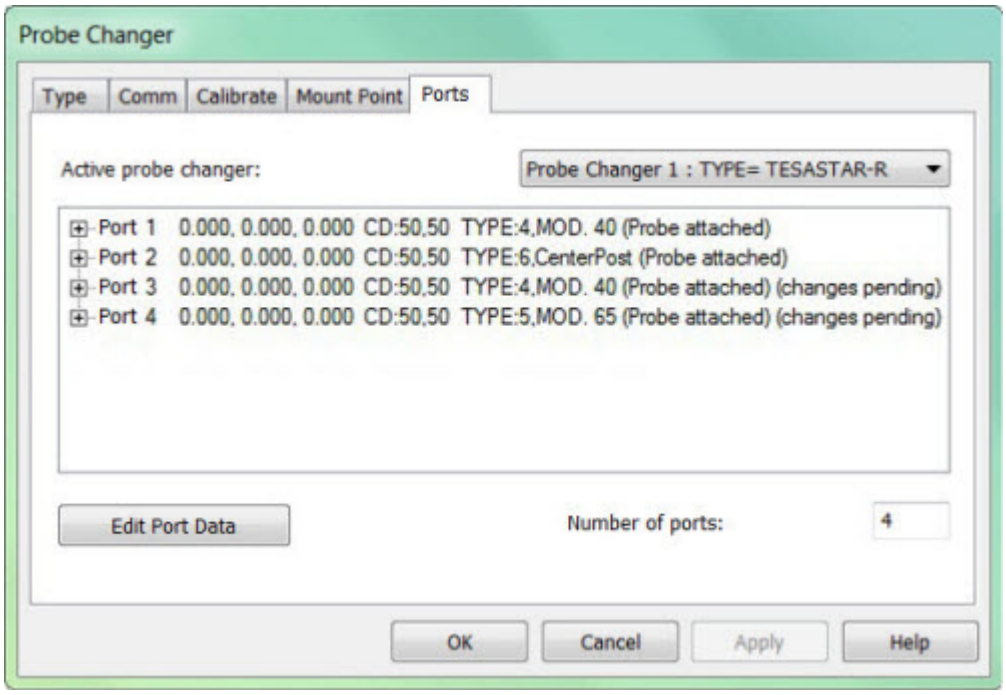
After you define the number of ports, you need to define the configuration of each port. You can do several different configurations depending on the size and location of the port hardware. For the proper configuration of each port, consult your probe changer's documentation.

1. Select the port item in the list and then click **Edit Port Data** to display the **Probe Changer Port Data** dialog box:



Probe Changer Port Data dialog box

2. In the **Probe Changer Port Data** dialog box, if **Port type** shows UNDEFINED, select the appropriate type for the port.
3. Click **OK** to return to the **Probe Changer** dialog box.
4. Define any remaining ports. As you define each port type, the port description in the list shows the "(changes pending)" text appended.
5. Click **Apply**. The text is removed on all of the ports.



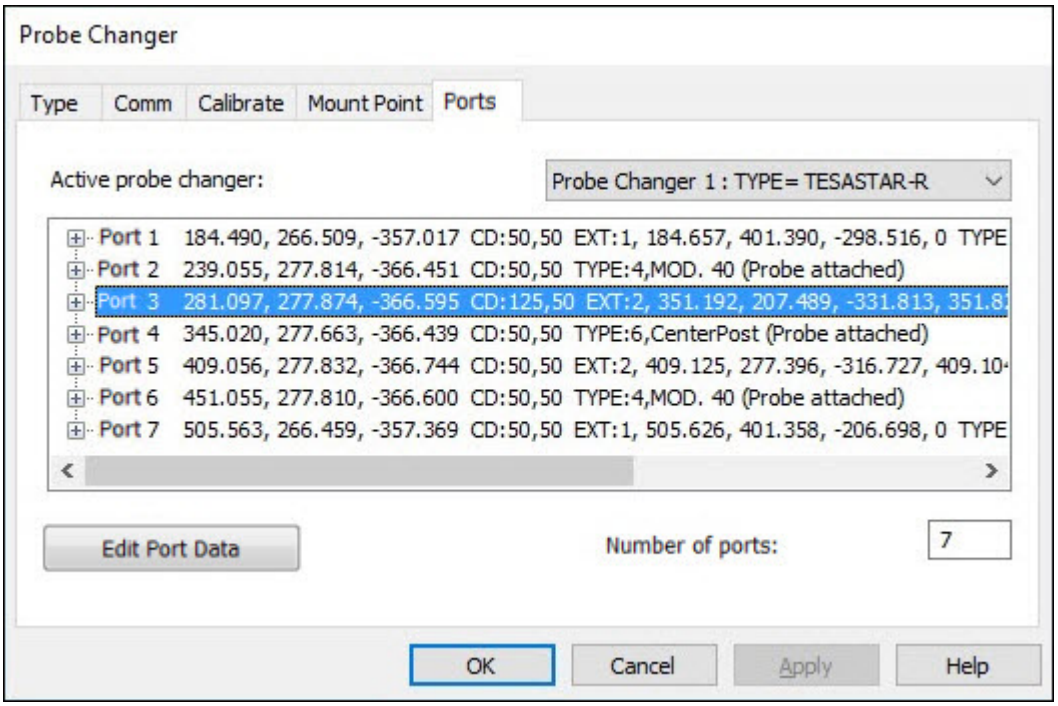
Probe Changer dialog box with all ports defined

If you plan to use any of the ports to hold probe extensions, you need to define them in this step before you proceed. Ports that hold extensions require additional steps in the calibration process where you need to take additional hits on the datum sphere with and without the extension.

You are now ready to begin calibration.

Example of Defining Ports

The example below shows seven defined ports:



Example of Probe Changer dialog box with seven defined ports

In this example, ports 1 and 7 are HD extension-only ports. Ports 3 and 5 are TKJ extension-only ports. The one in port 3 has a 90-degree rotation of the bottom joint.

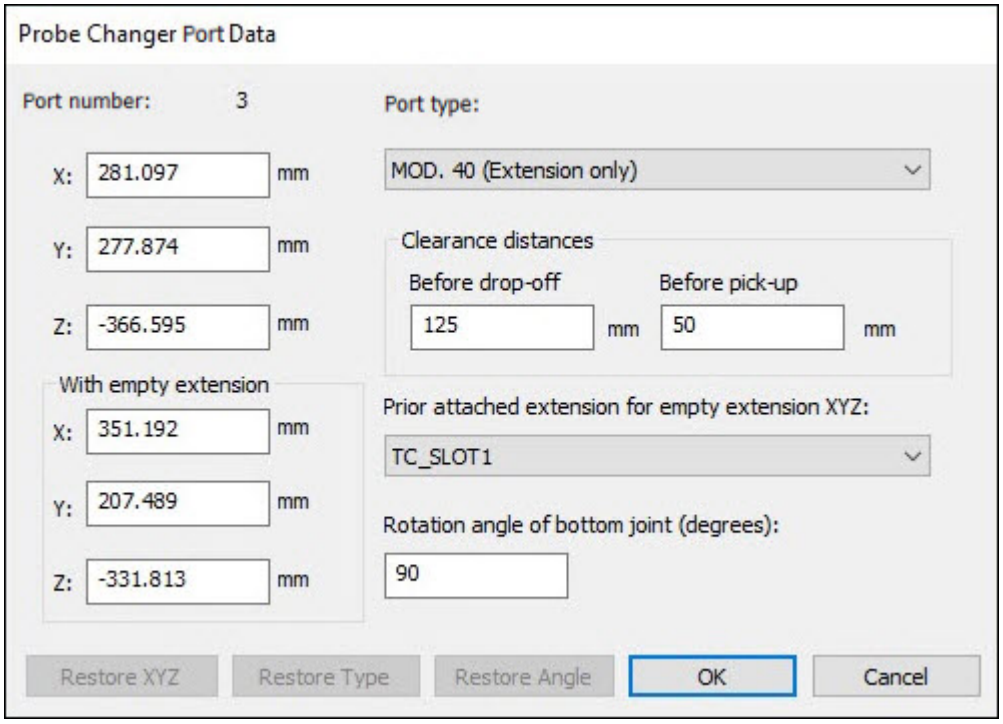
Note the following:

- If you combine HD extensions with regular TKJ extensions by loading an HD extension and then use it to load a TKJ extension, and if you have more than one HD port with an extension that can be used with the TKJ extension, the incremental offset gained by loading that TKJ extension varies slightly depending on which HD extension you used it with.
- If you use multiple HD extensions with TKJ extensions, the calibration requires that you attach and measure the TKJ extension with each HD extension. After calibration, there is a separate XYZ for the "With empty extension" result for each HD extension it was used with. You can select which result to view or edit by selecting the port associated with the HD extension it was used with.

- If you do not have more than one HD extension, or if you have not yet calibrated to allow the multiple results to become available, no selection is available.

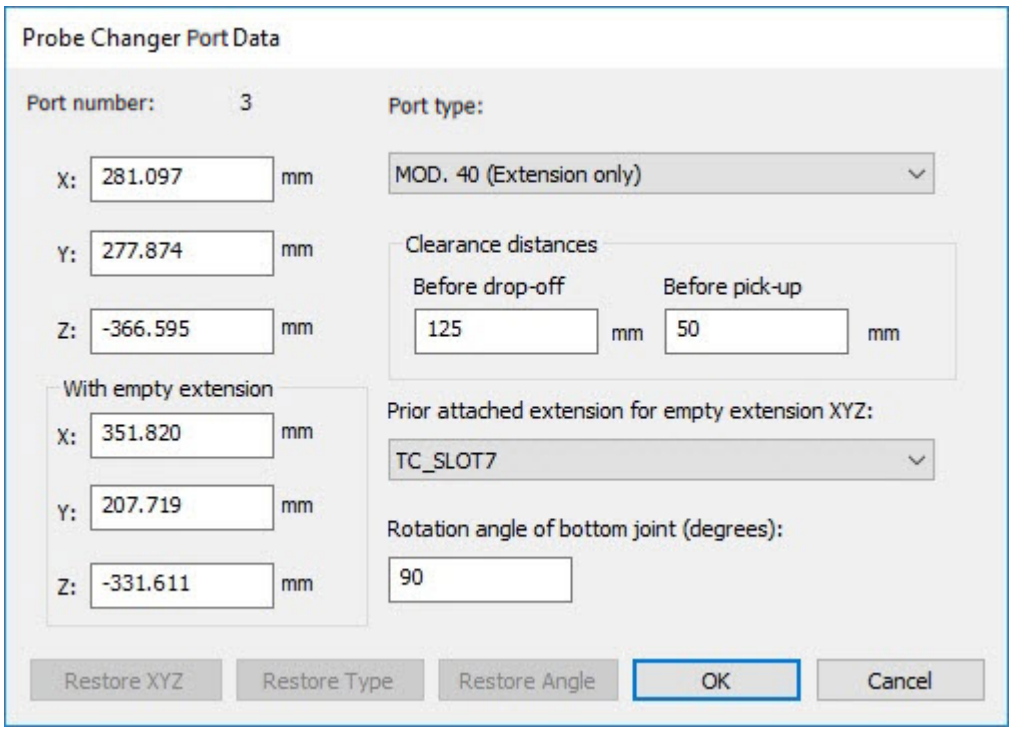
If you select port 3 (a TKJ extension-only port) and then click the **Edit Port Data** button, the **Probe Changer Port Data** dialog box appears. In the **Prior attached extension for empty extension XYZ** list, you would select the port with the results you want to view.

- The image below shows the results with the HD extension from port 1:



Example of Probe Changer Port Data dialog box

- The image below shows the results if you use the same TKJ extension with the HD extension in port 7:



Example of Probe Changer Port Data dialog box

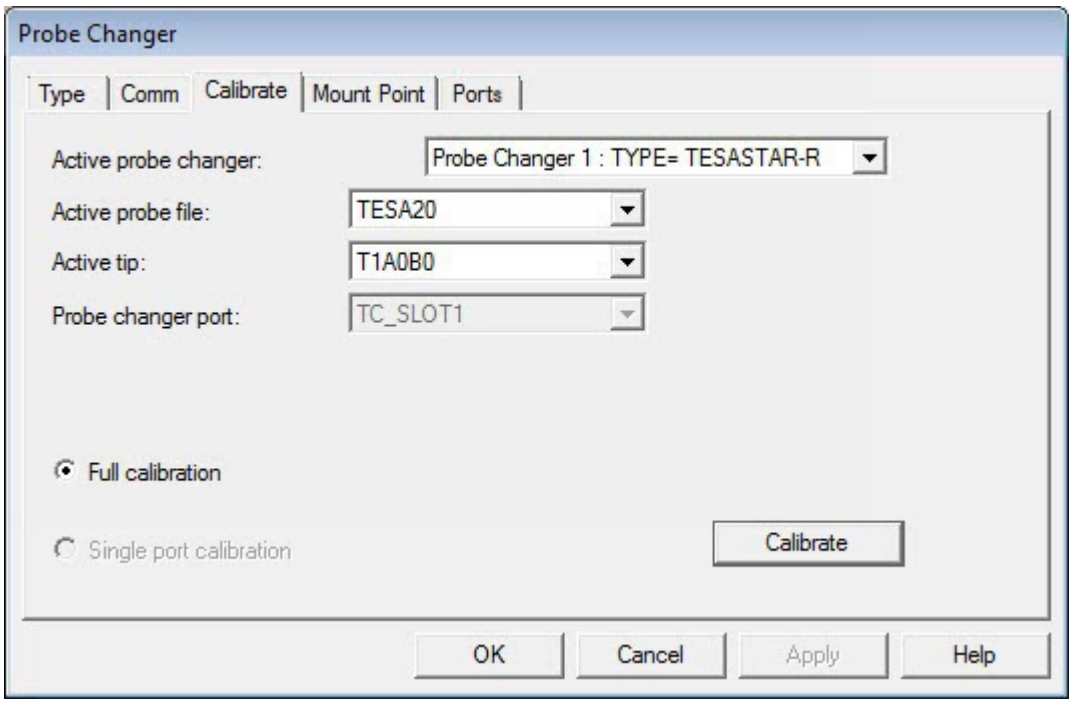
The differences in the extension-only location for the port 1 and port 7 scenarios above are relatively small. However, they are significant for correct positioning for probe change purposes.

The next step starts the calibration process.

Step 5 - Prepare for Calibration

To begin the calibration process for the TESASTAR-R / HR-R Probe Changer:

1. Select the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):

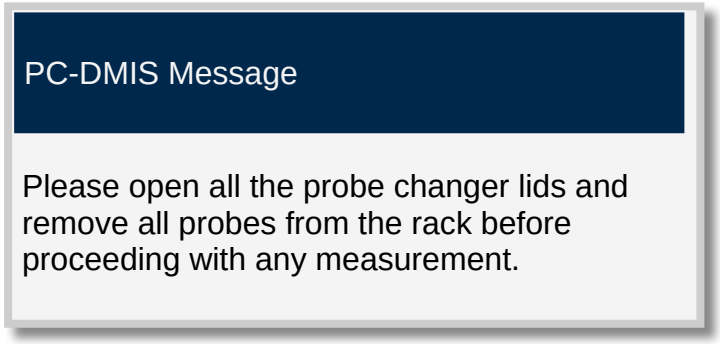


Probe Changer Dialog Box - Calibrate Tab

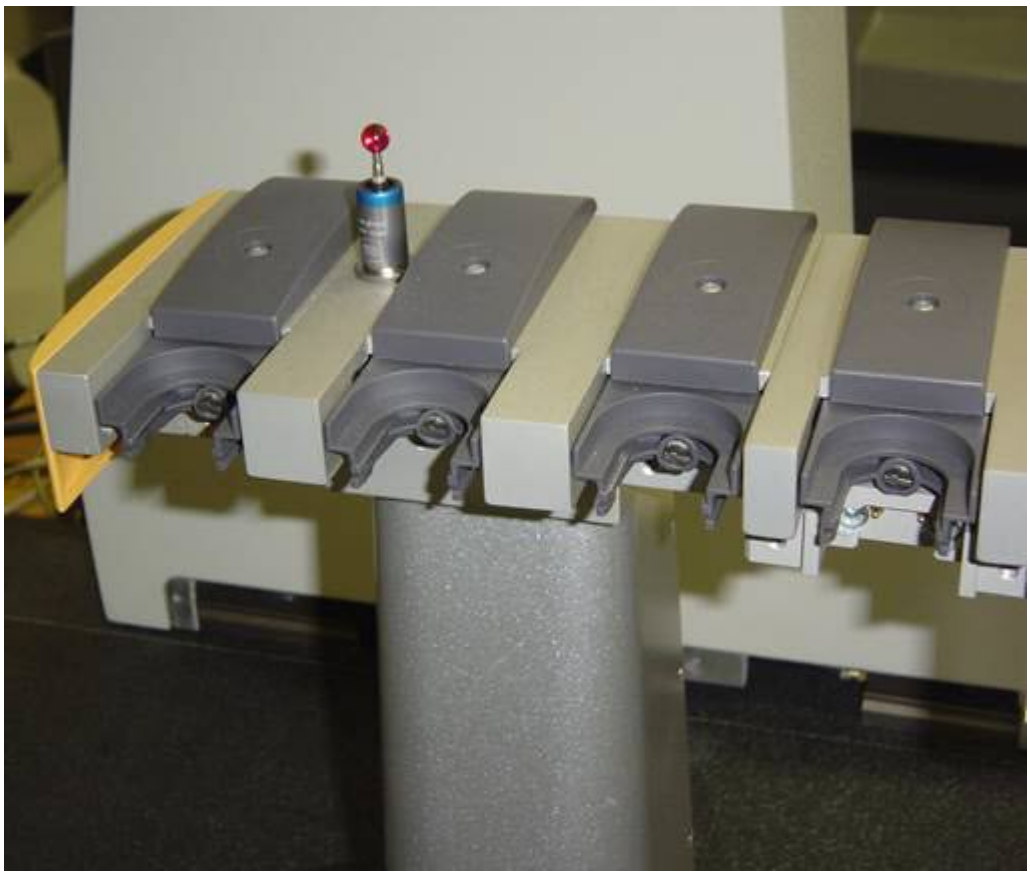
2. Click the **Calibrate** button.

3. The **Active probe file** and **Active tip** items both default to the current measurement routine settings. If needed, change these to the probe and tip that you intend to use for the probe changer calibration.

4. Open the lids on each port by sliding them back until they click into place.



PC-DMIS prompt to open the port lids before calibration.



Example showing the open port lids before calibration.

In the next step, you take the first manual hit.

Step 6 - Take the First Manual Hit

In this step for the TESASTAR-R / HR-R Probe Changer, PC-DMIS prompts you to take a manual hit on the port. This is the first of two hits required to fully define the orientation of this rack in the machine's XY plane. You do not need to align the rack to any single axis since the manual hits identify any rotation involved.

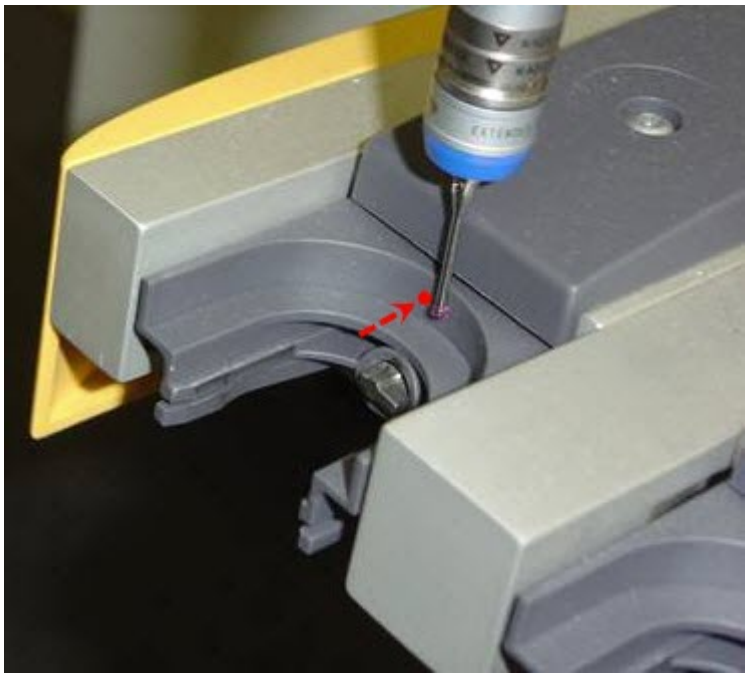
PC-DMIS moves you through the process of measuring the manual hits through a series of message boxes:

PC-DMIS Message
Please take a hit in the back of the circle for port 1. The hit should be taken in the middle of the larger circle above and behind the key.

Prompt for the first manual hit in the back of the first port

1. If any modules or styli reside in the ports, remove them now by sliding them forward and out of the ports.

2. When you are ready to take the first measurement, click **OK**.
3. Follow the prompts and take the needed hits as directed in the instructions for each hit. If you have HD ports, you will take the first hit on the **first regular port** and **not** on any HD port that may precede it in the rack.



Use your machine's jog box to carefully take the first manual hit on the vertical face of the radius in the back of the first port, as indicated by the bottom photo

In the next step, you take the second manual hit.

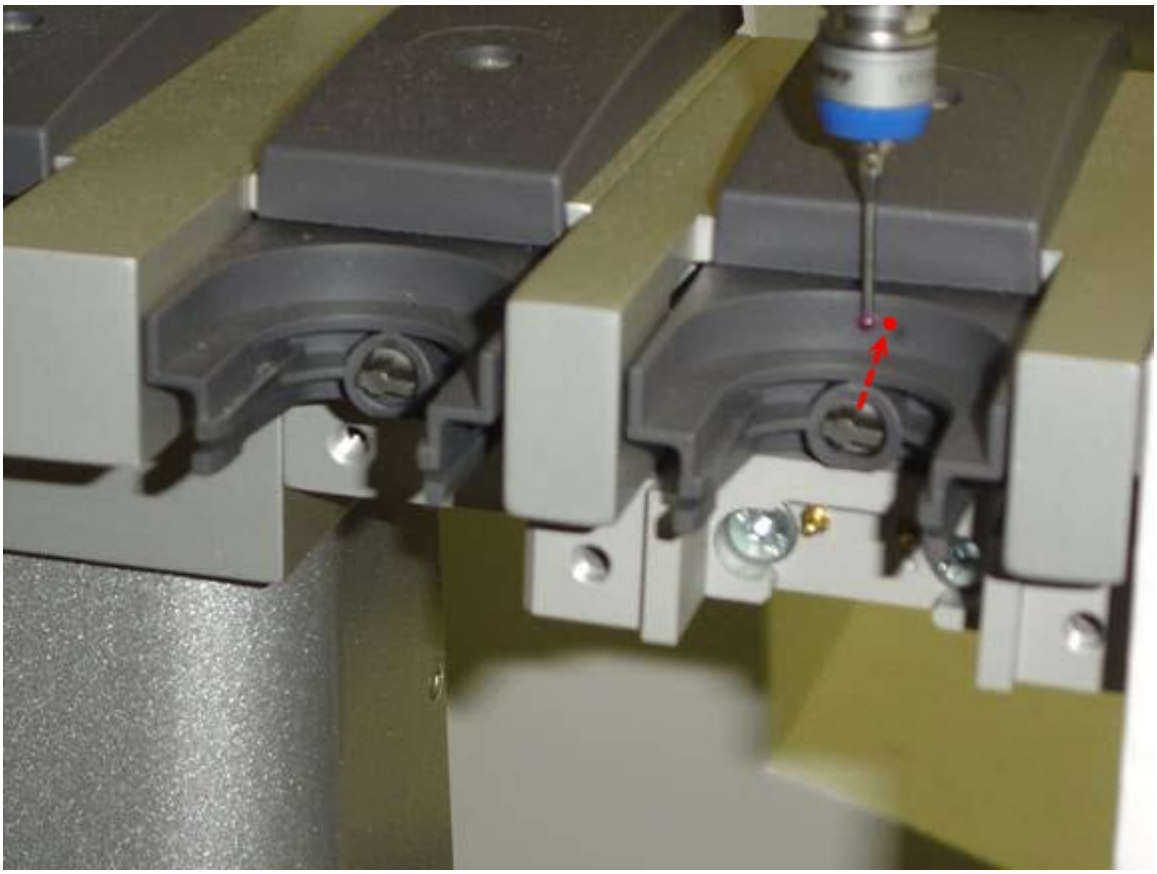
Step 7 - Take the Second Manual Hit

In this step for the TESASTAR-R / HR-R Probe Changer, take the second manual hit on the vertical face of the radius in the back of the last regular port.

PC-DMIS Message
Please take a hit in the back of the circle for port 4.

The hit should be taken in the middle of the larger circle above and behind the key.

Prompt for the second manual hit inside the last regular port



Use your machine's jog box to carefully take the second manual hit on the vertical face of the radius in the back of the last regular port, as indicated by the bottom photo

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

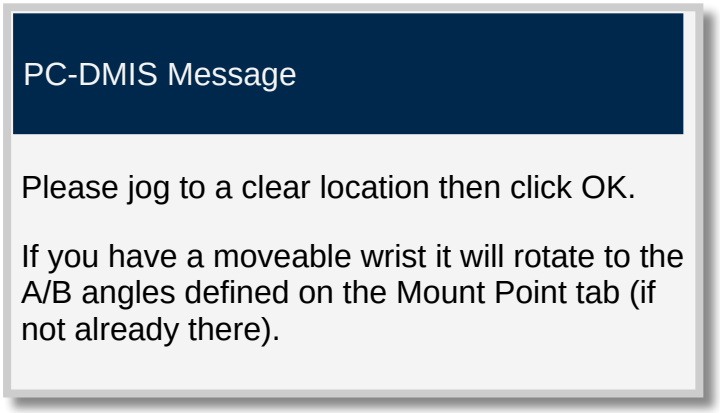
After you take this hit on the back of the last regular port, PC-DMIS drives in DCC Mode and takes additional measurements, working backward from the last regular port toward the first port.

When this is complete, and if you are using an HD wrist, it takes additional measurements working backwards from the last HD port towards the first HD port. When this finishes, PC-DMIS positions the probe above the rack and provides instructions to proceed.

In the next step, you determine the location of the datum sphere.

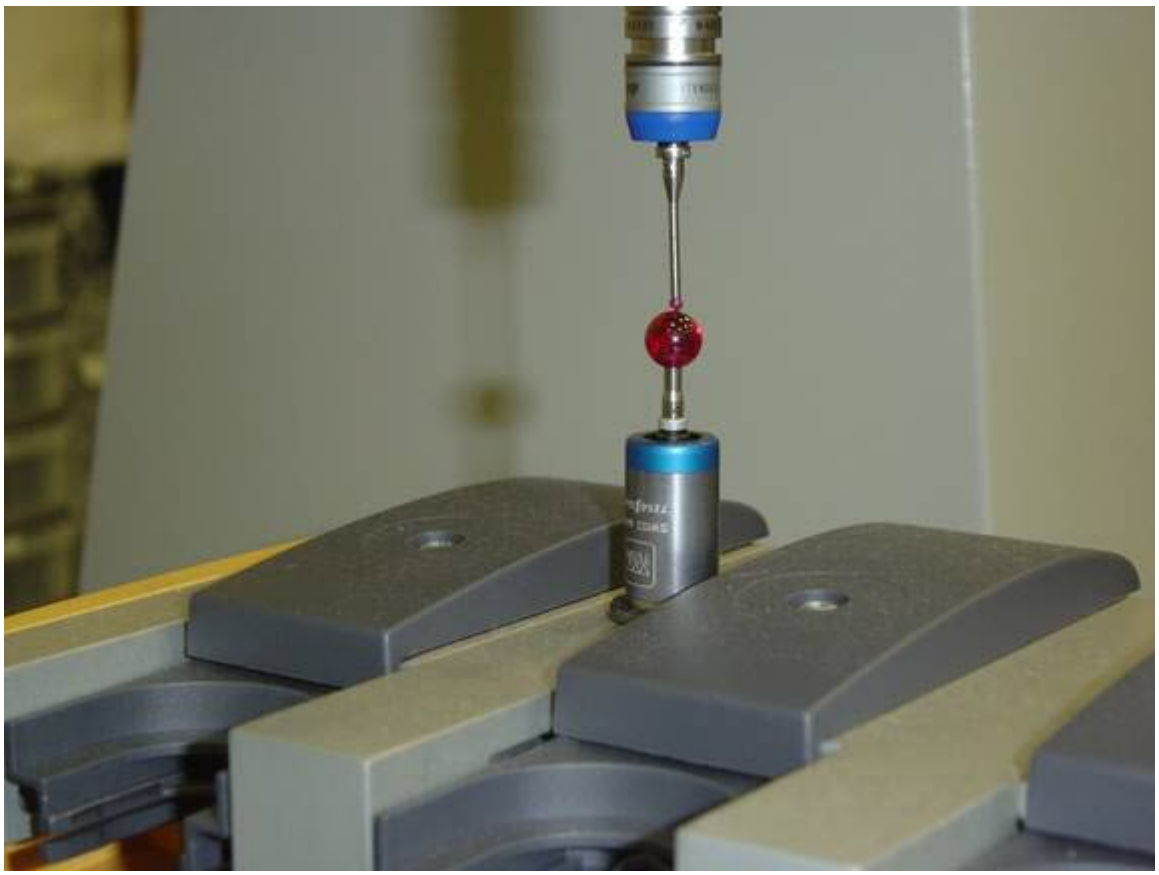
Step 8 - Take the Probe Hit on the Datum Sphere

After the initial DCC port measurement finishes, you must accurately determine the location of the datum sphere. You do this by taking a series of hits on the datum sphere itself. A prompt appears to move the probe clear of the rack in case it needs to turn the wrist:



PC-DMIS prompt to move the probe to a safe location before wrist adjustment.

1. Move the probe to the safe location and then click **OK**.
2. When the **Execution** dialog box prompts you, use the bottom of the stylus ruby to take a manual hit on the top of the datum sphere ruby:



Use your machine's jog box to take a manual hit on the top of the datum sphere

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

Once the hit is taken, the system moves into DCC and measures three sample hits on the datum sphere. It then measures five more hits for the sphere feature.

Finally, it lifts above the sphere and displays the following prompt:

PC-DMIS Message

Please jog to a clear location then click OK.

If you have a moveable wrist it will rotate to the A/B angles defined on the Mount Point tab (if not already there).

PC-DMIS prompt to prepare for wrist rotation.

In the next step, you take the AutoJoint hit on the datum sphere.

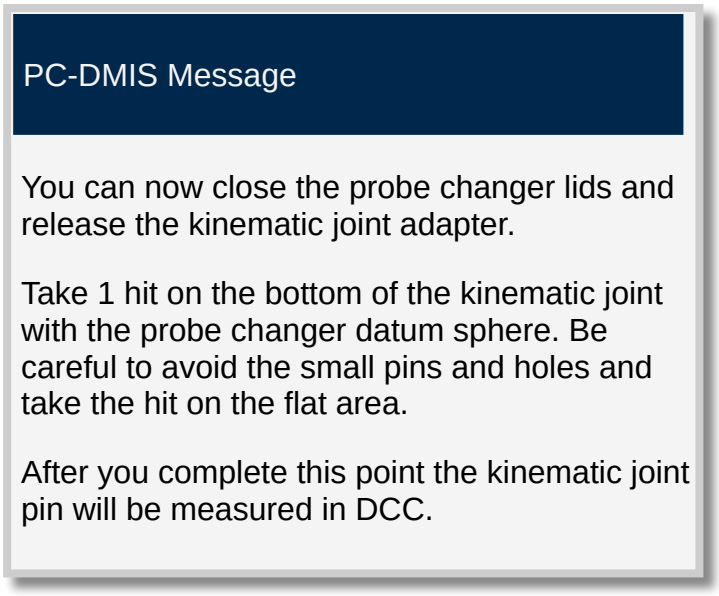
Step 9 - Take the AutoJoint Hit on the Datum Sphere

To determine the overall probe length, the system needs one hit on the probe and then another hit on the quick-connect kinematic joint (or AutoJoint). Instructions to remove the probe for this second hit on the datum sphere appear. The instructions for the hit varies if you have an HD wrist. Both sets of instructions are included in this section.

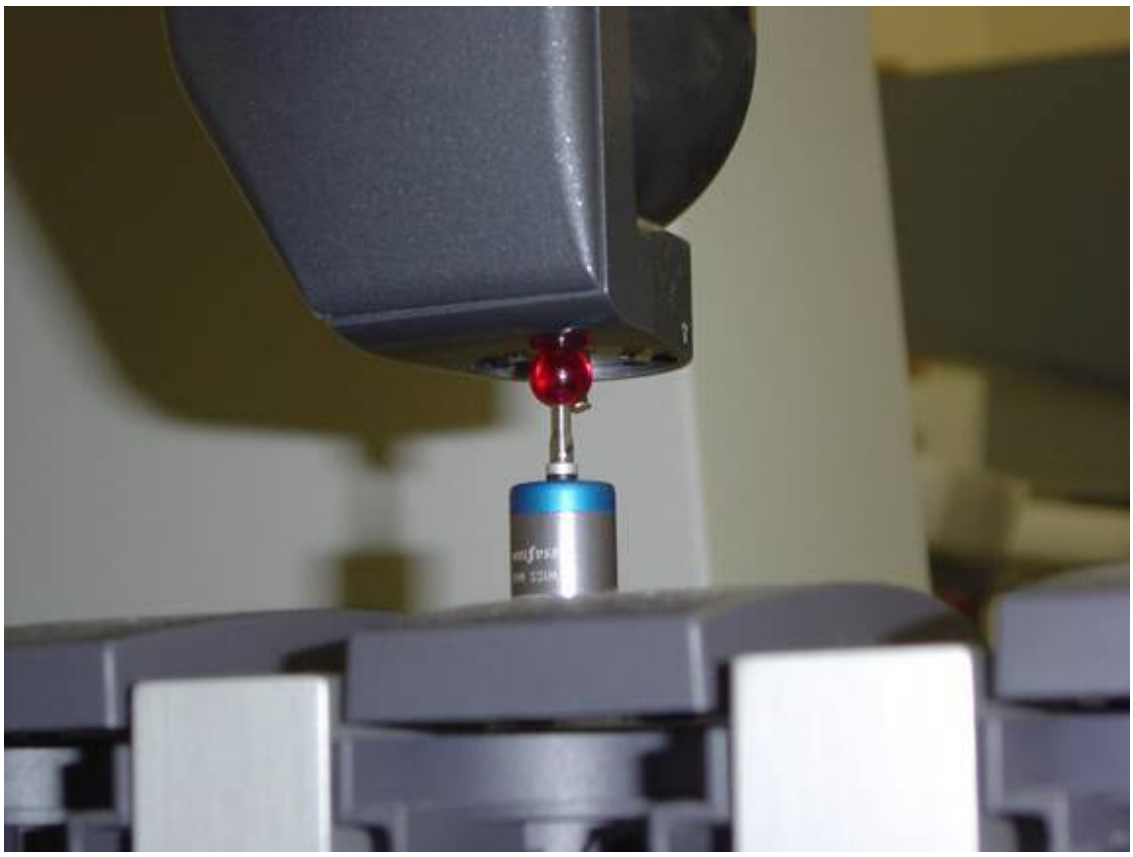
WARNING: At different times throughout this procedure, the machine moves in DCC mode. When this happens, to avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

1. Take a manual hit as instructed.

    - For the AutoJoint:



PC-DMIS prompt to take a hit on the datum sphere with AutoJoint.



Use your machine's jog box to position the AutoJoint connection above the datum sphere and take a manual hit on the top of the datum sphere

- For the HD AutoJoint:

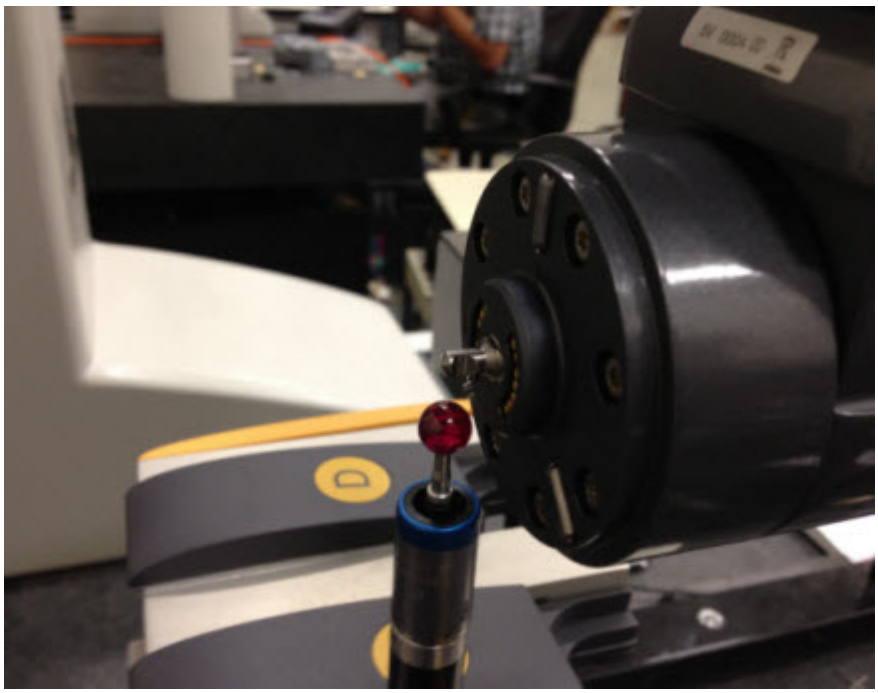
PC-DMIS Message

You can now close the probe changer lids and release the HD kinematic joint adapter.

Take 1 hit on the side of the kinematic joint close to the joint pin with the probe changer datum sphere. Be careful to avoid the small pins and holes and take the hit on a flat area.

After you complete this point the HD kinematic joint pin will be measured in DCC.

PC-DMIS prompt to take a hit on the datum sphere with HD AutoJoint.



Use your machine's jog box to take a manual hit on the side of the datum sphere using the empty AutoJoint connection

2. After this manual hit, lift the wrist clear of the datum sphere. The system proceeds under DCC to measure the sphere with the pin that is protruding from the bottom of the AutoJoint.

   When this finishes, calibration is complete.

PC-DMIS Message
All measurement is now complete. Please reconnect the probe used to measure the ports and then click OK.

In the next step, you measure any defined extensions.

Step 10 - Measure Extensions

After you measure the AutoJoint, you are asked to measure any defined extensions.

PC-DMIS Message
Please attach only the extension to be used in port 2. When you click OK if you have a wrist it may rotate (if needed) to allow for any rotation of the bottom joint.

When prompted then take 1 hit on the bottom of the kinematic joint with the probe changer datum sphere.

Be careful to avoid the small pins and holes and take the hit on a flat area.

After you complete this point the kinematic joint pin will be measured in DCC.

Prompt for measuring any defined extensions

1. Attach the extension and take a hit on the bottom of the extension as directed.
2. After the manual hit, lift the wrist clear of the datum sphere.

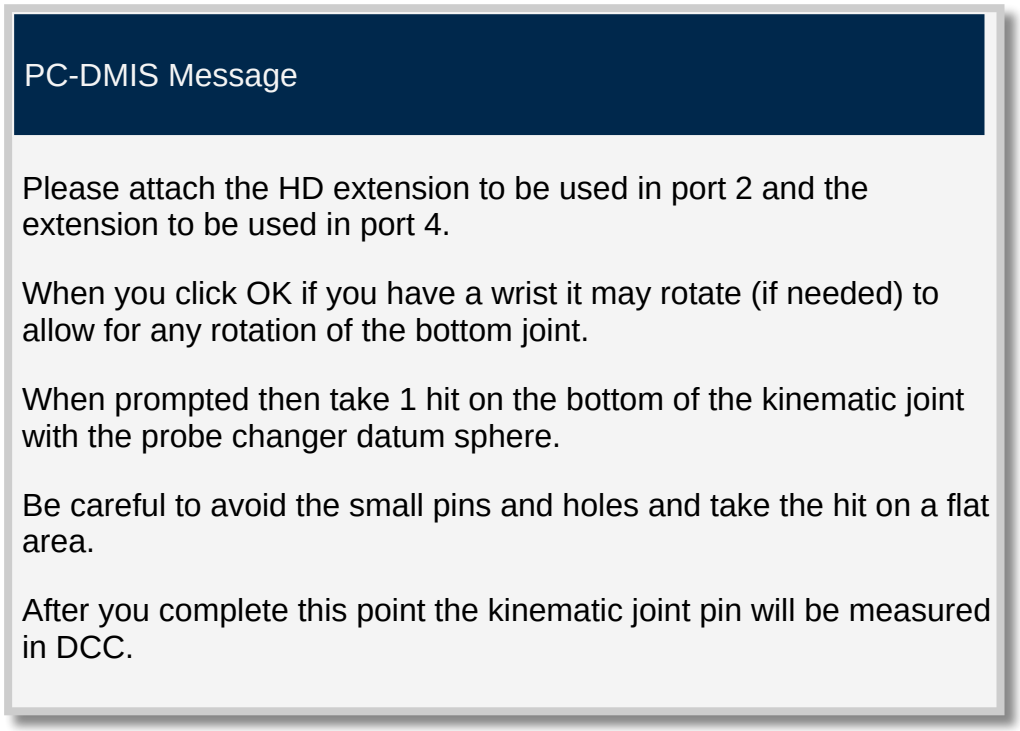
> **WARNING:** When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

The system then goes into DCC Mode and proceeds to measure the sphere with the pin that is protruding from the bottom of the extension.

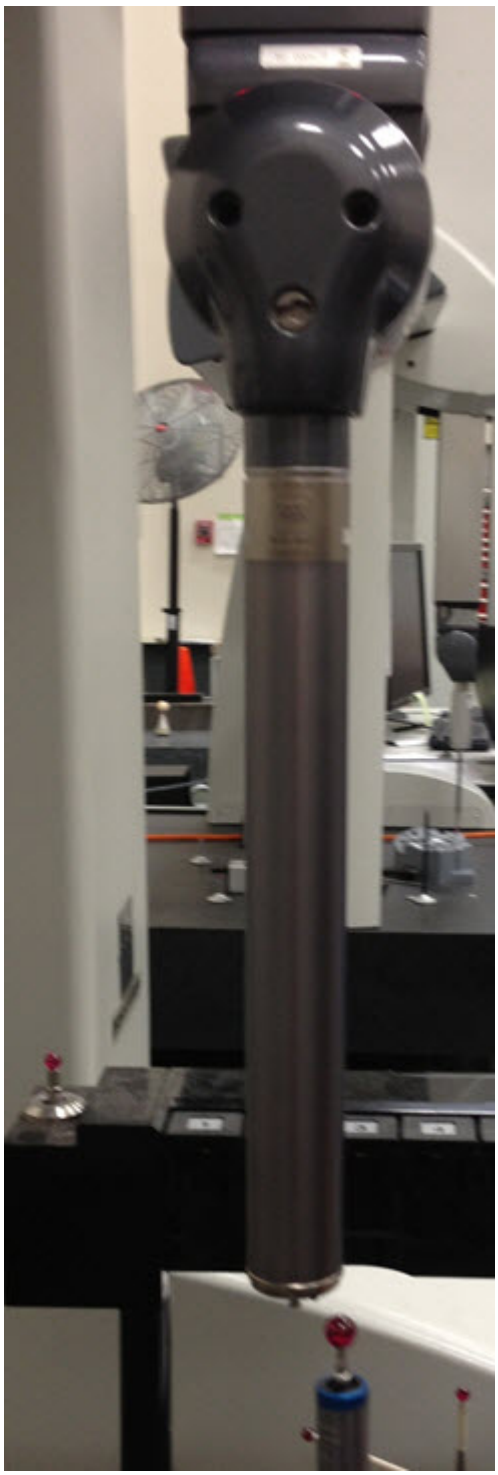
Use your machine's jog box to take a manual hit on the top of the datum sphere using the empty extension

3. After the HD extension has been measured, you are asked to measure each TKJ extension by individually attaching them to the HD extension and measuring the joint at the bottom.

   After you measure the TKJ extensions, if you have additional HD extensions, you will be asked to repeat the sequence of attaching and measuring just the HD extension followed by attaching and measuring each TKJ extension.



Prompt for measuring any remaining extensions

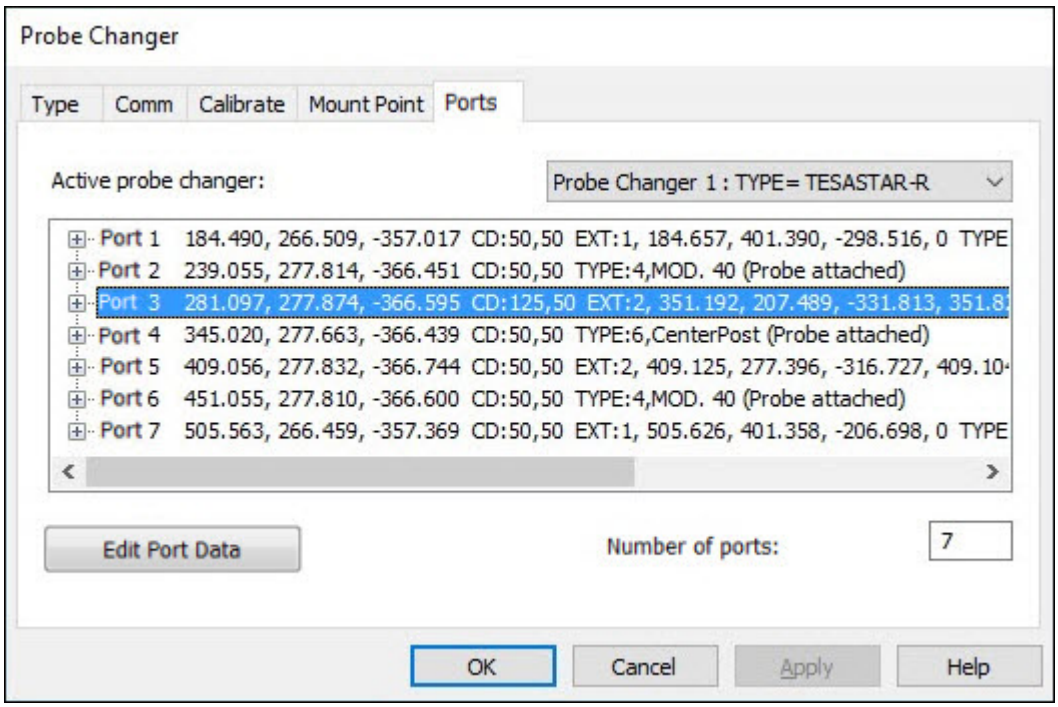


Use your machine's jog box to take a manual hit on the top of the datum sphere using the empty extension

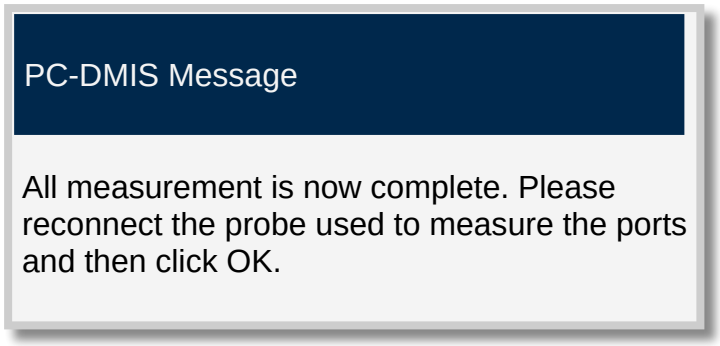
In the next step, you review the calibration results.

Step 11 - Review the Calibration Results

1. When the calibration of the TESASTAR-R / HR-R Probe Changer is complete, select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). The calibration information now exists for the location of each calibrated port. For example:



Ports tab with calibration results



Prompt for reconnecting the probe

2. When you view the results, look for the following. Any significant deviations from these expectations may be due to a bad hit.

    - The probe changer must be aligned parallel to either the X or the Y axis of the CMM.
    - The Z values for all regular ports should be nearly the same and the Z for all HD ports should be nearly the same. However, the Z for regular ports will not be the same as the Z for HD ports.

    When you use an HD wrist, you should remove the datum sphere from the rack after calibration is complete. This prevents collisions when using the two adjacent ports for tool changes.

    How a `LOADPROBE` command works with the TESASTAR-R / HR-R Probe Changer:

1. During measurement routine execution, the probe entities that you added to each port are automatically picked up from the port whenever PC-DMIS executes a `LOADPROBE` command for that probe.
2. Before picking it up, the probe body moves to the mount point and then into the empty port to drop off the current probe.
3. The rack's keys rotate to the release position. The current probe remains in the port while the probe body lifts away to detach.
4. The probe body moves over the load position above the port that contains the probe.
5. The probe body moves down onto the new probe. The keys again rotate to automatically engage the new module.
6. The probe body moves back out of the port and over to the rack’s mount point.
7. The CMM continues to measure the part with the newly loaded probe.

The probe change cycle varies slightly from the steps described above for HD ports and extensions.

Calibrating the TP20 Probe Changer

The calibration process for the TP20 Probe Changer represents the steps that you would take to prepare to use any of the probe changers that PC-DMIS supports. The process in this documentation is specific to the TP20 Probe Changer.

Inserts or extensions are not used for any of the port positions.

TP20 Probe Changer Rack

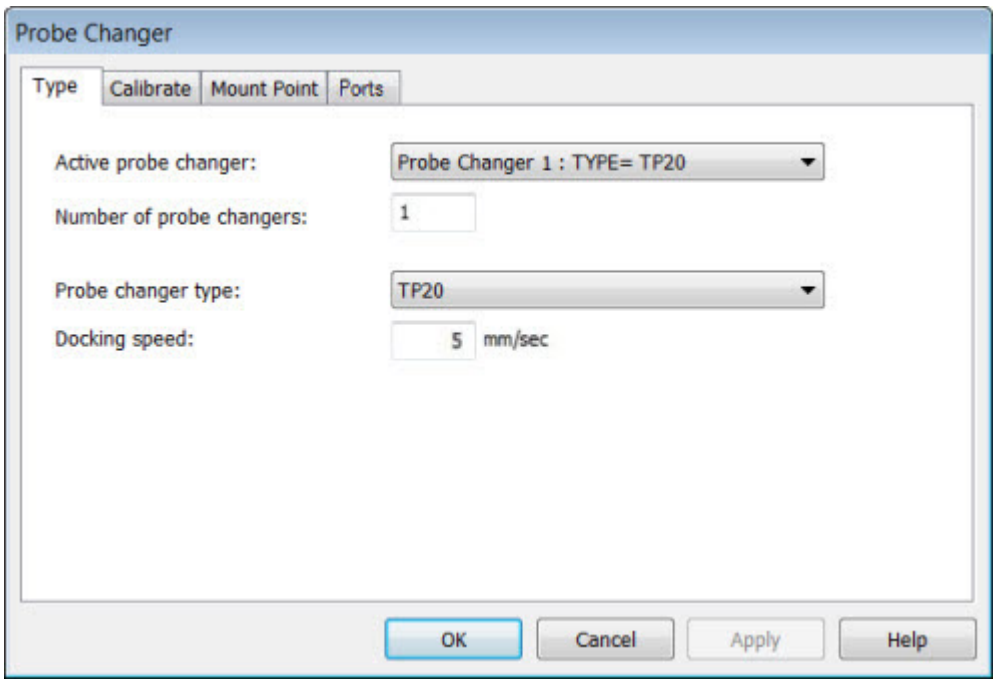
> **!** This probe changer DOES NOT need to be mounted on the machine table parallel to a machine axis, such as the X or Y axis. For mounting instructions, consult the documentation that came with your probe changer.

To calibrate your probe changer:

Step 1 - Select the TP20 Probe Changer

To select the TP20 Probe Changer:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **TP20**:



Probe Changer Dialog Box - Type Tab

3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.

4. In the **Active probe changer** box, select the list item that represents the probe changer you want to define. If this is the first probe changer, this shows **Probe Changer 1: TYPE=None**.

5. In the **Number of probe changers** box, specify the number of different types of probe changers you want to define.

6. In the **Docking speed** box, type a value. A value between 10-20 mm/sec is appropriate for this machine configuration. You can adjust this value at any time to speed up or slow down the system.

   To avoid equipment damage due to excessive docking speed, gradually increase the **Docking speed** value.

7. Click **Apply** to apply any changes made for this probe changer, and then click **OK** to close the dialog box.

For details on controller configuration settings, see the documentation that came with your controller.

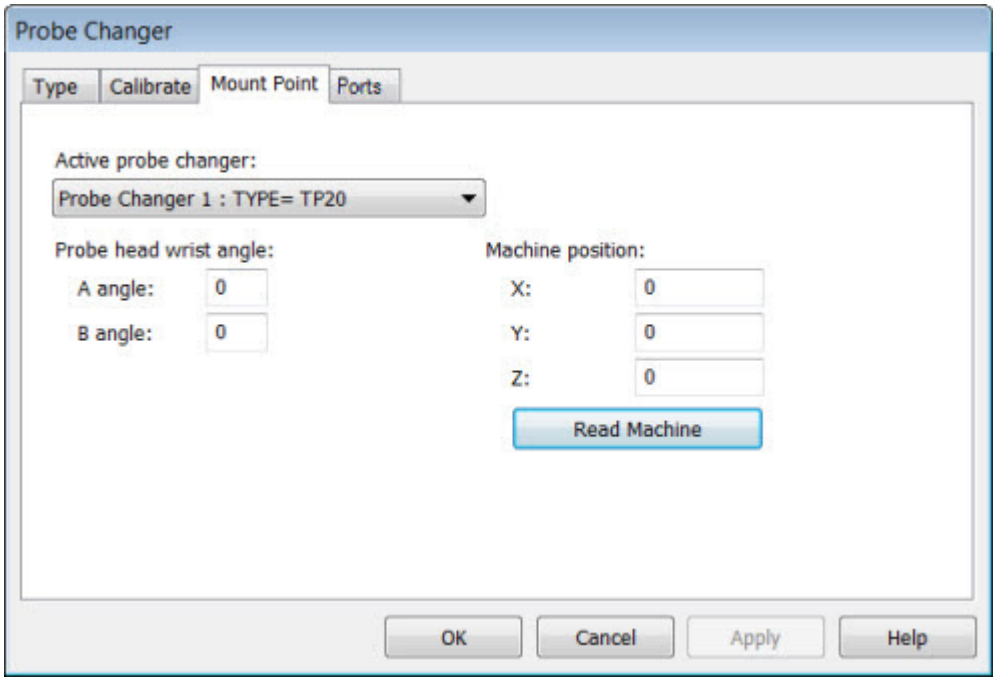
In the next step, you define the location your probe body moves to when using the probe changer to switch probe components.

Step 2 - Define the Mount Point and Wrist Angle

The probe changer mount point is the location in front of the probe changer where the machine moves to before it picks up or drops off a probe. You should pick a location that avoids collisions with the probe changer, the part, clamps, or any other object in the workspace.

To define the mount point for your probe changer, follow these steps:

1. Select the **Mount Point** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**).



Probe Changer Dialog Box - Mount Point Tab

2. In the **Active Probe Changer** list, select **TYPE=TP20**.
3. If necessary, alter the probe head wrist angle for both **A angle** and **B angle**. Often, but not always, these values are both 0 (zero). You need to use a probe rotation to ensure the probe has the ability to move in and out of the probe changer during the necessary steps of the probe rack calibration procedure.
4. Use your jog box to manually move your machine to the desired mount point position.
5. Click the **Read Machine** button to populate the **X**, **Y**, and **Z Machine position** values with the current position. You can also manually type these values.
6. To save your changes, click **Apply**.

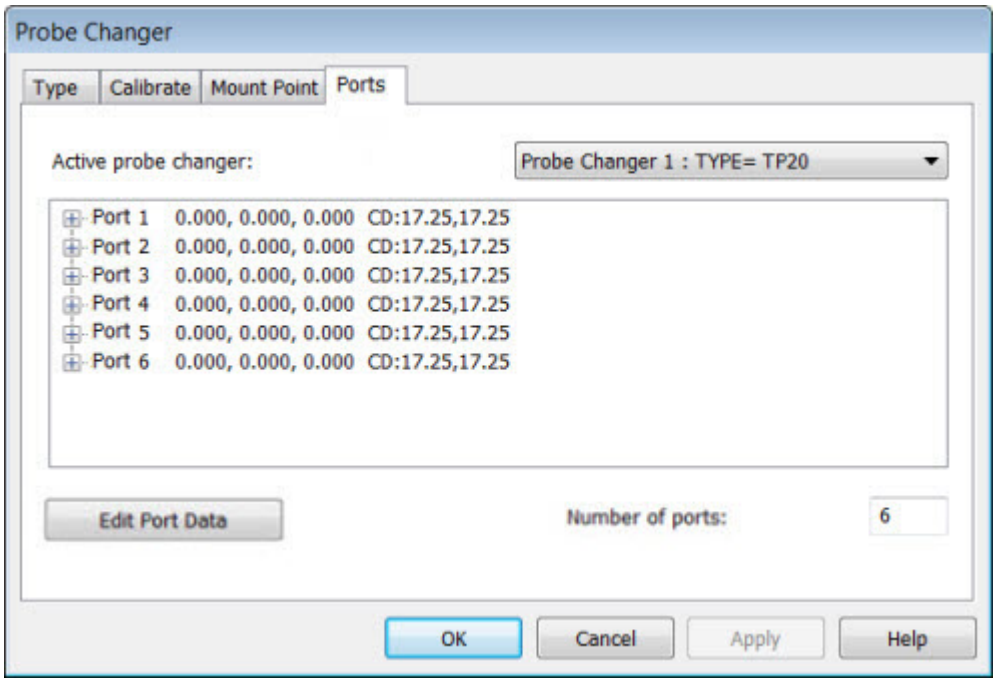
In the next step, you define the ports for your system.

Step 3 - Define the Ports

The final step prior to the actual calibration of the TP20 Probe Changer is to define the ports on the rack that you are calibrating.

To define the ports, do the following:

1. Select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Ports Tab

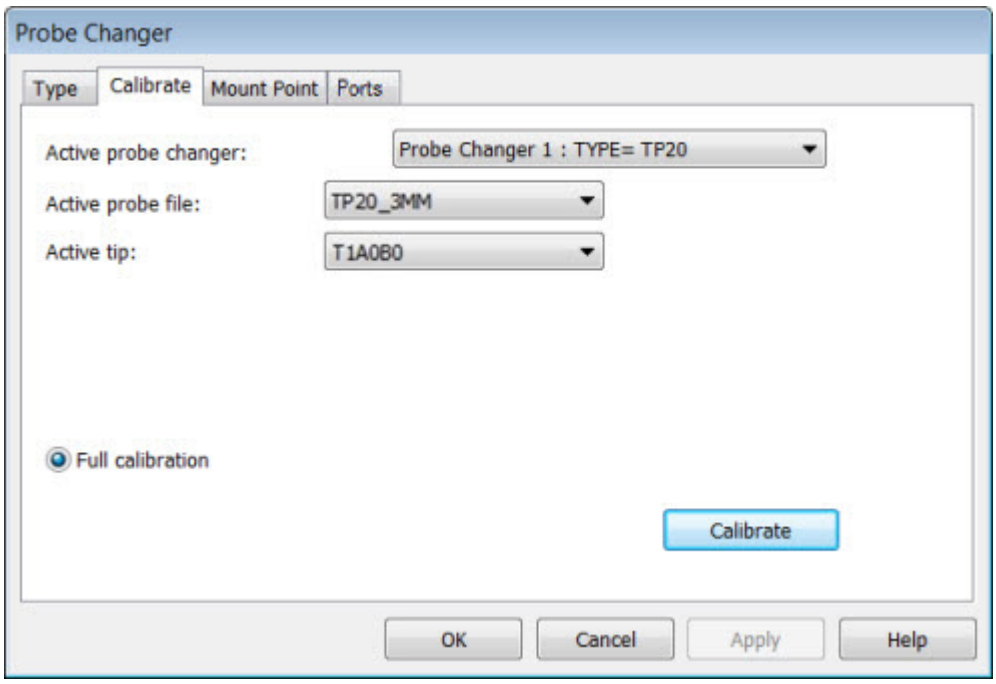
2. In the **Active probe changer** list, select **TYPE=TP20**.
3. In the **Number of ports** box, type the number of ports that you want to define.
4. Click **Apply** to store this parameter.

The next step starts the calibration process.

Step 4 - Prepare for Calibration

To begin the calibration process for the TP20 Probe Changer:

1. Select the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):

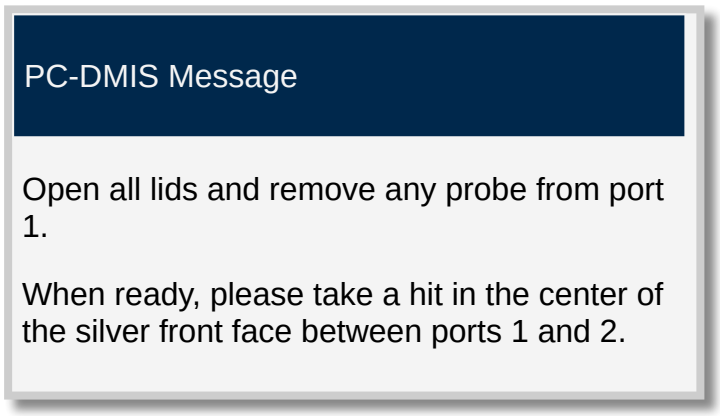


Probe Changer Dialog Box - Calibrate Tab

2. Click the **Calibrate** button.

3. The **Active probe file** and **Active tip** items default to the current measurement routine settings. If needed, change these to the probe and tip that you intend to use for the probe changer calibration.

4. Open the lids on each port by sliding them back until they click into place.



PC-DMIS prompt to open the port lids prior to calibration.

Open port lids prior to calibration.

In the next step, you take the first manual hit.

Step 5 - Take the First Manual Hit

When you start the calibration procedure for the TP20 Probe Changer, the ports must be emptied of all probes.

You will take the first hit on the front face to the left of the first port. This message prompts you to open the lids and take the first hit:

PC-DMIS Message

Open all lids and remove any probe from port 1.

When ready, please take a hit in the center of the silver front face between ports 1 and 2.

PC-DMIS prompt to take the first hit to the left of port 1.

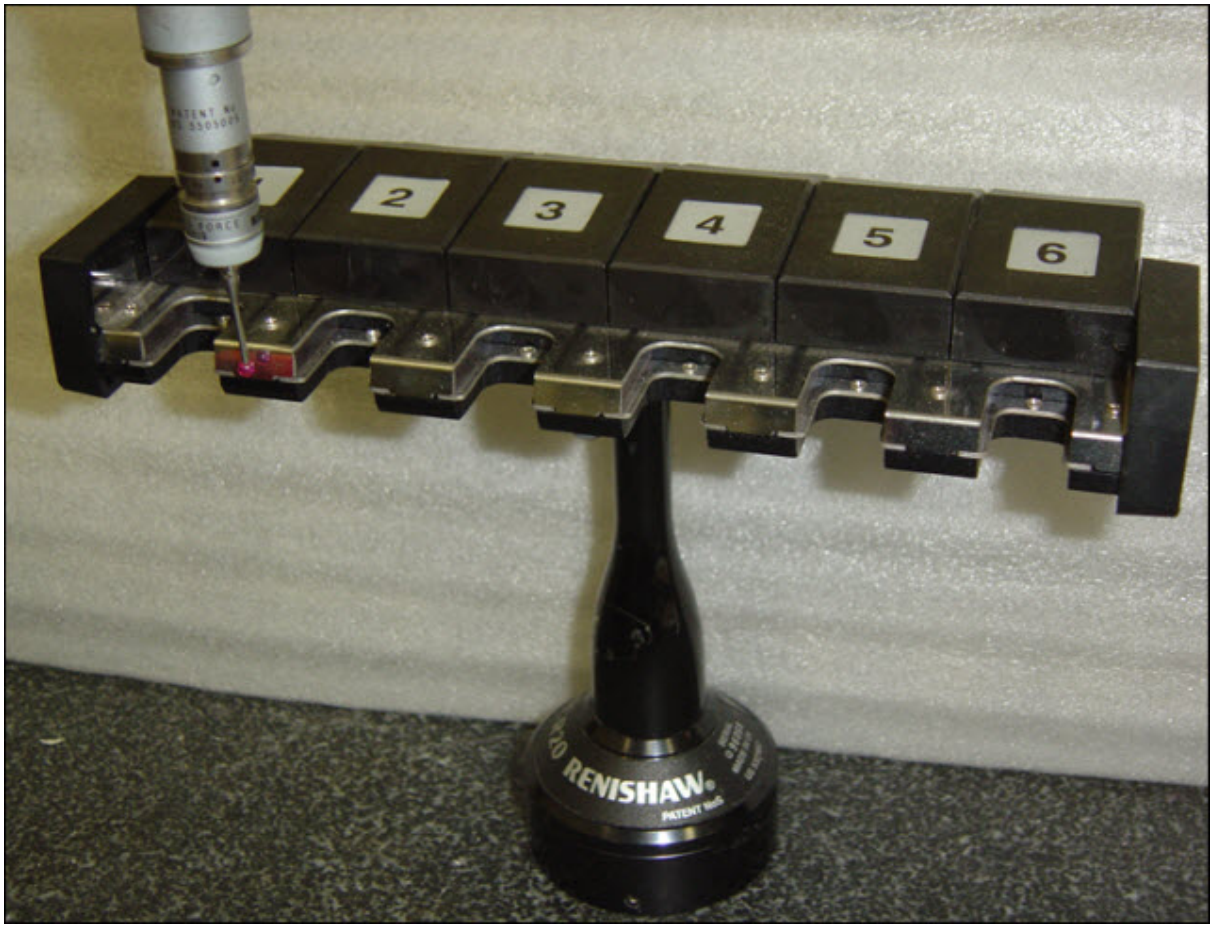
1. When you are ready to take the first measurement, click **OK**.
2. Remove all of the modules and styli by sliding them forward and out of the ports.

   You are prompted through the process of measuring three manual hits through a series of messages. Three hits are required to fully define the orientation of this rack in the machine's XY plane. It is not necessary to align the rack to any single axis, as

the manual hits identify any rotation involved. Follow the prompts and take the needed hits as directed in the instructions for each hit.

You will take the first manual hit in the XY plane, on the vertical face in the back of port 1.

3. Use your machine's jog box to measure the first hit on the front face to the left of port #1:

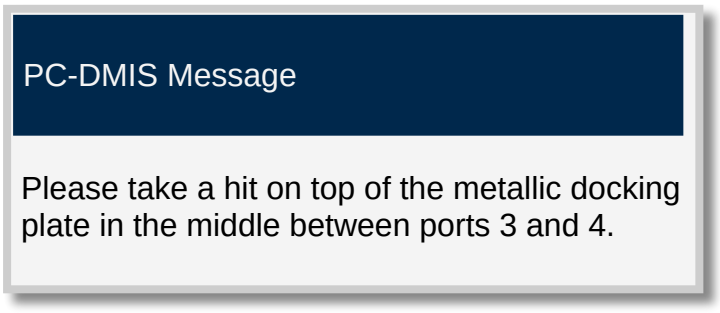


Example showing the location of the first manual hit during TP20 calibration.

In the next step, you take the second manual hit.

Step 6 - Take the Second Manual Hit

For the TP20 Probe Changer, you will take the second manual hit on the top metal surface between ports 3 and 4.



PC-DMIS prompt to take the second hit on the top, in the middle of the rack.

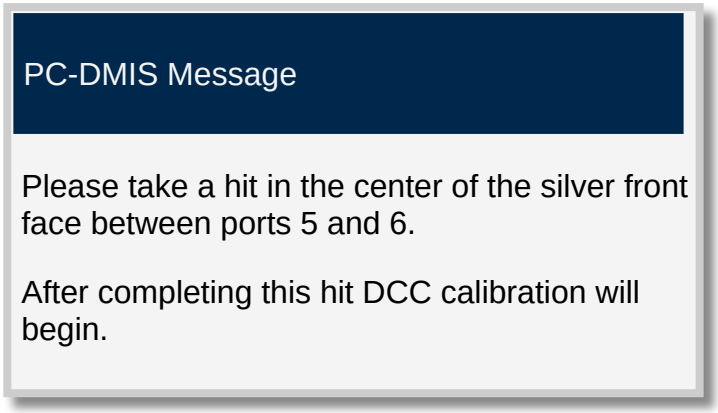
Use your machine's jog box to measure the second hit on the top surface between ports 3 and 4:

Example showing the location of the second manual hit during TP20 calibration.

In the next step, you take the third manual hit.

Step 7 - Take the Third Manual Hit

For the TP20 Probe Changer, you will take the third hit on the front surface and to the left of the last port.



PC-DMIS prompt to take the third hit on the top, to the left side of the last port.

Use your machine's jog box to measure the third hit on the top surface to the left of the last port:

Example showing the location of the third manual hit during TP20 calibration.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

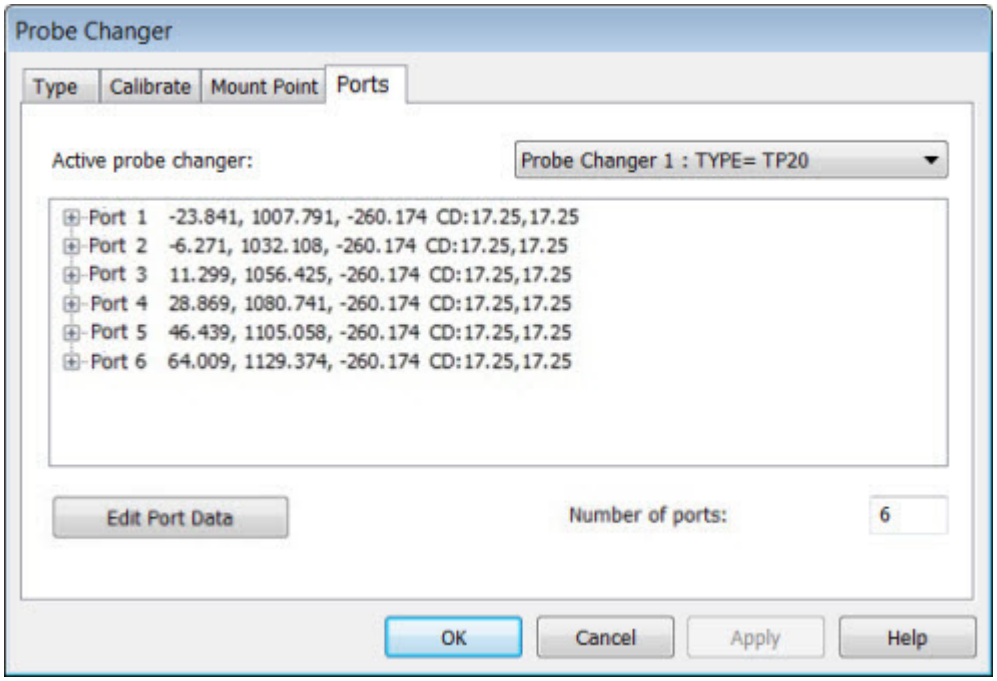
After it takes this hit on the back of the last port, PC-DMIS drives in DCC Mode and takes some additional measurements. It works backwards from the last port toward the first port. It actually measures the same three locations in reverse order in DCC Mode. Two additional hits are then taken on either side of port 1.

There is no specific message to indicate that the calibration is complete. The PC-DMIS **Execution** dialog box closes, and the **Calibrate** tab reappears.

The next step is to review the calibration results.

Step 8 - Review the Calibration Results

1. When the calibration of the TP20 Probe Changer is complete, select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). The calibration information now exists for the location of each calibrated port. For example:



Probe Changer dialog box - Ports tab with calibration results

2. When you view the results, look for the following. Any significant deviations from these expectations may be due to a bad hit.

    - This probe changer is not necessarily aligned parallel to any axis of the CMM. However, the X and Y values should show equal spacing between ports (roughly 30 mm apart).
    - The Z values should be nearly identical since the ports are all at the same height.

The results during measurement routine execution are:

1. Probe entities that are added to each port are automatically picked up from that location whenever PC-DMIS executes a `LOADPROBE` command for that probe.
2. The probe body moves to the mount point and then into the "unload" port to drop off the current probe.
3. The current probe remains in the port while the probe body lifts away to detach.
4. From there, the probe moves over to the next "load" position and then down onto the new probe, and automatically engages the new module.
5. It then moves back out of the port and over to the probe changer’s mount point.

6. From there, it continues to measure.

Calibrating the TP200 Probe Changer

The calibration process for the TP200 Probe Changer represents the steps that you would take to prepare to use any of the probe changers that PC-DMIS supports. The process discussed here is specific to the TP200 Probe Changer.

Inserts or extensions are not used for any of the port positions.

TP200 Probe Changer Rack

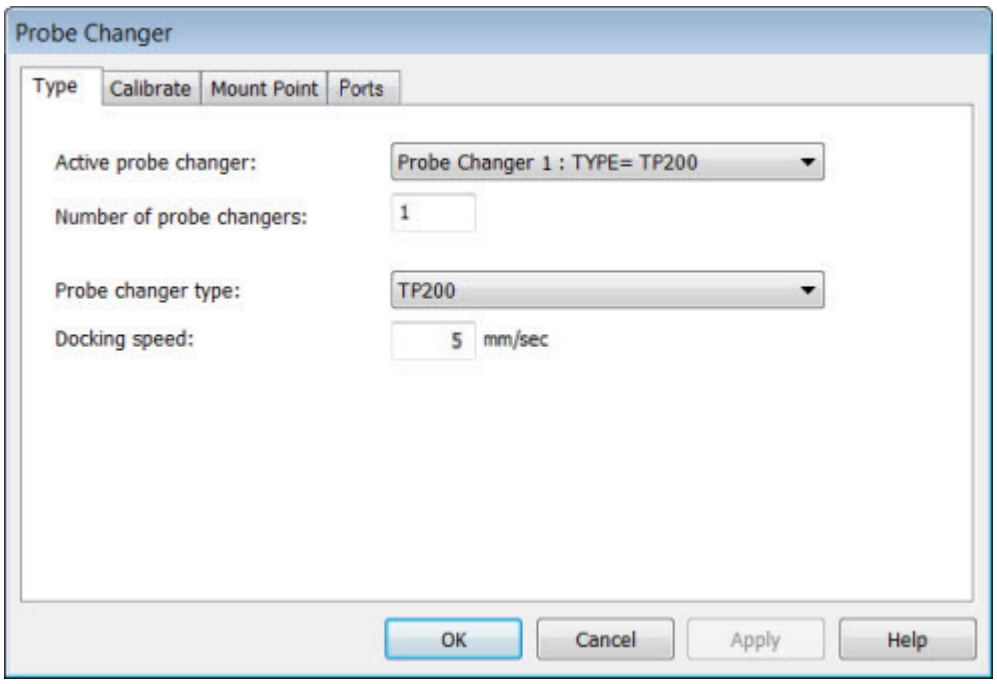
> This probe changer DOES NOT need to be mounted on the machine table parallel to a machine axis, such as the X or Y axis. For mounting instructions, consult the documentation that came with your probe changer.

To calibrate your probe changer:

Step 1 - Select the TP200 Probe Changer

To select the TP200 Probe Changer:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **TP200**:



Probe Changer Dialog Box - Type Tab

3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.

4. In the **Active probe changer** box, select the list item that represents the probe changer that you want to define. If this is the first probe changer, this shows **Probe Changer 1: TYPE=None**.

5. In the **Number of probe changers** box, specify the number of different types of probe changers that you want to define.

6. In the **Docking speed** box, type a value. A value between 10-20 mm/sec is appropriate for this machine configuration. You can adjust this value at any time to speed up or slow down the system.

   To avoid equipment damage due to excessive docking speed, gradually increase the **Docking speed** value.

7. Click **Apply** to apply any changes made for this probe changer, and then click **OK** to close the dialog box.

For details on controller configuration settings, see the documentation that came with your controller.

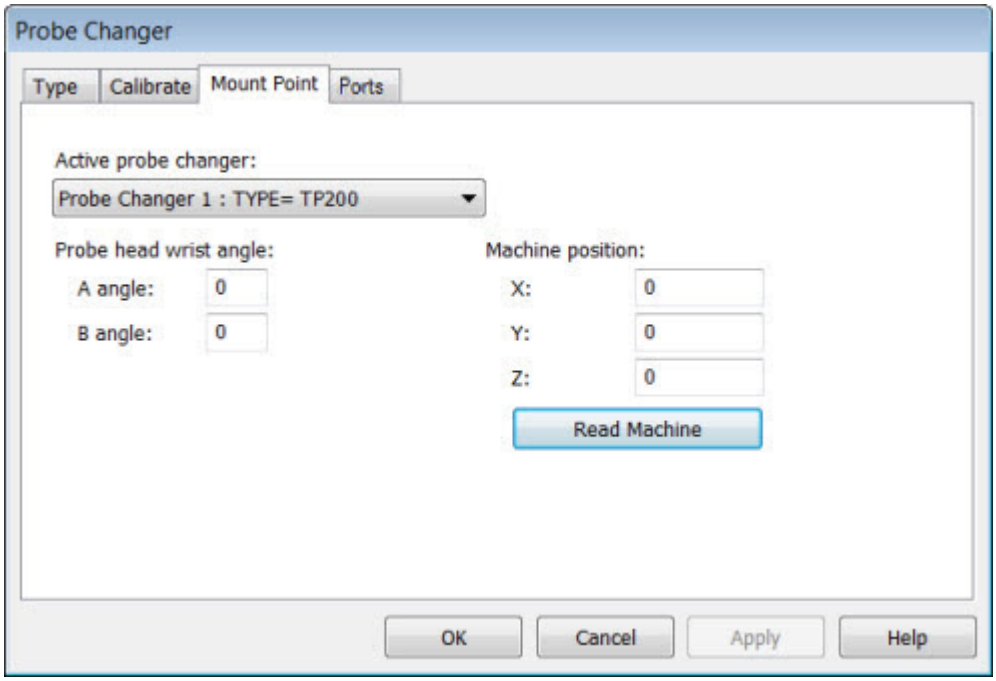
In the next step, you define the location your probe body moves to when using the probe changer to switch probe components.

Step 2 - Define the Mount Point and Wrist Angle

The probe changer mount point is the location in front of the probe changer where the machine moves to before it picks up or drops off a probe. You should pick a location that avoids collisions with the probe changer, the part, clamps, or any other object in the workspace.

To define the mount point for your probe changer, follow these steps:

1. Select the **Mount Point** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Mount Point Tab

2. From the **Active Probe Changer** list, select **TYPE=TP200**.
3. If necessary, alter the probe head wrist angle for both **A angle** and **B angle**. Often, but not always, these values are both 0 (zero). You need to use a probe rotation to ensure the probe has the ability to move in and out of the probe changer during the necessary steps of the probe rack calibration procedure.
4. Use your jog box to manually move your machine to the desired mount point position.
5. Click the **Read Machine** button to populate the **X**, **Y**, and **Z Machine position** values with the current position. You can also manually type these values.
6. To save your changes, click **Apply**.

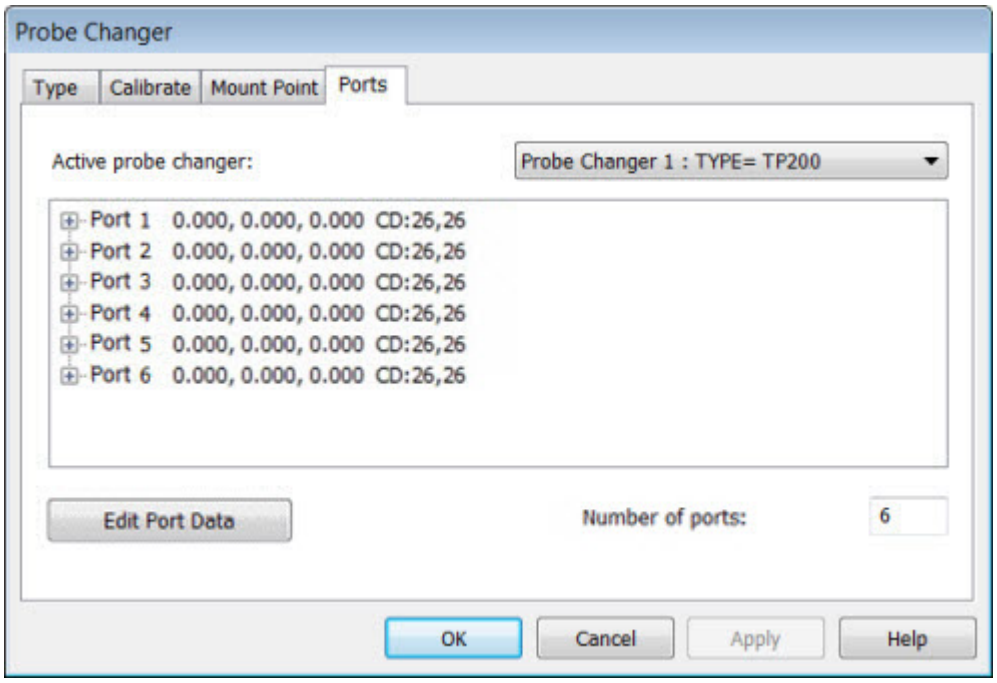
In the next step, you define the ports for your system..

Step 3 - Define the Ports

The final step prior to the actual calibration of the TP200 Probe Changer is to define the ports on the rack that you are calibrating.

To define the ports, do the following:

1. Select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Ports Tab

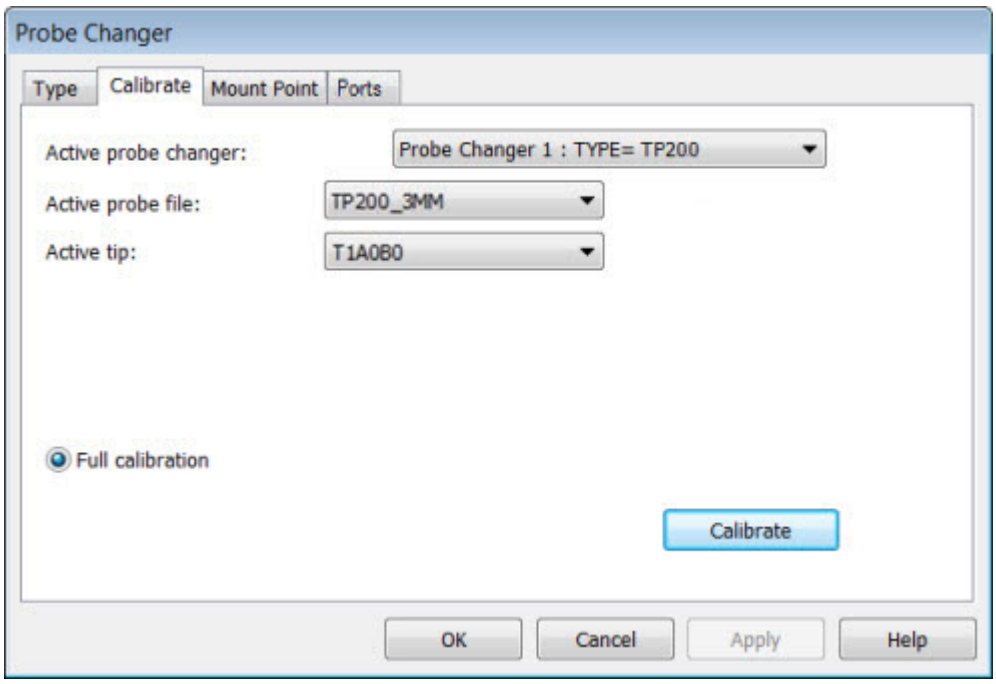
2. In the **Active probe changer** list, select **TYPE=TP200**.
3. In the **Number of ports** box, type the number of ports that you want to define.
4. Click **Apply** to store this parameter.

The next step starts the calibration process.

Step 4 - Prepare for Calibration

To start the calibration process for the TP200 Probe Changer:

1. Select the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Calibrate Tab

2. Click the **Calibrate** button.
3. The **Active probe file** and **Active tip** items default to the current measurement routine settings. If necessary, change these to the probe and tip that you intend to use for the probe changer calibration.
4. Open the lids on ports 3 and 4 on each side of the divider (center post) by sliding them back and slightly to the side until they click into place.

Example showing the open port lids before calibration.

In the next step, you take the first manual hit.

Step 5 - Take the First Manual Hit

When you start the calibration procedure for the TP200 Probe Changer, the ports must be emptied of all probes.

You will take the first hit on the front (vertical) face of the divider, to the right of port 3. This message box prompts you to open the lids and take the first hit:

PC-DMIS Message

Unplug the cable from the rack, open lids 3 and 4 and remove any probe from ports 3 and 4.

When ready, please take a hit on the front face of the divider between ports 3 and 4.

The hit should be taken on the lower widest portion as close as possible to the outer edge on the left-hand side next to port 3.

PC-DMIS prompt for the first hit.

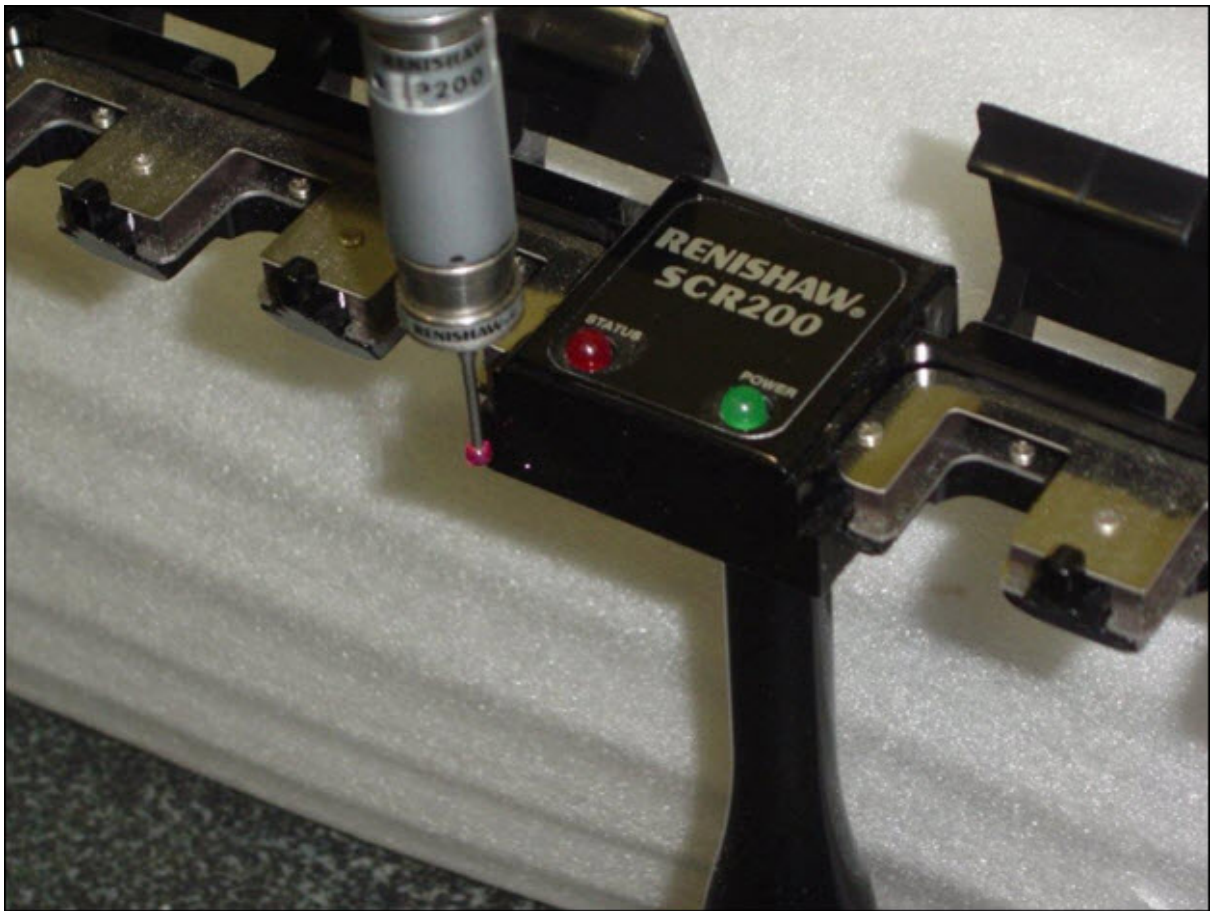
1. When you are ready to take the first measurement, click **OK**.

2. Remove all of the modules and styli by sliding them forward and out of the ports.

   You are prompted through the process of measuring three manual hits through a series of messages. Three hits are required to fully define the orientation of this rack in the machine’s XY plane. It is not necessary to align the rack to any single axis, as the manual hits will identify any rotation involved. Follow the prompts and take the needed hits as directed in the instructions for each hit.

   You will take the first manual hit in the XY plane on the front (vertical) face of the divider, to the right of port 3.

3. Use your machine's jog box to measure the first hit on the front (vertical) face of the divider, to the right of port 3:



Example showing the location of the first manual hit during TP200 calibration.

In the next step, you take the second manual hit.

Step 6 - Take the Second Manual Hit

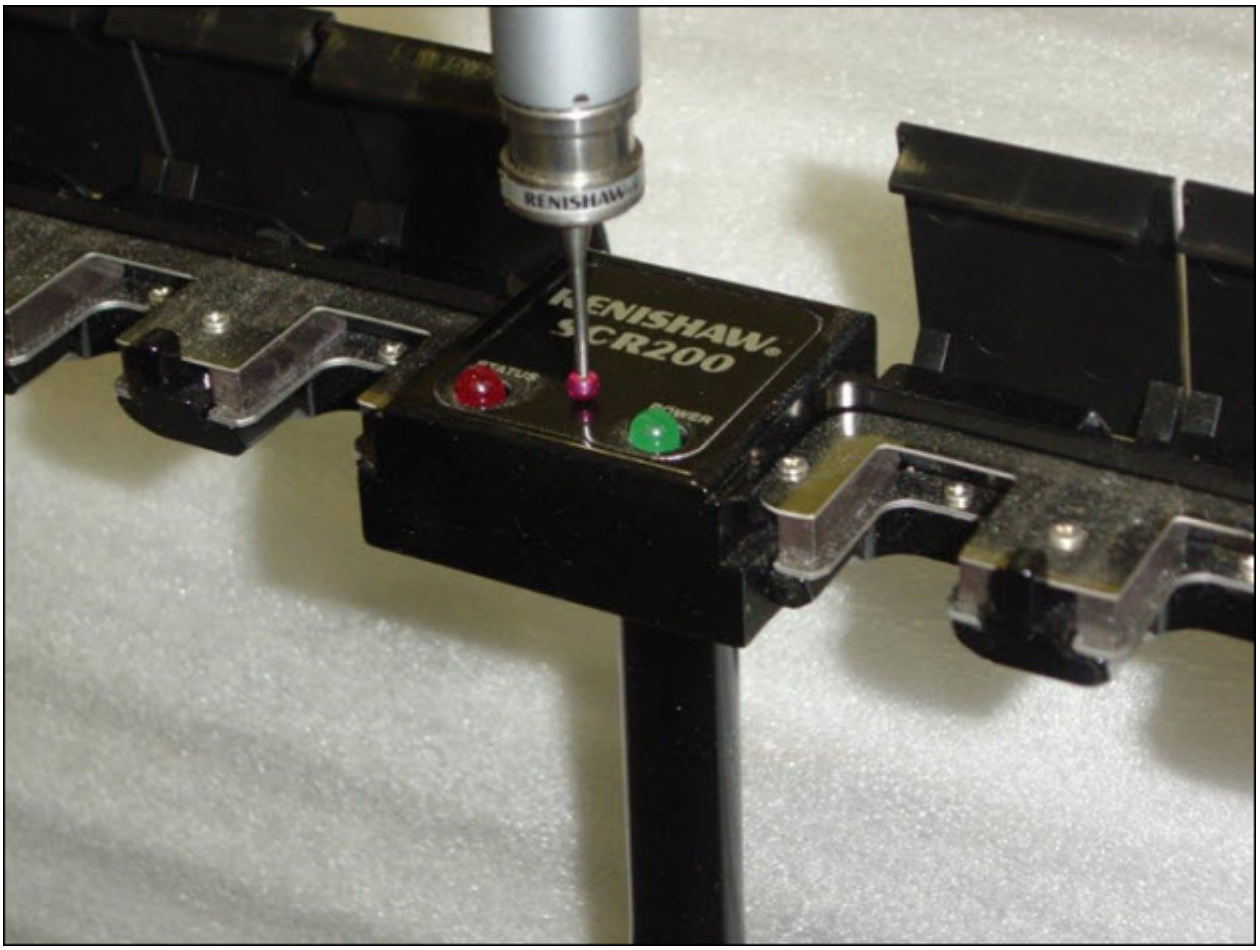
For the TP200 Probe Changer, you will take the second manual hit on the top (horizontal) face of the divider and between ports 3 and 4. The message box is:

PC-DMIS Message

Please take a hit on the top in the middle of the rack.

PC-DMIS prompt for the second hit.

Use your machine's jog box to measure the second hit on the top (horizontal) surface of the divider and between ports 3 and 4:



Example showing the location of second manual hit during TP200 calibration.

In the next step, you take the third manual hit.

Step 7 - Take the Third Manual Hit

For the TP200 Probe Changer, you will take the third hit on the front (vertical) face of the divider and to the left of port 4.

PC-DMIS Message

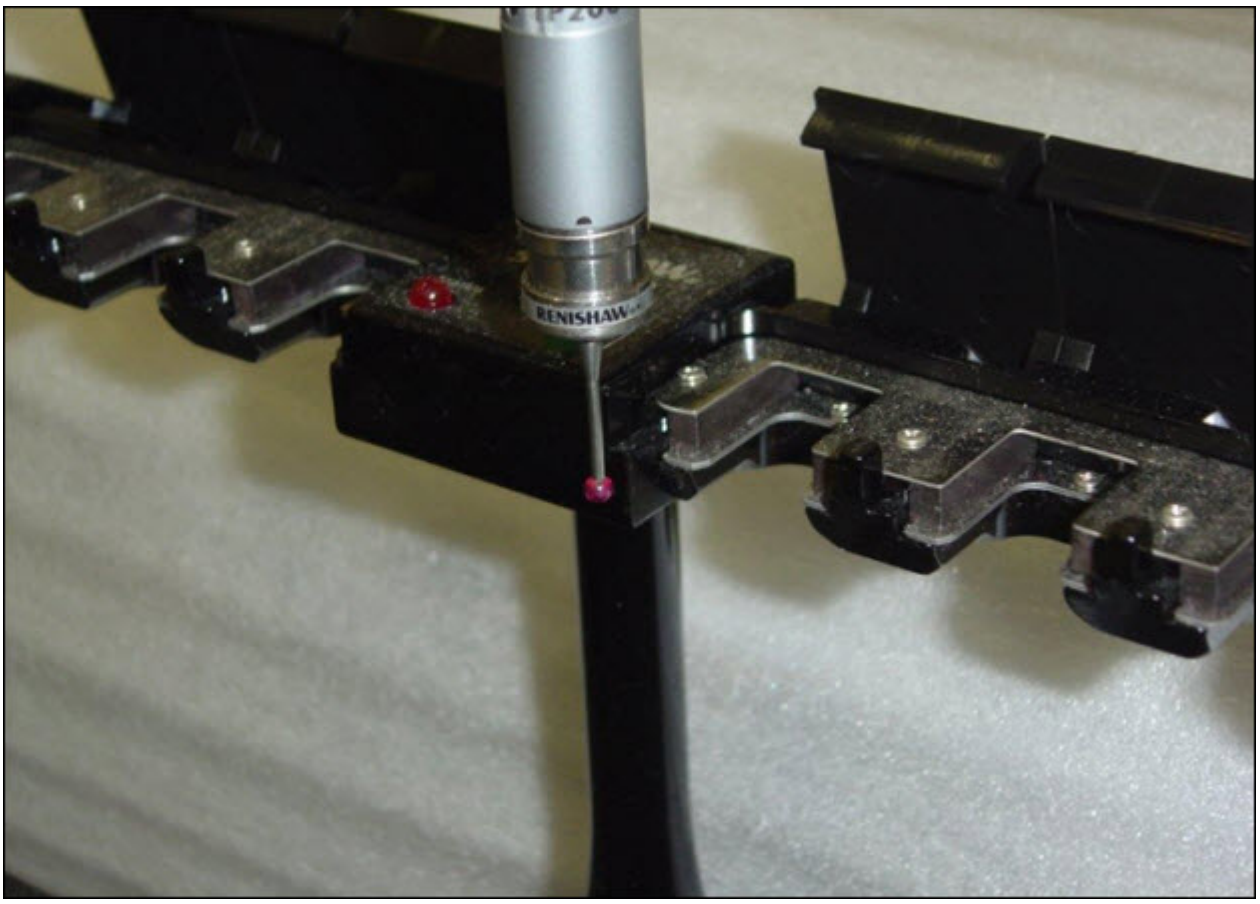
Please take a hit on the front face of the divider between ports 3 and 4.

The hit should be taken on the lower widest portion as close as possible to the outer edge on the right-hand side next to port 4.

After completing this hit DCC calibration will begin.

PC-DMIS prompt for the third hit.

Use your machine's jog box to measure the third hit on the front (vertical) surface of the divider, to the left of port 4:



Example showing the location of the third manual hit during TP200 calibration.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

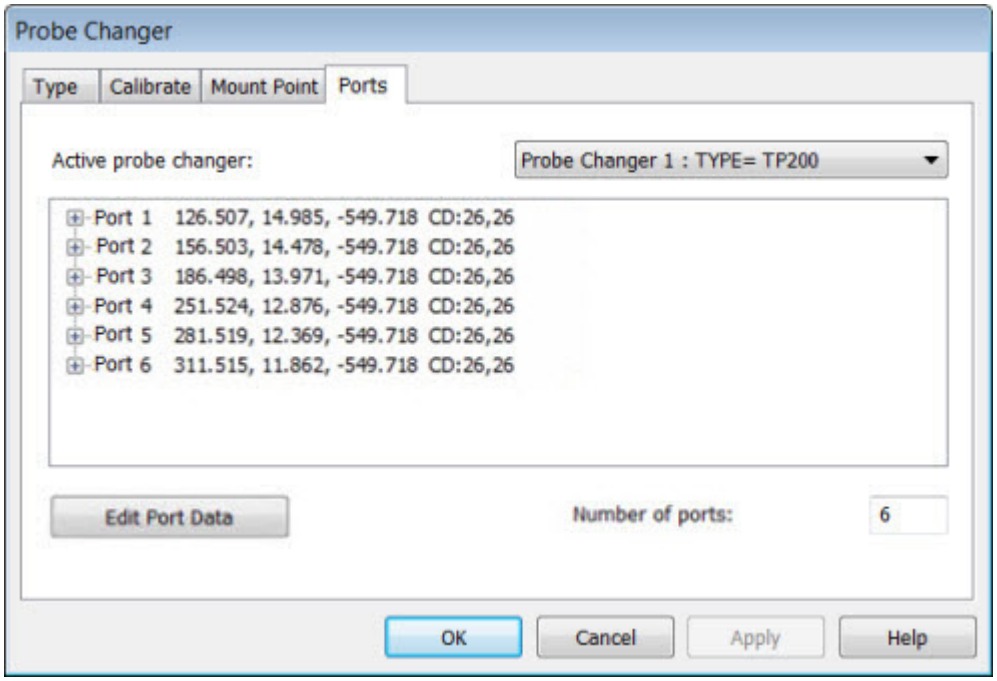
After it takes this hit on the back of the last port, PC-DMIS drives in DCC Mode and takes some additional measurements. It works backwards from the last port toward the first port. It actually measures the same three locations in reverse order in DCC Mode. Two additional hits are taken on either side of port 1.

There is no specific message to indicate that the calibration is complete. The PC-DMIS **Execution** dialog box closes, and the **Calibrate** tab reappears.

The next step is to review the calibration results.

Step 8 - Review the Calibration Results

1. When the calibration of the TP200 Probe Changer is complete, select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). The calibration information now exists for the location of each calibrated port:



Probe Changer dialog box - Ports tab with calibration results

2. When you view the results, watch for the following discontinuities. Any significant deviations from these expectations may be due to a bad hit.

   - This probe changer is not necessarily aligned parallel to any axis of the CMM. However, the X and Y values should show equal spacing between ports (roughly 30 mm apart), with about 65 mm between ports 3 and 4 for the divider.
   - The Z values should be nearly identical since the ports are all at the same height.

The results during measurement routine execution are:

1. Probe entities that are added to each port are automatically picked up from that location whenever PC-DMIS executes a `LOADPROBE` command for that probe.

2. The probe body moves to the mount point and then into the "unload" port to drop off the current probe.
3. The current probe remains in the port while the probe body lifts away to detach.
4. From there, the probe moves over the next "load" position and then down onto the new probe, and automatically engages the new module.
5. It then moves back out of the port and over to the probe changer's mount point.
6. From there, it continues to measure.

Calibrating the Travel Rack HR-X1-TR

The calibration process discussed in this section is specific to the Travel Rack HR-X1-TR.

The probe changer mounts onto the drive leg of the CMM. For mounting instructions, consult the documentation that came with your Travel Rack HR-X1-TR.

Mounted Travel Rack HR-X1-TR

The probe changer travels with the moving portal of the machine. The stylus change is done horizontally. Therefore, the TESASTAR-M brings the sensor into the right position.

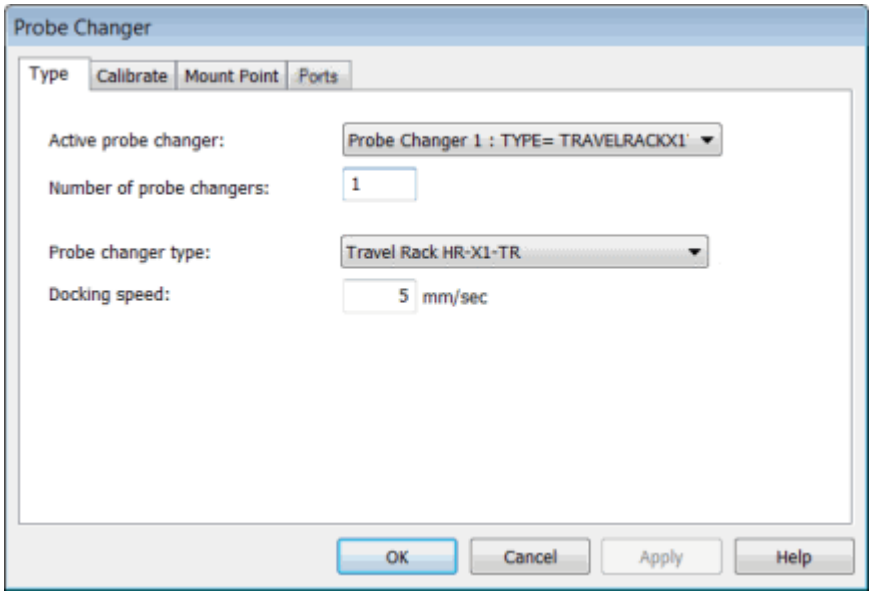
Since the change rack moves with the portal, there are no additional travelling distances to perform a change of configuration, as would be the case with a standard rack. This enables quick changes of the styli configuration anywhere in the measurement volume.

To calibrate your probe changer:

Step 1 - Select the Travel Rack HR-X1-TR

To select the Travel Rack HR-X1-TR:

1. In the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**), select the **Type** tab.
2. In the **Probe changer type** list, select **Travel Rack HR-X1-TR**:



Probe Changer Dialog Box - Type Tab

3. To make this probe changer active and load the settings that are relevant to this probe changer, click **Apply**. Other tabs become visible after you click **Apply**.
4. In the **Active probe changer** box, select the list item that represents the probe changer that you want to define. If this is the first probe changer, this shows **Probe Changer 1: TYPE=None**.
5. In the **Number of probe changers** box, specify the number of probe changers you want to define.
6. In the **Docking speed** box, type a value. A value between 10-20 mm/sec is appropriate for this machine configuration. You can adjust this value at any time to speed up or slow down the system.

> ⚠ To avoid equipment damage due to excessive docking speed, gradually increase the **Docking speed** value.

7. Click **Apply** to apply any changes made for this probe changer, and then click **OK** to close the dialog box.

For details on controller configuration settings, see the documentation that came with your controller.

In the next step, you define the location your probe body moves to when using the probe changer to switch probe components.

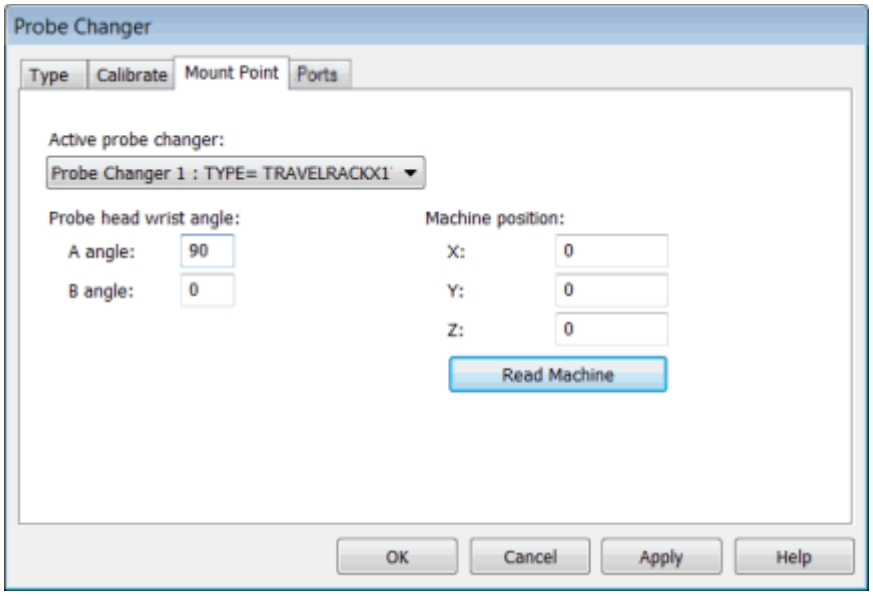
Step 2 - Define the Mount Point

The probe changer mount point is the location in front of the probe changer where the machine moves to before it picks up or drops off a probe. You should pick a location that avoids collisions with the probe changer, the part, clamps, or any other object in the workspace.

To define the mount point for your probe changer, follow these steps:

The Travel Rack HR-X1-TR is capable of changing the probe at any location of one machine axis (the default is the machine X axis for the Leitz CMM). Therefore, the mount point is effective for only the other two axes.

1. Select the **Mount Point** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Mount Point Tab

2. In the **Active probe changer** list, select **TYPE=TRAVELRACKX1V**.
3. Enter the probe head wrist angle for both **A angle** and **B angle**. The A and B angle combination should be one for which the probe is pointing either parallel to or away from the rack. It is automatically rotated into the rack during the change. We recommend that you set this to A=90 and B=0.

> For this probe changer, never set these probe angles to A=90 and B=90. If you do, PC-DMIS shows an error message and cannot change probes.

4. Use your jog box to manually move your machine to the desired mount point position.
5. Click the **Read Machine** button to populate the **X**, **Y**, and **Z** machine position values with the current position. You can also type these values.
6. To save your changes, click **Apply**.

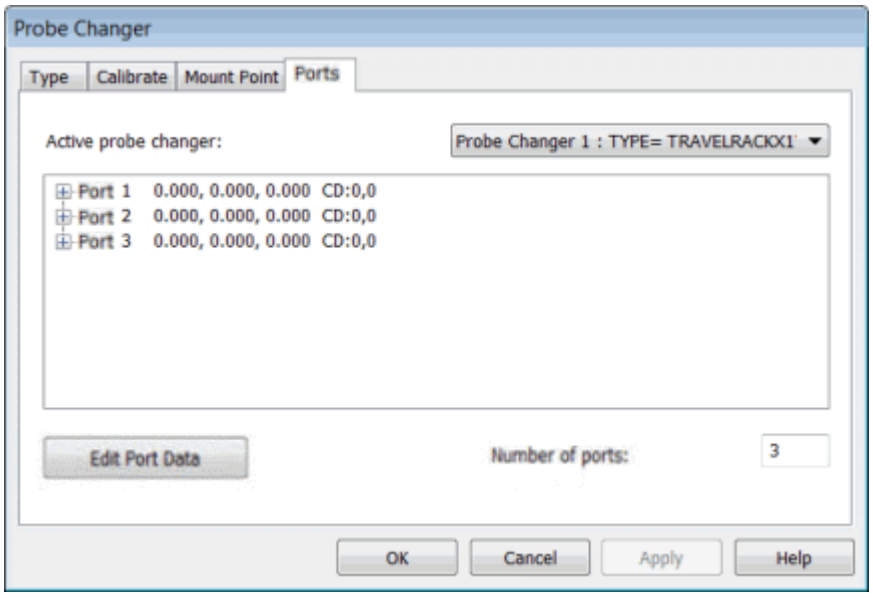
In the next step, you define the ports.

Step 3 - Define the Ports

The final step prior to calibrating the Travel Rack HR-X1-TR is to define the ports on the rack.

To define the ports, do the following:

1. Select the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Ports Tab

2. In the **Active probe changer** list, select **TYPE=TRAVELRACKX1V**.
3. In the **Number of ports** box, type the number of ports on your probe changer.
4. To save your changes, click **Apply**.

The next step starts the calibration process.

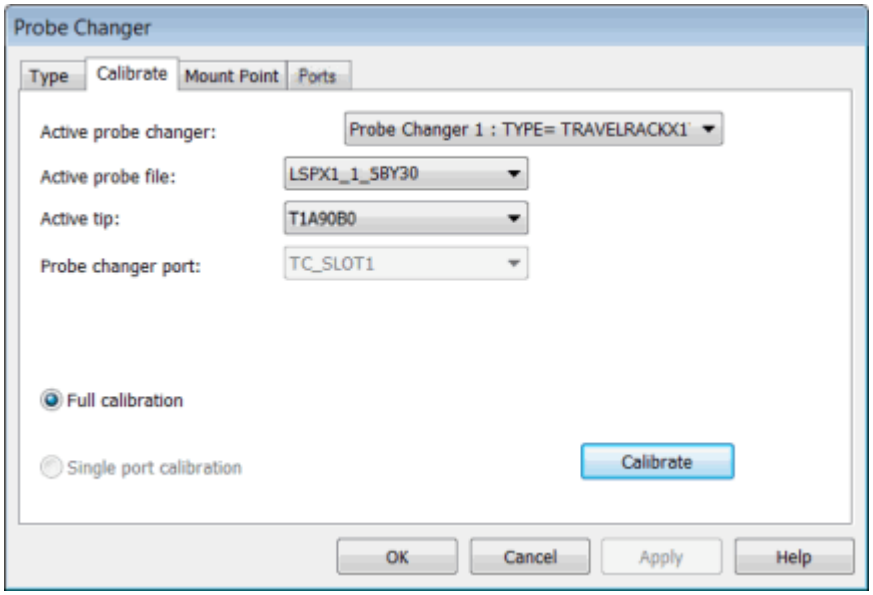
Step 4 - Prepare for Calibration

This step starts the calibration process for the Travel Rack HR-X1-TR. The calibration process requires a tip with at least 50 mm of length. It should not exceed 5 mm in diameter.

To calibrate the probe changer, you need tip angles A90 and B90.

To start the calibration process:

1. Select the **Calibrate** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**):



Probe Changer Dialog Box - Calibrate Tab

2. In the **Active probe changer** list, select **Probe Changer 1: TYPE=TRAVELRACKX1V**.
3. The entry in the **Active probe file** list defaults to the current measurement routine setting. If this is not what is to be used for the rack calibration, select the proper probe.
4. The entry in the **Active tip** list defaults to the angles from the **Mount Point** tab, but this rack type requires a different tip for the calibration. It must be the one that points directly into the rack so that it can take measurements inside the ports. This is usually T1A90B90.
5. Click **Calibrate**.
6. When you are ready to take the first measurement, click **OK**.

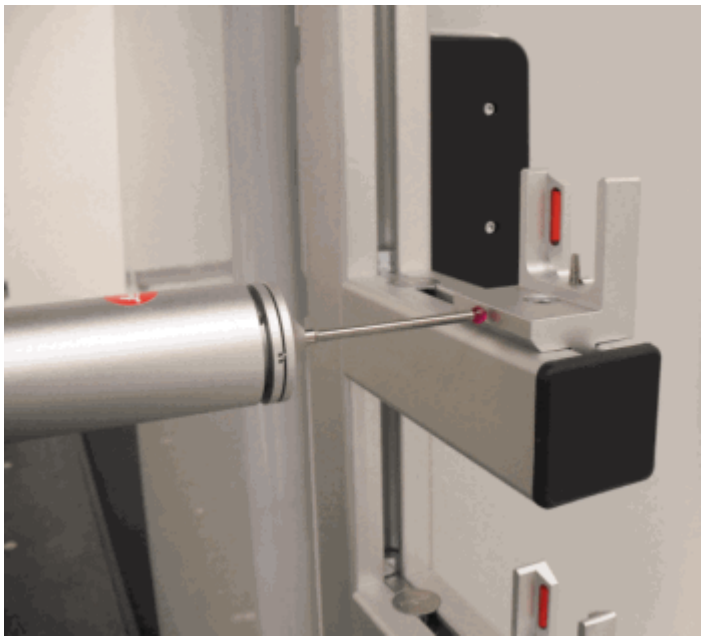
In the next step, you take the manual hits.

Step 5 - Take the Manual Hits

When you start the calibration procedure for the Travel Rack HR-X1-TR, a series of message boxes prompts you through the process of measuring the manual hits. These hits are required to fully define the orientation of this rack. Follow the prompts and take the needed hits as directed in the instructions for each hit.

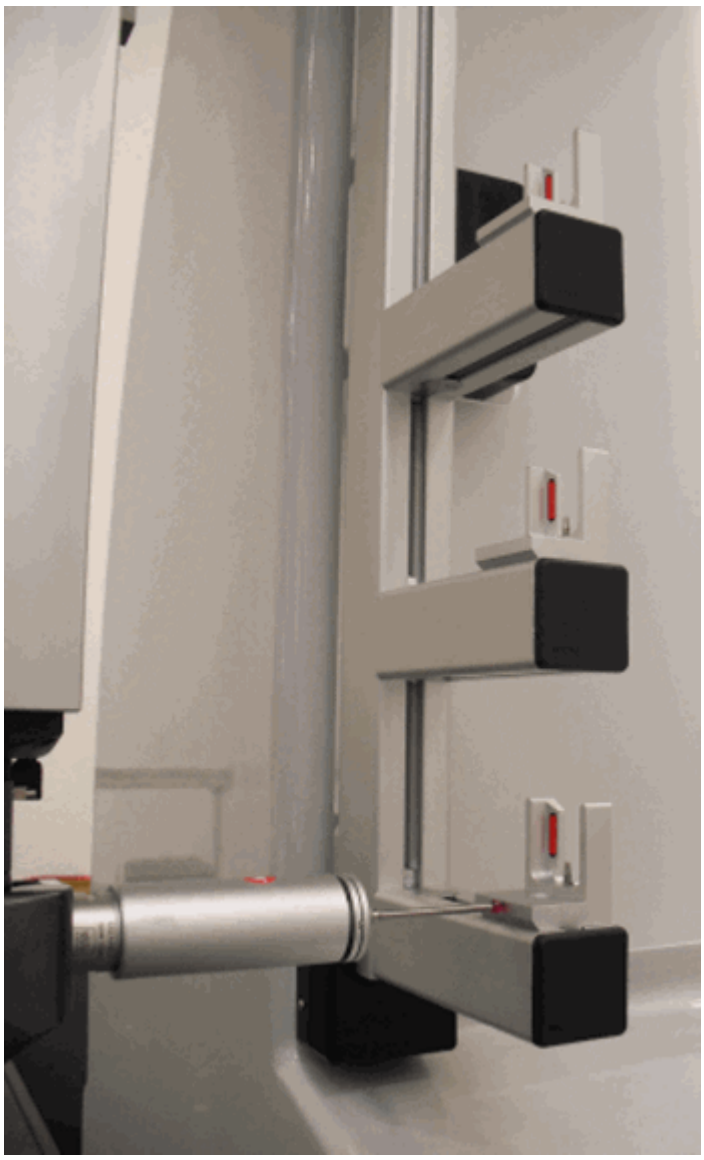
To take the manual hits:

1. Remove all of the probes that may be in any of the ports.
2. Take a horizontal hit on the flat, vertical front surface of port 1 (the top port) as shown in the view below:

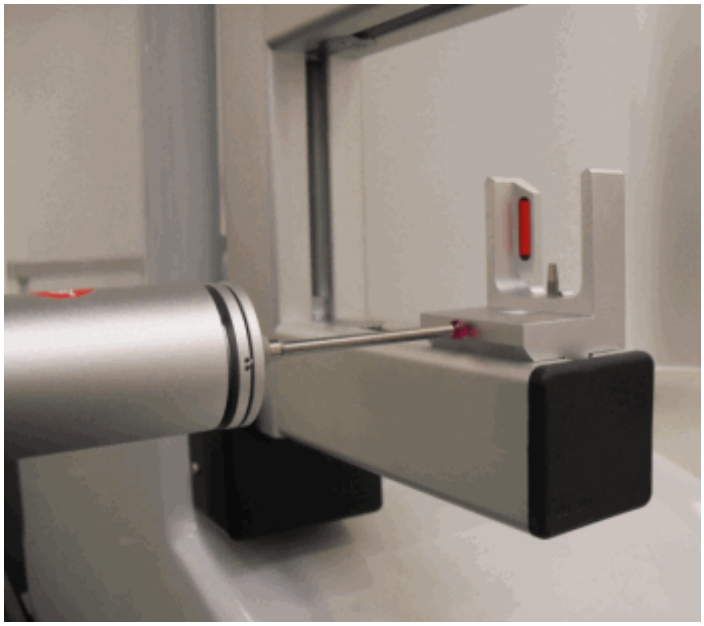


Horizontal hit on flat and vertical front surface of top port

3. Take a horizontal hit on the flat, vertical front surface of the bottom port as shown in the two views below:



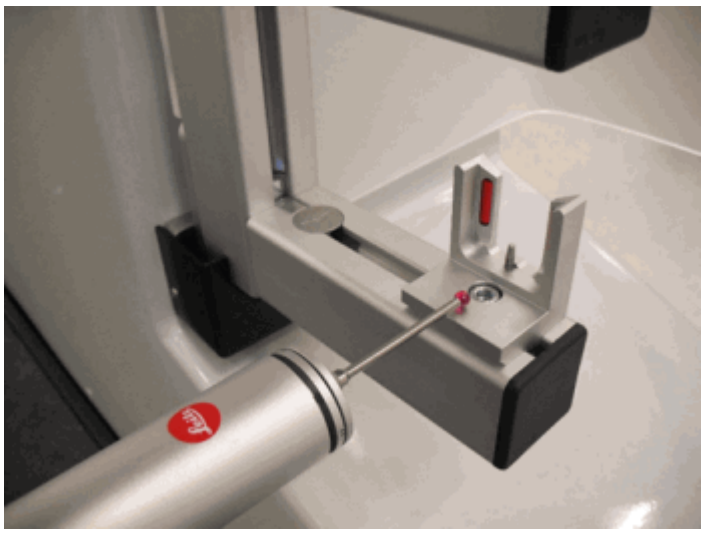
Horizontal hit on flat and vertical front surface of bottom port - view 1



Horizontal hit on flat and vertical front surface of bottom port - view 2

4. Take a vertical hit on the flat, horizontal surface of the bottom port anywhere between the edge and screw as shown in the two views below:

Vertical hit on flat and horizontal surface of bottom port - view 1



Vertical hit on flat and horizontal surface of bottom port - view 2

5. Now you are prompted to take a similar vertical hit on the flat, horizontal surface of each additional port, in the order of lower to higher, with the final hit being on the top port.

6. Use your machine's jog box to take all of the manual hits.

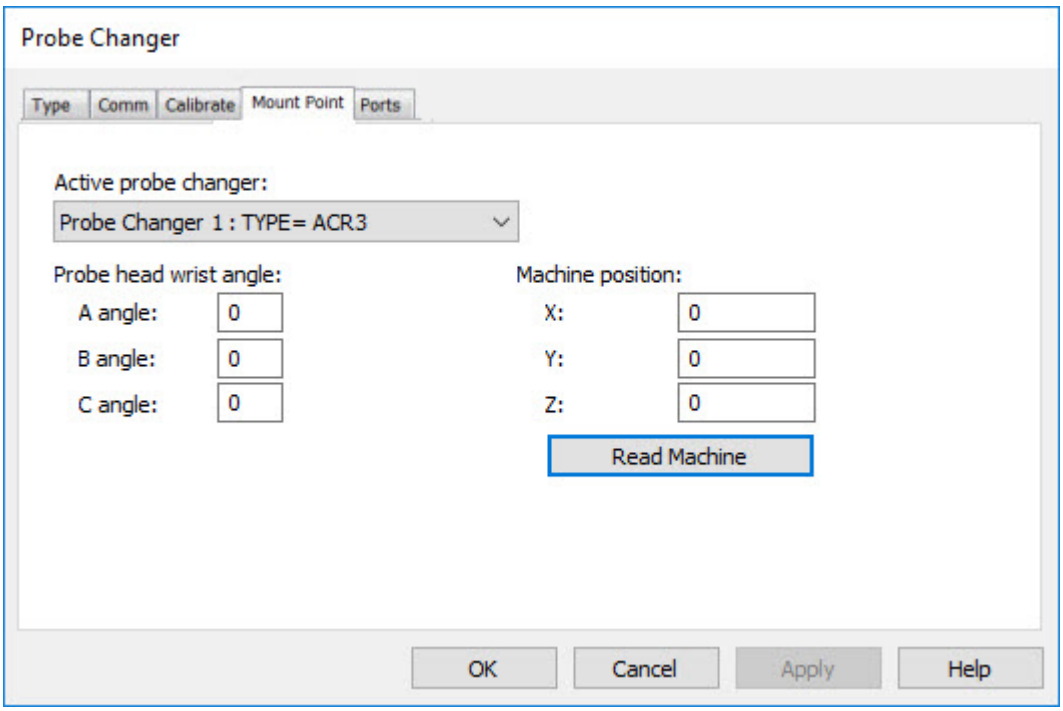
PC-DMIS performs the rest of the calibration in DCC Mode.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

Mount Point Tab

You can use the **Mount Point** tab to change the values for the probe head wrist angles and define a safe position that the CMM can move to before each change cycle. You can do this for the probe changers that you defined on the **Type** tab.

To open the **Probe Changer** dialog box, select **Edit | Preferences | Probe Changer**.



Probe Changer Dialog Box - Mount Point Tab

Active probe changer

From the **Active probe changer** list, you can select the probe changer. For the probe changer, you need to define the probe head wrist angles to perform the change, and a CMM position. For more information about this list, see "Type Tab".

Probe head wrist angle

The **A angle**, **B angle**, and **C angle** boxes indicate the position of the probe head. You need these values when you slide the probe configurations in place. In the respective **Probe head wrist angle** boxes, you can type the values. If an angle is not available in the probe head, the value for that angle should be 0 (zero).

> Some probe changers do not support the C angle. The **C angle** box does not appear for those probe changers.

When you calibrate ports that hold extensions, you should define the probe head wrist angles before calibration. If you change the angles after calibration of the port, a warning message appears and informs you that recalibration is needed.

Machine position

You can use the **Machine position** area to indicate a safe location to which the CMM can move prior to each change cycle. Usually, this safe location is approximately 2 inches above and in front of the probe changer rack. However, you may find it necessary to move to some other location, depending on the type of probe changer.

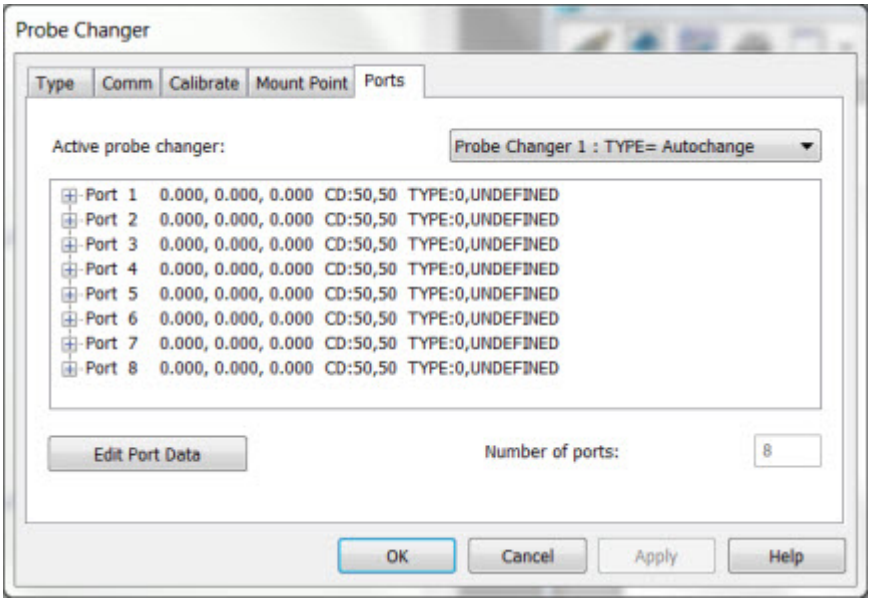
To change the values for the CMM position:

1. Select the previous value of the **X**, **Y**, or **Z** box that you want to change.

2. Type the correct values in the appropriate boxes. You can also click the **Read Machine** button to insert the current position of the CMM.

Ports Tab

To display the **Ports** tab in the **Probe Changer** dialog box, select **Edit | Preferences | Probe Changer**:



Probe Changer Dialog Box - Ports Tab

The probe changer is a rack that provides ports for different probe configurations. Use the **Ports** tab to define the probe configuration for each port that is used. The default for each port is "**(no probe)**". You can define the probe configuration for each port of the selected probe changer.

To Define the Probe Configuration for Each Port

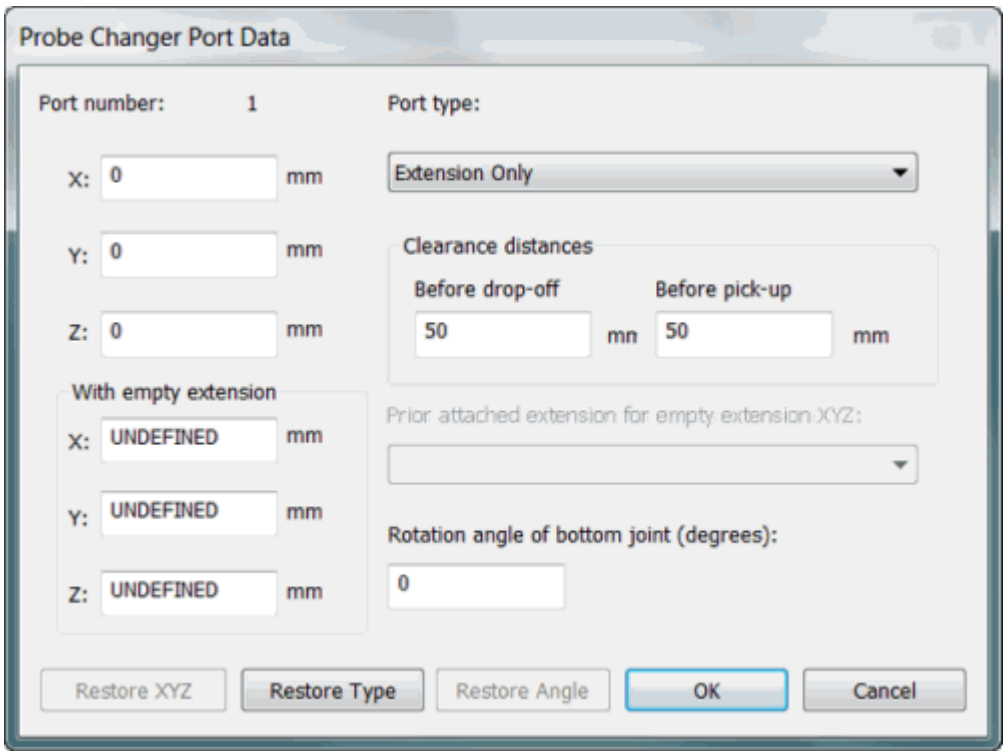
1. Select the appropriate probe changer from the **Active probe changer** list on the **Ports** tab (**Edit | Preferences | Probe Changer**).
2. Click the plus sign (**+**) to the left of the port number. PC-DMIS displays a "**(no probe)**" item as the default.
3. Double-click or right-click on the "**(no probe)**" item. A list appears.
4. Assign the appropriate probe file or extension to each port. (If you want to remove a probe file or an extension from a port, double-click it and then select the "**(no probe)**" item from the list.)
5. Select the port number and then click the **Edit Port Data** button. The **Probe Changer Port Data** dialog box appears. For help with this dialog box, see "To Manually Edit a Port's Data".

6. From the **Port type** list, specify the type of hardware that you want the ports to hold:
    - If you want it to hold a probe, select **Probe Attached.**
    - If you only want it to hold a probe extension, select **Extension Only.**
    - If the port is empty, select **UNDEFINED**.
    - For some probe changers, you can select specific inserts from the list.
7. Define the XYZ location for the port by typing the **X**, **Y**, and **Z** values for **Port number**.
8. If you are using an ACR1 or a TESASTAR-R / HR-R probe changer, and you have defined the port type as **Extension Only**, enter the value for the **Rotation angle of bottom joint (degrees)** box. You can also define the XYZ location of the bottom of the extension by defining the **X**,**Y**, and **Z** boxes in the **With empty extension** area.
9. Define the **Before drop-off** and **Before pick-up** clearance distance values as desired. For more information, see "About Port Clearance Distances".
10. Click **OK** to accept your changes.
11. Each probe configuration must be loaded into the rack using the **CMM Arm** and **Load Active Probe** option. (Do *not* insert the probe into the rack by hand.)

> **!** Extensions are not manufactured within the necessary tolerances to be interchangeable without recalibration. Therefore, if you have already configured a port for a specific extension, and you want that port to hold a different extension (even an extension of the same size), you need to recalibrate the port for the new extension.

To Manually Edit a Port's Data

1. Select the appropriate port from the **Active probe changer** list on the **Ports** tab (**Edit | Preferences | Probe Changer**).
2. Click the **Edit Port Data** button. The **Probe Changer Port Data** dialog box appears. For all probe changer types, the **X**, **Y**, and **Z** boxes should be available to edit. While you can use these boxes to manually enter a position if needed, these values are normally determined by measurements that result from running the calibration procedure for the probe changer. You can use this dialog box to change a port's type and XYZ location. For TESASTAR-R / HR-R and Autochange (ACR1) probe changers, you can also use it to edit an extension's XYZ location and edit the rotation angle of the bottom joint.



Example of the Probe Changer Port Data dialog box for an ACR1 Probe Changer.

Some probe changer types support multiple possible configurations for each port. Some example probe changer types that allow this include the Autochange (ACR1) and TESASTAR-R / HR-R.

- When you use a changer that has multiple possibilities for each port, the **Port type** list is active and filled with selections that are appropriate for that changer type.
- To specify the appropriate configuration, choose the appropriate entry from the list. For more in-depth information on the meaning of the selections available for a particular changer type, consult your hardware documentation for the probe changer.
- When port type selections are available, you should set them before you run the calibration procedure for the probe changer. If you change them later, this typically requires a recalibration of the probe changer or at least the individual ports that were changed.

Some probe changer types have port types that let you use empty extensions that do not have actual probes attached. Some example probe changer types that allow this include the Autochange (ACR1) and the TESASTAR-R / HR-R.

- When you use a probe changer that supports empty extensions, and if you have defined a port as **Extension Only**, the **With Empty Extension** area and the **Rotation angle of bottom joint (degrees)** box become active.
- While you can manually enter the XYZ location for the empty extension, this is normally determined from calibrating the probe changer.

- Some extension bars have a bottom joint that is rotated by some amount relative to the top joint. If you use one of these extension bars, you must define the amount of rotation in the **Rotation angle of bottom joint (degrees)** box before you calibrate the probe changer. Changing it later will require re-calibration of the probe changer, or at least the individual ports that were changed.

3. If desired, define separate **Before drop-off** and **Before-pick up** clearance distances in the **Clearance distances** area. For more information, see "About Port Clearance Distances".

4. After you specify the desired values, click **OK**. PC-DMIS closes the dialog box and shows a summary of the specifications for that port in the **Probe Changer** dialog box. If you changed any values, it also indicates "changes pending" for the port.

5. If you want to revert a port to its previous value, you can select that port and then click the **Edit Port Data** button. In the **Probe Changer Port Data** dialog box, click the **Restore XYZ**, **Restore Type**, or **Restore Angle** button as applicable. These buttons are only available if you made changes but have not yet clicked **OK** or **Apply** in the **Probe Changer** dialog box.

6. If you are ready to accept your changes, click **OK** or **Apply** in the **Probe Changer** dialog box.

To Change a Defined Probe Back to the "(no probe)" Default

1. Select the appropriate probe changer from the **Active Probe Changer** list on the **Ports** tab (**Edit | Preferences | Probe Changer**).

2. Double-click on the port to change. A list appears.

3. Select "(**no probe)**" from the list.

To Add or Remove Ports

You can define the number of ports for some types of probe changers.

1. Select the appropriate probe changer from the **Active probe changer** list on the **Ports** tab (**Edit | Preferences | Probe Changer**).

2. Change the value in the **Number of ports** box. (This box is unavailable if your probe changer does not allow you to change the number of ports.)

3. To immediately see the changes, select the **Apply** button.

To Drop off a Probe without Picking Up a New Probe

You may want to drop off the current probe into the probe changer without picking up a new probe from the changer. To do this:

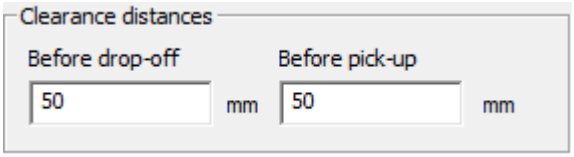
1. Create a dummy probe file in the **Probe Utilities** dialog box (**Insert | Hardware Definition | Probe**) for a probe that doesn't exist. Name it something like "unload".

   > The "dummy" probe used for the unload procedure must be completely defined. For details on how to define a new probe, see the "Defining Probes" topic in the "Defining Hardware" chapter.

2. Click the **Setup** button. The **Probe Setup** dialog box appears.
3. Select this probe file from the **Probe file used with probe changer for unload only** list.
4. Click **OK** to close the **Probe Setup** dialog box.
5. Open the **Ports** tab in the **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**). Ensure that the probe is NOT assigned to any port in the probe changer.
6. Click **OK** to close the **Probe Changer** dialog box.

About Port Clearance Distances

Use the **Clearance distances** area in the **Probe Changer Port Data** dialog box to define two different clearance distances from the port that your machine can use before dropping off and picking up hardware.



Clearance distances Area

You can also define clearance distances and tie them to specific probe tips. To do this:

1. From the menu, select **Insert | Hardware Definition | Probe** to display the **Probe Utilities** dialog box.
2. From the **Probe Utilities** dialog box, click the **Setup** button to display the **Probe Setup** dialog box.
3. Make your changes in the **Clearance distances** area and then click **OK**.

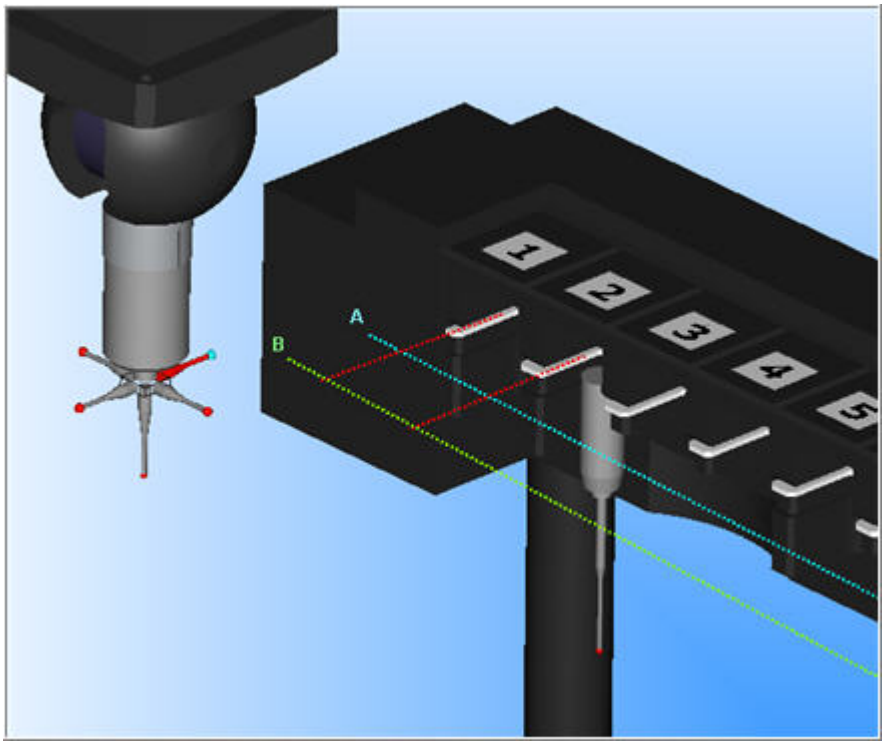
Any probe-specific values defined take precedence over those defined in the **Clearance distances** area. For more information, see "Using Probe-Specific Port Clearance Distances".

In versions prior to PC-DMIS 2009, there was only a single clearance distance that you could specify, and you had to use the PC-DMIS Settings Editor. Now you can define these different distances directly within PC-DMIS. These distances affect the motion during a probe change operation.

Before drop-off - Specifies the clearance distance PC-DMIS uses when the probe is still attached. This distance applies before dropping off a probe to the port, but it also applies after picking up a probe from this port.

Before pick-up - Specifies the clearance distance PC-DMIS uses when there is no probe attached.

The main reason for having these two distinct clearance values available to each port is to better accommodate probe configurations that have a stylus pointing back into the rack. In the example below, the star probe contains a stylus pointing towards the rack. Some example clearance lines are also provided on the image to illustrate the two separate clearance distances.



Example showing the clearance distance before pick-up (line A) and before drop-off (line B).

In these types of probe configurations, you may need an additional clearance distance to move to the clearance location without colliding with other probes stored in the rack. For example, using the sample image above, if you define a mount point in a central area of the rack (such as the area in front of port 4 or 5), then for a probe change that drops off the current star probe in port 1 and picks up the new one from port 2, when moving from the mount point to the clearance location for port 1, a collision could occur between the star probe's stylus that points toward the rack and the probe in port 2. In this case, a **Before drop-off** distance (indicated as line B) would provide the needed clearance. Yet, since that extra clearance distance is no longer needed when moving between the drop-off and pick-up ports with no probe attached, the **Before pick-up** distance (indicated as line A) is also beneficial.

Consider this Example

Again, using the image above, a typical probe change cycle, where the current probe is dropped off into port 1 and a new probe is picked up from port 2, could be described as follows:

1. The machine moves to the defined mount point for the probe changer.
2. The machine moves to the **Before drop-off** clearance location for port 1 (line B).
3. The machine moves into port 1 and drops off the current probe.
4. The machine moves back out to the **Before pick-up** clearance location for port 1 (line A).
5. It moves to the **Before pick-up** clearance location for port 2 (line A).
6. It moves into port 2 and picks up the new probe.

7. It backs out to the **Before drop-off** clearance location for port 2 (line B).
8. It moves back out to the defined mount point.

Affected Probe Changers

Although you can specify these clearance values for almost all tool changer types, it's possible that they may not have any effect in some cases. For some of the machine-specific changer types, where the change cycle is handled by the particular machine interface, it's possible that the interface has not implemented this functionality. Additionally, there may be some machine-specific changer types where the change cycle motion is handled by the machine controller itself and therefore is not under the direct control of PC-DMIS.

Initial Default Clearance Values

You can modify the appropriate entries in the PC-DMIS Settings Editor to change the initial default clearance values for specific probe changer types. These entries are in the **Option** section of the Settings Editor:

- `TCDefaultClearanceBeforeDropoff_<Changer>` - This is the before drop-off clearance distance in millimeters for the probe changer type referred to by <Changer>.
- `TCDefaultClearanceBeforePickup_<Changer>` - This is the before pick-up clearance distance in millimeters for the probe changer type referred to by <Changer>.

For example, a TP20 probe changer would have variable names of:

- `TCDefaultClearanceBeforeDropoff_TP20`
- `TCDefaultClearanceBeforePickup_TP20`

If you have not customized these new variables for a given changer type, PC-DMIS still looks for the possible existence of a customized value from the older clearance-related entry that was available for some types. If found, it applies that value to both clearances until you delete that older variable, or you save the new customized values using the above entries. You should consider these older clearance-related entries as deprecated:

- `AutochangeClearance`
- `ACR3Clearance`
- `FCR25Clearance`
- `SCP80Clearance`
- `TESASTAR-PRClearance`
- `TESASTAR-RClearance`

- `TP20Clearance`

Using Probe-Specific Port Clearance Distances

While you can use the **Probe Changer Port Data** dialog box to define a **Before drop-off** clearance distance for each port in a probe changer, this approach may not provide enough flexibility due to the specific needs of some probe and styli configurations. Sometimes, switching to a new measurement routine may require you to load a different probe configuration into a given port. Your new probe configuration may need a different clearance distance to avoid collisions when entering the port to drop it off or leaving the port after picking it up.

PC-DMIS provides you with the ability to define a clearance distance tied to the probe. This overrides any specified distance in the **Probe Changer Port Data** dialog box.

To Define a Probe-Specific Port Clearance Distance

1. Press F9 on the desired LOADPROBE command in your measurement routine to open the **Probe Utilities** dialog box.
2. Click the **Setup** button to open the **Probe Setup** dialog box.
3. Define a clearance distance in the **Clearance distance for tool changer port when this probe is loaded** box. The value uses the same measurement units as the measurement routine that is currently open.
4. Click **OK** to close the **Probe Setup** dialog box.
5. Click **OK** to close the **Probe Utilities** dialog box.

Any clearance distance that you specify in the **Probe Setup** dialog box overrides the **Before drop-off** value in the **Probe Changer Port Data** dialog box regardless of what port takes the probe. If you do not specify a clearance distance in the **Probe Setup** dialog box, then PC-DMIS uses the value from the **Probe Changer Port Data** dialog box.

With this approach, your probe changer setup can have values that may be adequate for most probes in general. This provides you with the ability to define probe-specific values for other desired probes.

Additional Notes

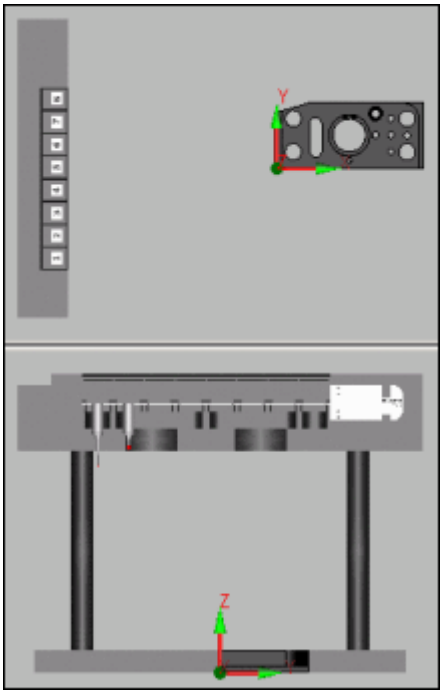
- The intent of this functionality is to avoid complications arising from particular styli configurations. Therefore, if you have a complex probe change operation where the stylus holder/configuration is kept in one port or probe changer and then extensions or other probe bodies are involved from another port or probe changer, this value only applies to the initial drop-off (when unloading) or final pickup (when loading) for the probe when the styli are attached. During intermediate portions of the overall probe change, where no styli are attached, PC-DMIS assumes that you do not need the extra clearance. During such intermediate portions, PC-DMIS uses the clearance value from the general probe changer setup instead.

- This clearance setting is used on the probe changer types that PC-DMIS handles directly (with the exception of the ACR2) in a machine interface-independent manner. For probe changer types where the changer is specific to a particular type of machine, and the change is handled within the associated machine interface, that machine interface may or may not make use of this value.

Showing an Animated Probe Changer

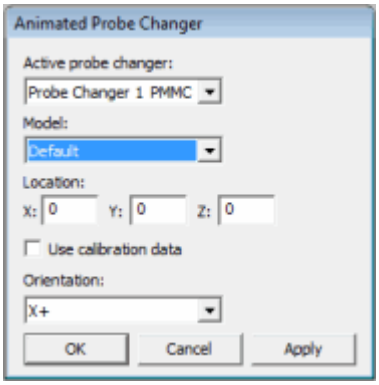
PC-DMIS provides the ability to display an animated graphical representation of a pre-defined probe changer inside the Graphic Display window.

To define a probe changer, see "Defining Probe Changers".



Example of an animated probe changer shown in the Graphic Display window in the Z+ view (top picture) and the X+ view (bottom picture)

Use the **Animated Probe Changer** dialog box (**Insert | Hardware Definition | Animated Probe Changer**) to specify the position and orientation of the probe changer.



Animated Probe Changer dialog box

The items in this dialog box are discussed in the "To Display the Probe Changer in the Graphic Display Window" topic.

To Display the Probe Changer in the Graphic Display Window

1. Access the **Animated Probe Changer** dialog box (**Insert | Hardware Definition | Animated Probe Changer**).

   
   Animated Probe Changer Dialog Box

2. Select an existing pre-defined probe changer from the **Active probe changer** list. If you don't see any probe changers in this list, you can define a probe changer from the "Defining Probe Changers" topic in the "Defining Hardware" chapter.

3. The **Model** list allows you to animate a custom model of a PMMC probe changer. This list only becomes available for selection if you first select a PMMC probe changer from the **Active probe changer** list. The **Default** entry in the **Model** list is the standard PMMC model supplied with the PC-DMIS install. For custom items to appear in the **Model** list for selection, you need to first configure a customized PMMC model. To do this, follow the instructions in the "To Load in a Custom PMMC Probe Changer" topic.

4. Define the location and orientation of the probe changer. You can do this by either using calibration data for the location and orientation or by specifying the XYZ location and orientation directly into the dialog box.

   - To use existing calibration data select the **Use calibration data** check box. PC-DMIS fills in the location boxes with the XYZ values from the calibration.

- *To directly specify the location and orientation*, type values into the **X**, **Y**, and **Z** boxes, and then select an orientation from the **Orientation** list.

5. Click **Apply**. PC-DMIS draws the animated probe changer in the specified position and orientation in the Graphic Display window. PC-DMIS also inserts a `LOADPROBECHANGER` command into the Edit window.

6. Click **OK** when you're satisfied with the orientation and position.

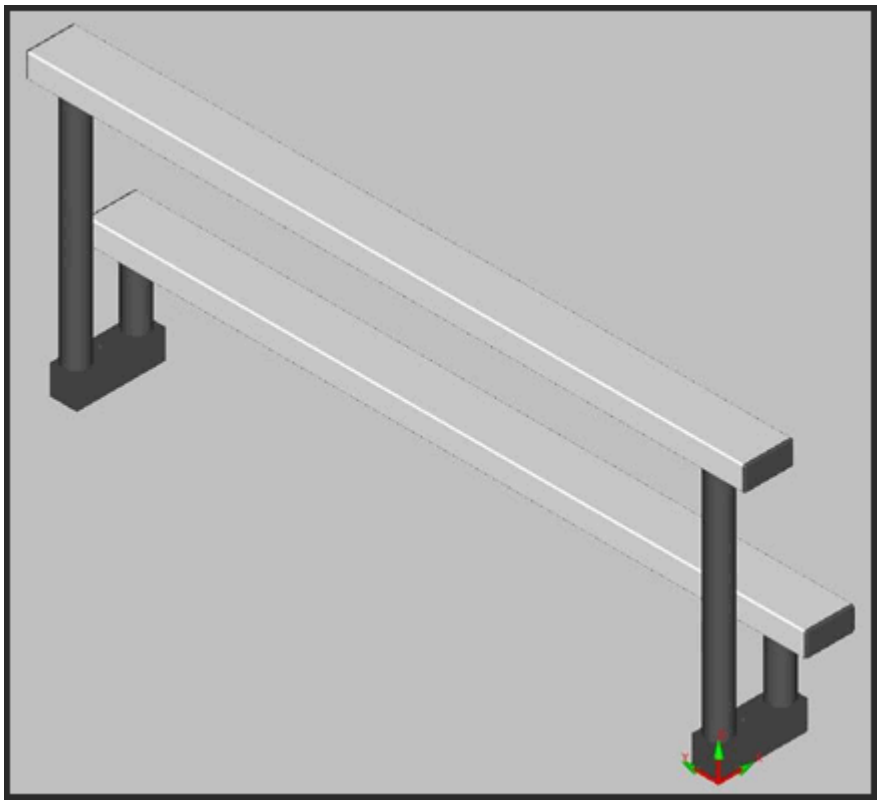
To Delete the Probe Changer from the Graphic Display Window

Access the Edit window, and delete the `LOADPROBECHANGER` command. This doesn't delete your pre-defined changer, just the animation of it inside the Graphic Display window.

To Load in a Custom PMMC Probe Changer Model

A custom PMMC probe changer model consists of two parts: the rack and the port or ports. These models have the following requirements:

- They need to be stored in a ".draw" file format.
- They need to have a consistent 0,0,0 coordinate-system location. This needs to be defined in the model's CAD creation software *before* you import the model into PC-DMIS. The trihedron in this image indicates where this position should be defined:

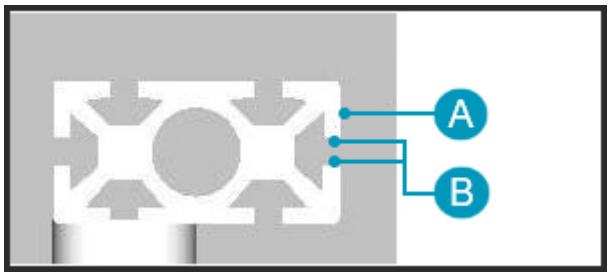


A sample Two-Tier PMMC model showing the 0,0,0 position (Red and Green trihedron).

- All the geometry must be stored in one CAD level.

You can load a custom PMMC Probe Changer model into PC-DMIS by following this procedure:

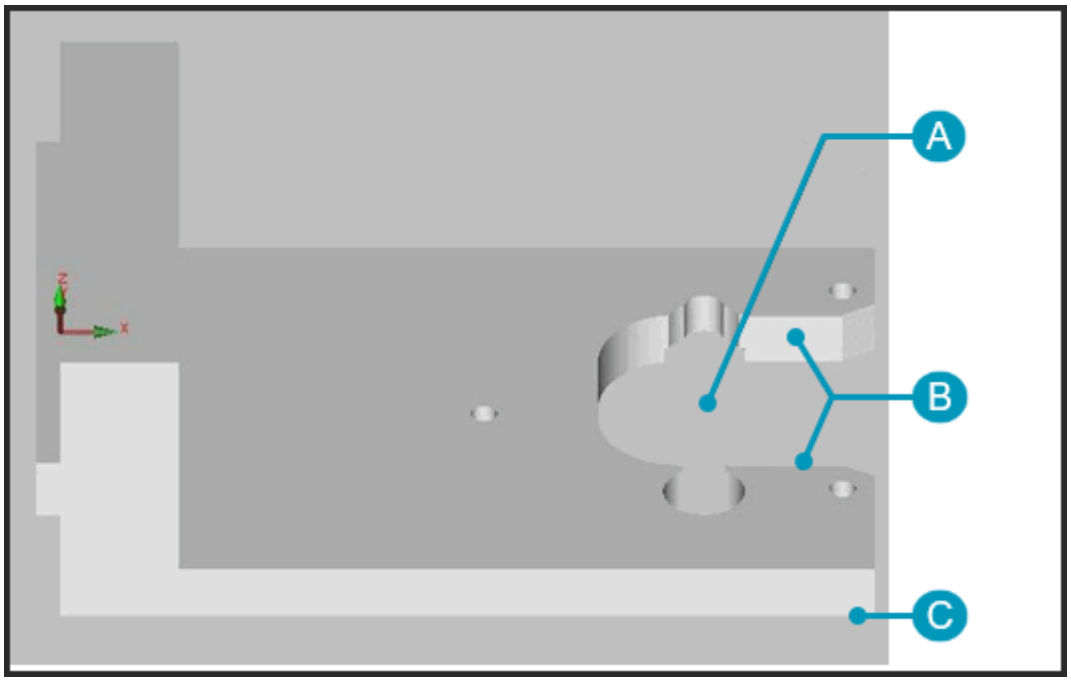
1. Create a new measurement routine.
2. Import the custom model files into PC-DMIS as you would a standard part model. PC-DMIS generates a .cad file for the model during import.
3. Find out what X and Z values should be for the rack. The Y value is not needed.



A sample model of the rack.

   - To determine the X value, measure a point on the surface, indicated by **A** in the above graphic. Make a note of the X value.
   - To determine the Z value, measure the midpoint between the two surfaces, indicated as **B** in the graphic above. Make a note of the Z value.

4. Find out what the X, Y, and Z values should be for the port.



A sample model of the port.

   - To determine the X value, measure the center point of the port opening, indicated by **A** in the above graphic. Make a note of the X value.

- To determine the Y value, measure the mid-point between the two surfaces, indicated by **B** in the above graphic. Make a note of the Y value.
- To determine the Z value, measure the bottom surface of the port, indicated by **C** in the above graphic. Record this value somewhere. Make a note of the Z value.

5. Inside Windows Explorer, rename the ".cad" extension to a ".draw" extension.
6. Copy and paste these .draw files into the same directory where the model files that ship with PC-DMIS are located. By default, these are located in the "Models\Toolchangers\" sub-folder under the PC-DMIS install directory.
7. Create an empty text file named userprobechanger.dat in the same directory as the probechanger.dat file. This should be in the "C:\ProgramData\Hexagon\PC-DMIS\2026.2" folder.
8. Open the userprobechanger.dat file inside of a text editor, and configure its contents so that a custom model entry follows the format given below. Items in angle brackets indicate where you would put your own text:

```
   ITEM:<DRAW FILE NAME> ARM
   comment lower <Rack X> 99999 <Rack Z>
   comment garage <Port X> <Port Y> <Port Z>
leitz_Ref_2-Tier_port.draw
   cadgeom 0 0 0 1 0 0 0 1 0 0 0 1 1 <DRAW FILE
NAME>.draw
```

`<DRAW FILE NAME>` - The name of the .draw file (without the .draw filename extension).

`<Rack X>` - The X value of the rack from step 3 above.

`<Rack Z>` - The Z value of the rack from step 3 above.

`<Port X>` - The X value of the port from step 4 above.

`<Port Y>` - The Y value of the port from step 4 above.

`<Port Z>` - The Z value of the port from step 4 above.

For example, a finished entry in the userprobechanger.dat file for a single-tier rack might look something like this:

```
   ITEM:Custom_Model ARM
   comment lower 110.798 99999 394
   comment garage 82.75 4.675 -19 leitz_Ref_2-
Tier_port.draw
   cadgeom 0 0 0 1 0 0 0 1 0 0 0 1 1 Custom_Model.draw
```

For information on defining a two-tier rack, see the sub-topic below.

9. If you followed the above procedure correctly, your custom PMMC model should now appear in the **Model** list of the **Animated Probe Changer** dialog box. See the "To Display the Probe Changer in the Graphic Display Window:" topic.

Defining a Two-Tier Rack

PC-DMIS also supports a two-tier rack (shown above in the first image of this topic). The line "comment upper <Rack X> 99999 <Rack Z>" is used to specify the upper tier on this type of rack. Therefore, a two tier model would require your entry in the .dat file to include both "comment upper" and "comment lower" lines, while a single-tier rack would need to include the "comment lower" line.

For example, the following entries show a two-tiered rack definition followed by a single-tiered rack definition:

```
ITEM:Leitz_Ref_2-Tier ARM
comment upper 82.5 99999 447.7
comment lower 182.5 99999 162.7
comment garage 82.75 4.675 -19 leitz_Ref_2-Tier_port.draw
cadgeom 0 0 0 1 0 0 0 1 0 0 0 1 2 Leitz_Ref_2-Tier.draw
ITEM:Reference_Frank ARM
comment lower 110.798 99999 394
comment garage 82.75 4.675 -19 leitz_Ref_2-Tier_port.draw
cadgeom 0 0 0 1 0 0 0 1 0 0 0 1 1 Reference_Frank.draw
```

Protecting Probes from Probe Changer Collisions

Depending on a variety of circumstances, including user errors, there’s the possibility that a physical crash happens during a probe change cycle. PC-DMIS provides multiple levels of protection against that event.

To avoid a collision in this situation, you can add this line of code to your measurement routine to enable the probe changer safety feature option:

```
ASSIGN/RESERVED_TOOLCHANGE_SAFETY_MODE=1
```

When you enable this entry and you have the above line of code in your measurement routine, if PC-DMIS detects that the wrong probe is loaded in the pickup slot of the probe changer than what is expected, it issues a warning message similar to this:

Click **OK** to continue without making any changes.

If you decide not to use this collision avoidance feature and PC-DMIS performs the probe change as described in the above scenario, it may cause a collision and result in damage to your equipment.

Click **Cancel** to end the execution of the measurement routine. With the execution of the measurement routine ended, you can fix the issue and then restart the measurement routine.

Working with Rotary Tables

Except where specified, the following Rotary Table commands were developed to support the PC-DMIS/NC (Numerical Control) for use on CNC machine tools. However, you can use them in regular CMM measurement routines as well. For more information on how to use CNC machines with PC-DMIS, see the PC-DMIS/NC Help file.

Ignore Rotary Table

When you have a rotary table defined for use, PC-DMIS usually assumes that you place the parts to measure on the rotary table. Essentially, PC-DMIS expects you to use the rotary table.

With the `IGNOREROTAB` command, you can determine whether the measurement routine uses the rotary table.

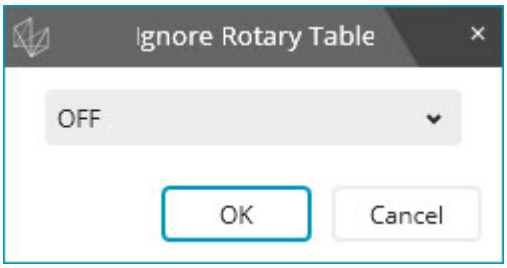
To insert an `IGNOREROTAB` command into the measurement routine, select **Insert | Parameter Change | Probe | Ignore Rotary Table**.

You can also insert an `IGNOREROTAB` command:

- When you type `IGNOREROTAB` and you are in Command Mode.
- When you are in Summary Mode, right-click and select **Add Command** to open the **Add Command** dialog box. From the dialog box, select **Ignore Rotary Table** and click **OK**.

Modify Ignore Rotary Table command in Summary Mode and Command Mode

You can press F9 on the `IGNOREROTAB` command to open the **Ignore Rotary Table** dialog box.



Ignore Rotary Table Dialog Box

From the list, select either **OFF**, **ON**, or **CALIBRATION**.

The options are as follows:

IGNOREROTAB/OFF

This command means PC-DMIS does not ignore the rotary table. In this state, PC-DMIS adjusts any measured data collected from the machine by using the data from the rotary table's calibration. This is the default state. If you want to measure parts with the use of a rotary table, you do not need to add this command.

```
IGNOREROTAB/OFF
```

IGNOREROTAB/ON

This command means PC-DMIS ignores the rotary table. Thus, the measured data that PC-DMIS collects does not have a rotary table adjustment applied to it. This might be used when a part that you want to measure is placed on a CMM table and not on a rotary table. You want to measure the part without using the rotary table even though your table exists.

```
IGNOREROTAB/ON
```

IGNOREROTAB/CALIBRATION

This command means PC-DMIS ignores the rotary table. You can use this command when you want to calibrate the rotary table.

```
IGNOREROTAB/CALIBRATION
```

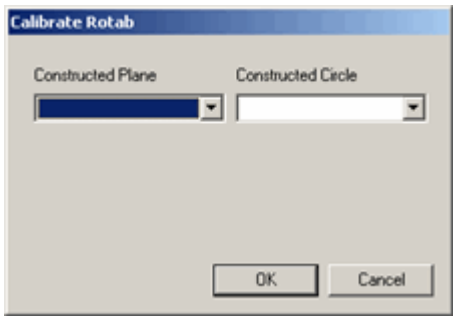
How to calibrate the rotary table using measurement routine

To calibrate the rotary table, follow these steps:

1. Attach a proper calibration artifact (a sphere) to the rotary table.
2. Add the `IGNOREROTAB/CALIBRATION` command to your measurement routine.
3. Measure the sphere at three or more positions of a rotary table.
4. Construct a plane through the resulting sphere centers.
5. Create an alignment to level this constructed plane to the axis of rotation of the rotary table.
6. Construct a circle through the resulting sphere centers.
7. Once you have constructed the plane and circle, you can use them as inputs to the `CALIBRATEROTAB` command.
8. Insert the `CALIBRATEROTAB` command. To insert the command, select the **Insert | Calibrate | Rotary Table from Features** menu item.

   ```
   CALIBRATEROTAB/PLANE=TABLE_PLN, CIRCLE=TABLE_CIR,
   MEAS/XYZ=0,0,0, MEAS/IJK=0,0,0
   ```

   This command tells a suitable measurement routine to calibrate the rotary table during measurement routine execution.
9. Press F9 on the command to display the **Calibrate Rotab** dialog box.



Calibrate Rotab Dialog Box

10. From the **Constructed Plane** list, select the constructed plane in step 4. From the **Constructed Circle** list, select the constructed circle in step 6.
11. Click **OK**. PC-DMIS updates the command to use the constructed features.
12. When you execute the measurement routine, PC-DMIS uses the constructed features to update the rotary table calibration data. The `MEAS/XYZ` and `MEAS/IJK` portions in the command block show the result for the center point and plane of rotation for the table.

For information on how to set up your rotary table, see the "Defining the Rotary Table" topic in the "Setting Your Preferences" chapter.

Rotate the Table to the Active Angle (Not Supported in PC-DMIS NC)

The actual rotary table angle on the machine and the active angle specified in your measurement routine don't always match. The **Operation | Rotate Table to Active** menu item automatically causes the actual table to rotate until its angle matches the active angle in the measurement routine at your cursor's location.

Configuring Advanced Mouse Devices

Most PC-DMIS systems use a standard mouse and keyboard configuration. Your setup may have more advanced hardware, such as a ZMouse or a 3D Mouse or motion controller. To configure those devices, see the topics below:

Configuring a Z-Rail Mouse

Certain systems offer a track ball style of mouse referred to as a ZMouse. This enables you to control the movement of the mouse pointer from the Z rail.

The last line of the parameter file (DOWNLOAD) should read:

N1000 ZMOUSE2
or
N500 ZMOUSE2

To enable the ZMouse, verify that the last line of the DOWNLOAD file reflects the above statement. Modify the line, if necessary.

Configuring 3Dconnexion 3D Mouse Devices

3Dconnexion 3D Mouse devices communicate with PC-DMIS through the 3DxWare interface. Information can be found in the following topics.

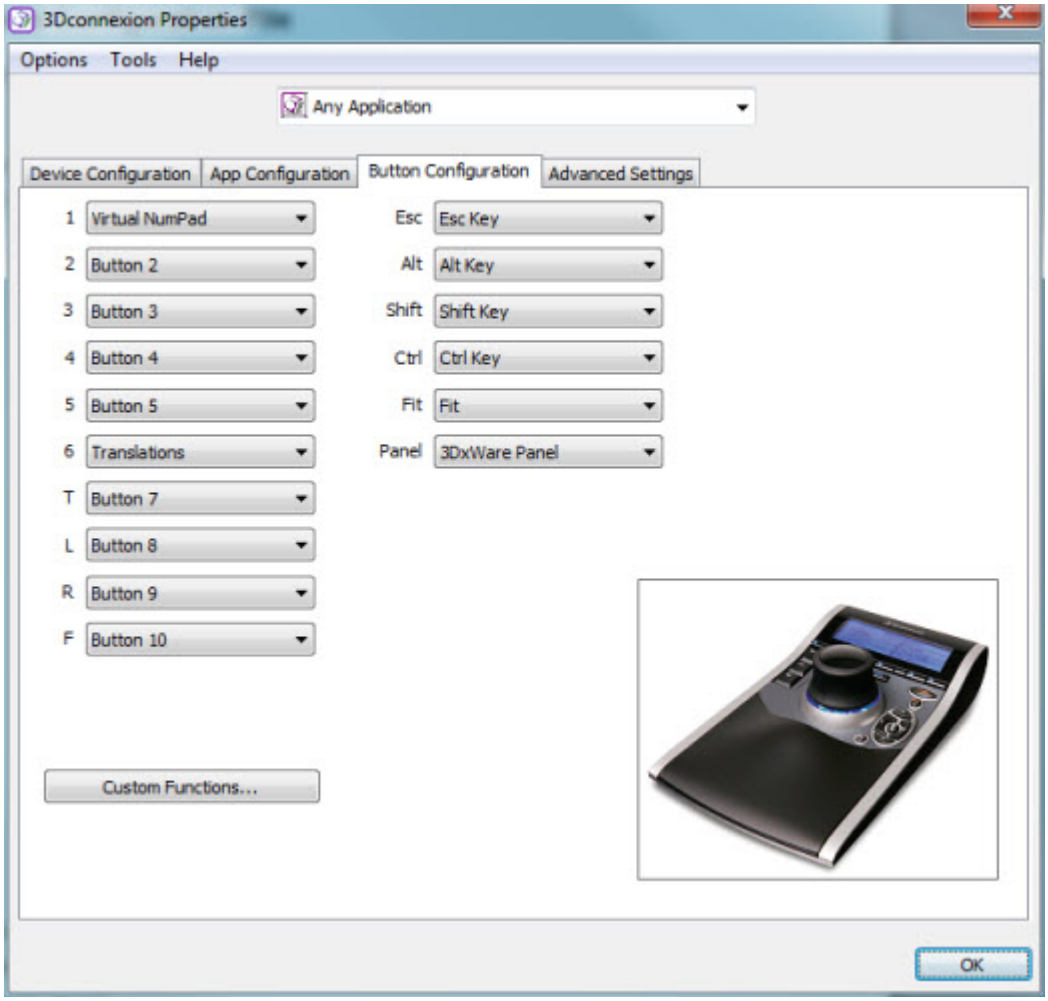
Contact a 3DConnexion representative for support on these devices.

Please contact Hexagon Technical Support for any 3rd-party files you may need for your hardware.

Editing the 3DxWare Configuration File

1. Start the PC-DMIS application.

2. Double-click the 3DxWare icon on your system tray to open the **3Dconnexion Properties** dialog box.



3Dconnexion Properties Dialog Box

   a. See if the **Application** list in the top-center of the **3Dconnexion Properties** dialog box contains an entry for something like "WAI Applications".

   b. If "WAI Applications" is available, then select it as the current configuration, and follow the information in the topic "Assigning Functions to Buttons on 3Dconnexion 3D Mouse Devices". Otherwise, continue with this procedure.

   c. If "WAI Applications" is not available, and you only see "Any Application", select **File | Save As** and save the name of the "Any Application" configuration to "My PC-DMIS", "WAI Applications", or whatever you like. PC-DMIS uses this configuration to define the rotation speed and other settings.

   d. Close the **3Dconnexion Properties** dialog box.

3. Close your PC-DMIS application.

4. Navigate to this directory, where <user> is your Windows user name:

   C:\Users\<user>\AppData\Roaming\3Dconnexion\3DxWare\profiles

5. Use a text editor (such as Microsoft WordPad or Notepad) to edit the most recent "user??.scg" file (for example, user00.scg).
6. In the "[IDENTIFICATION]" section of this file, compare the "APPLICATION_NAME" to what you entered in step 2c above to verify this is the file you just saved. Note that a comma might be preceded by a backslash (\).

   ```
   [IDENTIFICATION]

   APPLICATION_NAME = "My PC-DMIS"
   ```

7. In the "[CONFIGURATION]" section, edit the "APP_CONTROLS_BUTTONS" and "EXECUTABLES" values to enable them for use with the PC-DMIS executable.

   ```
   [CONFIGURATION]

   APP_CONTROLS_BUTTONS = TRUE

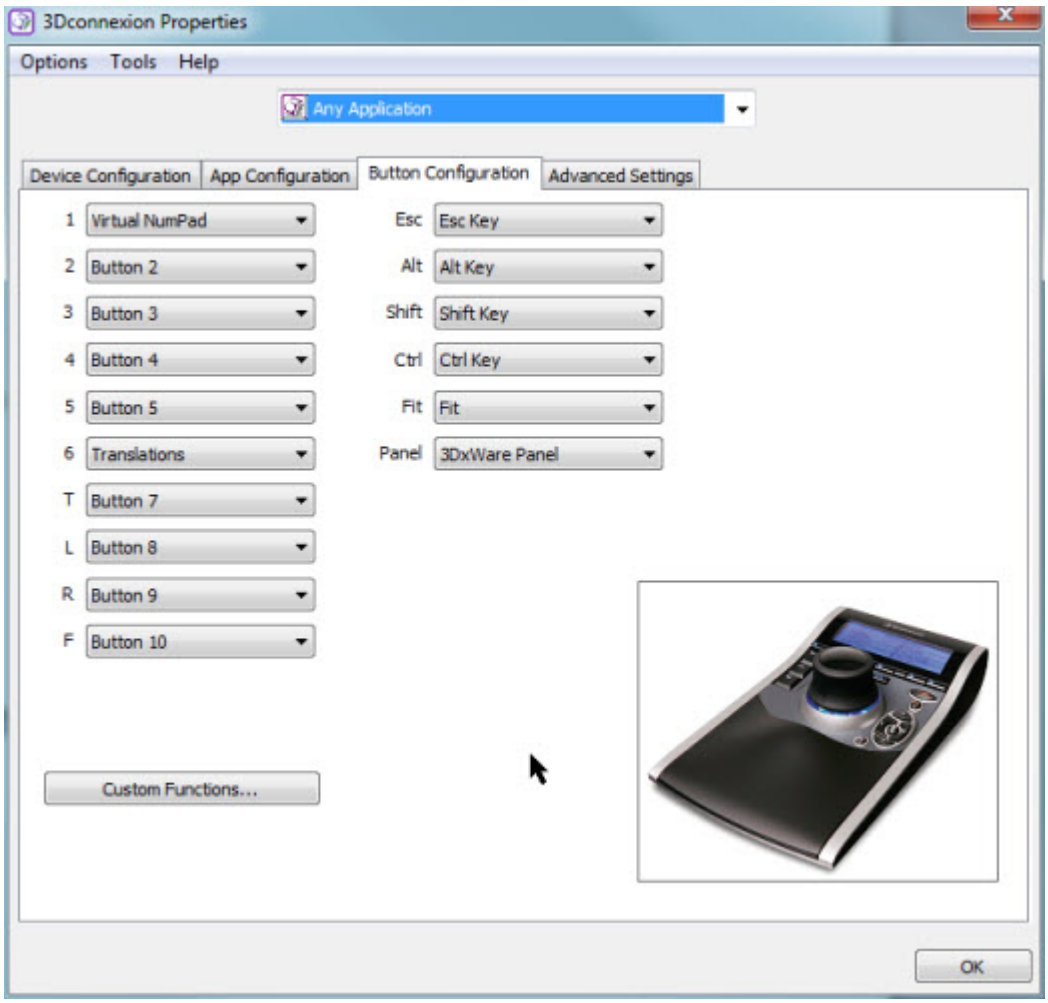
   EXECUTABLES = { "PCDLRN.exe"}
   ```

8. As you can see, the above "EXECUTABLES" indicates that this configuration file is used by PC-DMIS.
9. Save and close the file.
10. Follow the information in the "Assigning Functions to Buttons on 3Dconnexion 3D Mouse Devices" topic to map custom functions to your device's buttons.

Assigning Functions to Buttons on 3Dconnexion 3D Mouse Devices

This topic describes how to map PC-DMIS or PC-DMIS Planner functionality to the available buttons on 3Dconnexion 3D Mouse devices by using the **3Dconnexion Properties** dialog box.

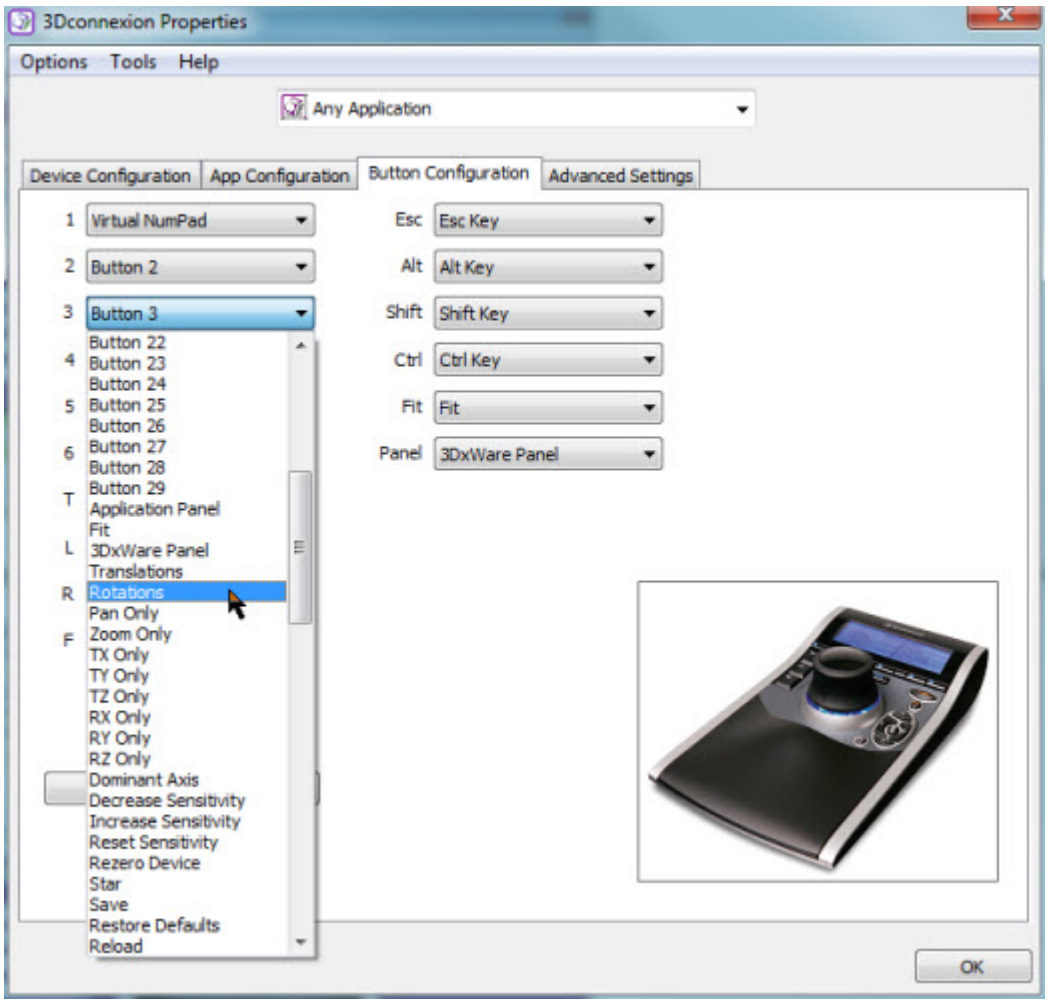
1. Start PC-DMIS or PC-DMIS Planner.
2. Load a measurement routine.
3. Double click the 3DxWare icon located in your System Tray. The **3Dconnexion Properties** dialog box opens showing a graphical depiction of your motion device.



3Dconnexion Properties dialog box showing a SpacePilot Device

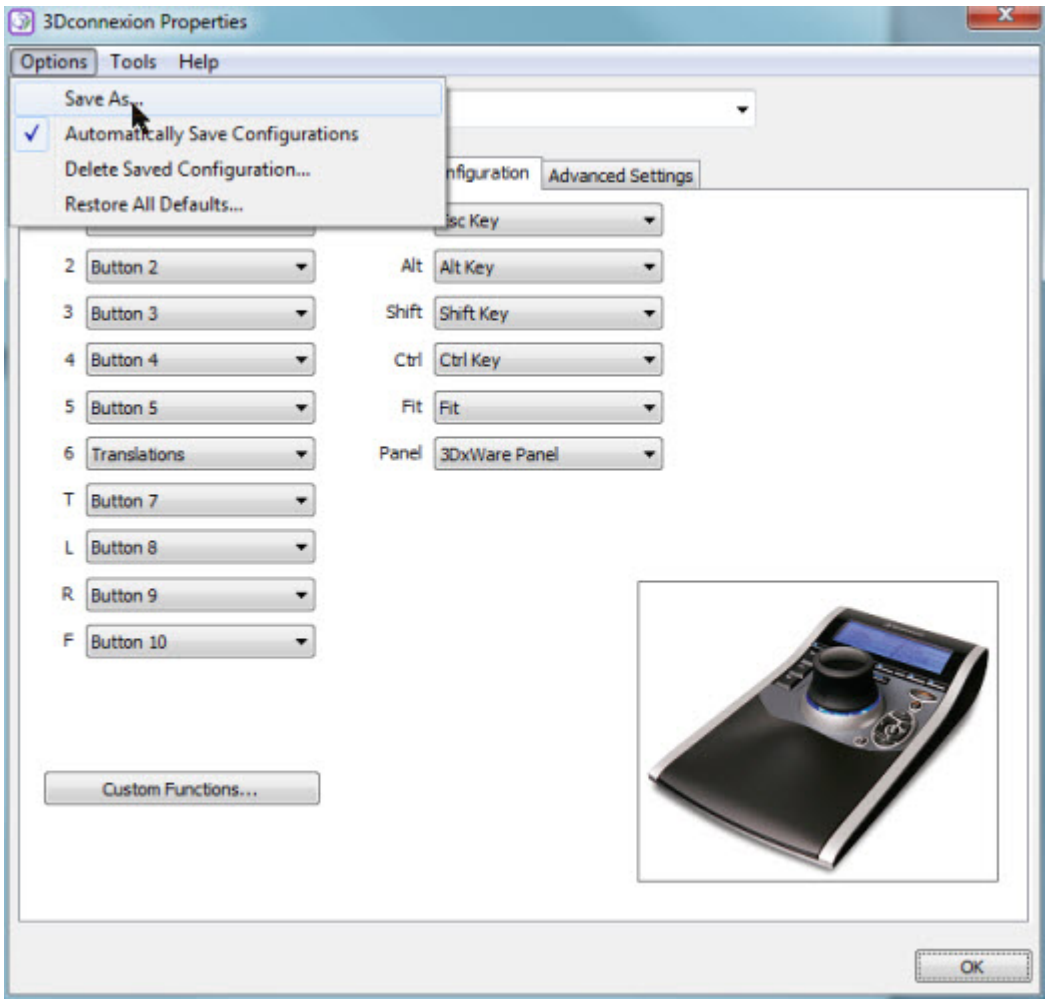
4. Select the correct configuration name from the **Application** list in the top-center of the **3Dconnexion Properties** dialog box. If a relevant name doesn't appear in the list, you probably need to add it to the 3DxWare configuration file. See "Editing the 3DxWare Configuration File".

5. To change map functionality to a button, select the button's list, click the down arrow icon to its right, and select the new function from the list.



3Dconnexion Properties dialog box for SpacePilot Showing Mapping of a Button

6. If the **Configuration | Automatically Save Configurations** menu item is checked, your changes will be saved in your current configuration file.



3Dconnexion Properties dialog box with the Automatically Save Configuration Menu Checked

7. Make any other changes as needed.
8. Click **OK** to accept your configuration and close the dialog box.

3Dconnexion 3D Mouse Device Modes

These devices are always in a certain mode. PC-DMIS displays a symbol in the lower right corner of the Graphic Display window to indicate the current mode for CAD PZR, PC-DMIS pan, or PC-DMIS Zoom.

Standard Modes

- Show cursor
- CAD PZR
- PC-DMIS rotate
- PC-DMIS pan
- PC-DMIS zoom

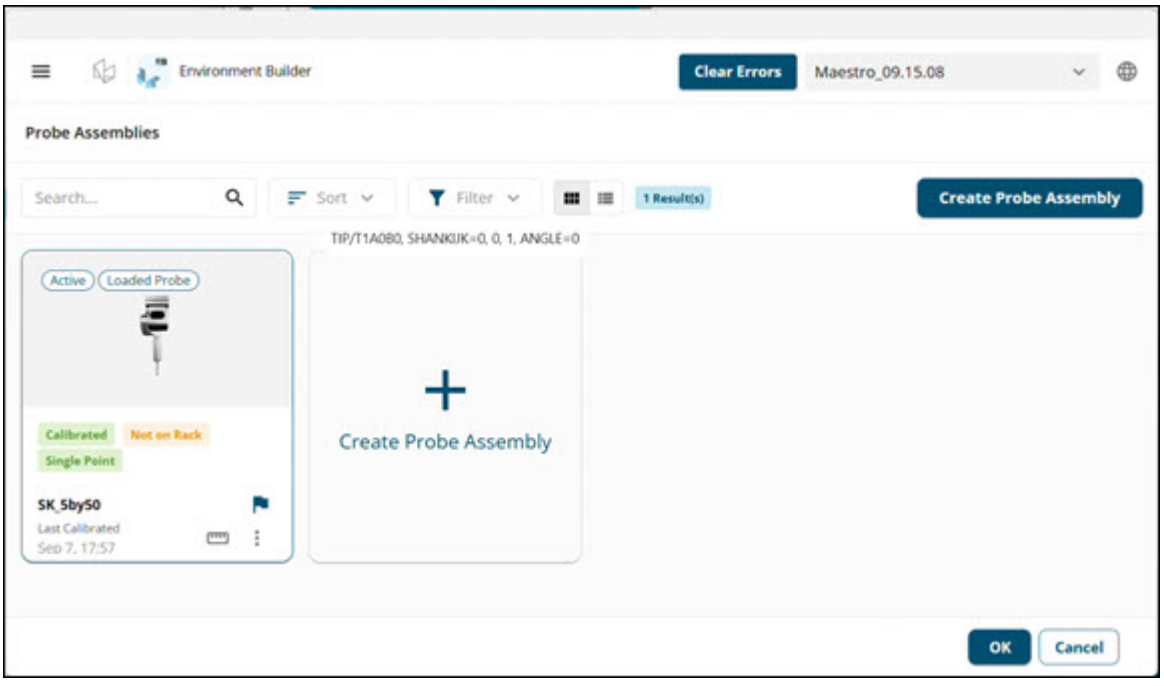
- CAD PZR dominant - The image in the lower-right corner of the Graphic Display window displays a "1" to signify that you can only use one of the three functions (Pan, Zoom, or Rotate) at a time.

Demo Mode

These devices can also place the Graphic Display window into a Demo mode. This mode causes the Graphic Display window to rotate automatically several times a second. To enter or exit the Demo mode, press the Ctrl key, and then press the programmed **Scale to Fit** button on the device.

Working with Environment Builder

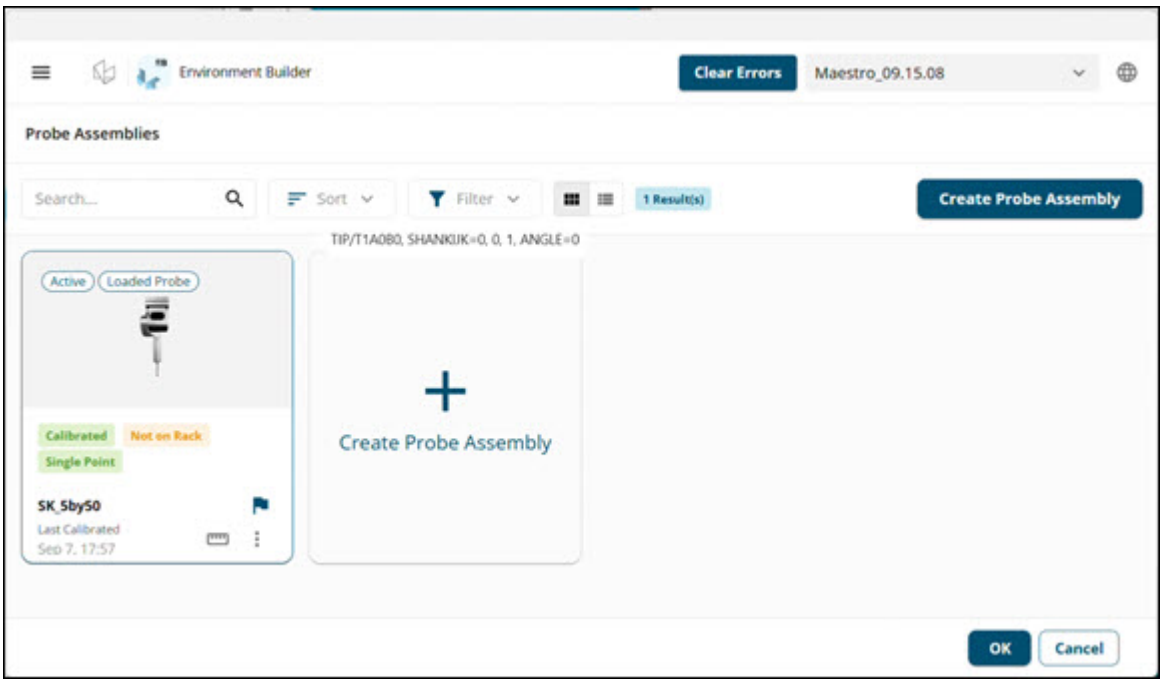
This section of the PC-DMIS documentation explains how to use the Environment Builder tool to define, build, and edit probe assemblies, probe changers, and machines for Maestro CMM users.



Environment Builder Window

Environment Builder - Getting Started

If you are a Maestro CMM user, your system must be properly configured to use the Environment Builder tool. An Applications Engineer should have already configured your system. If this is not the case, reach out to Hexagon Manufacturing Intelligence Customer Support.



Environment Builder Dialog Box

When your system is configured for a Maestro CMM, you can open the Environment Builder tool in these ways:

- Each time you create a new PC-DMIS measurement routine, the **Environment Builder** tool opens automatically.
- When your cursor is on the `LOADPROBE` command in the Edit window, press the F9 key to open the Environment Builder tool.
- You can press the keyboard combination of Ctrl + Alt + P to open the Environment Builder tool anywhere within the PC-DMIS environment.
- You can select the PC-DMIS **Insert | Hardware Definition | Probe** menu option to open the Environment Builder tool.
- You can select the PC-DMIS **Operation | Calibrate/Edit | Probe Changer** menu option to open the Environment Builder tool.

To prevent loss of data, before you open the Environment Builder tool, make sure you save your PC-DMIS measurement routine.

Be aware that when you modify probe assembly settings, it can affect measurement accuracy and efficiency of your measurement routine.

Tips for Efficiency

Familiarize yourself with the keyboard shortcuts (such as the F9 key and the Ctrl + Alt + P key combination) so you can quickly access the Environment Builder tool.

Use the calibration and editing features of the Environment Builder tool to maintain optimal performance of your probe assemblies.

The Environment Builder Menu

To open the slide-out menu panel, select the menu button ( ) in the upper-left corner of the window. Use the panel to open any page of Environment Builder:

- **Probe Assemblies** – This page shows the probe assemblies defined for the current machine. For information on how to create probe assemblies, see "Creating Probe Assemblies".
- **Results** – This page shows the results of your probe assembly calibrations. For information on how to review calibration results, see "Reviewing Calibration Results".

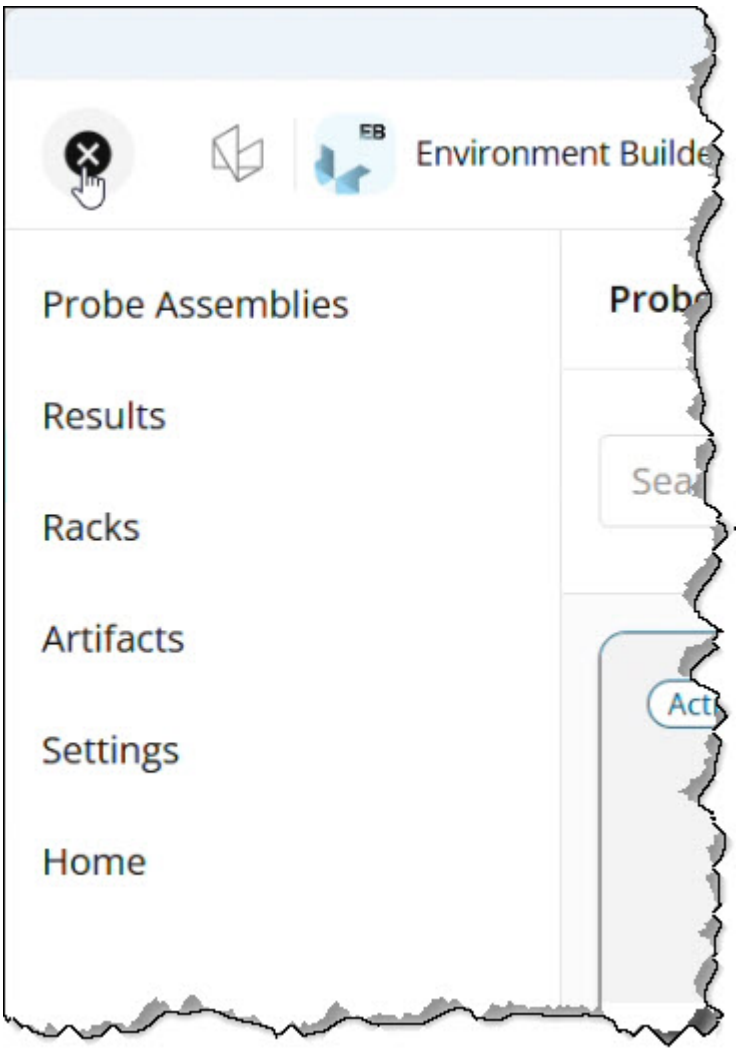
  This option is not available in offline mode.

- **Racks** – This page shows the probe changers on the CMM table and the probe assemblies assigned to them. For information on probe changers, see "Probe Changers".
- **Artifacts** – This page shows the calibration artifacts on the CMM table. For information on how to add calibration artifacts, see "Adding Calibration Artifacts in Environment Builder".
- **Settings** – Use this page to configure the calibration limits, clearances, and interface preferences that Environment Builder applies. For information on how to configure Environment Builder settings, see "Configuring Environment Builder Settings".

  This option is not available in offline mode.

- **Home** – Use this page to set up the machine and probe head that your environment is built around. For information on how to set up your machine, see "Setting Up Your Machine".

To hide the panel, select the **Close** button ( ). You cannot open the menu while a calibration is in progress.

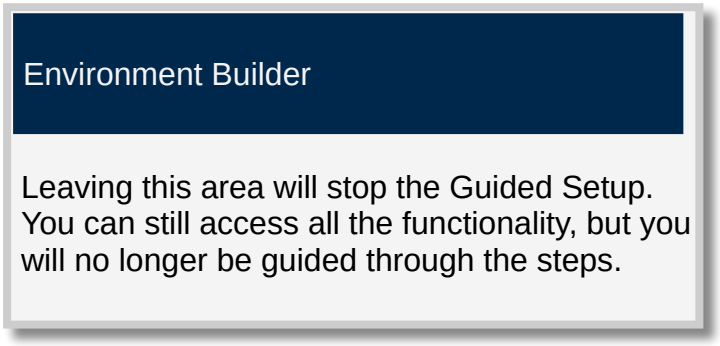


Using the Guided Setup

The first time you use Environment Builder, it offers a Guided Setup that guides you through the minimum steps required to set up a working environment. The Guided Setup includes these steps, in order:

- **Machine Setup** – In this step, you select the machine and probe head.
- **Reference Probe** – In this step, you build the probe assembly that Environment Builder uses as the reference probe for calibration.
- **Choose Artifact** – In this step, you select and place a calibration artifact.
- **Measure Artifact** – In this step, you measure the artifact you placed.
- **Choose Rack** – In this step, you select and place a probe changer.
- **Measure Rack** – In this step, you align and calibrate the probe changer.

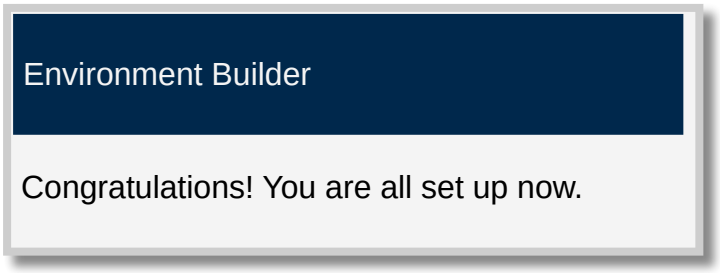
Select **Continue to Rack Setup** to move from the artifact steps to the rack steps. Environment Builder keeps you in the Guided Setup until you complete it. If you navigate away from the setup, Environment Builder displays the following confirmation message:



Select **Yes, leave** to exit the Guided Setup, or select **Cancel** to remain on the page.

When Environment Builder runs in offline mode, the Guided Setup skips the calibration steps. If the connection to the machine changes while you are using the Guided Setup, Environment Builder notifies you that the setup steps have changed and retains the data you already entered.

When you complete all the steps, Environment Builder displays the following message:



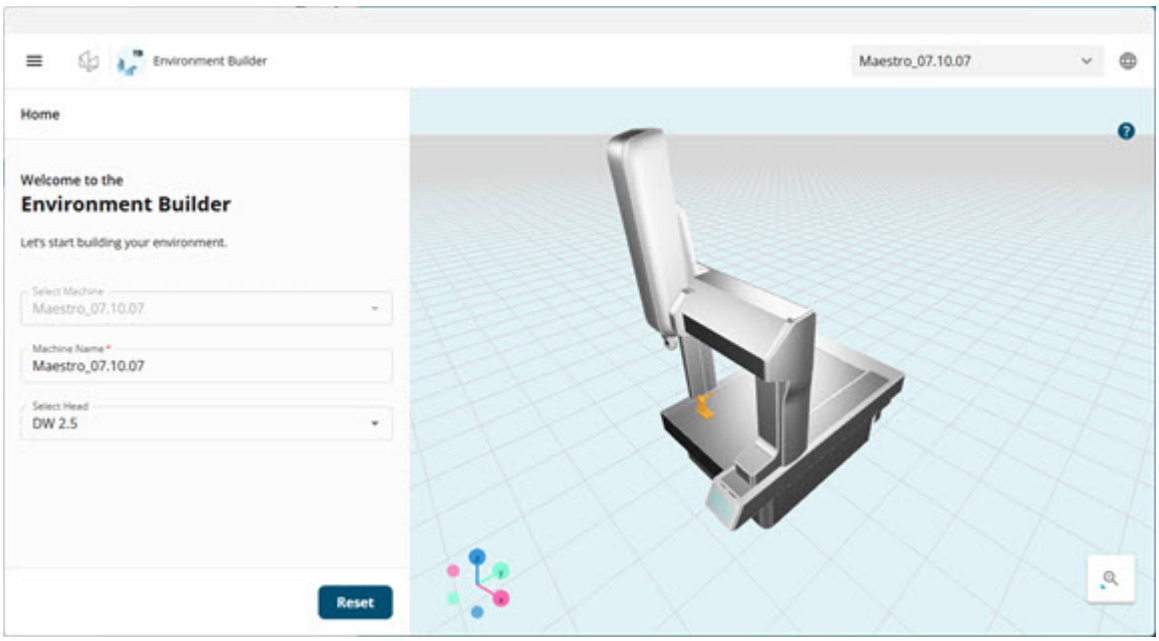
Select **Let's Get Started** to begin working.

Setting Up Your Machine

The **Home** page is where you select the CMM and the probe head that Environment Builder uses to build your environment. Environment Builder shows the **Home** page the first time you start the tool, and you can return to it at any time.

To set up your machine:

1. Open the slide-out menu panel and select the **Home** menu option.
2. From the **Select Machine** list, select your CMM. If Environment Builder detects your machine, it displays the message "Machine is auto-detected." and selects the machine automatically.
3. In the **Machine Name** box, type a nickname that identifies the machine.
4. From the **Select Head** list, select the probe head installed on the machine.
5. Select the **Save Machine** button.



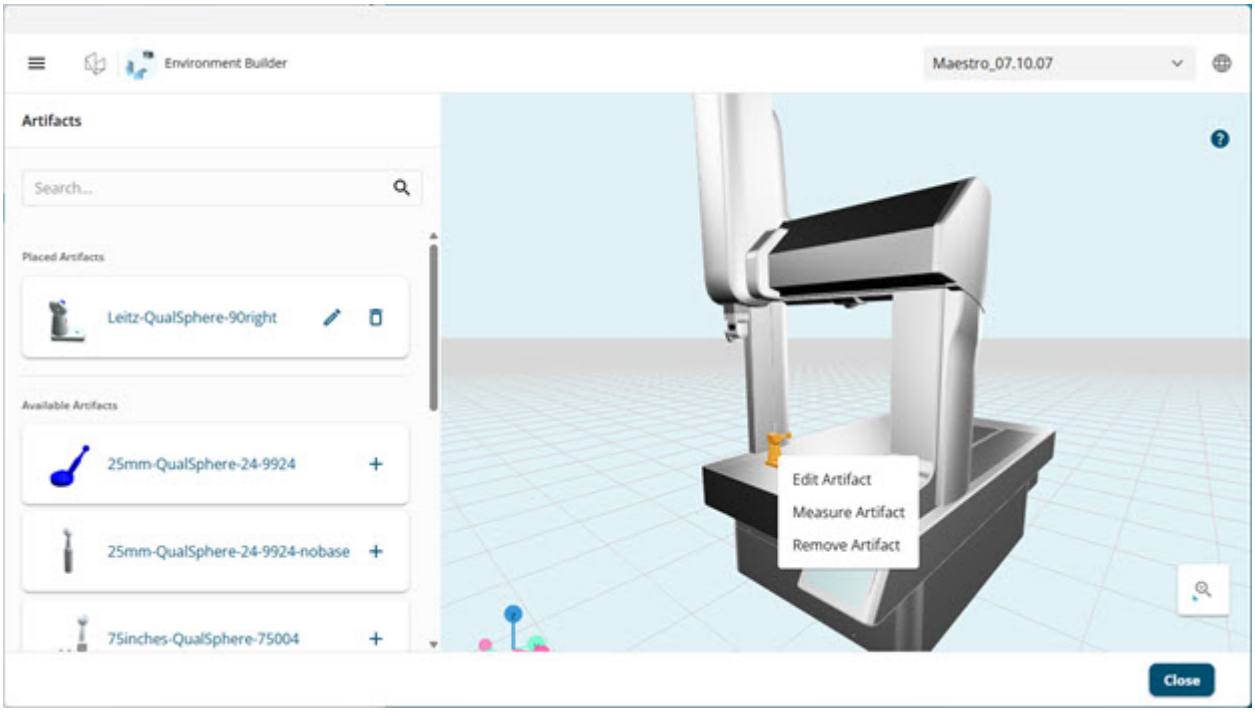
Machines that you have already defined appear under **Available Machines**. Select **New Machine** to define another machine, or select **Delete Machine** to remove a machine. If you delete the machine that you are currently using, Environment Builder resets the environment.

- Changing the probe head on a saved machine affects the probe assemblies. If the new head has the same connection type as the current head, Environment Builder updates the probe assemblies to use the new probe head. Otherwise, Environment Builder deletes the probe assemblies. In both cases, Environment Builder also deletes all probe calibrations and rack assignments.
- After you complete the initial setup, Environment Builder locks the machine selection. Select the **Reset** button to clear the selection.
- Your license limits the number of machines that you can define. When you reach this limit, Environment Builder displays the following message: "Upgrade your license to create more machines."
- Machine selection is unavailable when Environment Builder runs in the read-only user role. For information on the read-only user role and offline mode, see "Working in a Read-Only Role or Offline".

To configure how Environment Builder connects to the machine, select the **Settings** menu option, open the **Machine Configuration** tab, and then configure the **Controller Type**, **Firmware Type**, **CMM IP Address**, and **CMM IP Port**.

Navigating and Working in the 3D Scene

Environment Builder shows your machine, probe changers, calibration artifacts, and probe assemblies in an interactive 3D scene.



Example of a context menu for a selected calibration artifact in the 3D scene.

Help - To view the mouse controls currently in effect, hover over the question mark icon. Environment Builder supports two sets of mouse controls. To change the mouse control, open the slide-out menu panel, select the **Settings** menu option, and then select the **Mouse Controls** tab:

- **PCDMIS FUSION** – Drag with the left mouse button to orbit, drag with the right mouse button to pan, and scroll the mouse wheel to zoom in or out. This is the default option.
- **PCDMIS** – Drag with the middle mouse button (mouse wheel) to orbit, drag with the right mouse button to pan, and scroll the mouse wheel to zoom in or out. In this mode, the wheel zooms in the opposite direction to match PC-DMIS.

In both modes, you can hold the Ctrl key and drag with the right mouse button to orbit instead of pan. On a touch device, drag with one finger to orbit, drag with two fingers to zoom, and hold the spacebar while you drag with one finger to pan.

Camera Focus - Select **Camera Focus** and then select the object you want to center in the 3D scene.

To open a context menu, right-click in the 3D scene. The contents of the menu depend on the object you right-click:

- The CMM table – **Add Artifact**, **Add Rack**, and **Create Probe Assembly**.
- A calibration artifact – **Edit Artifact**, **Measure Artifact**, and **Remove Artifact**.
- A probe changer – **Edit Rack**, **Measure Rack**, **Place Probe Assembly**, **Clear Rack**, **Remove Rack**, and **Switch On** or **Switch Off**.
- A module on a probe changer – **Edit Module** and **Remove Module**.
- A probe assembly on a probe changer – **View Probe Assembly** and **Clear Port**.

Select **Hide 3D Scene** to collapse the scene and provide more space for the rest of the window. Select **Show 3D Scene** to display the scene again.

When you position racks and artifacts, Environment Builder indicates whether snapping is enabled or disabled by displaying **Snapping Enabled** or **Snapping Disabled**.

Configuring Environment Builder Settings

To configure how Environment Builder behaves, open the slide-out menu panel, and then select the **Settings** menu option. Environment Builder groups the settings into these tabs:

- **Machine Configuration** – Use this tab to define the **Controller Type**, **Firmware Type**, **CMM IP Address**, and **CMM IP Port** that Environment Builder uses to communicate with your machine.
- **Calibration Limits** – Use this tab to define the **Sphere Standard Deviation Limit** and **Tip Diameter Error Limit**. When a calibration exceeds either limit, Environment Builder displays a notification for the corresponding deviation type.
- **Clearance Distance** – Use this tab to define the clearances that Environment Builder applies during qualification: along the qualification tool shank vector for non-continuous wrists, along the qualification tool shank vector for continuous wrists, in Z when the qualification tool shank is perpendicular to the Z axis, along the tip shank vector during qualification, and for the tool changer port when a probe is loaded.
- **Calibration Validity** – Use this tab to define the **Calibration Interval** after which a calibration is no longer valid.

  You can override the global calibration interval for a single probe assembly by using **Set Overdue Frequency**. For information on the probe assembly options, see "Probe Assembly Options".
- **Mouse Controls** – Use this tab to define the mouse control scheme for the 3D scene. For information on how to navigate and work in the 3D scene, see "Navigating and Working in the 3D Scene".
- **Precision** – Use this tab to define the number of decimal places that Environment Builder displays for numeric values.

Working in a Read-Only Role or Offline

Environment Builder can run in a read-only user role. In this role, you can inspect your environment but cannot change it. The menu and tile options display **View Probe Assembly**, **View Angles**, and **View Probe Assembly Settings** instead of the corresponding edit and calibration options. Environment Builder disables machine selection, and the boxes in the **Edit Artifact** and **Edit Rack** dialog boxes are read-only.

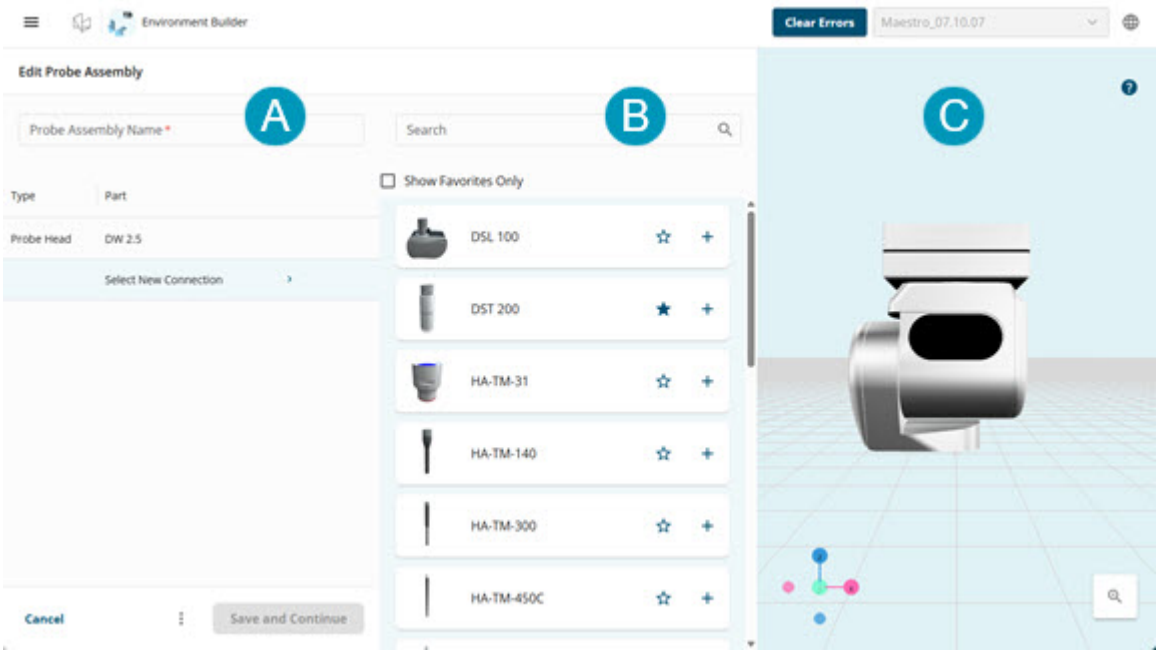
Environment Builder also runs when the connection to the machine is unavailable. In offline mode:

- Environment Builder displays an **Offline Mode** label and notifies you when the connection to the machine is lost or re-established.
- Calibration is unavailable. Calibration options display the message "Calibration is unavailable in offline mode."
- Environment Builder hides the **Results** and **Settings** menu options.
- The Guided Setup skips the calibration steps.

Creating Probe Assemblies

Environment Builder provides you with an intuitive workflow to design and create your probe assemblies.

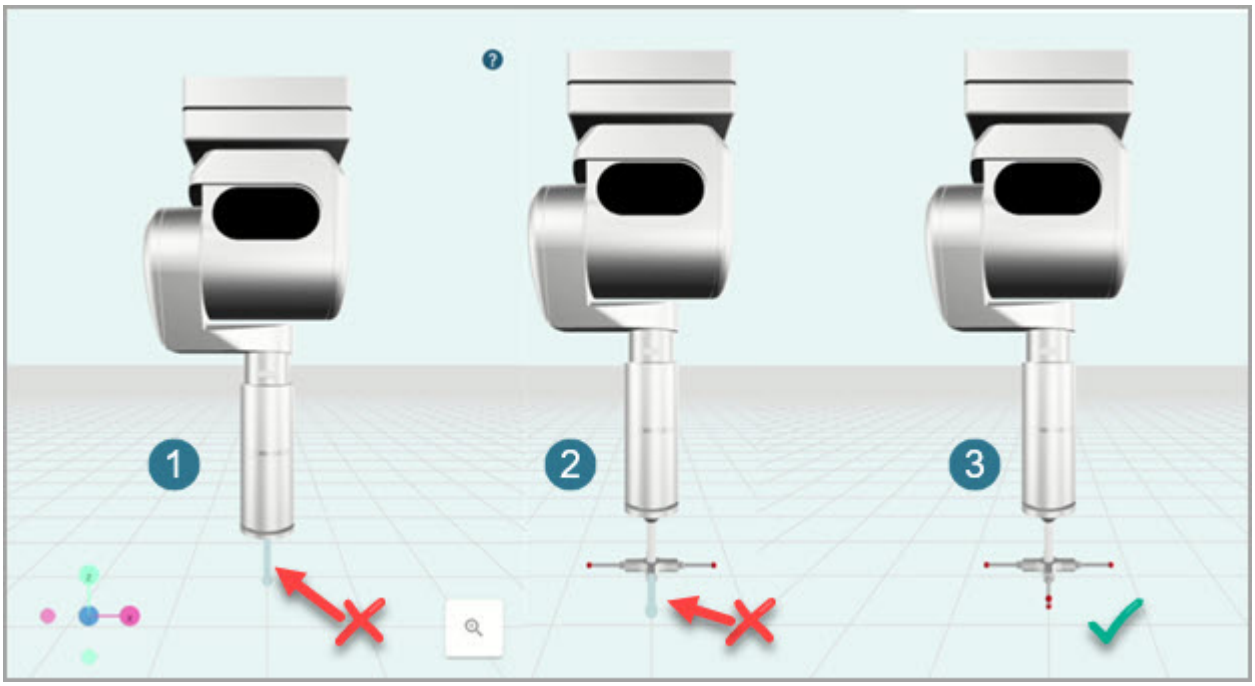
When Environment Builder starts, it typically displays the **Probe Assemblies** page that you can use to edit an existing probe assembly or create a new probe assembly. Select the **Create Probe Assembly** tile to show a blank **Edit Probe Assembly** window with a pre-selected probe head based on your machine configuration. An example is shown below:



Edit Probe Assembly Window

A - Probe Assembly details area
B - Probe Assembly component listing
C - Probe Assembly View area

Environment Builder shows the status of your probe assembly in the Probe Assembly View area as you build it. Below, you can see the stages of building a Star probe assembly. Environment Builder prompts you for the next component in a light blue shade when it detects that the probe assembly is incomplete.



Stages of building a Star probe assembly in Environment Builder

1. *Incomplete probe assembly with a DST-200 sensor component selected*
2. *Incomplete probe assembly with the 5-Way DST module selected*

3. *Completed Star probe assembly*

To change the view of your probe assembly:

- Right-click and drag in the Probe Assembly View area to move the probe assembly left-right, up-down, and diagonally.
- Rotate the wheel on your mouse to zoom in and out.
- Press and hold the wheel button and drag to change the probe assembly perspective.

You can also use the Trihedron to change the view of your probe assembly to the selected coordinate view. To do this, click one of the colored nodes on the Trihedron to rotate to the selected perspective.

Environment Builder Trihedron

X – Shown in pink, click on the X node or its opposite to rotate to the +X axis view or the -X axis view.

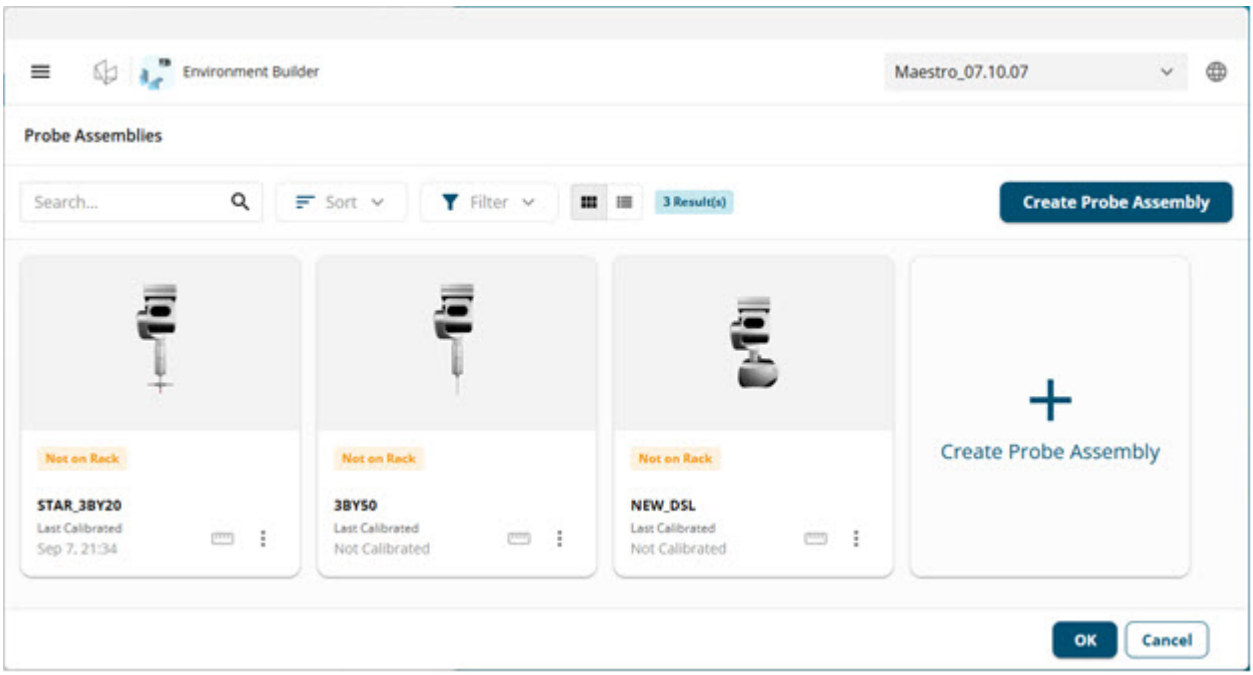
Y – Shown in blue, click on the Y node or its opposite to rotate to the +Y axis view or the -Y axis view.

Z – Shown in light cyan, click on the Z node or its opposite to rotate to the +Z axis view or the -Z axis view.

This section shows you how to create various probe assemblies that you can use as examples to design and create your own probe assemblies for your specific needs.

Managing the Probe Assemblies List

The **Probe Assemblies** page lists all probe assemblies defined for the current machine.



Search - Type all or part of a probe assembly name to filter the list to matching assemblies.

Sort - Select to change the order in which probe assemblies appear.

Filter - Select to narrow the list to probe assemblies that match the criteria you choose.

Card View - Select to show the probe assemblies as tiles.

List View - Select to show the probe assemblies as rows in a list.

Each probe assembly shows its calibration status:

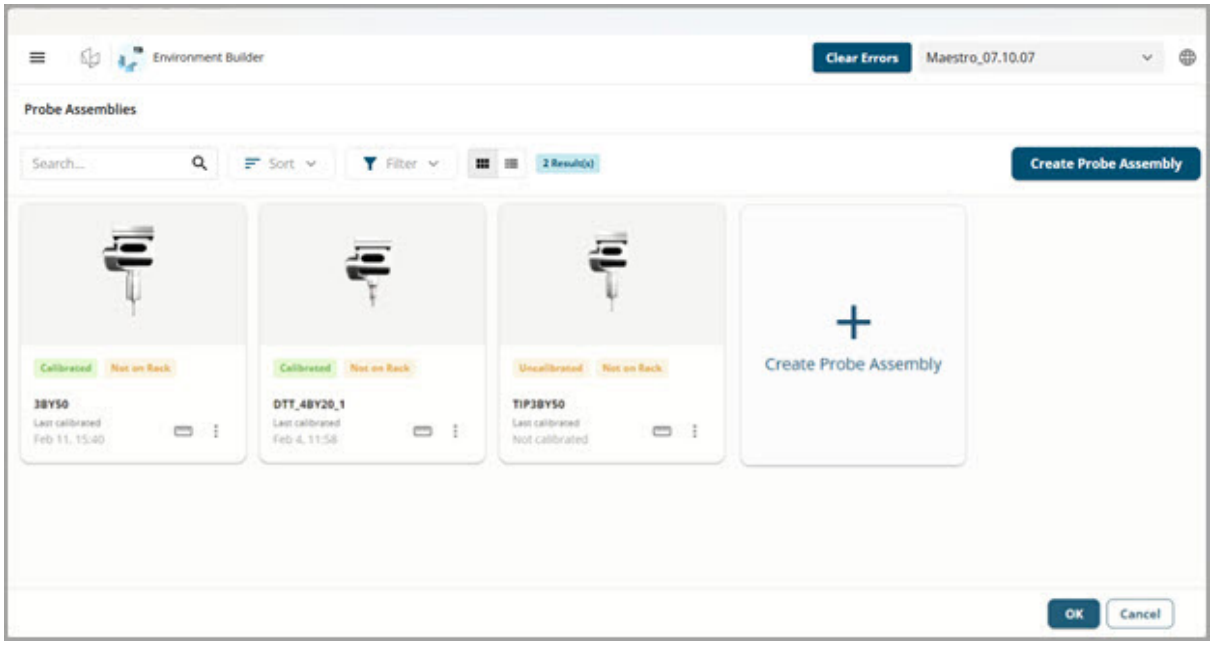
- **Calibrated** (green) – All selected angles are calibrated and the calibration is still valid.
- **Fast Calibrated** – Environment Builder calibrated the assembly using FastCal.
- **Partially Calibrated** – Some, but not all, angles are calibrated.
- **Uncalibrated** (orange) – The assembly has not been calibrated.
- **Calibration Overdue** – The calibration is older than the interval set in the Environment Builder settings or older than the assembly's own overdue frequency.
- **Calibration Error** – The last calibration failed.
- **Calibration in Progress** – A calibration is running for the assembly.

The tile also shows when the assembly was last calibrated, whether it is assigned as a reference probe, whether it is the loaded or active probe, and where its parts are on a probe changer: **Placed on Rack**, **Partially on Rack**, or **Not on Rack**.

Creating a DSL Probe Assembly

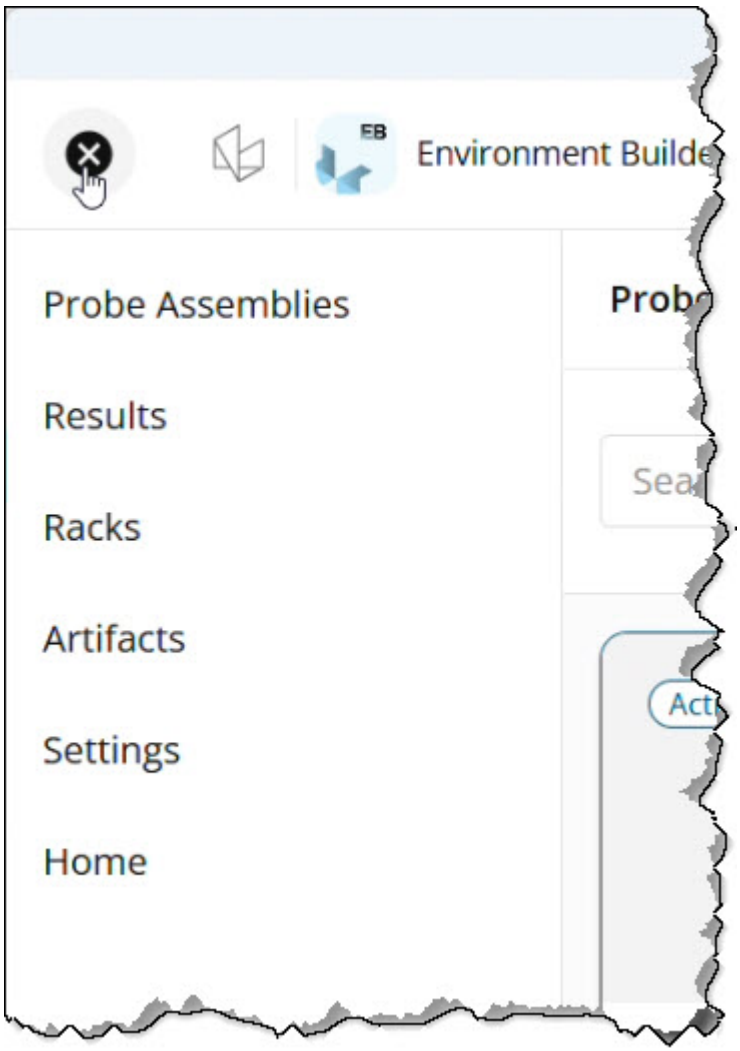
To create a Digital Scanning Laser (DSL) probe assembly with Environment Builder:

1. Open the Environment Builder main window. You can see a list of probe assemblies created in Environment Builder.



To open Environment Builder, you can use any of the options detailed in the "Environment Builder - Getting Started" topic in the PC-DMIS documentation.

If you do not see the **Probe Assemblies** window, click the menu button ( ) located in the upper-left of the window to show the slide-out menu panel and select the **Probe Assemblies** menu option.

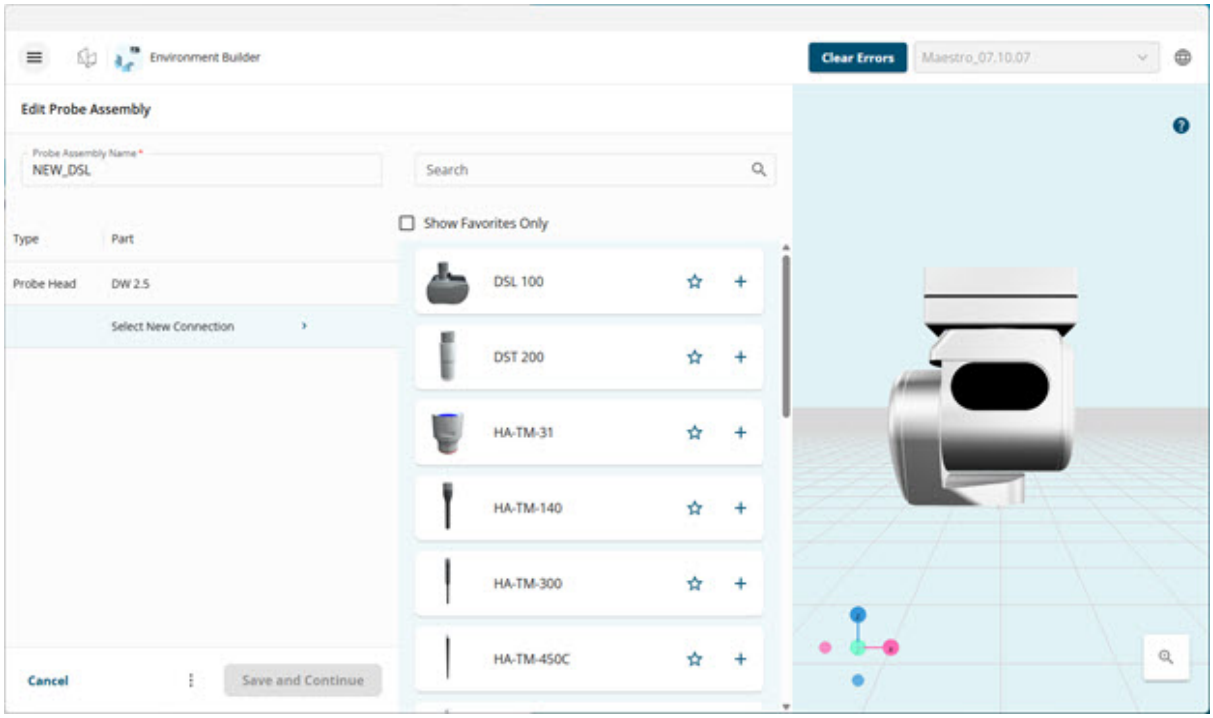


Click the **Close** button ( ) to hide the slide-out menu panel.

2. Select the **Create Probe Assembly** tile or button, and then confirm that the DW-2.5 probe head is selected for the machine configuration.

> As you select new components for your probe assembly, Environment Builder updates the probe component listing to only show components that are compatible with the last component you added.

3. For this example, from the list of sensors that are compatible with the selected DW-2.5 probe head, select the DSL-100 sensor.



Environment Builder dynamically updates the probe assembly with the selected components.

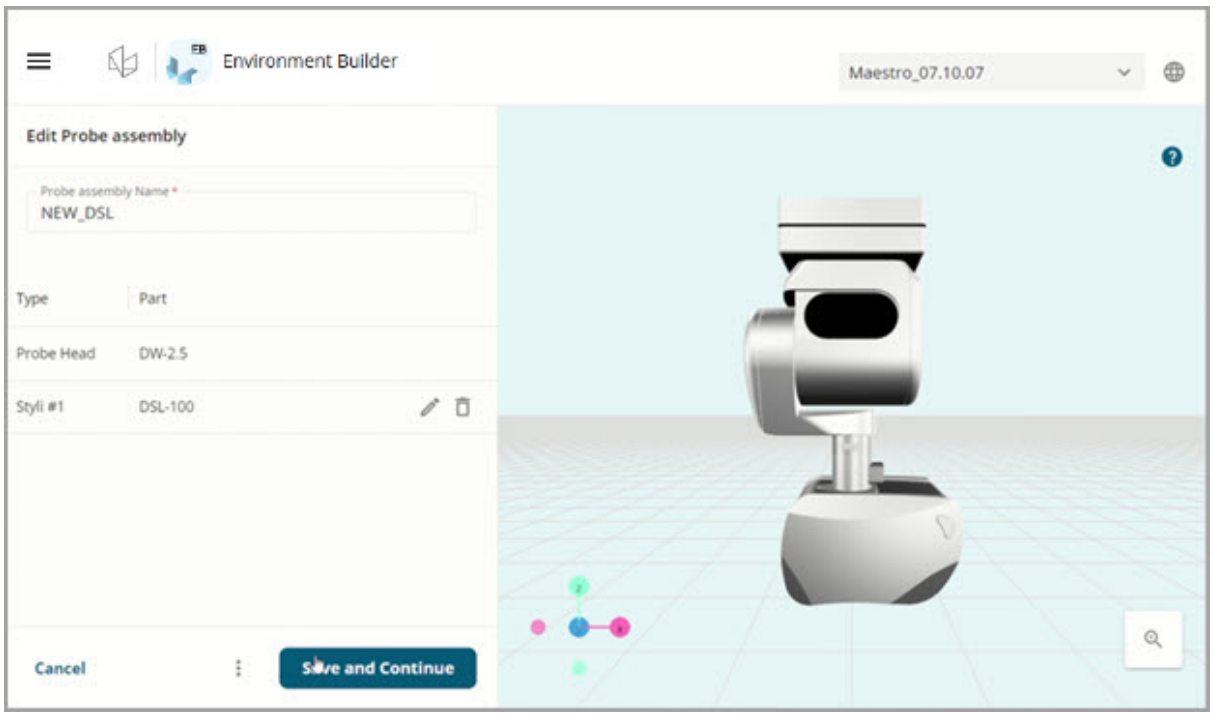
To make changes to any probe assembly component, you can use the associated **Edit** button ( ).

To remove any probe assembly component, you can use the associated **Delete** button ( ).

Be aware that you cannot save an incomplete probe assembly. When you delete a component from your assembly, you must replace it with another compatible component.

4. In the **Probe Assembly Name** box, type a unique name for your new probe assembly, and then do one of the following:
   - To save your changes and open the **Edit Angles** dialog box, select **Save and Continue**.
   - To save your changes and return to the **Probe Assemblies** page, select **More Options** ( ) and then select **Save and Close** .

You must type a unique name. Environment Builder prompts you to re-type the name if it detects that the probe assembly name is already in use.



5. Verify that the new probe assembly is available in the list of probe assemblies on the Environment Builder main window. This confirms that the creation of the new probe assembly was successful, and you can add it into your PC-DMIS measurement routines.

Tips for Efficiency

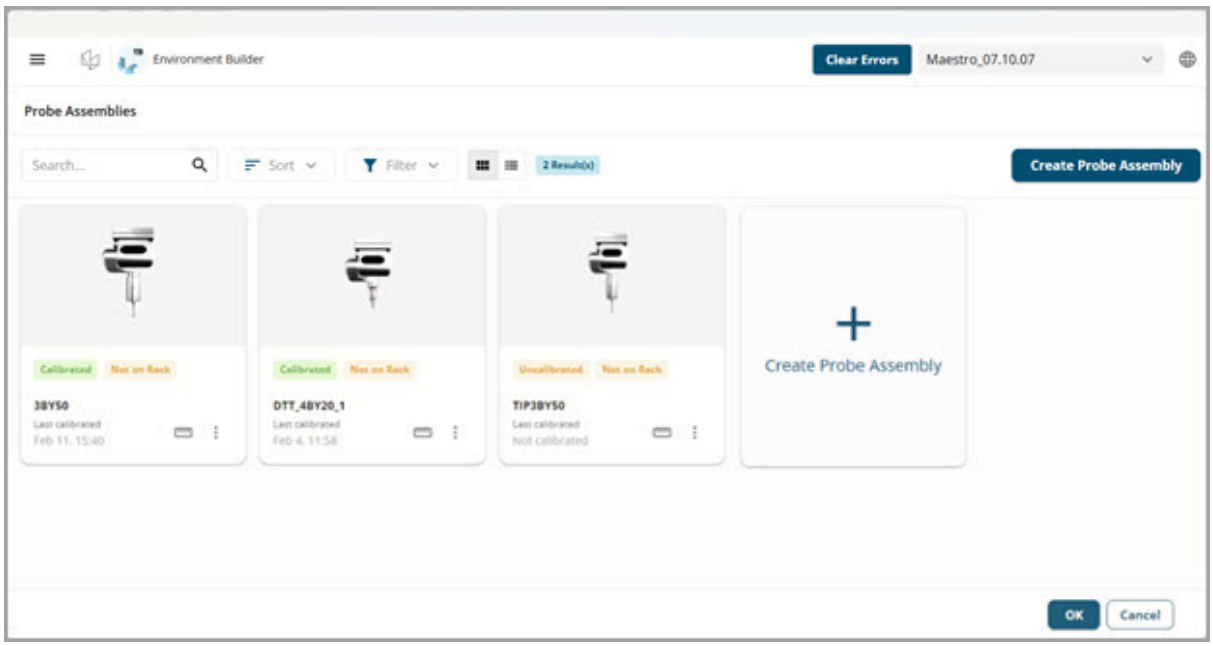
To speed up the probe assembly build process, familiarize yourself with the available components in Environment Builder.

Follow a naming convention to maintain consistency with identifiers for ease of retrieval.

Creating a DST Probe Assembly

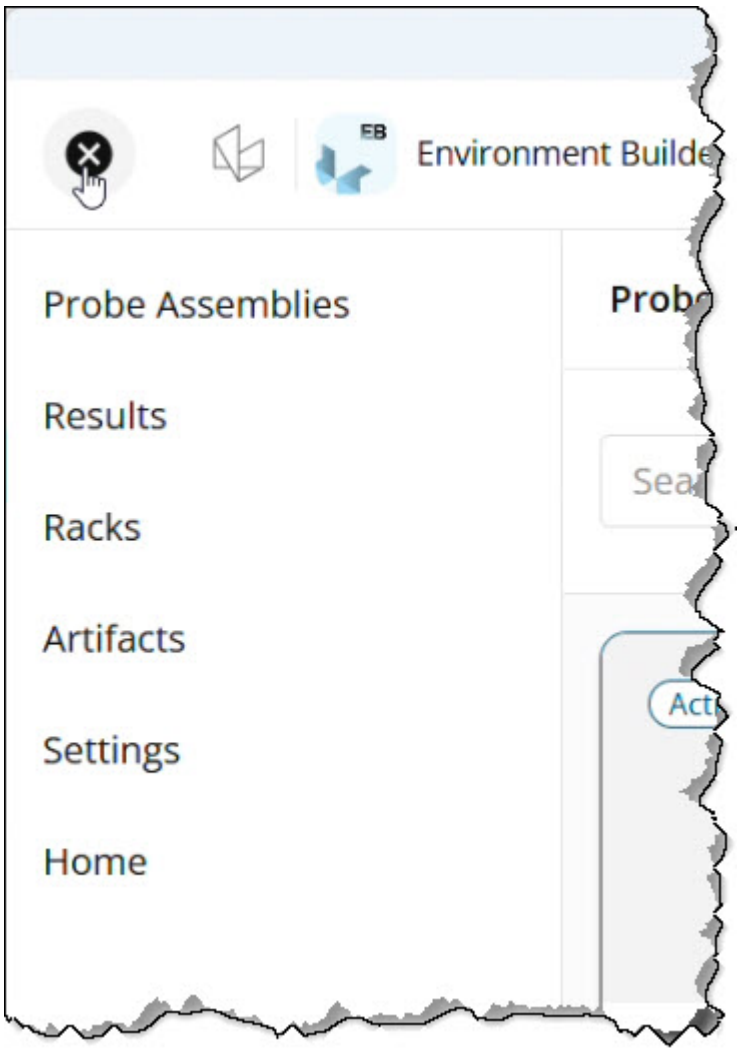
To create a Digital Scanning Tactile (DST) probe assembly with Environment Builder:

1. Open the Environment Builder main window. You can see a list of probe assemblies created in Environment Builder.



To open Environment Builder, you can use any of the options detailed in the "Environment Builder - Getting Started" topic in the PC-DMIS documentation.

If you do not see the **Probe Assemblies** window, click the menu button ( ) located in the upper-left of the window to show the slide-out menu panel and select the **Probe Assemblies** menu option.

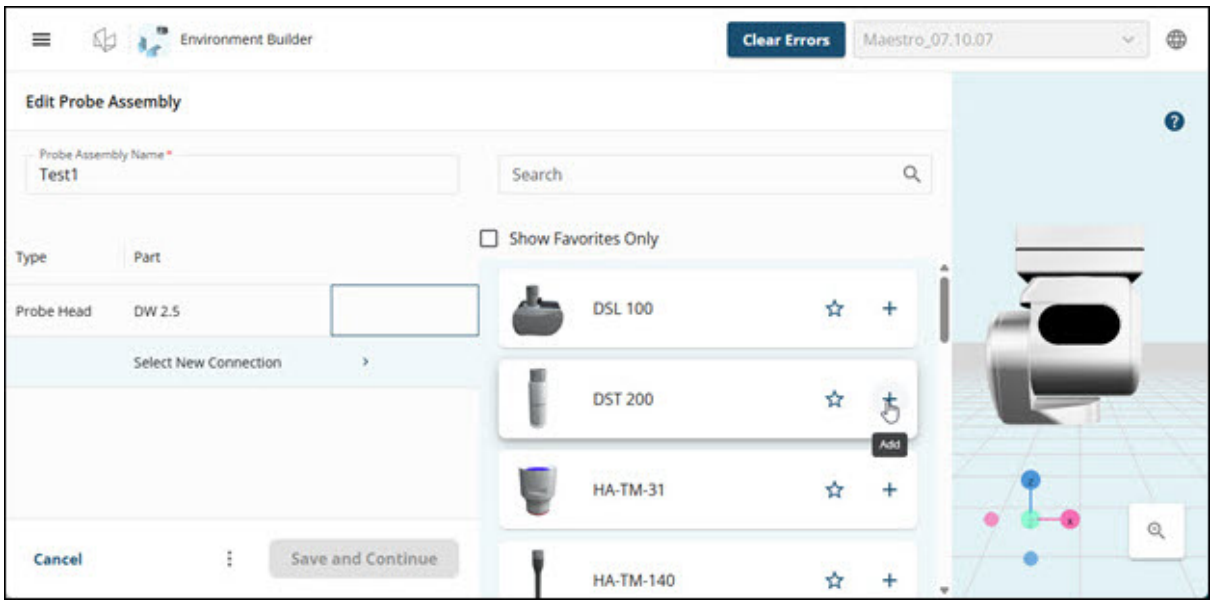


Click the **Close** button ( ) to hide the slide-out menu panel.

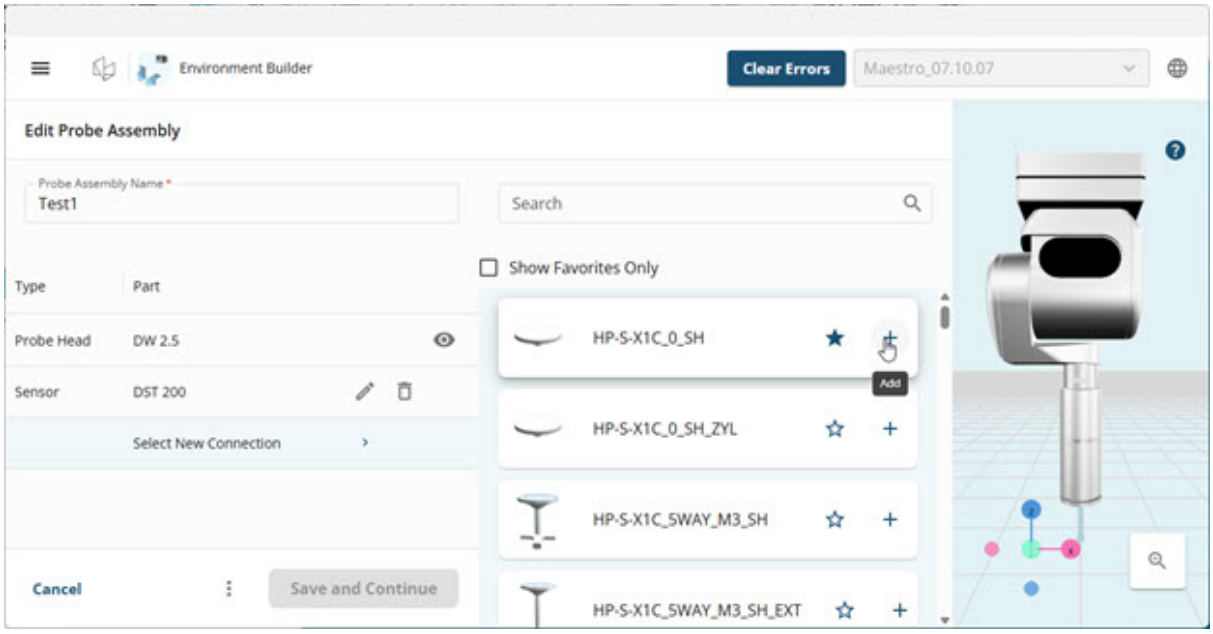
2. Select the **Create Probe Assembly** tile or button, and then confirm that the DW-2.5 probe head is selected for the machine configuration.

> As you select new components for your probe assembly, Environment Builder updates the probe component listing to only show components that are compatible with the last component you added.

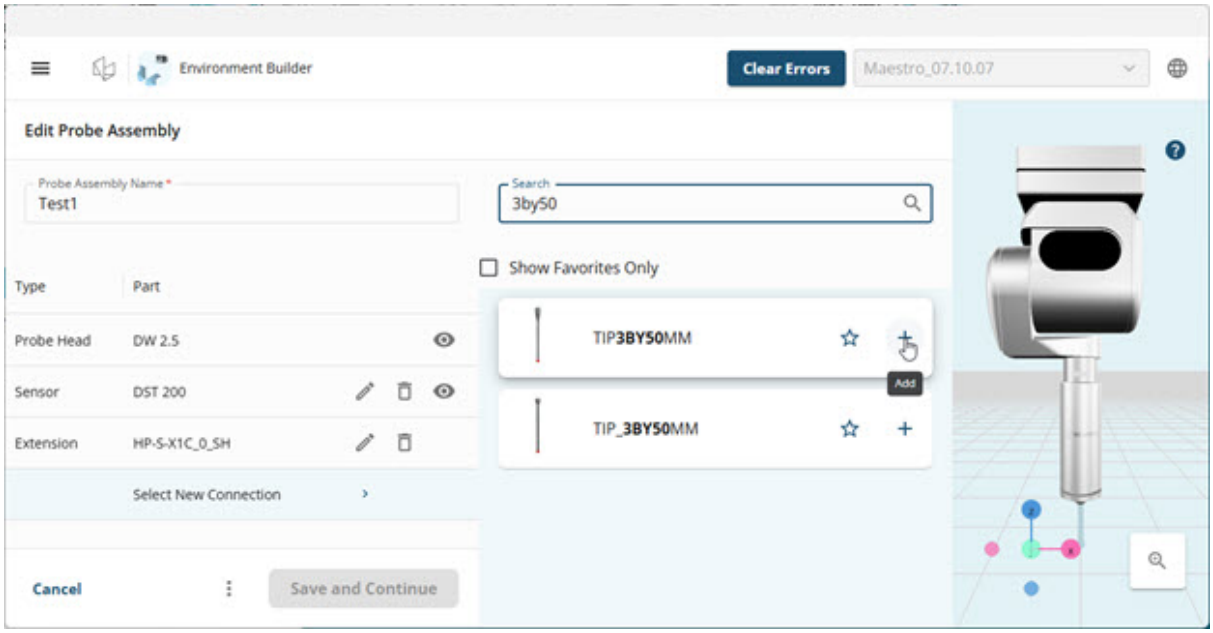
3. For this example, from the list of sensors compatible with the selected DW-2.5 probe head, select the DST-200 sensor.



4. The next component that you need to add to the probe assembly is the DST module. Select the HP-S-X1C_0_SH module from the list.



5. The final component that you need to add to the probe assembly is the stylus. Select the 3x50 stylus from the list.



Make sure it is the correct fit for your probe assembly.

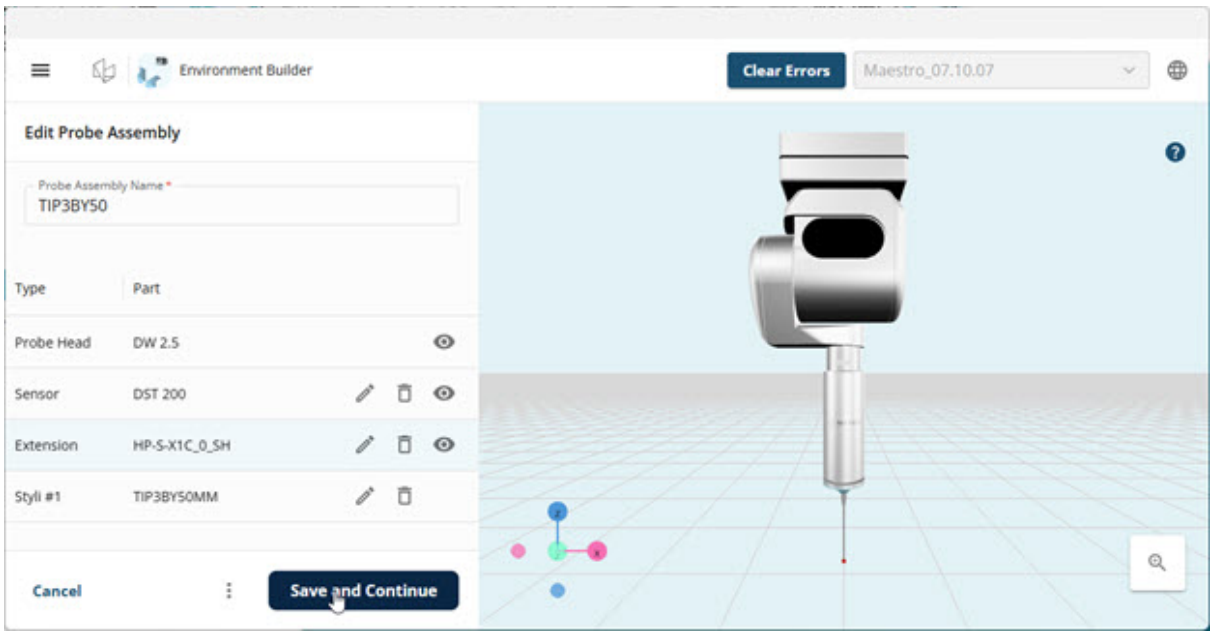
To make changes to any probe assembly component, you can use the associated **Edit** button ( ).

To remove any probe assembly component, you can use the associated **Delete** button ( ).

> Be aware that you cannot save an incomplete probe assembly. When you delete a component from your assembly, you must replace it with another compatible component.

6. In the **Probe Assembly Name** box, type a unique name for your new probe assembly, and then do one of the following:
   - To save your changes and open the **Edit Angles** dialog box, select **Save and Continue**.
   - To save your changes and return to the **Probe Assemblies** page, select **More Options** ( ) and then select **Save and Close** .

> You must type a unique name. Environment Builder prompts you to re-type the name if it detects that the probe assembly name is already in use.



7. Verify that the new probe assembly is available in the list of probe assemblies on the Environment Builder main window. This confirms that the creation of the new probe assembly was successful, and you can add it into your PC-DMIS measurement routines.

Tips for Efficiency

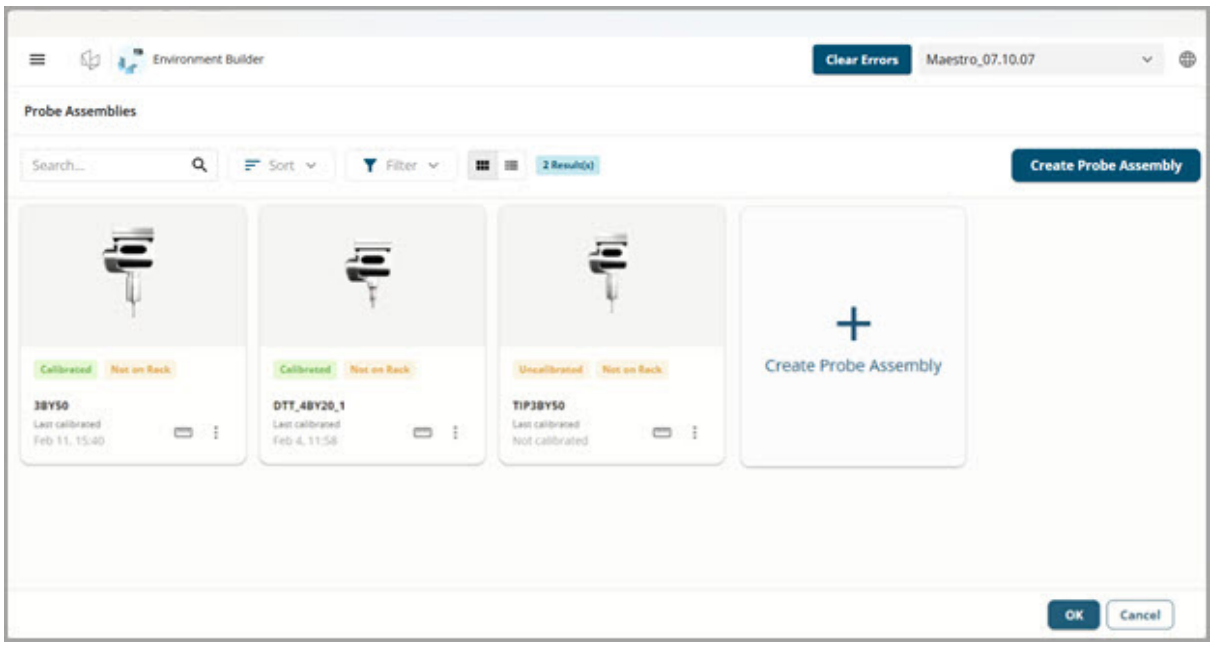
To speed up the probe assembly build process, familiarize yourself with the available components in Environment Builder.

Follow a naming convention to maintain consistency with identifiers for ease of retrieval.

Creating a DTT Probe Assembly

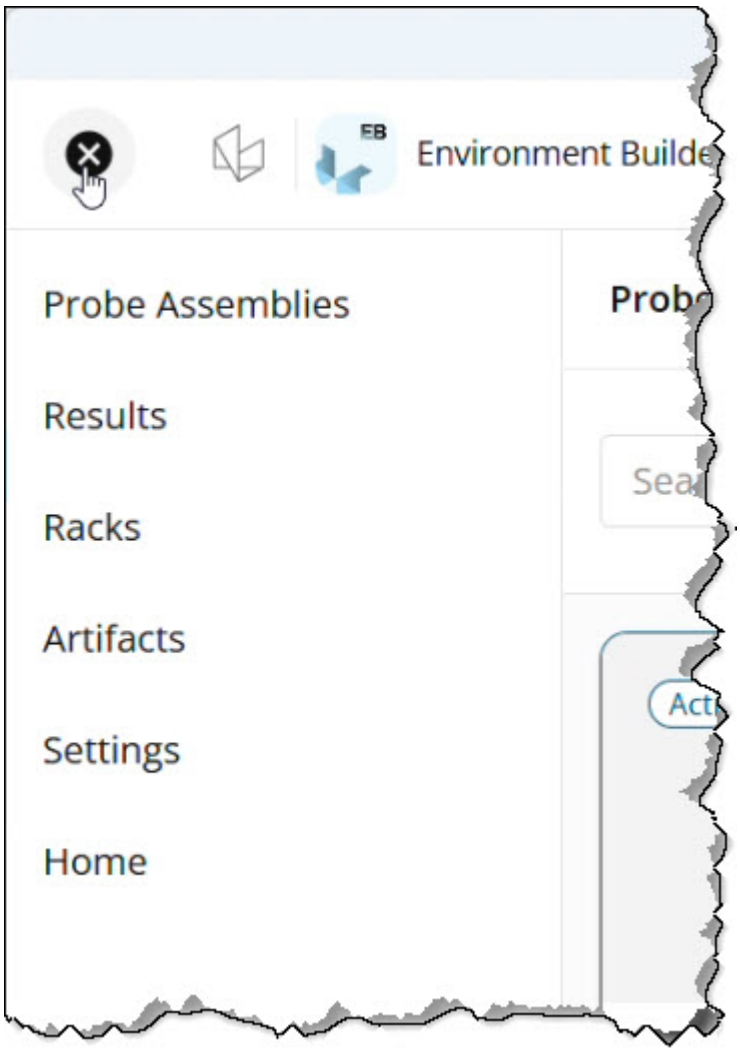
To create a Digital Touch Trigger (DTT) probe assembly with Environment Builder:

1. Open the Environment Builder main window. You can see a list of probe assemblies created in Environment Builder.



To open Environment Builder, you can use any of the options detailed in the "Environment Builder - Getting Started" topic in the PC-DMIS documentation.

If you do not see the **Probe Assemblies** window, click the menu button ( ) located in the upper-left of the window to show the slide-out menu panel and select the **Probe Assemblies** menu option.

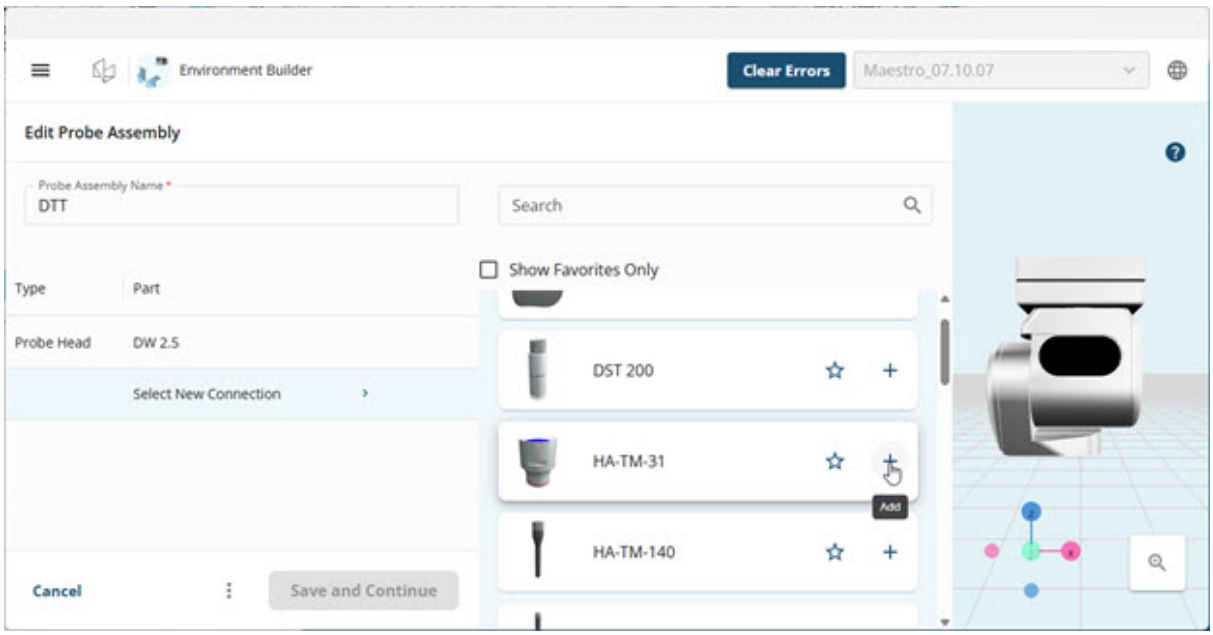


Click the **Close** button ( ) to hide the slide-out menu panel.

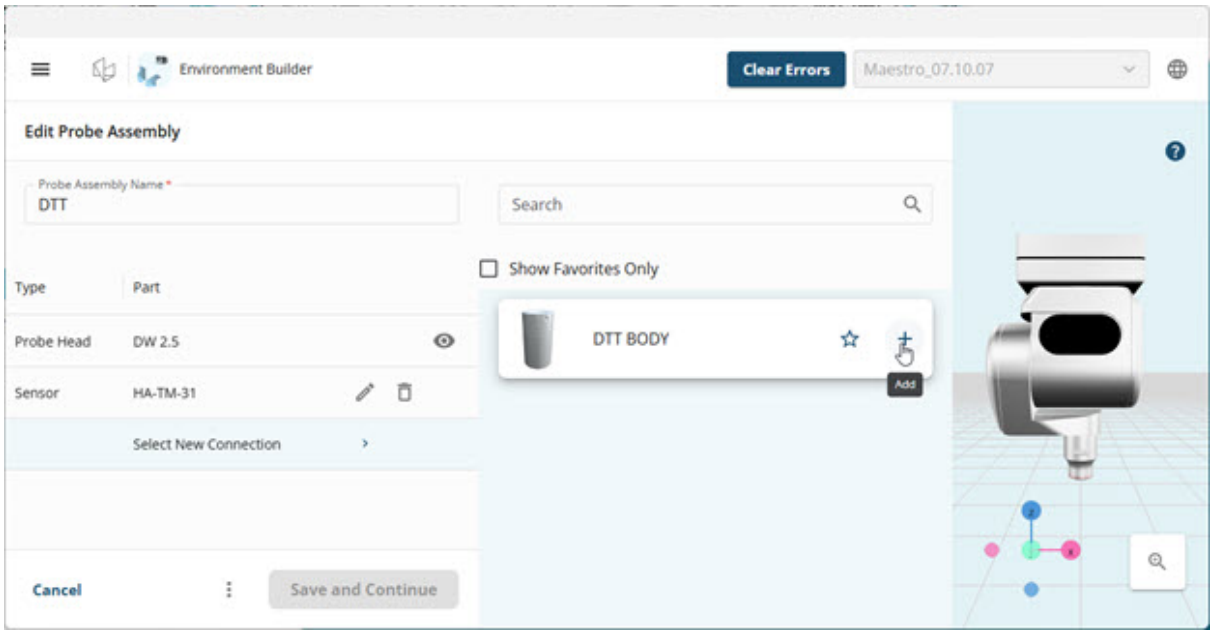
2. Select the **Create Probe Assembly** tile or button, and then confirm that the DW-2.5 probe head is selected for the machine configuration.

> As you select new components for your probe assembly, Environment Builder updates the probe component listing to only show components that are compatible with the last component you added.

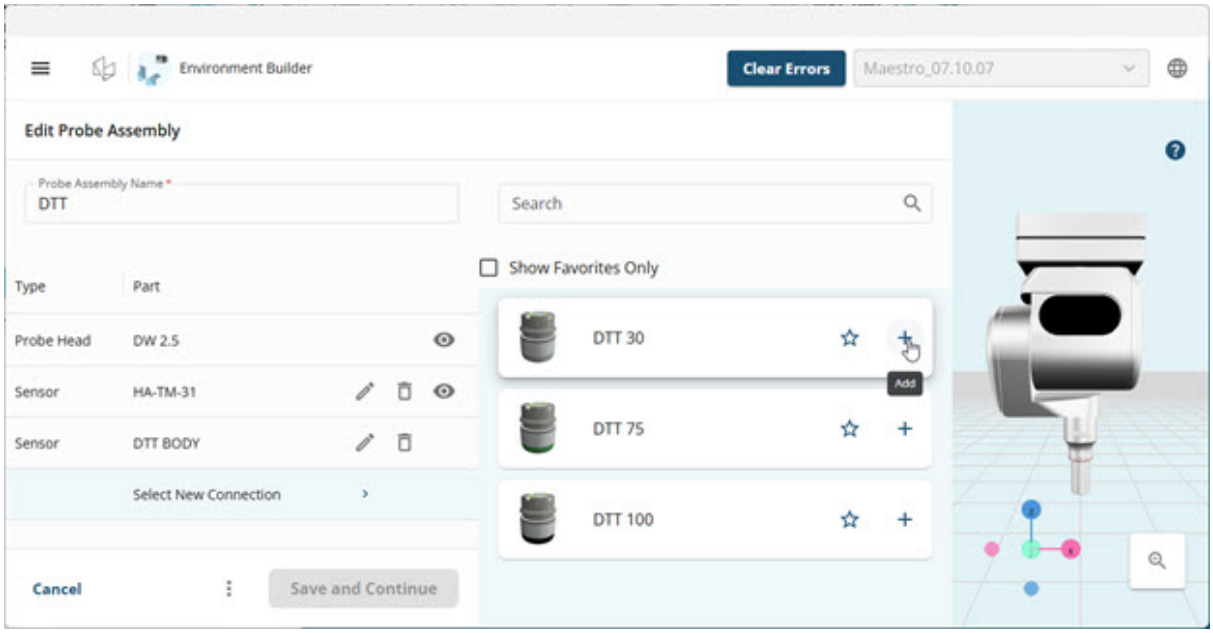
3. For this example, from the list of adapters compatible with the selected DW-2.5 probe head, select the HA-TM-31 adapter.



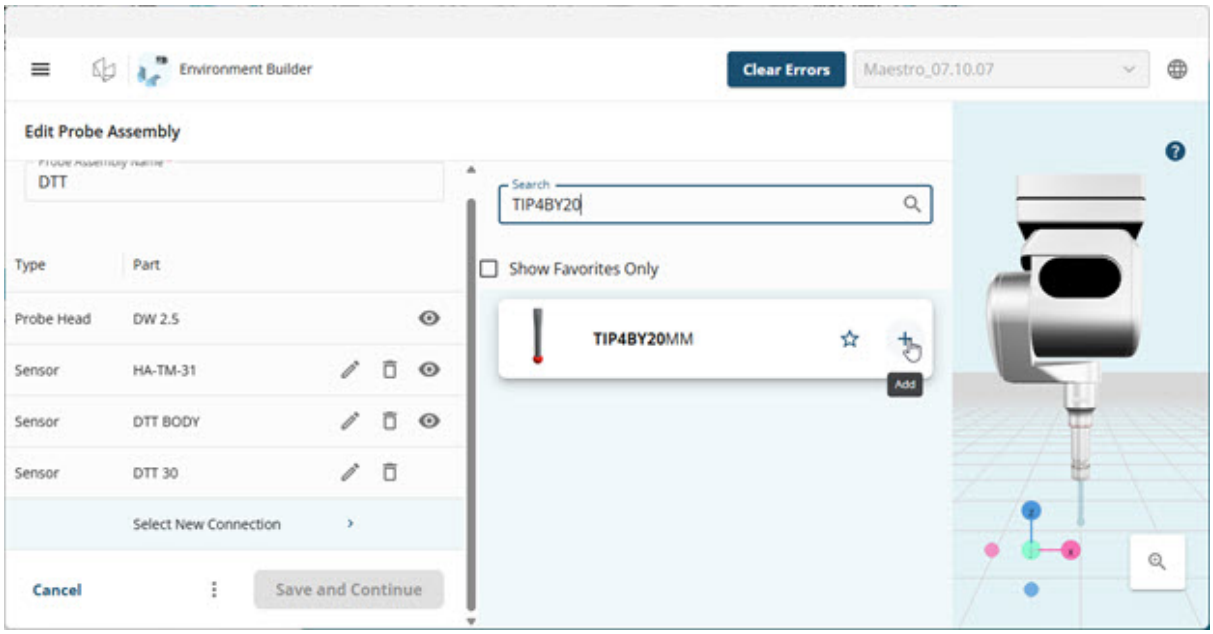
4. The next component that you need to add to the probe assembly is the digital touch trigger body. Select the DTT_BODY sensor option from the list.



5. The next component that you need to add to the probe assembly is the digital touch trigger module. Select the DTT-30 module option from the list.



6. Finally, select the 4x20 stylus option from the list.



Make sure it is the correct fit for your probe assembly.

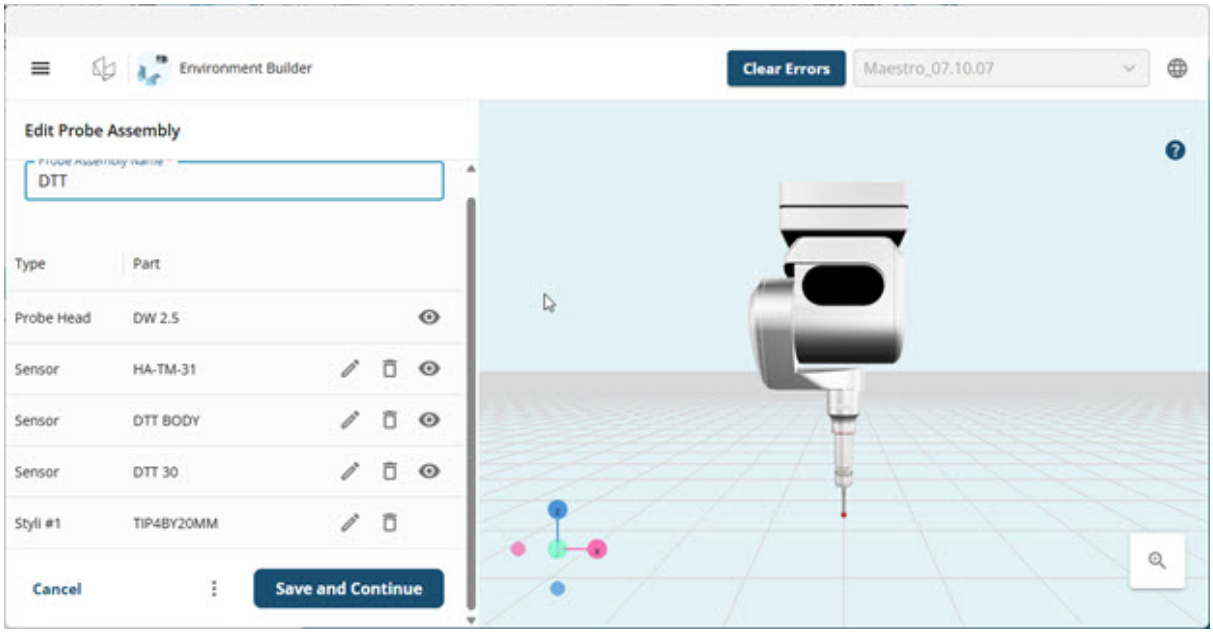
To make changes to any probe assembly component, you can use the associated **Edit** button ( ).

To remove any probe assembly component, you can use the associated **Delete** button ( ).

> Be aware that you cannot save an incomplete probe assembly. When you delete a component from your assembly, you must replace it with another compatible component.

7. In the **Probe Assembly Name** box, type a unique name for your new probe assembly, and then do one of the following:
   - To save your changes and open the **Edit Angles** dialog box, select **Save and Continue**.
   - To save your changes and return to the **Probe Assemblies** page, select **More Options** ( ) and then select **Save and Close** .

> You must type a unique name. Environment Builder prompts you to re-type the name if it detects that the probe assembly name is already in use.



8. Verify that the new probe assembly is available in the list of probe assemblies on the Environment Builder main window. This confirms that the creation of the new probe assembly was successful, and you can add it into your PC-DMIS measurement routines.

Tips for Efficiency

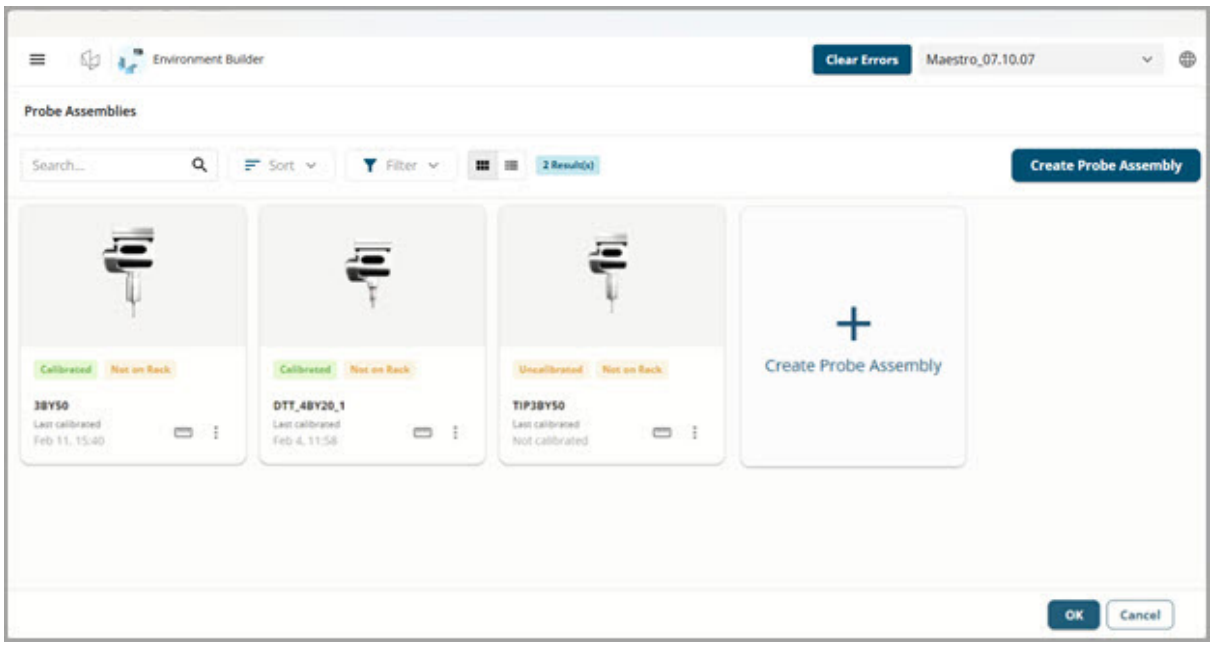
To speed up the probe assembly build process, familiarize yourself with the available components in Environment Builder.

Follow a naming convention to maintain consistency with identifiers for ease of retrieval.

Creating a Star Probe Assembly

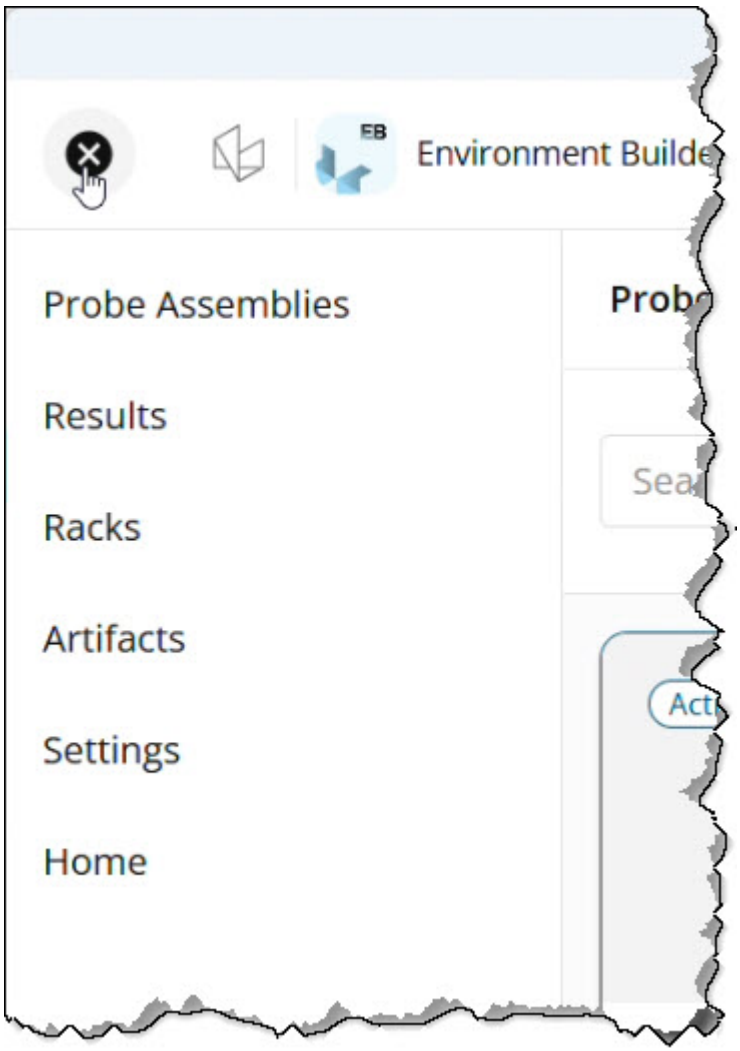
To create a Star probe assembly with Environment Builder:

1. Open the Environment Builder main window. You can see a list of probe assemblies created in Environment Builder.



To open Environment Builder, you can use any of the options detailed in the "Environment Builder - Getting Started" topic in the PC-DMIS documentation.

If you do not see the **Probe Assemblies** window, click the menu button ( ) located in the upper-left of the window to show the slide-out menu panel and select the **Probe Assemblies** menu option.

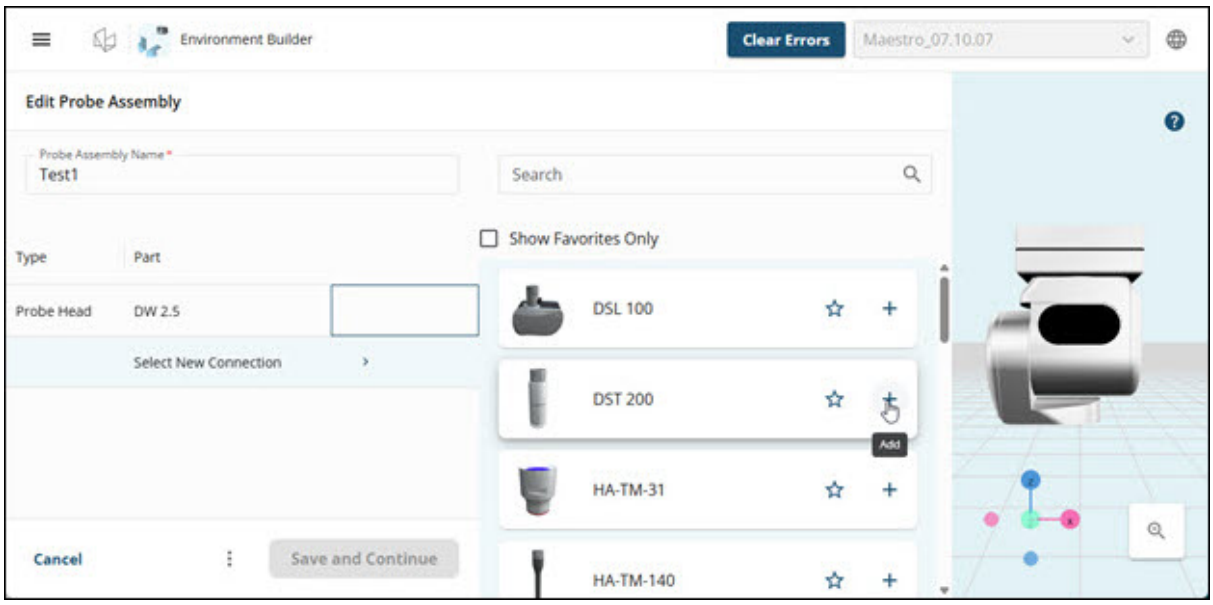


Click the **Close** button ( ) to hide the slide-out menu panel.

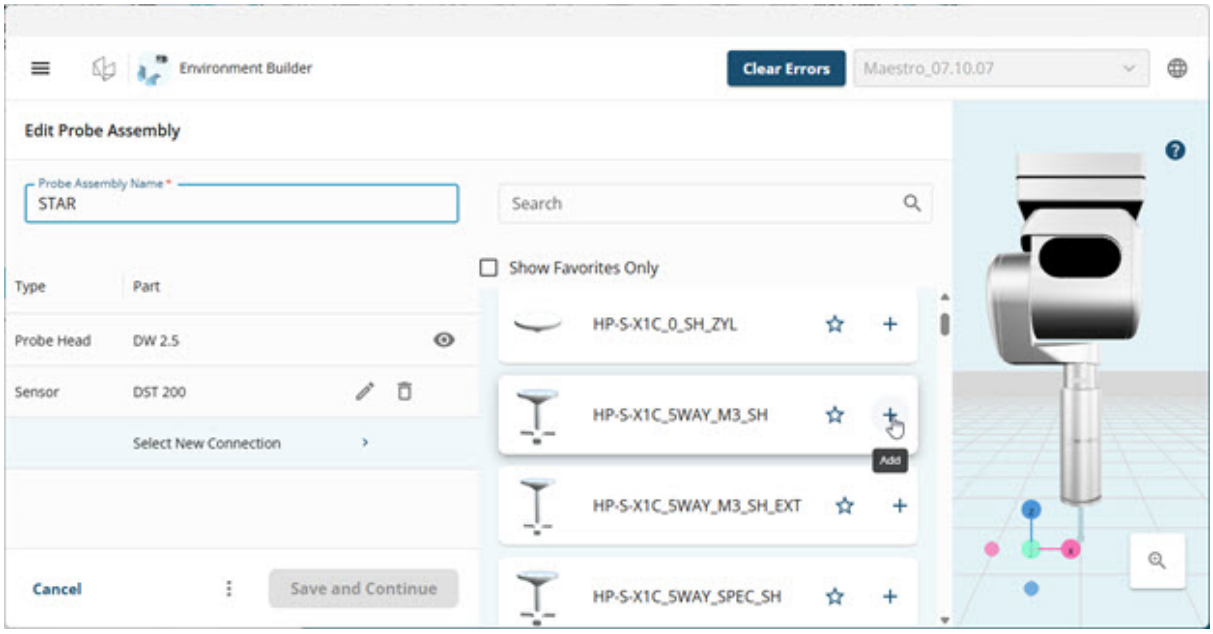
2. Select the **Create Probe Assembly** tile or button, and then confirm that the DW-2.5 probe head is selected for the machine configuration.

> As you select new components for your probe assembly, Environment Builder updates the probe component listing to only show components that are compatible with the last component you added.

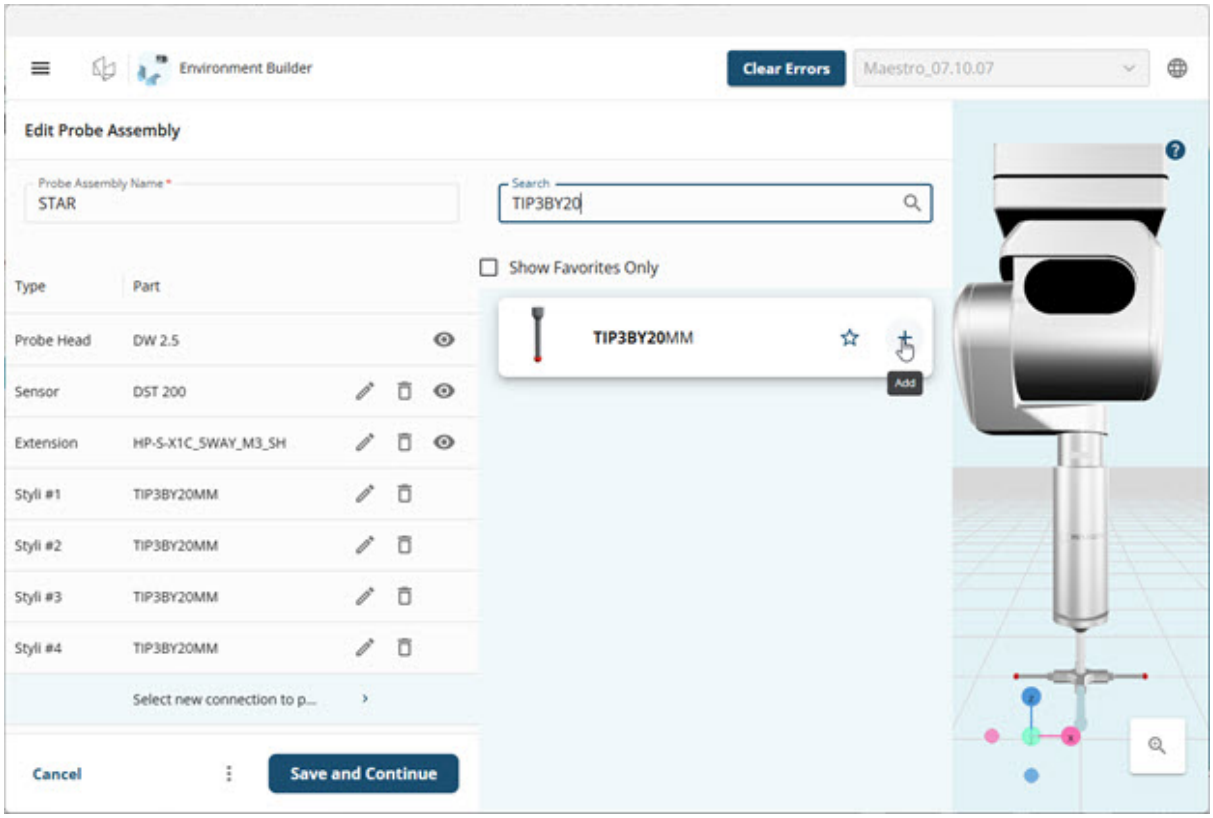
3. For this example, from the list of sensors compatible with the selected DW-2.5 probe head, select the DST-200 sensor.



4. The next component that you need to add to the probe assembly is the HP-S-X1C_5WAY_M3_SH module. From the list of components, select that module.



There are five ports on the module that you can outfit with compatible styli. Environment Builder automatically selects the first port which is the bottom port. After you add the stylus to Port 1, Environment Builder moves in a counterclockwise rotation to each of the remaining ports, starting with Port 2 in the X+ direction.



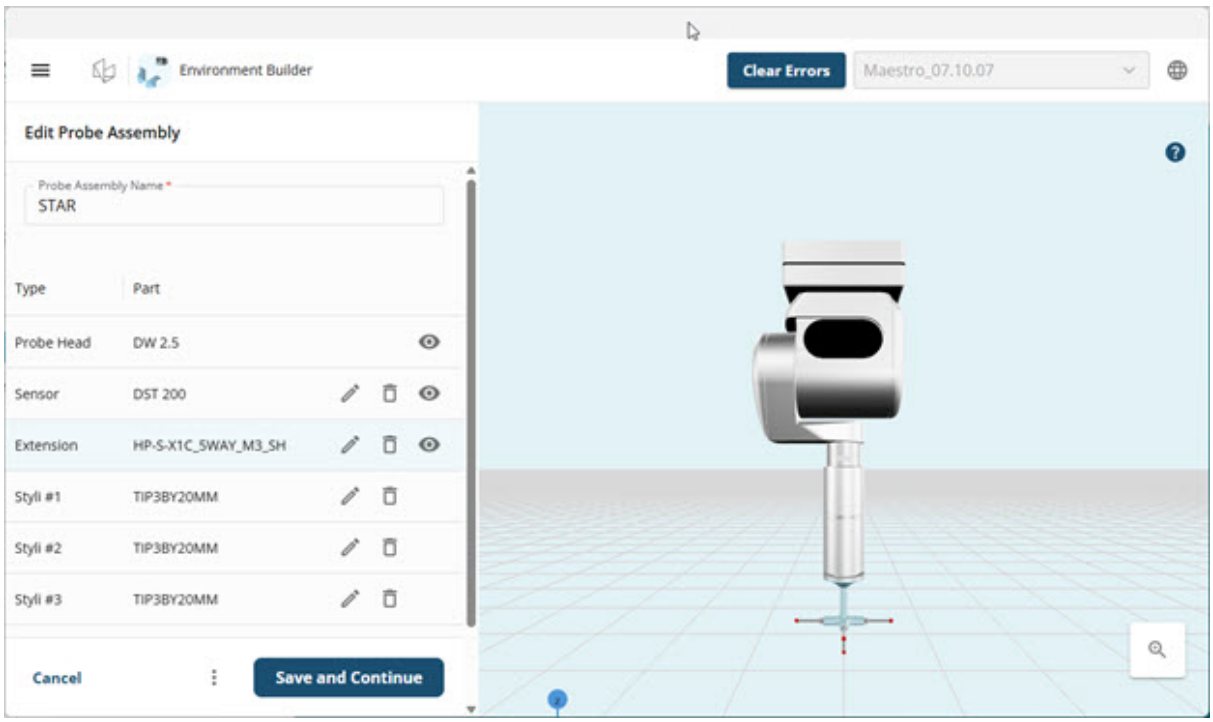
To make changes to any probe assembly component, you can use the associated **Edit** button ( ).

To remove any probe assembly component, you can use the associated **Delete** button ( ).

> Be aware that you cannot save an incomplete probe assembly. When you delete a component from your assembly, you must replace it with another compatible component.

5. In the **Probe Assembly Name** box, type a unique name for your new probe assembly, and then do one of the following:
   - To save your changes and open the **Edit Angles** dialog box, select **Save and Continue**.
   - To save your changes and return to the **Probe Assemblies** page, select **More Options** ( ) and then select **Save and Close** .

> You must type a unique name. Environment Builder prompts you to re-type the name if it detects that the probe assembly name is already in use.



6. Verify that the new probe assembly is available in the list of probe assemblies on the Environment Builder main window. This confirms that the creation of the new probe assembly was successful, and you can add it into your PC-DMIS measurement routines.

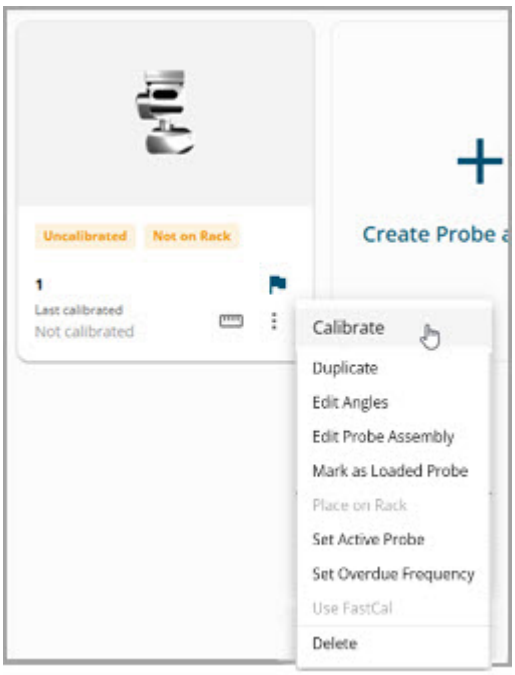
Tips for Efficiency

To speed up the probe assembly build process, familiarize yourself with the available components in Environment Builder.

Follow a naming convention to maintain consistency with identifiers for ease of retrieval.

Probe Assembly Options

To open a probe assembly's menu, select **More Options** ( ) in the lower-right corner of its tile. The menu contains the following options:



- **Edit Probe Assembly** – Change the components in the assembly.
- **Edit Angles** – Add, edit, or remove angles for the assembly. For information on adding angles to probe assemblies, see "Adding Angles to Probe Assemblies in Environment Builder".
- **Calibrate** – Calibrate the assembly. For information on calibrating a probe assembly, see "Probe Assembly Calibration Procedure".
- **View Calibration Result** – Display the results of the last calibration.
- **Place on Rack** – Assign the assembly, or part of it, to a port on a probe changer. For information on placing probe assemblies on a probe changer, see "Placing Probe Assemblies on a Probe Changer".
- **Set Active Probe** – Set the probe assembly that Environment Builder returns to PC-DMIS when you close it.
- **Mark as Loaded Probe** – Specify which probe assembly is physically mounted on the machine.
- **Use FastCal** / **Unset FastCal** – Turn FastCal on or off for the assembly. While FastCal is active, the angle options are unavailable and Environment Builder displays the message "These options are unavailable while FastCal is active."
- **Set Overdue Frequency** – Set the duration, in days or hours, after which this assembly's calibration becomes overdue, independent of the interval set in the Environment Builder settings.
- **Duplicate** – Create a copy of the assembly that you can modify.

- **Delete** – Remove the assembly. If one or more artifacts use the assembly as their reference probe, Environment Builder warns you that deleting the assembly might affect dependent operations.

In the read-only user role, **Edit Probe Assembly** and **Edit Angles** become **View Probe Assembly** and **View Angles**, respectively. Options that modify the environment are unavailable. For information on the read-only user role and offline mode, see "Working in a Read-Only Role or Offline".

Showing and Hiding Assembly Components

While editing a probe assembly, you can hide individual components to focus on the parts of the assembly you are working on. In the probe assembly component list, select the **Show/Hide** button next to a component to show or hide it.

Environment Builder saves the visibility settings with the probe assembly, so the same components stay hidden the next time you open it.

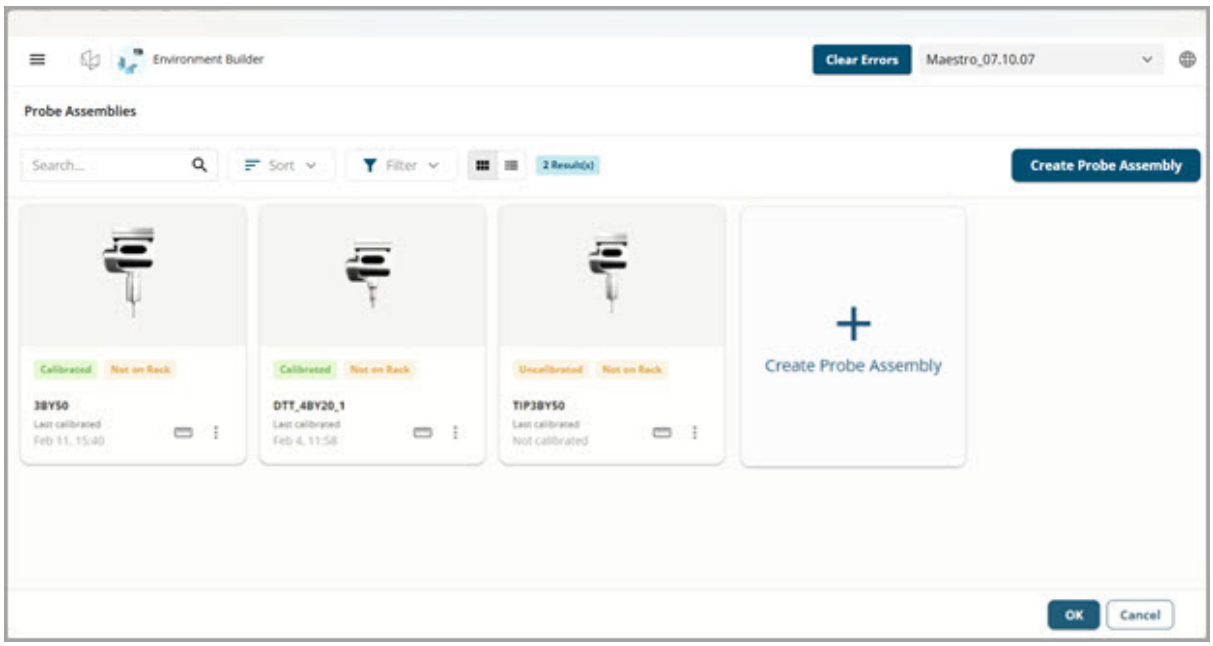
Calibrating Probe Assemblies

This section provides you with the workflow that you can use to calibrate your probe assembly in Environment Builder.

Adding Calibration Artifacts in Environment Builder

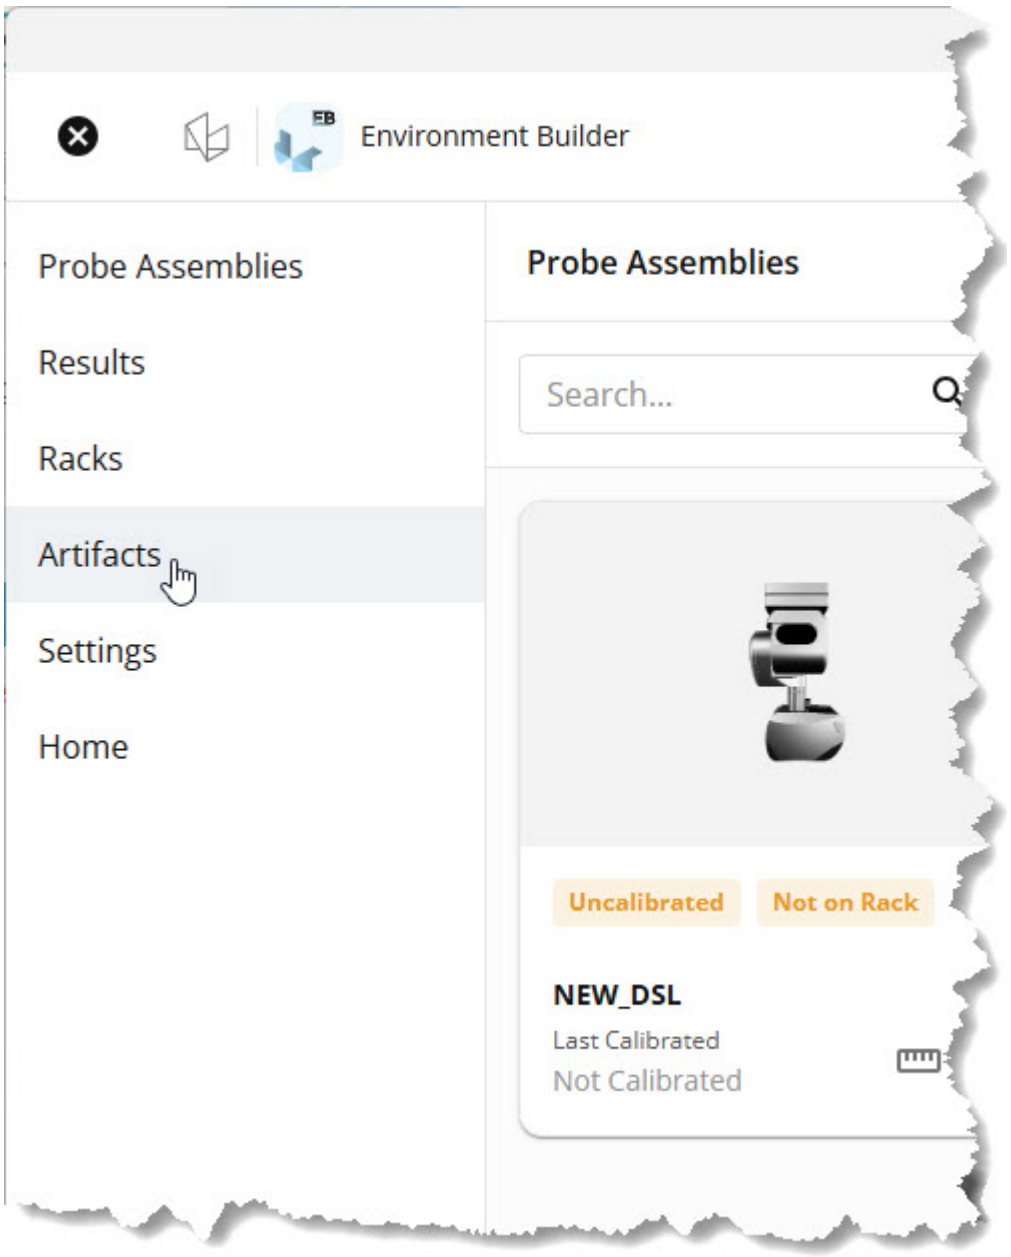
Follow this procedure to add and configure new calibration artifacts in Environment Builder that you can use to calibrate your probe assemblies.

1. Open the Environment Builder main window. You can see a list of probe assemblies created in Environment Builder.

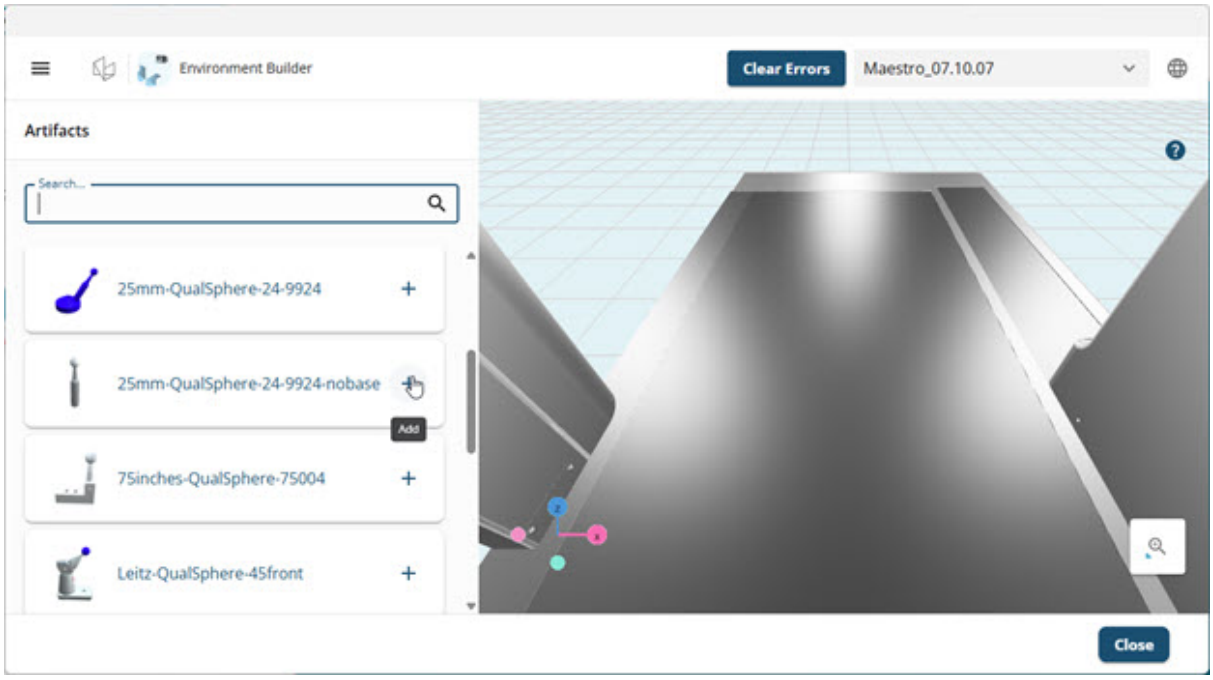


To open Environment Builder, you can use any of the options detailed in the "Environment Builder - Getting Started" topic in the PC-DMIS documentation.

2. Select the menu button ( ) in the upper-left corner of the window to show the slide-out menu panel and select the **Artifacts** menu option.

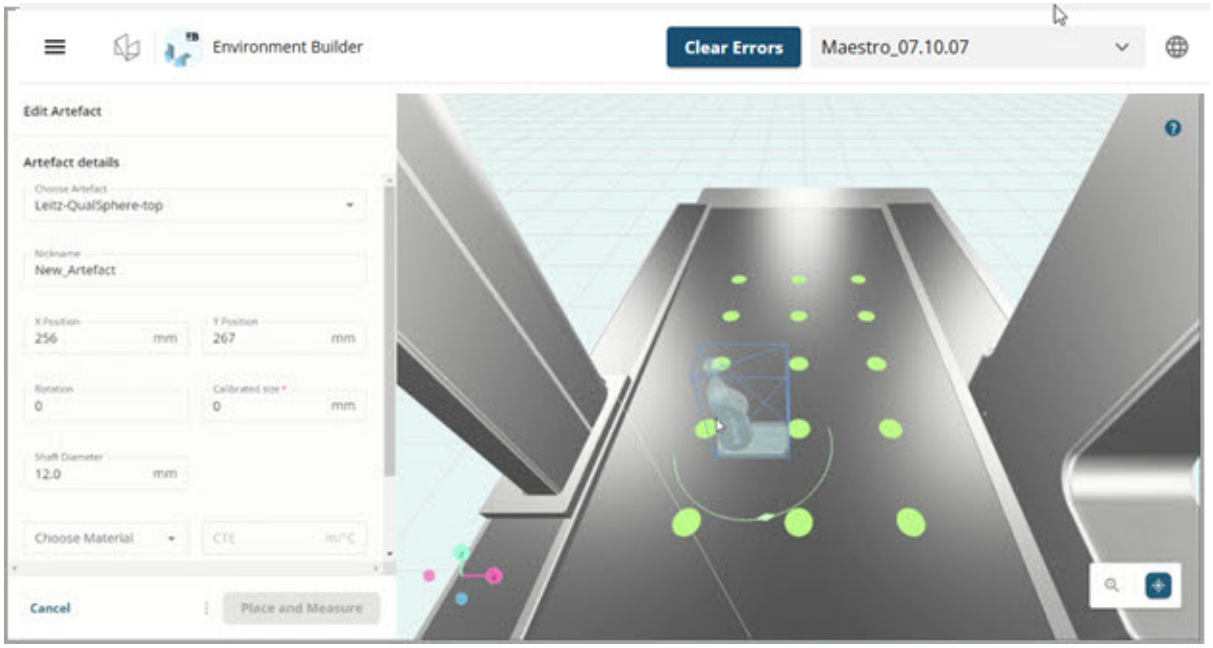


3. Scroll through the list of artifacts and select the one that matches your CMM.



4. Select the **+** button on the right side of the artifact tile to add the artifact to the CMM table and open the **Edit Artifact** dialog box.

5. In the **Nickname** box, type a new name to replace the factory default nickname for easier identification in the future.



6. On the CMM table in the 3D scene, drag and drop the artifact on top of a green dot to define its rough position.

7. Click and drag the green arc near the artifact to define its rough rotation.

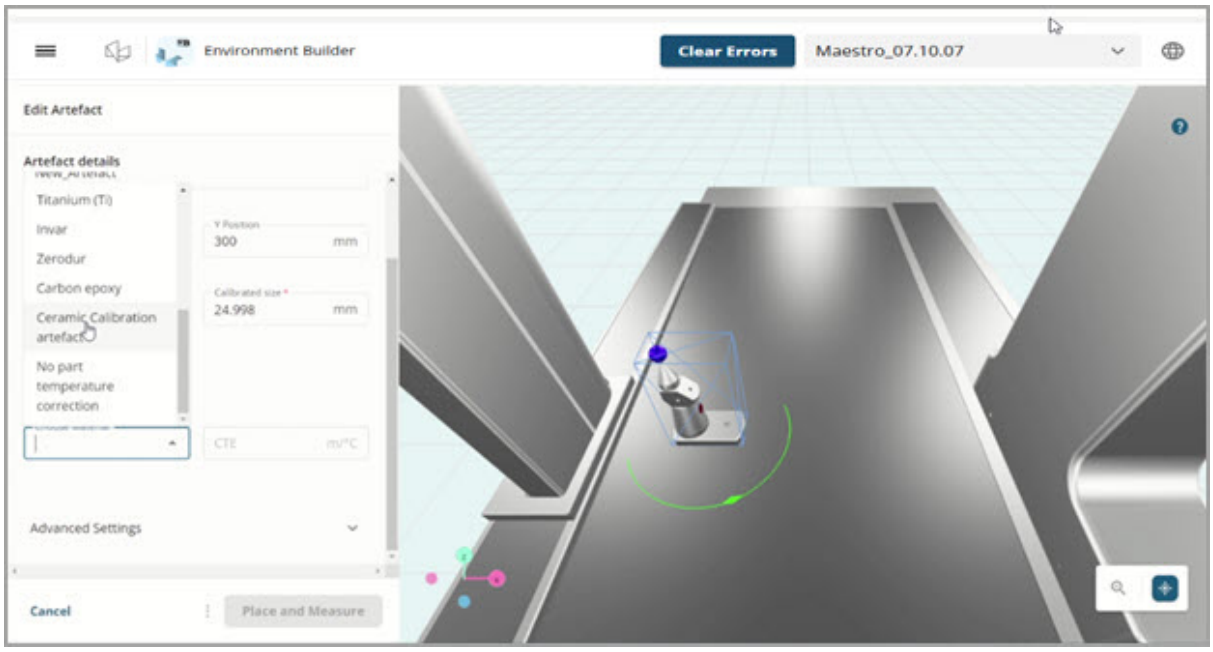
8. You can use the **Edit Artifact** dialog box to refine the artifact's position. To do this, type the value into the **X Position** and **Y Position** boxes (or click in each box and

use the Up and Down arrow keys on your keyboard to increment or decrement the current value).

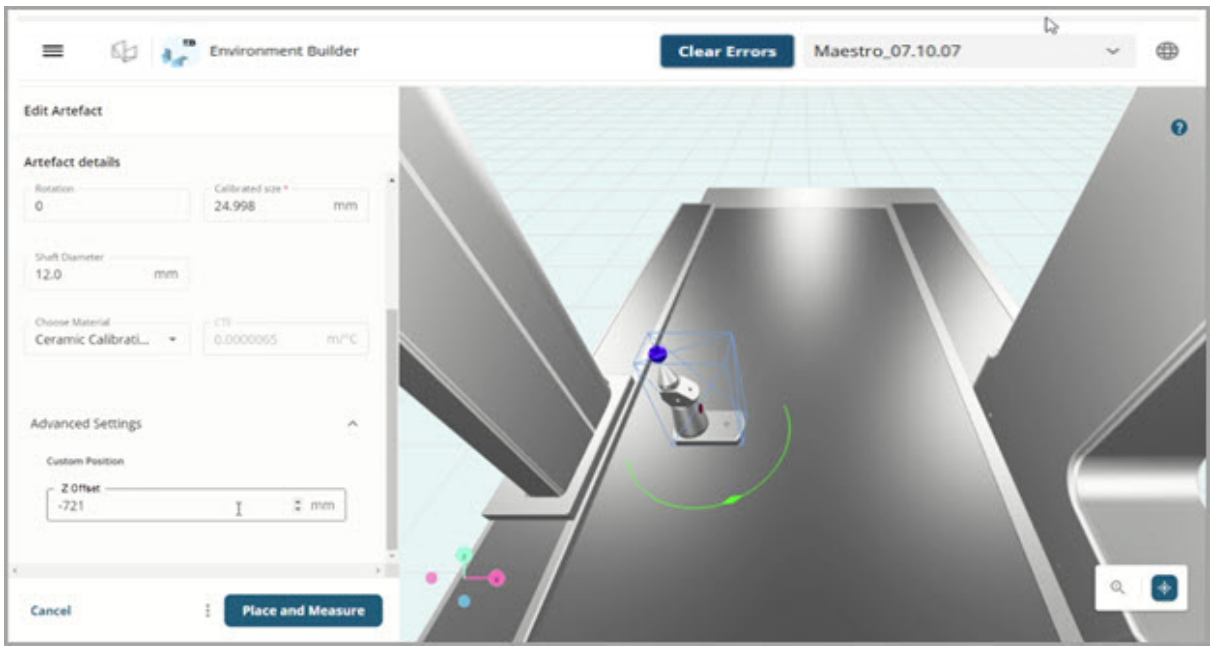
9. From the **Edit Artifact** dialog box, you can define a finer rotation. Type the artifact's angle into the **Rotation** box.

10. Environment Builder inserts a default artifact size value. Type the calibrated size of your artifact into the **Calibrated Size** box. It is stamped somewhere on your artifact's body.

11. From the **Choose Material** list, select the artifact's material type.



12. To define the Z Rise value, in the **Advanced Settings** section of the **Edit Artifact** dialog box, type it into the **Z Rise** box (or use the up and down arrows in the box). This is necessary if the artifact is mounted on a table fixture or has an extension.



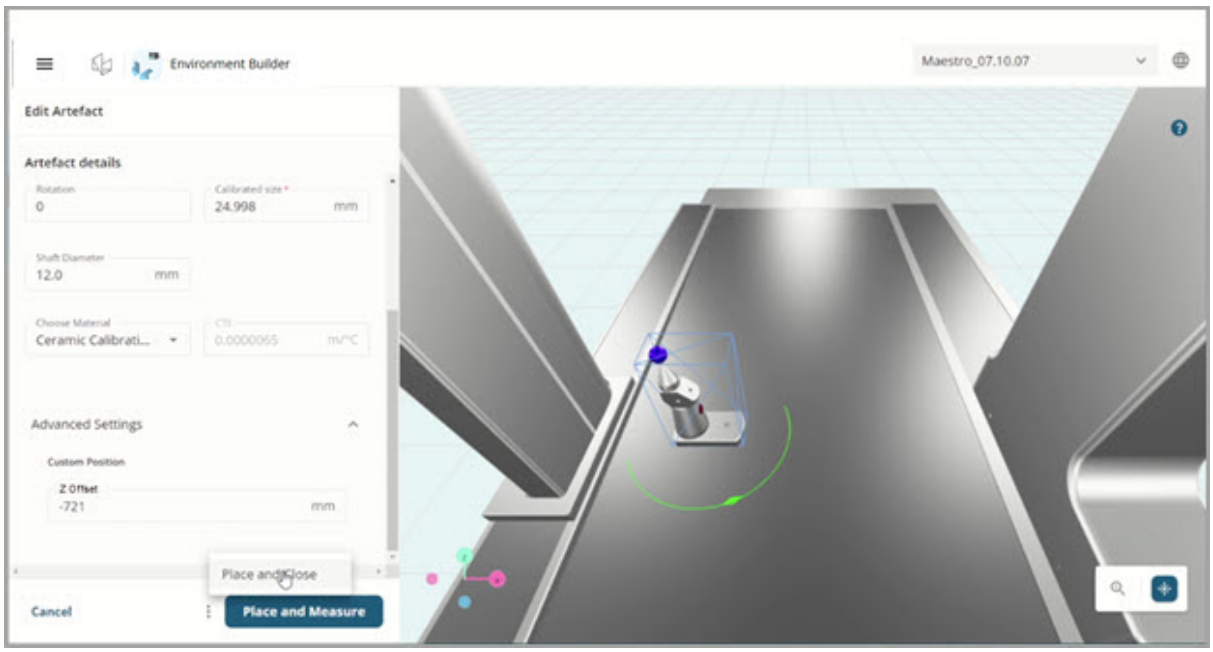
Make sure that all setup options match your physical CMM configuration.

13. Do one of the following:

    - To place the artifact on the virtual CMM for use in probe calibrations, select **Place and Measure**.
    - To save your changes and open the **Artifacts** page, select **More Options** ( ), and then select **Place and Close**.

When you edit an artifact that is already placed, these buttons read **Update and Measure** and **Update and Close**.

> **!** Make sure that all artifact configuration settings are correct before you use it in your measurement routines.



To avoid calibration errors, make sure that the artifact size and material match the artifact's physical specifications.

For accurate probe readings, make sure that you position the artifact correctly.

Tips for Efficiency

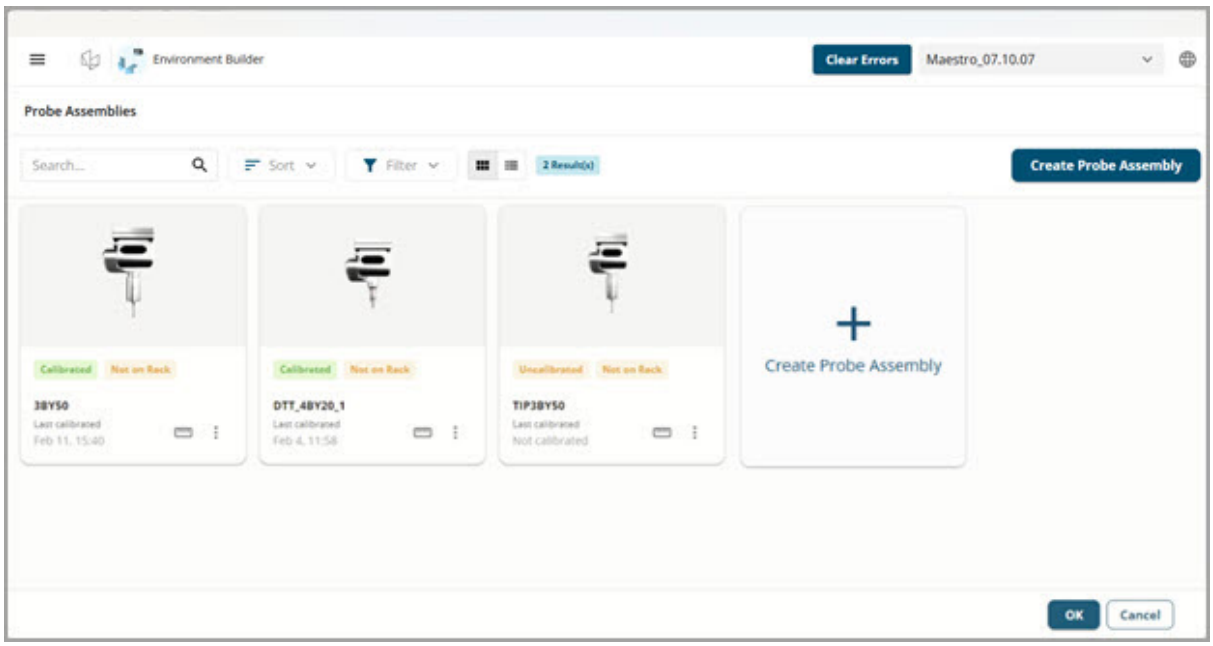
To speed up the setup and calibration processes, familiarize yourself with the Environment Builder's interface.

To reduce future setup time, create a template for common artifacts.

Adding Angles to Probe Assemblies in Environment Builder

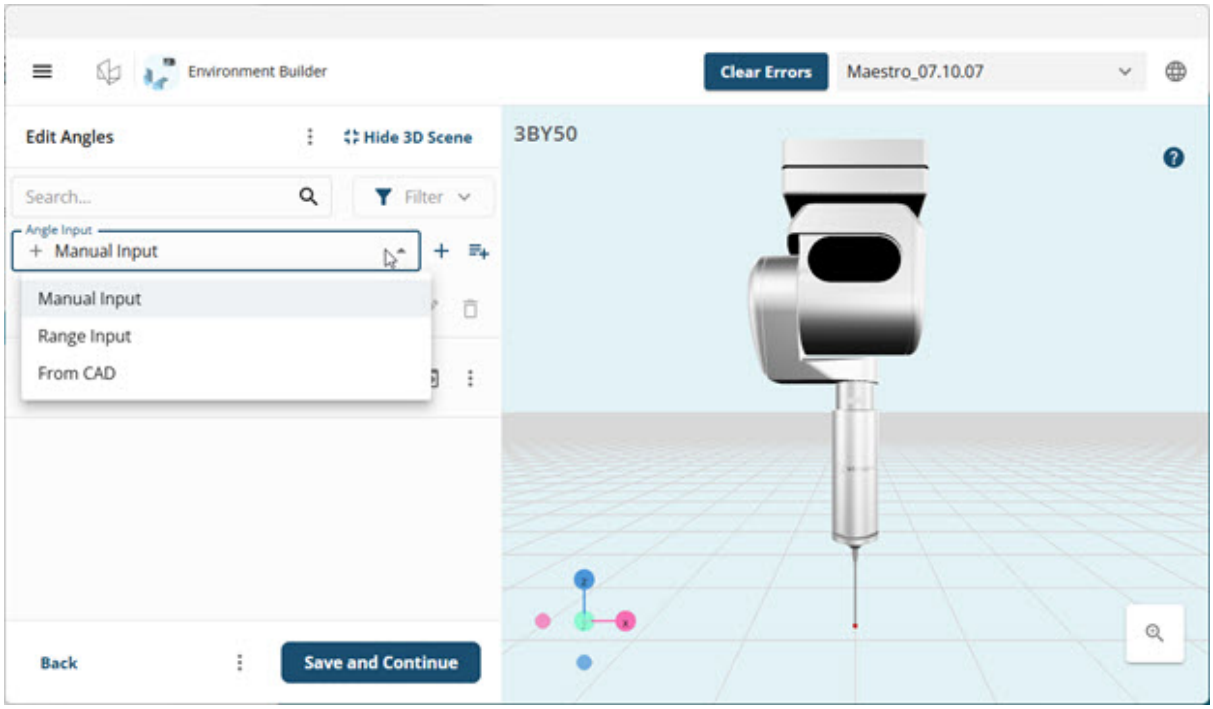
Follow this procedure to add and manage angles in existing Environment Builder probe assemblies.

1. Open the Environment Builder main window. You can see a list of probe assemblies created in Environment Builder.



To open Environment Builder, you can use any of the options detailed in the "Environment Builder - Getting Started" topic in the PC-DMIS documentation.

2. In the **Probe Assemblies** page, on the tile for the probe assembly that you want to add an angle to, select **More Options** ( ) and then select **Edit Angles** to open the **Edit Angles** dialog box.

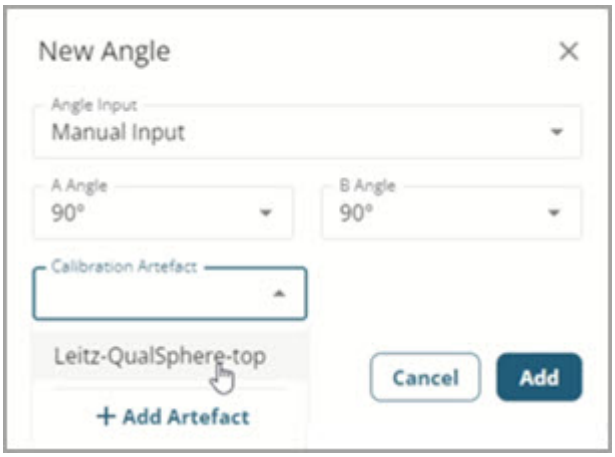


3. In the **Edit Angles** dialog box, add angles using one of these input methods:

If the input method is already selected, select the **+** (**New Angle**) button beside the **Angle Input** list to open the **New Angle** dialog box.

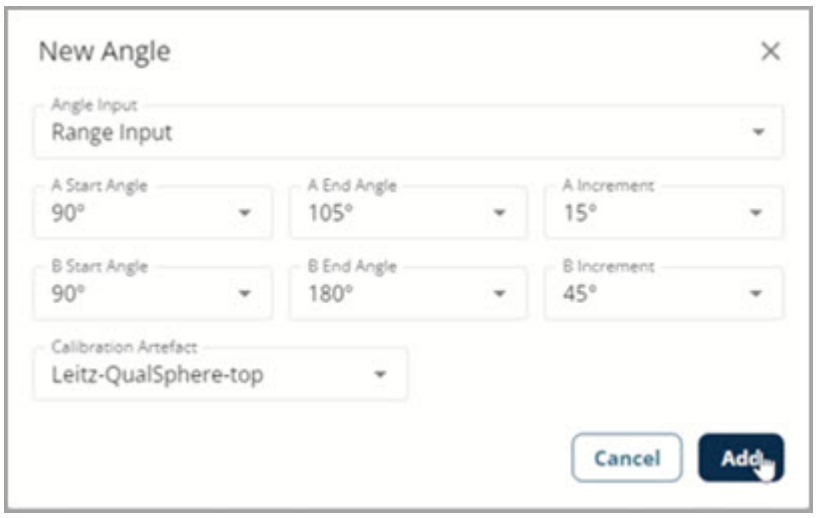
- **Manual Input**

  1. From the **Angle Input** list, select **Manual Input** to open the **New Angle** dialog box.
  2. In the **A Angle** and **B Angle** boxes, type or select the angle values.
  3. From the **Calibration Artifact** list, select the artifact to use, and then select **Add**.



- **Range Input**

  1. From the **Angle Input** list, select **Range Input** to open the **New Angle** dialog box.
  2. In the **A Start Angle**, **A End Angle**, and **A Increment** boxes, type or select the values to add a range of angles.
  3. In the **B Start Angle**, **B End Angle**, and **B Increment** boxes, type or select the values to add a range of angles.
  4. From the **Calibration Artifact** list, select the artifact to use, and then select **Add**.



- **From CAD**

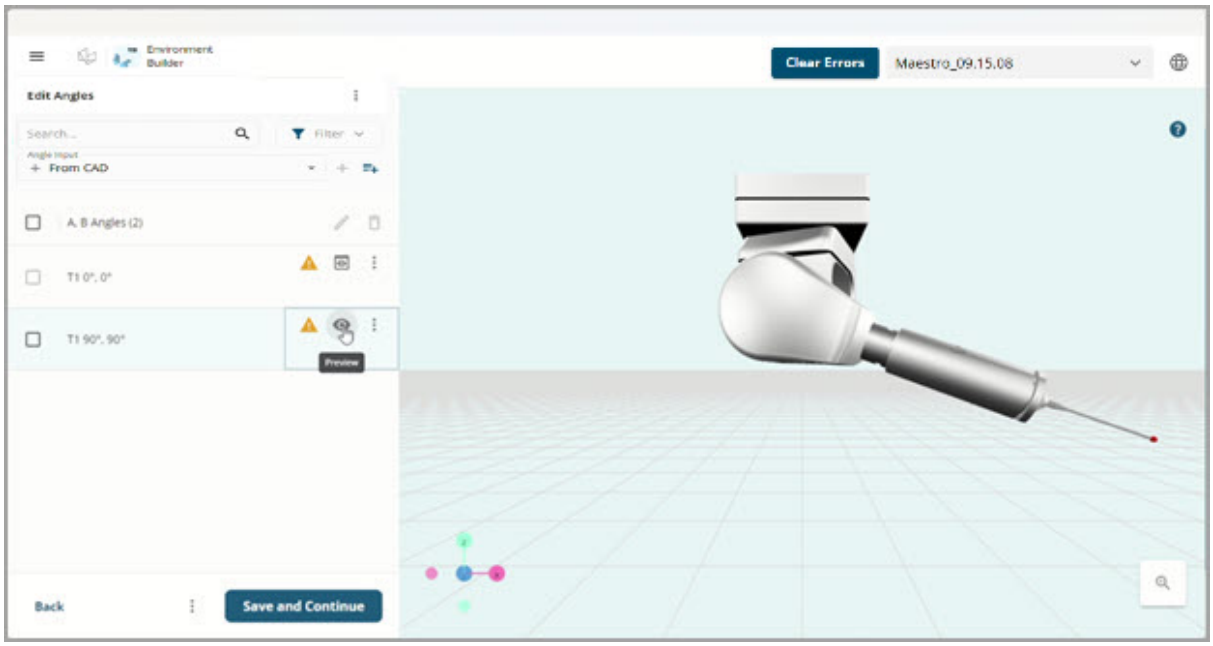
  1. From the **Angle Input** list, select **From CAD**, and then in the 3D scene, select the angle (or angles) directly on the CAD model. Environment Builder adds each selected angle to the list. Unlike **Manual Input** and **Range Input**, an angle that you add from CAD is created without a calibration artifact. It is marked with an asterisk and shows **No Artifact Assigned**.

  2. To assign a calibration artifact, select the angle (or select the **A, B Angles** group), select **Edit** ( ), and then, in the **Select Artifact** dialog box, select the **Calibration Artifact** and select **Update**. Environment Builder assigns the artifact to the selected angles.

You must assign a calibration artifact to every angle before you can select **Save and Continue** or **Save and Close**.

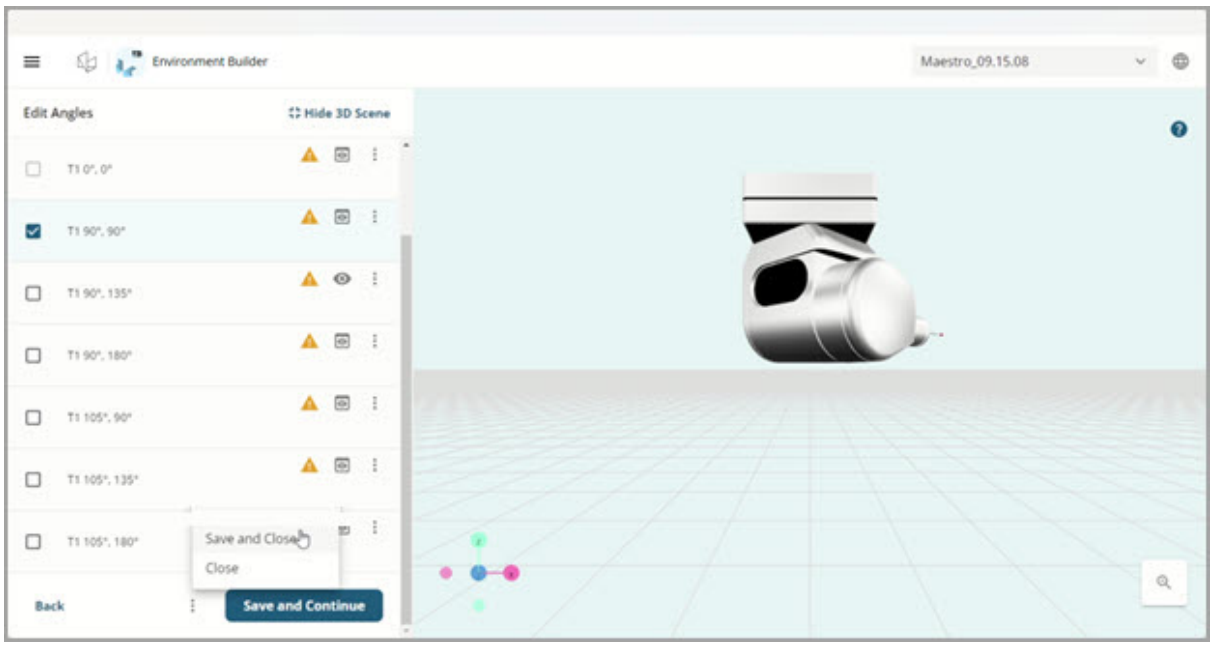
- **Add and select angles from routine** - Select this option to add angles from measurement routines.
  - **This Routine** - Search the current measurement routine for AB angles.
  - **All Routines** - Search for tips used in other measurement routines by the currently-active probe file.

4. To preview an angle, in the **Edit Angles** dialog box, in the row for the angle, select the **Preview** button ( ) to view a simulation of the probe assembly at that angle.



> Be aware of **Caution** icons ( ) next to the tips. These indicate uncalibrated tips. You must calibrate tips before you can use them in your measurement routines. For details, follow the calibration procedures described in the "Calibrating Probe Assemblies" section of the PC-DMIS documentation.

5. Select **More Options** ( ) to show the **Edit**, **Edit Artifact**, and **Delete** options.
6. Review the added angles in the list, and then do one of the following:
   - To save your changes and start calibrating the probe assembly, select the **Save and Continue** button.
   - To save your changes and return to the **Probe Assemblies** page, select **More Options** ( ), and then select **Save and Close**.



To avoid calibration errors, make sure that the angles are calibrated correctly.

Be cautious when you edit or remove angles, as this may cause the angle values to reset to their original, default values.

Tips for Efficiency

Preview angles regularly to confirm their positions before you finalize them.

Selecting a Qualification Algorithm

When you start a calibration, Environment Builder asks you to select an algorithm from the **Select Qualification Algorithm** list. The available algorithms depend on the sensor or styli in your probe assembly:

- **Ball Stylus** – The available algorithms are **Tactile TRAX Qualification**, **Tactile Dynamic Qualification**, and **FastCal Qualification**.
- **Cylinder Stylus** – The available algorithm is **Cylinder Qualification**.
- **Disc Stylus** – The available algorithm is **Disc Qualification**.
- **Line Laser** – The available algorithm is **Line Laser Qualification**.

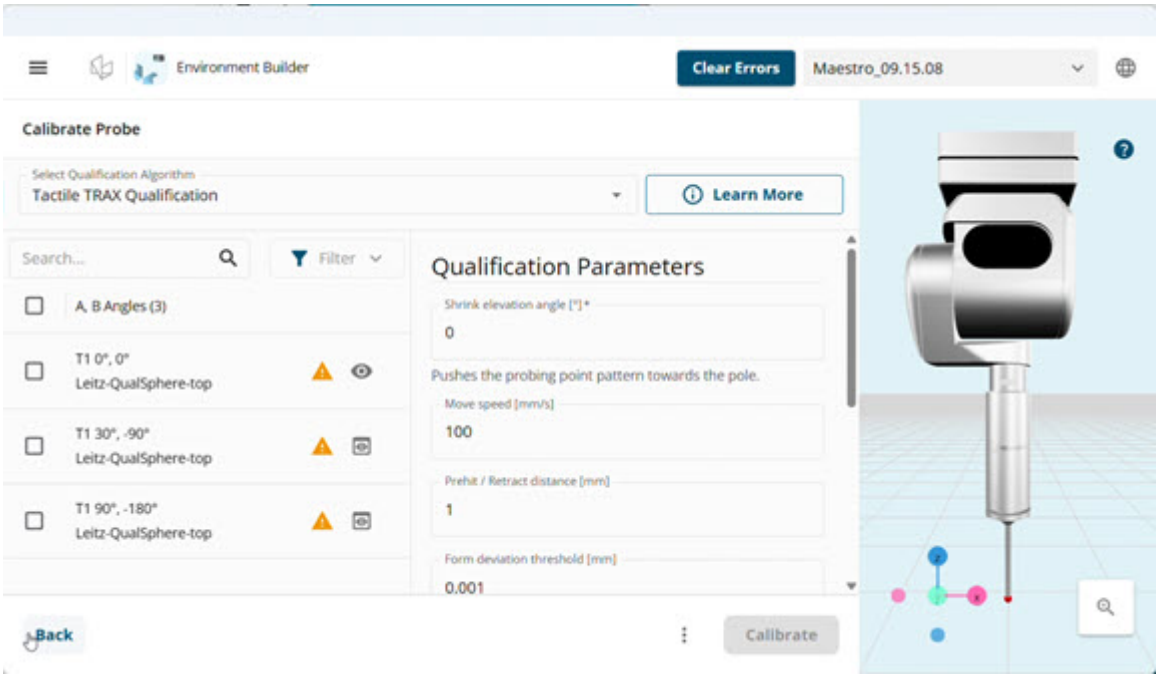
To view detailed information about an algorithm, select **Learn More** next to it.

You can also enable FastCal for a probe assembly without starting a calibration. On the assembly's tile, select **More Options** ( ) and then select **Use FastCal**. Environment Builder displays the confirmation message "Fast Calibration set successfully." To disable FastCal, select **Unset FastCal**. While FastCal is active for an assembly, you cannot edit its angles.

Defining Calibration Parameters

After you select an algorithm, Environment Builder displays the **Parameters** panel, where you select the angles to calibrate and define how the calibration runs. The parameter groups that Environment Builder displays depend on the algorithm you selected.

Use the **Load or create a parameter set** list to reuse a set of parameters. Select **Save Parameter Set** to save the current values with a name. Environment Builder displays the confirmation message "Parameter set <name> saved successfully." Select **Default Parameters** to restore the factory values. If you previously calibrated the assembly, Environment Builder restores your previous selections and displays the message "Angles selection and qualification parameters have been restored from the previous calibration."



The parameter groups are:

- **General Information** – Number of Hits, Prehit/Retract, Move Speed, and Touch Speed.
- **Type of Operation** – Calibrate Tips, Calibrate the Unit, Qualification Check, Home the Unit, and Calibrate ScanRDV.
- **Shank** – Shank Qual, Number of Shank Hits, and Shank Offset.

- **Calibration Mode** – Default Mode or User Defined. When you select User Defined, set the Number of Levels, Start Angle, End Angle, and Touch Speed.
- **Wrist Calibration** – Axis Start, Axis End, and Increments for each wrist axis, as well as Create New Maps or Replace Closest Map, and Tool Mounted on Rotary Table.
- **Fast Calibration** – User Cal Check, Recalibrate, and Reload Factory Map. Environment Builder displays this group only when you select the FastCal algorithm.
- **Tips to use if none are explicitly selected** – All or Used in Routine, as well as Abort Execution and Reset tips to Theo at start of calibration.
- **Calibration Order** – The order in which Environment Builder calibrates the selected angles, from top to bottom.

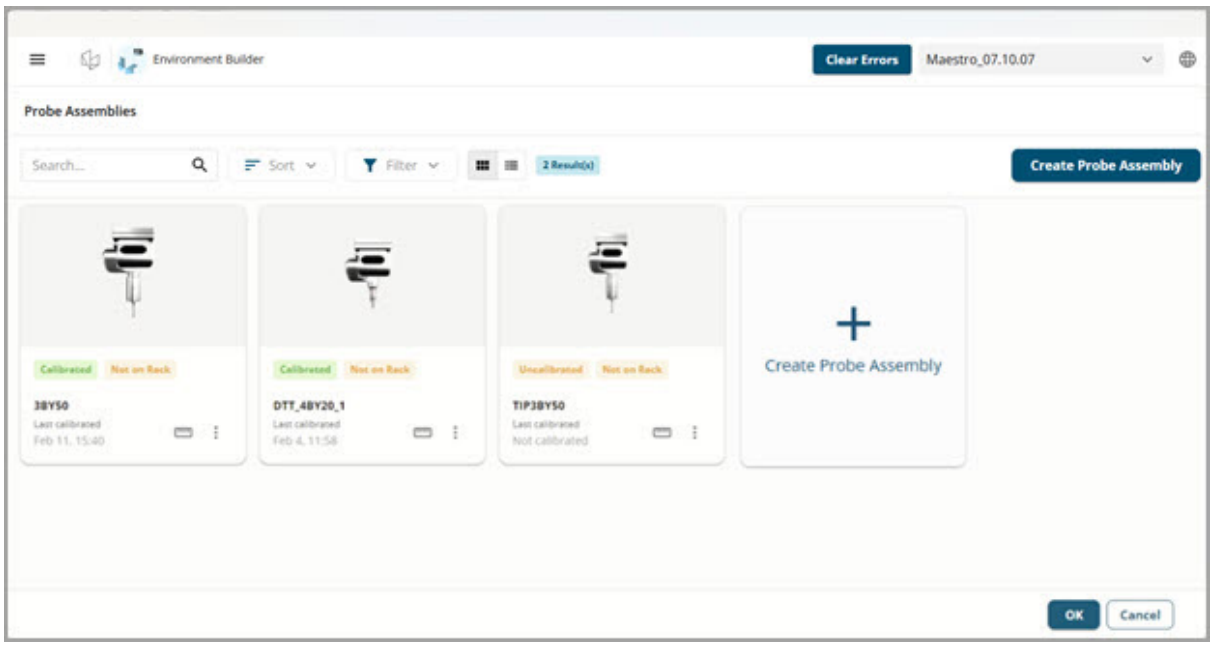
Calibration Order matters when the probe path between two angles could cause a collision. Select **User defined** and drag the angles into the order you want. Environment Builder preserves that order and does not sort the angles automatically. If you have not selected any angles, the group displays "No angles selected."

When you qualify star styli, be aware of possible collisions with the sphere support, depending on the wrist orientation and stylus length. To prevent collisions, adjust the elevation angle or the sphere orientation.

Probe Assembly Calibration Procedure

Follow this procedure to calibrate a probe assembly.

1. Open the Environment Builder main window. You can see a list of probe assemblies created in Environment Builder.

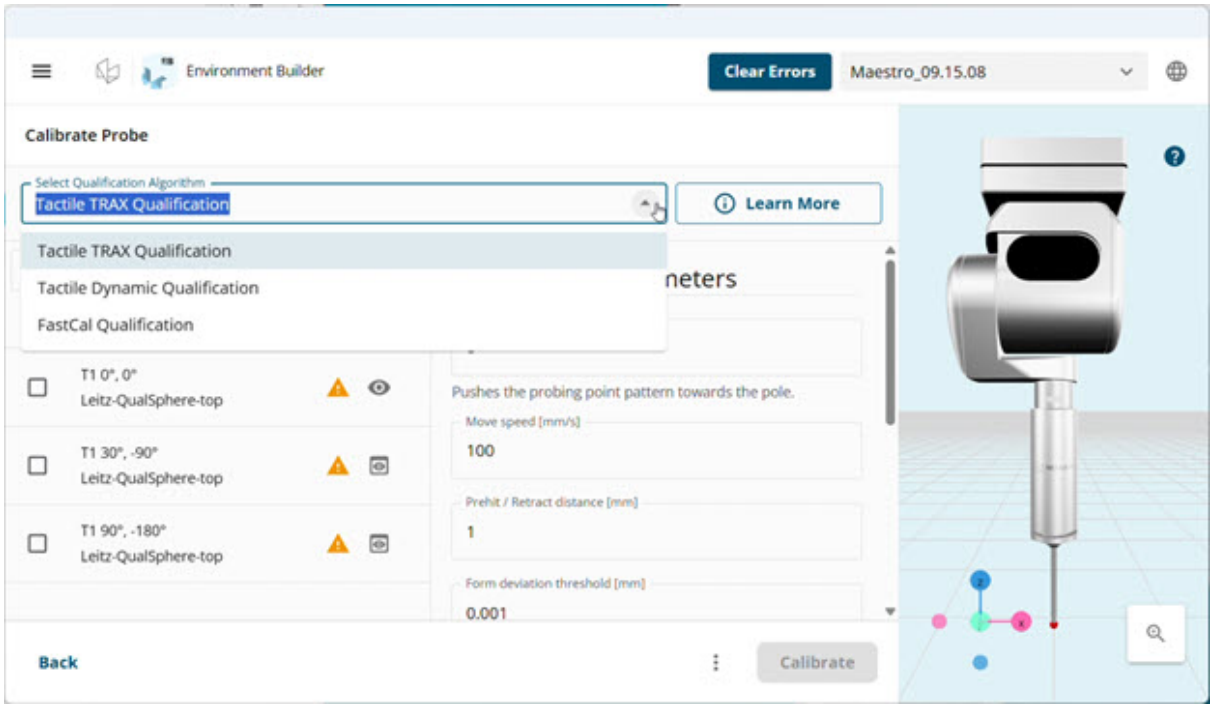


To open Environment Builder, you can use any of the options detailed in the "Environment Builder - Getting Started" topic in the PC-DMIS documentation.

- Probe assemblies that you have successfully calibrated have a green "Calibrated" message in their tiles.
- Probe assemblies that you have not yet calibrated show an orange "Uncalibrated" message in their tiles.

For information on the different calibration states, see "Managing the Probe Assemblies List".

2. From the **Probe Assemblies** page, identify the probe assembly that you want to calibrate. Select **Calibrate** ( ) or select **More Options** ( ) and then **Calibrate** to open the **Calibrate Probe** dialog box to select an algorithm and define the qualification parameters.
3. From the **Select Qualification Algorithm** list, choose a qualification algorithm. For more information, see "Selecting a Qualification Algorithm".



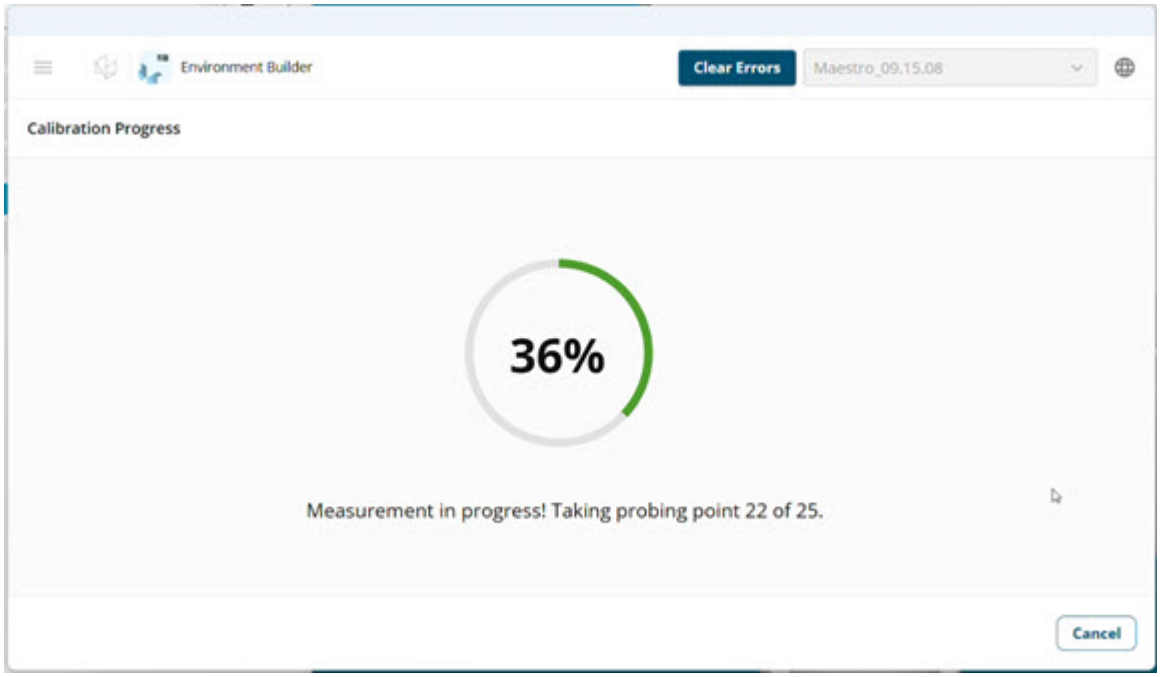
4. On the left side of the **Calibrate Probe** dialog box, select the angles you want to calibrate.

5. On the right side, under the **Qualification Parameters** area, define the qualification parameters. The parameters Environment Builder offers depend on the algorithm you choose.

6. Select **Calibrate** and Environment Builder displays the following message.

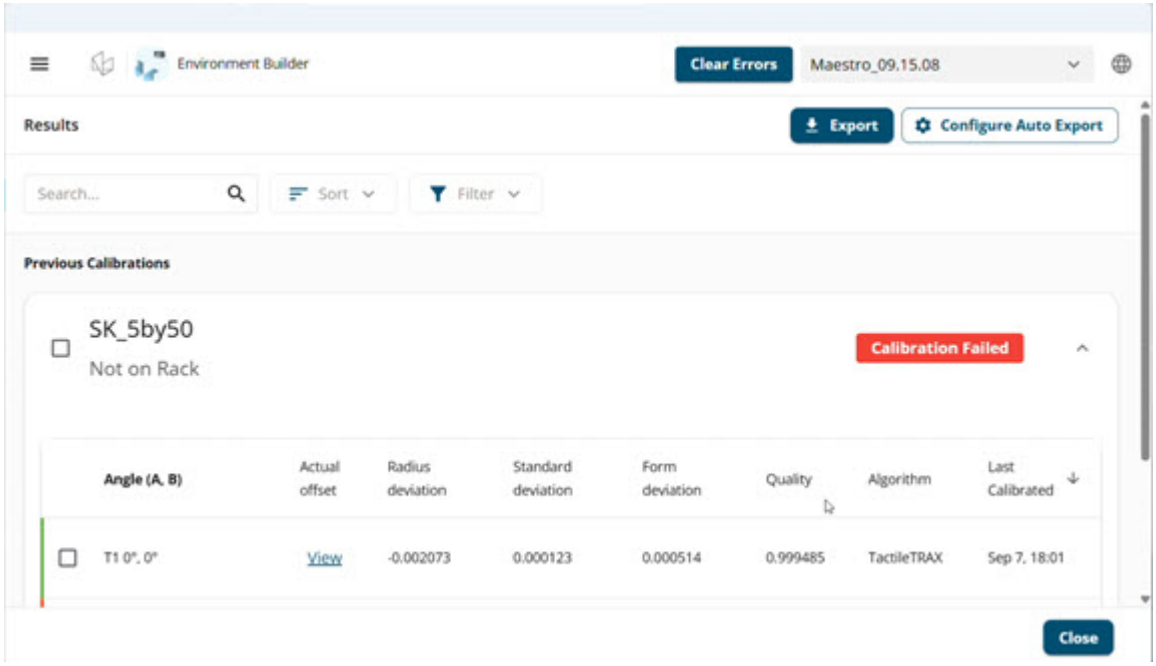
   - If you select **No**, Environment Builder opens the **Calibration Setup** dialog box where you need to select the qualification algorithm and define the qualification parameters and then select **Continue**.
   - If you select **Yes - DCC Hits** or **Yes - Manual Hit**, Environment Builder opens the **Calibration Progress** window.

7. Follow the on-screen instructions to complete the calibration process. A progress bar shows the status of the calibration process.



Environment Builder shows images associated with the probe calibration as it progresses through the calibration process.

8. When the calibration finishes, Environment Builder shows the calibration's **Results** dialog box.



9. Review the calibration results to make sure they meet your specifications. If the results do not meet your specifications, review all setup and parameter settings, make changes as needed, and then repeat this procedure.

Locating a Calibration Artifact

You must locate an artifact with the reference probe that was originally used to qualify it. This probe might not be the probe you selected for the calibration you are about to run. If the probes differ, Environment Builder tells you which reference probe the artifact requires and applies the parameters you set to locate the artifact.

Environment Builder also asks you to confirm whether the artifact has moved. When it displays the message "Has the position of the qualification artifact changed since the last calibration?", select one of the following:

- **No** – Uses the artifact's position from the last calibration.
- **Yes - Manual Hit** – Relocates the artifact by taking a manual hit.
- **Yes - DCC Hits** – Relocates the artifact automatically.

Before moving the wrist, Environment Builder reminds you to make sure that the probe is in a safe position for wrist movement.

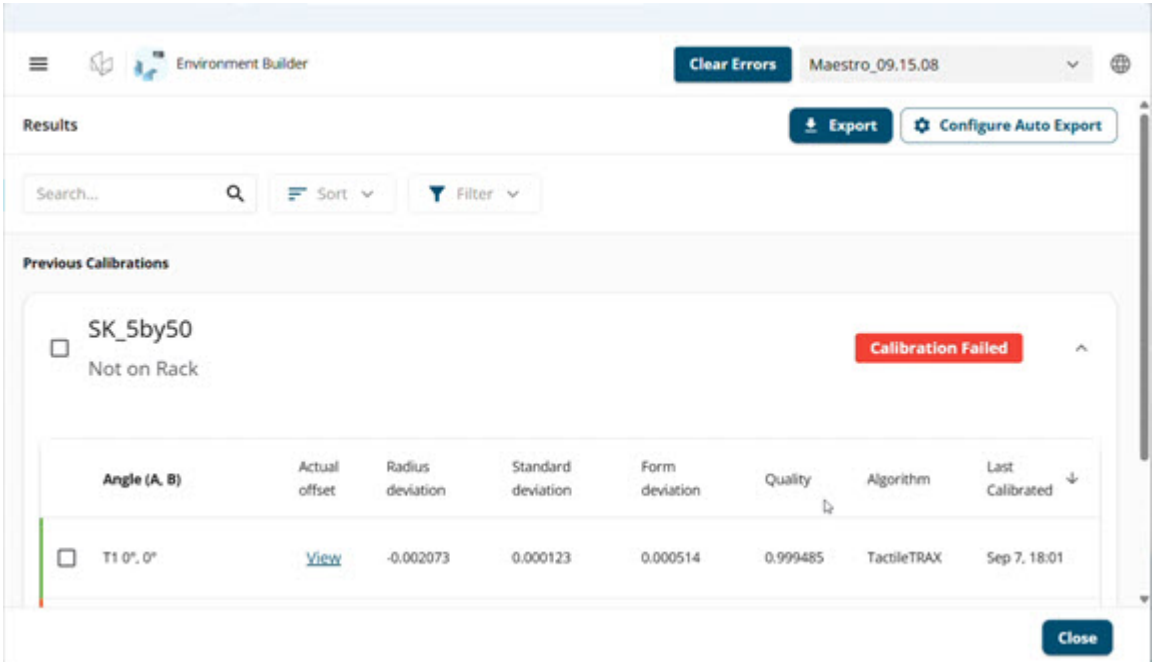
If Environment Builder cannot identify the currently loaded tip, it displays the message "Cannot identify the currently loaded tip! Ensure that you have a tip defined and loaded." To continue, do one of the following:

- Select a reference probe from the list.
- Assign the artifact to a tip. Open the **Edit Angles** dialog box for the loaded probe assembly, assign the artifact to a tip, and then locate the artifact.

You must recalibrate artifacts whose orientation can be changed by hand while they are in use. You cannot calibrate these artifacts in advance. If you change an artifact's **X Position** or **Y Position** after calibrating it, the previous alignment no longer applies. You must measure the artifact's position again.

Reviewing Calibration Results

To review your calibration results, select the menu button ( ) in the upper-left corner of the window, and then select **Results** to open the **Results** page.



The **Results** page contains the following sections:

- **In Progress Calibration** – Shows calibrations that are in progress or waiting to run.
- **Previous Calibrations** – Shows calibrations that have finished.

For each calibrated angle, Environment Builder reports the **Angle**, **X Meas. / Theo.**, **Y Meas. / Theo.**, **Z Meas. / Theo.**, **D Meas. / Theo.**, **Roundness**, and **Std. Dev.** values, along with a status of **Calibration Successful**, **Partially Calibrated**, **Calibration Failed**, or **Calibration Overdue**. Select **Repeat Calibration** to run the entire calibration again, or select **Calibrate Angle** to calibrate a single angle.

Expand a result to view the advanced values that Environment Builder recorded:

- **Tip Details** – Shows the **Size**, **Radial Dev**, **Form**, **Quality**, and **Sigma** for each tip.
- **Probe Offsets** – Shows the **X Offset**, **Y Offset**, and **Z Offset** for the probe.
- **Deflection Matrix** and **Transformation Matrix** – Show the matrices computed during calibration.
- **Maximum Error** – Shows the largest error found for each axis.

If a calibration exceeds the **Sphere Standard Deviation Limit** or **Tip Diameter Error Limit** set in the Environment Builder settings, Environment Builder notifies you and reports each type of deviation in a separate message.

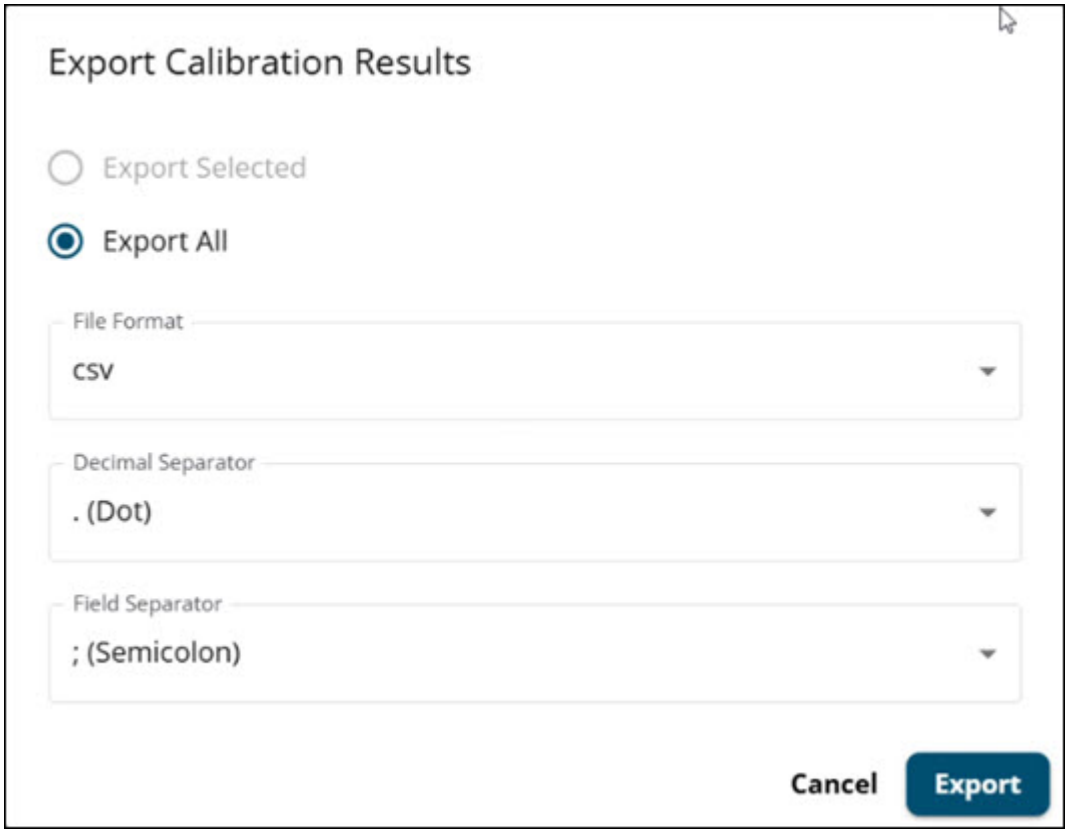
You can also reset a probe assembly's tips to their nominal values. To reset the probe tips, select **Reset Tips** in the **Edit Angles** dialog box. This resets the probe tip offsets to their nominal values and marks the probe assembly as uncalibrated. Use this option only when you intend to recalibrate the probe assembly.

Exporting Calibration Results

You can export calibration results to a file, either on demand or automatically after each calibration.

To export results on demand:

1. Select the menu button ( ) in the upper-left corner of the window, and then select **Results** to open the **Results** page.
2. Select the **Export** button to open the **Export Calibration Results** dialog box.



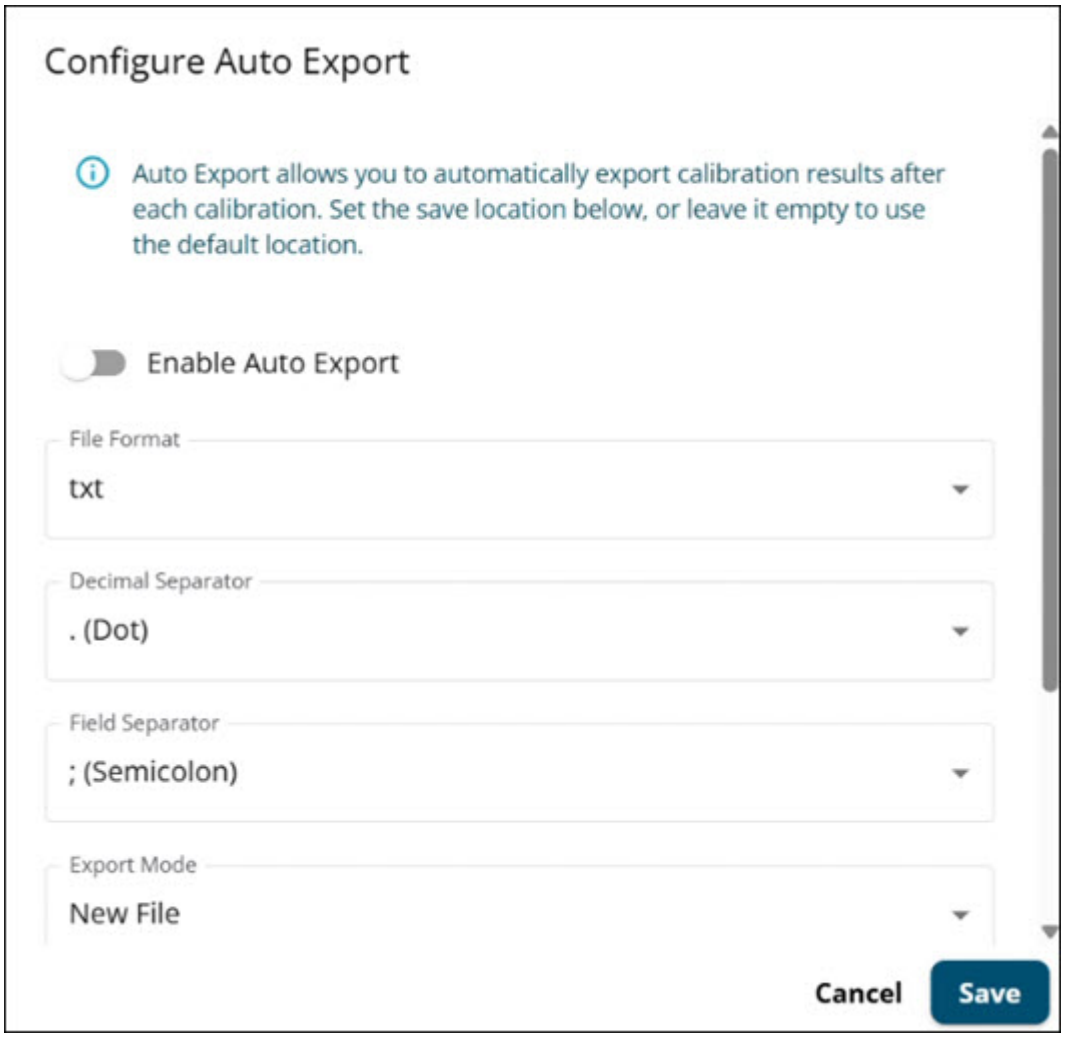
3. Select **Export All** to export every result, or **Export Selected** to export only the results that you selected.

> **Export Selected** is available only when you have selected one or more results in the **Results** page.

4. From the **File Format** list, select the format for the exported file (for example, **CSV**).
5. From the **Decimal Separator** list, select **Dot** or **Comma**.
6. From the **Field Separator** list, select **Comma**, **Semicolon**, or **Tab**.
7. Select the **Export** button to export the results.

To have Environment Builder export results automatically after each calibration:

1. Select the menu button ( ) in the upper-left corner of the window, select **Results**, and then select **Configure Auto Export** to open the **Configure Auto Export** dialog box.



2. Turn on the **Enable Auto Export** toggle.
3. From the **File Format** list, select the format for the exported file (for example, **CSV**).
4. From the **Decimal Separator** list, select **Dot** or **Comma**.
5. From the **Field Separator** list, select **Comma**, **Semicolon**, or **Tab**.
6. From the **Export Mode** list, select **New File** to write a new file each time, **Overwrite** to replace the existing file, or **Append** to add to it.
7. In the **File Name** box, type a name for the exported file. You can use letters, numbers, hyphens, and underscores only.
8. Select the **Save** button. PC-DMIS saves the files to your Downloads folder.

Probe Changers

This section provides you with the workflow that you can use to add, align, and calibrate probe changers in Environment Builder.

Adding Probe Changers in Environment Builder

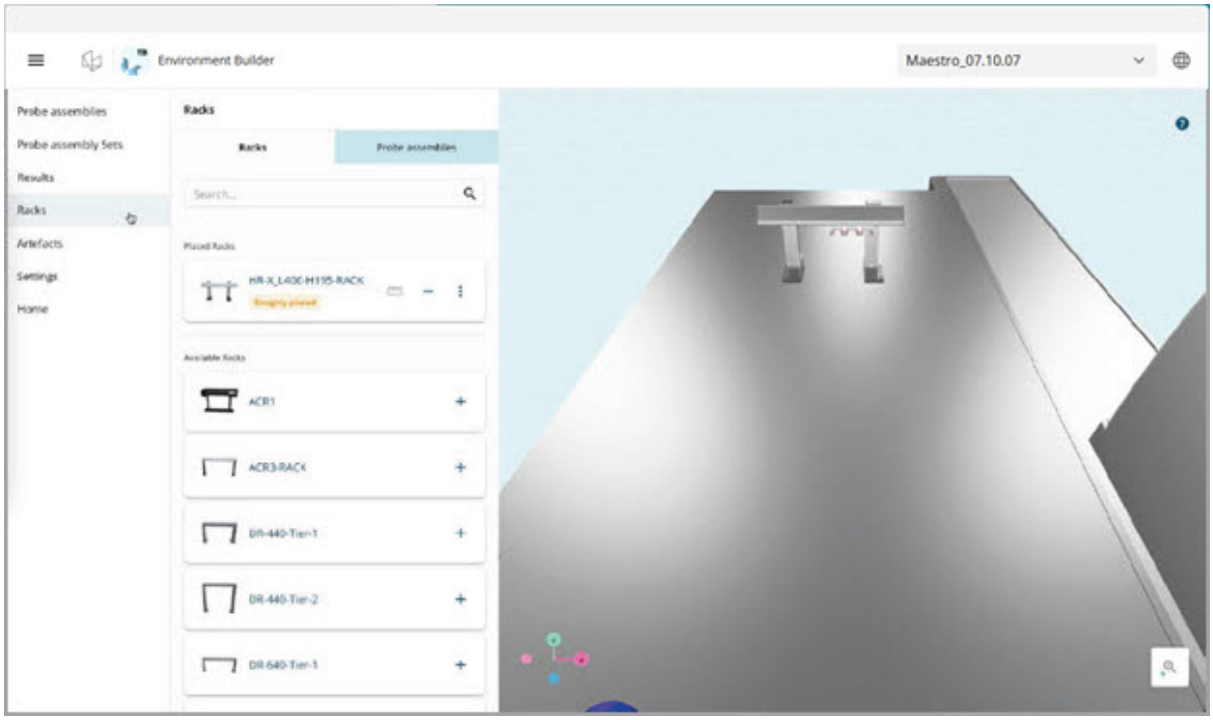
Follow this procedure to add and configure probe changers in Environment Builder.

Familiarize yourself with the list of available racks and their corresponding modules before starting.

Pay attention to part compatibility and probe changer placement.

- To avoid compatibility issues, make sure that the selected probe changer supports the modules that you want to add.
- To prevent operational errors, double-check the probe changer's placement on the CMM table.

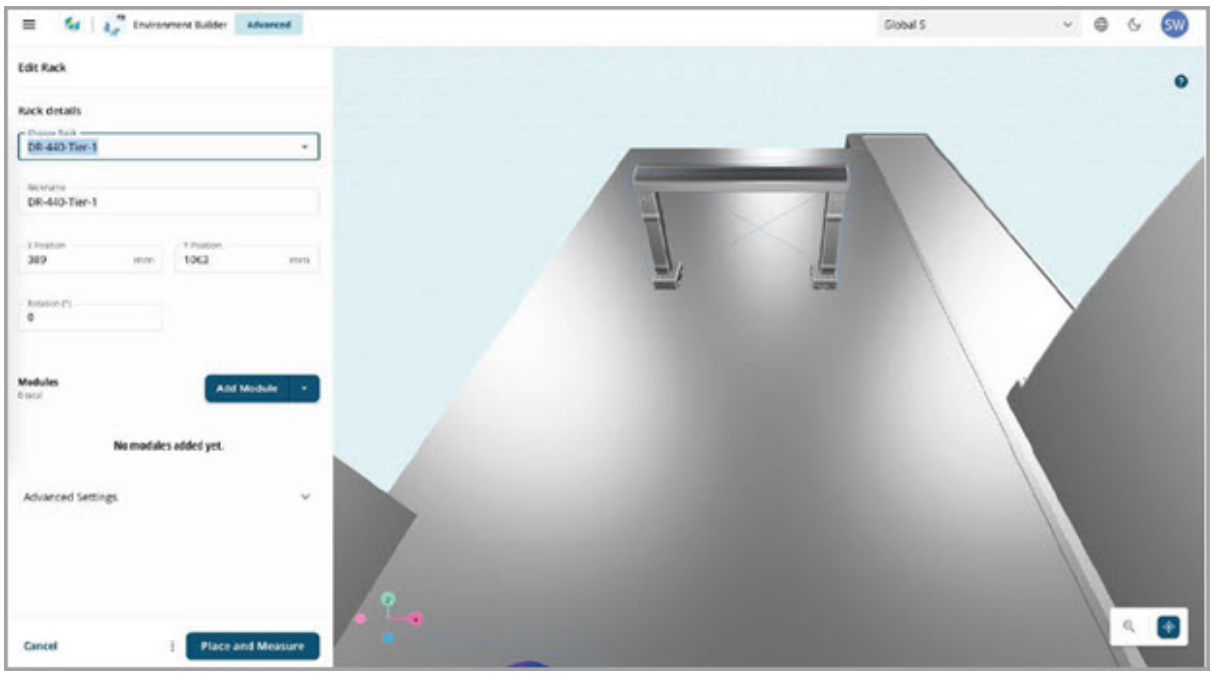
1. Open Environment Builder and click the menu button ( ) located in the upper-left of the window to show the slide-out menu panel and select the **Racks** menu option to open the **Racks** dialog box.



To open Environment Builder, you can use any of the options detailed in the "Environment Builder - Getting Started" topic in the PC-DMIS documentation.

Select the **Close** button ( ) to hide the slide-out menu panel.

2. From the **Racks** page, review the list of available probe changers and select the **Add** (**+**) button to place a probe changer on the CMM table. Drag and drop the probe changer onto a green circle close to where it is mounted on the actual CMM table. For this example, we select the Digital Rack 440 Tier 1 probe changer (DR-440-Tier-1).



3. Refine its position and angle. Select the probe changer in the 3D scene. Type the X, Y, and rotation values into the appropriate boxes (**X Position**, **Y Position**, and **Rotation**) to refine the placement of the probe changer to match the location on the actual CMM table.

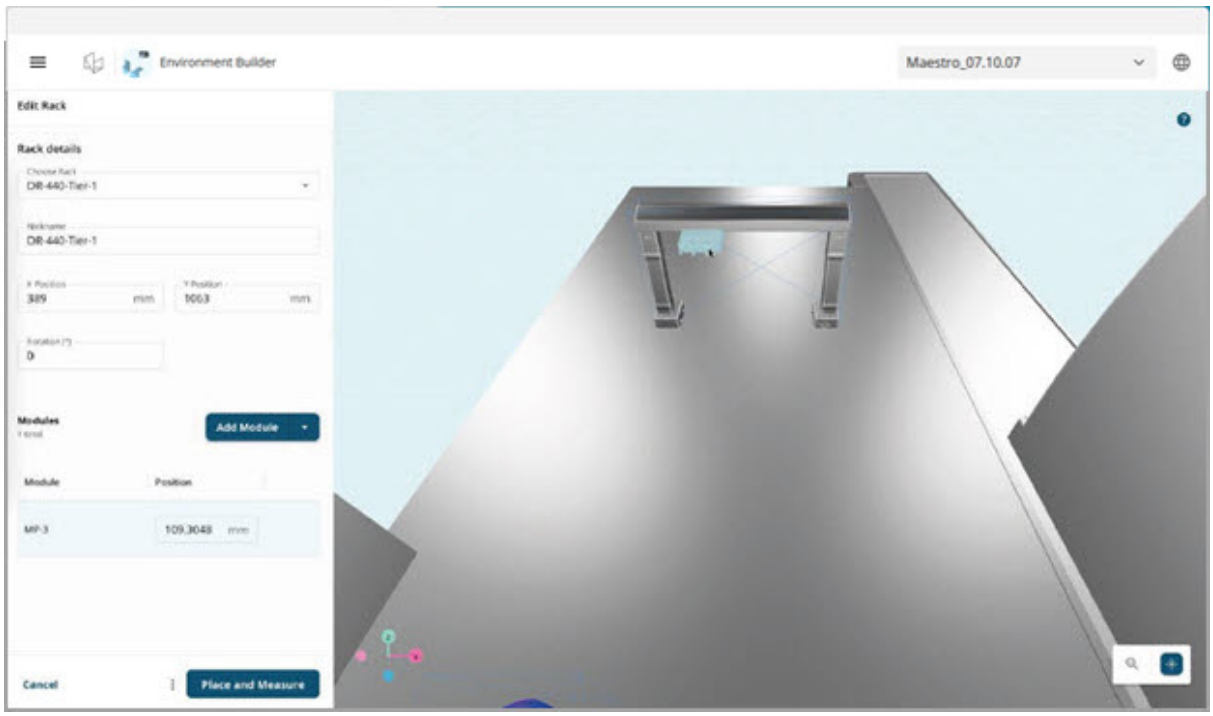
> Use the drag-and-drop functionality for quicker adjustments and positioning.

4. From the **Add Modules** list, select the first module you want to add to your probe changer. Environment Builder populates the list only with compatible modules based on the selected probe changer.

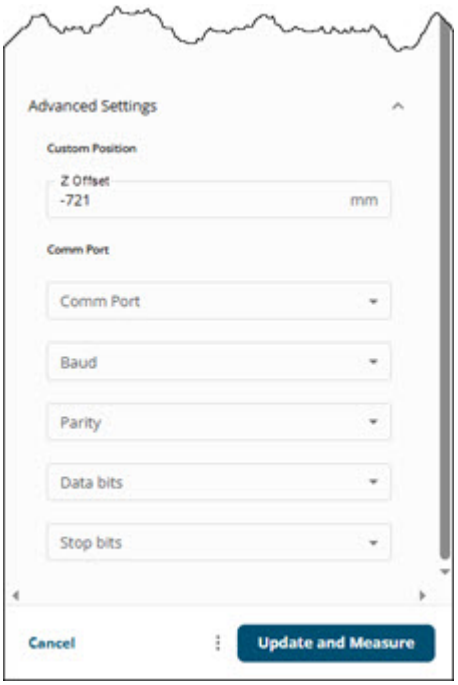
5. Add the remaining modules onto your probe changer. If you need to move a module to a different port on your probe changer, select it, then drag and drop the module onto the new port.

   You must make sure that the placement of each module on the probe changer in Environment Builder reflects the actual configuration of the modules on your CMM's physical probe changer.

   As you add new modules onto the probe changer, you can see the list of added modules with their name and position on the probe changer in the **Modules** section of the **Edit Rack** dialog box.



You have successfully added a probe changer and modules to the probe changer. If your probe changer is mounted on a block, you can account for the additional height by setting the **Z Offset** in the **Advanced Settings** section of the **Edit Rack** dialog box. Also, from the **Advanced Settings** area, you can define the communication settings if needed. These options are shown in the image below.



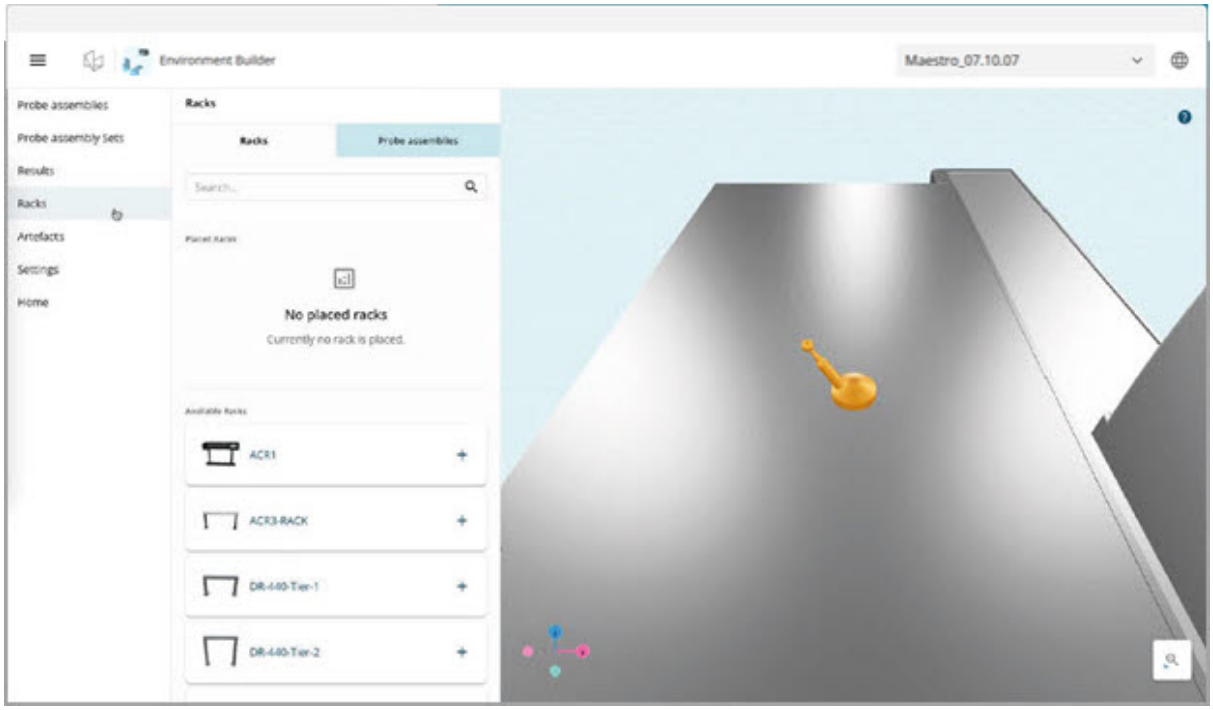
You now need to align and calibrate your probe changer.

Aligning and Calibrating Probe Changers in Environment Builder

Precise alignment and calibration of your probe changer is critical to the operational integrity of your measurement system. Follow this procedure to align and calibrate a probe changer in Environment Builder.

Before you start, familiarize yourself with the Environment Builder interface to move efficiently through the alignment and calibration process.

1. Open Environment Builder and select the menu button ( ) in the upper-left corner of the window to open the slide-out menu panel. Select **Racks** to open the **Racks** page.

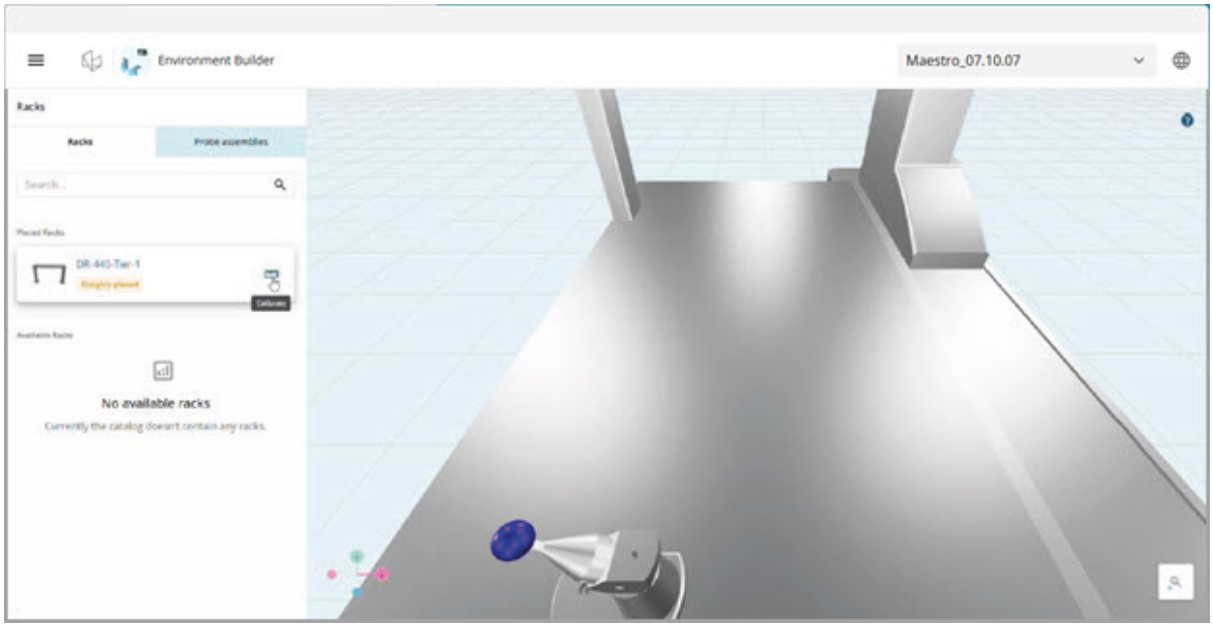


To open Environment Builder, you can use any of the options detailed in the "Environment Builder - Getting Started" topic in the PC-DMIS documentation.

Select the **Close** button ( ) to close the slide-out menu panel.

2. Verify that the probe changer is listed and add it to the Environment Builder CMM table. For information on adding a probe changer, see "Adding Probe Changers in Environment Builder".

3. Select **Calibrate** to open the **Calibration Setup** page. From the **Reference Probe** and **Angle** lists, select the probe assembly and angle to use to align the probe changer.



4. On the **Calibration Setup** page, select the check box for each alignment step that you want to run:

    - **Mount Point Definition** – Establishes the position and orientation of the probe changer.
    - **Tier Alignment** – Aligns the tiers of the probe changer. This step is not available in DCC mode.
    - **Port Alignment** – Aligns the individual ports.
    - **Automatic Port Calibration** – Calibrates the ports automatically. This step requires a valid license.
    - **Extension Alignment** – Calibrates the extensions. This step requires a valid license, and you must assign a tool to an active TKJ port.
    - **Full** – Selects all available steps.

    Before alignment starts, Environment Builder verifies that the required probe tips and angles are available:

    - Use only qualified probe tips referenced to A0, B0. If no qualified tips are available, Environment Builder displays the following message: "Calibration is not possible, as you do not have any qualified tips. Qualify tips to calibrate the rack."
    - For a rack installed along the short CMM axis (X), you need the A90, B180 angle. For a rack installed along the long CMM axis (Y), you need the A90, B90 angle. Environment Builder identifies the missing angle and prompts you to verify the axis along which the rack is installed.

- Select a probe assembly with a straight stylus between D3 mm × L20 mm and D5 mm × L50 mm, such as a DTT or DST sensor.

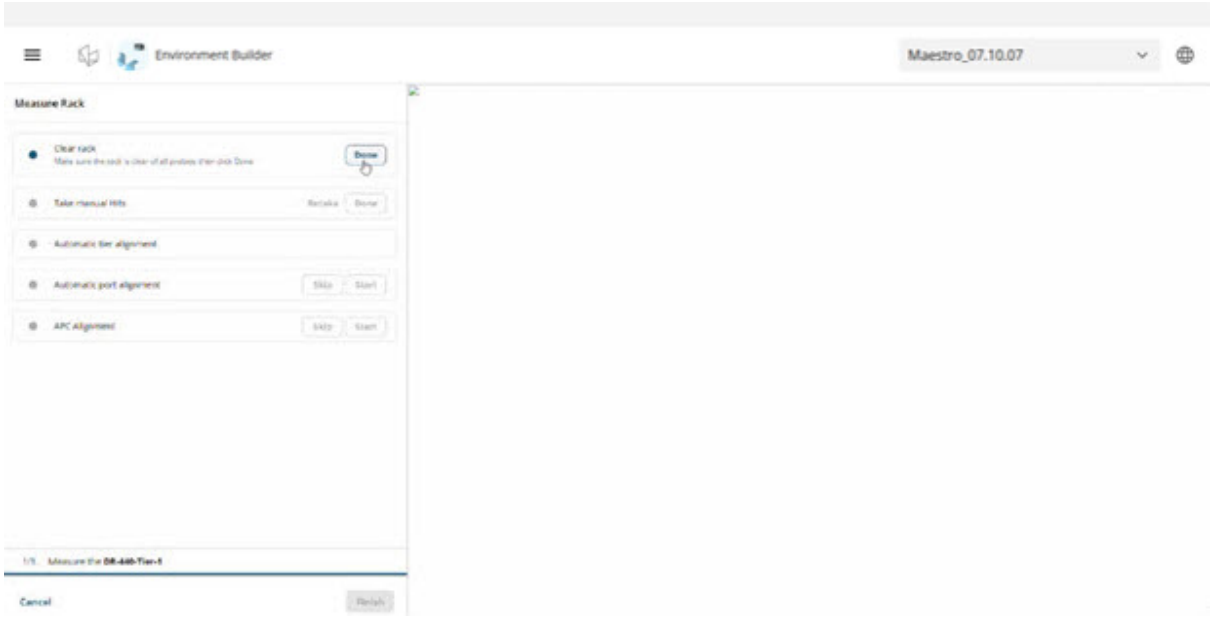
5. Select **Continue** to begin the automatic alignment adjustments and open the **Measure Rack** dialog box. The dialog box displays the probe changer calibration tasks that you must complete.

   All DCC measurements are taken 400 mm from the rack legs. Verify that this area is clear before you continue. In DCC mode, Environment Builder warns you that the machine moves immediately after you select **Continue**.

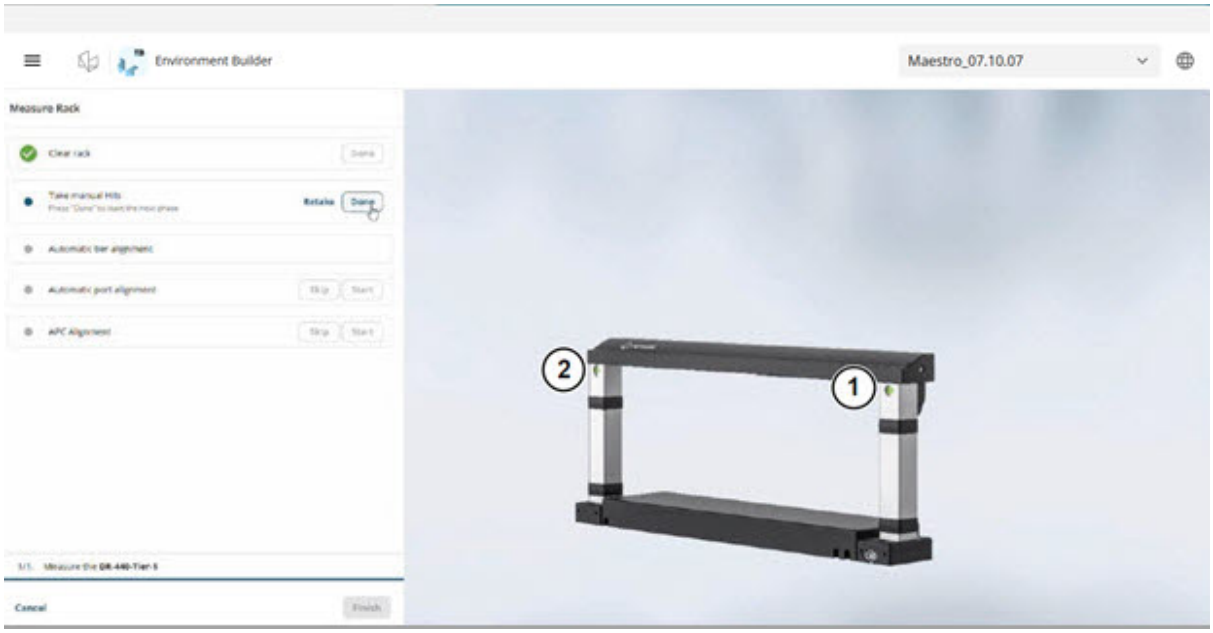
   To stop an alignment that is in progress, select **Stop**. Environment Builder displays the following message: "Are you sure you want to stop the rack calibration? The progress made will not be saved."

6. Verify that the rack is clear. Check that the path from the current probe assembly position to the probe changer is free of obstructions. Also verify that the rack is clear of tools and other objects and is properly adjusted and mounted.

   When the area is clear, select **Done** to complete the task. Environment Builder displays a green check mark for the completed task.



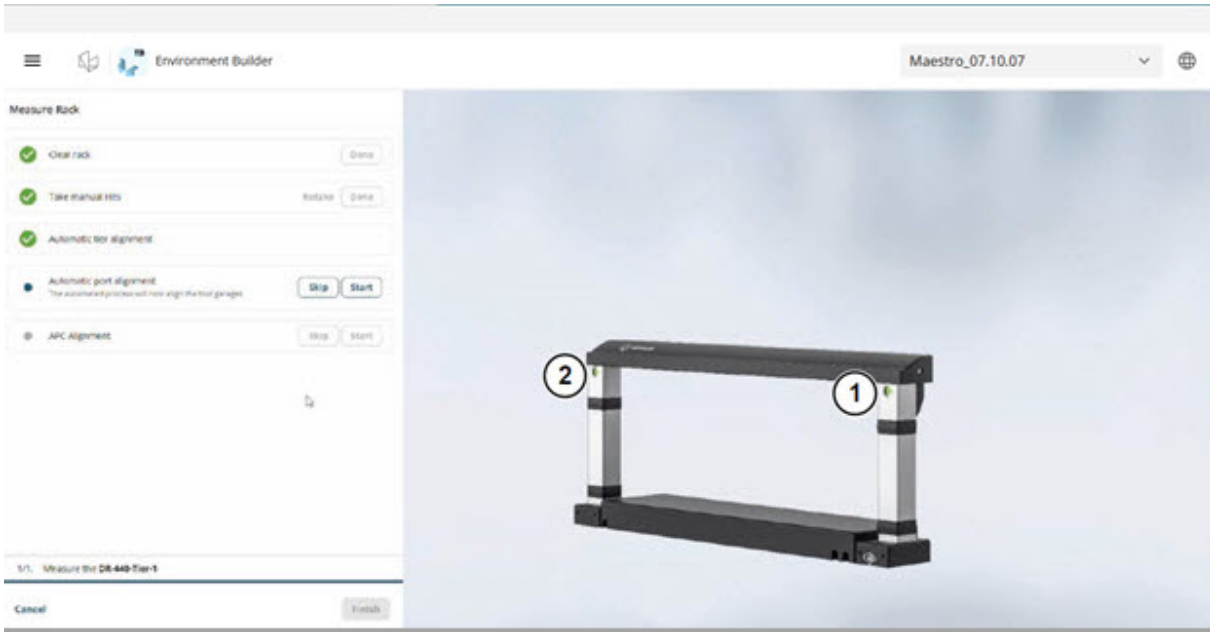
7. On the **Take manual hits** task, follow the Environment Builder prompts to take the first and second manual probe hits at the locations shown below.



You can take the hits anywhere on the flat area at the front of each leg near the top, below the rail connection. Environment Builder uses these hits only to set the orientation of the probe changer for the automatic hits in the next task.

After you take both hits, select **Done** on the **Take manual hits** task. Environment Builder displays a green check mark for the completed task.

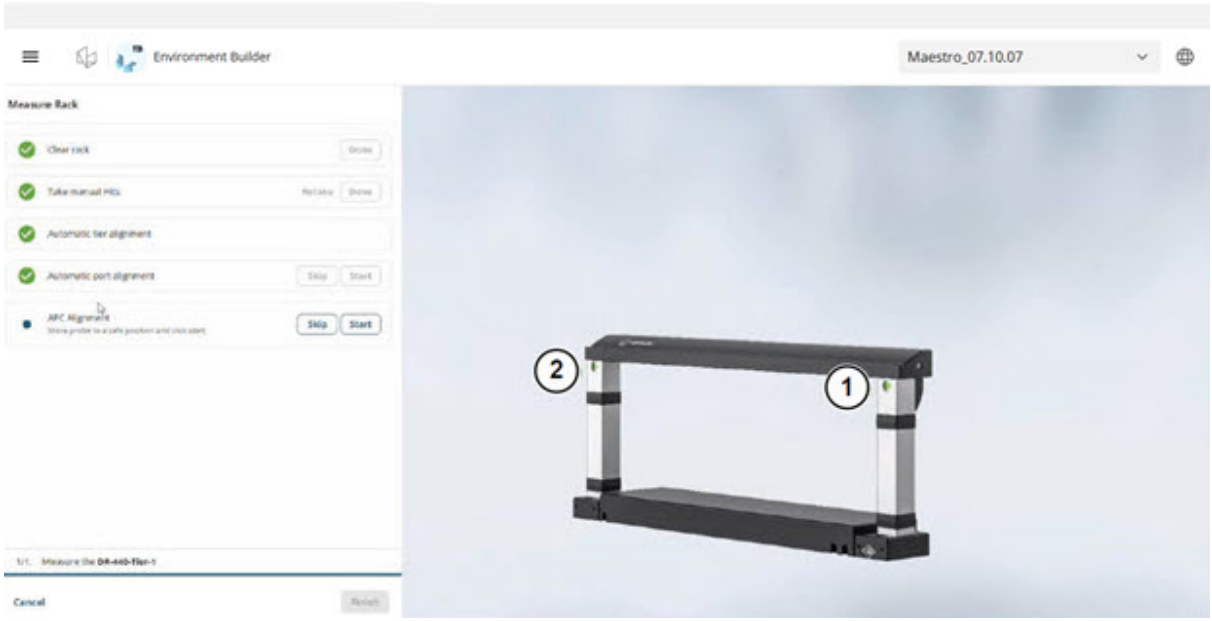
8. The **Mount Point Definition** task runs automatically. No user interaction is required. Environment Builder takes four automatic hits on each hole at the top-front of each probe changer leg, as shown below.



When the task is complete, Environment Builder displays a green check mark for the task.

9. The **Tier Alignment** and **Port Alignment** tasks align the tiers and individual ports of the probe changer. You can start or skip each task.

   Follow the Environment Builder prompts to complete a task. When a task is complete, Environment Builder displays a green check mark and advances to the next task.



If you select **Skip** for an optional task, Environment Builder displays a green check mark for the task and advances to the next task.

10. The **Automatic Port Calibration** task calibrates the ports automatically. You can start or skip this task. A valid license is required. Without a valid license, Environment Builder displays the following message: "Automatic Port Calibration functionality requires a valid license."

    > For example, you can skip this task if you have an X1 sensor and want to change only the stylus configurations (modules), not the sensor.

    To start the task, select **Start** and follow the prompts to take manual hits on the datum sphere. Environment Builder then displays five additional tasks, as shown below.

    
    After you take the required hits, select **Done** on the **Take hit on datum sphere** task. Environment Builder displays a green check mark for the completed task.

11. Prepare for TKJ pin calibration. Unmount the TKJ assembly, and then move the probe assembly to a safe location. Verify that the path between the probe assembly and the probe changer is clear.

    On the **Unmount sensor at the wrist to start TKJ pin qualification** task, select **Done**. Environment Builder displays a green check mark for the completed task.

12. Calibrate the TKJ pin. On the **TKJ pin qualification** task, select **Start**. Environment Builder prompts you to take manual hits on the datum sphere.

    After you complete the required hits, select **Done**. Environment Builder displays a green check mark for the completed task.

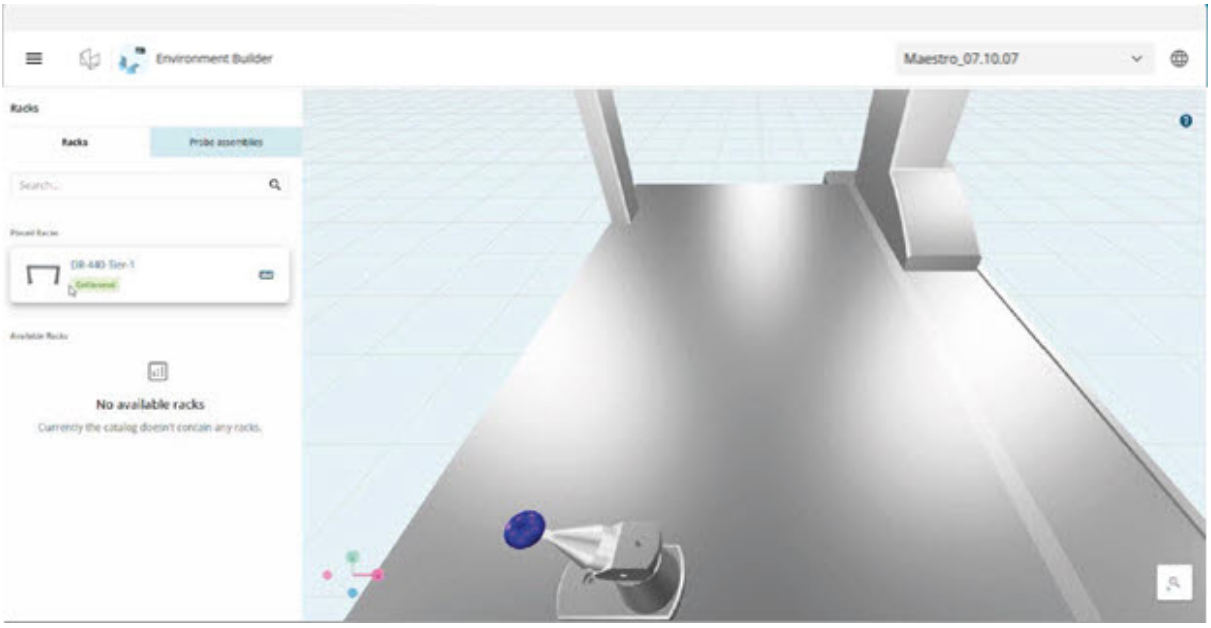
13. The **Extension Alignment** task calibrates each extension in the probe changer. Attach each extension one at a time, and then select **Start** to perform the

qualification check. Repeat this process until you have attached and calibrated all extensions. Then select **Done**.

Environment Builder displays a green check mark for the completed task.

This task requires a valid license, and you must assign a tool to an active TKJ port. Until you meet these requirements, Environment Builder displays the following message: "Extension Alignment is unavailable until a tool is assigned to an active TKJ port."

14. When you complete all the tasks, select **Finish** on the **Qualification is done** task to confirm that the probe changer was aligned and calibrated successfully.



Environment Builder returns to the **Racks** page. The probe changer displays a green "Calibrated" message. You can now use the calibrated probe changer in your measurement routines.

Placing Probe Assemblies on a Probe Changer

After you add and align a probe changer, you can assign probe assemblies to its ports so that the machine knows where to find and return them. You can place an entire probe assembly or only the part that physically sits in the port, called a probe sub-assembly.

To place a probe assembly on a probe changer:

1. From the **Probe Assemblies** page, open the menu on the probe assembly's tile and select **Place on Rack**. You can also right-click a probe changer in the 3D scene and select **Place Probe Assembly**.

2. On the **Parts Selection** step, select one or more adjacent parts to place as a probe sub-assembly. If a part is already placed, Environment Builder tells you where it is: "Part already placed on <rack>, <port>".

3. Select **Continue** to move to the **Rack and Port Selection** step.
4. From the **Choose Rack**, **Choose Module**, and **Choose Port** lists, select where to place the probe sub-assembly.
5. Select **Place**.

The **Racks** page has a **Probe Assemblies** tab that shows **Placed Probe Assemblies** and **Available Probe Assemblies**. Each placed probe assembly shows its location: the rack and port name, **Partially Placed** if only some of its parts are on a rack, or **Placed in Multiple Ports** if its parts are spread across several ports.

Be aware of the following:

- Make sure that the placement of each probe assembly in Environment Builder matches the actual configuration of the physical probe changer.
- If you try to assign the same parts to more than one port, Environment Builder asks you to confirm that you have multiple physical copies of those parts. Otherwise, you cannot assign the same set of parts to another port.
- Use **Probe Utilities** to mark a probe assembly as one that you use with the rack for unloading only.

Clearing Ports and Racks

To remove probe assemblies and modules from a probe changer, right-click in the 3D scene and select one of the following options:

- **Clear Port** – Removes all probe sub-assemblies from the port you right-clicked. Environment Builder asks, "Are you sure you want to remove all probe sub-assemblies?"
- **Clear Rack** – Removes all probe sub-assemblies from the probe changer. Environment Builder tells you how many probe assemblies are affected before you confirm the action.
- **Remove Module** – Removes a module from the probe changer.
- **Remove Rack** – Removes the probe changer from the CMM table.

You can also remove a single probe sub-assembly or all parts of a probe assembly from the racks that contain them. Environment Builder asks you to confirm each action before making the change.

Enabling and Disabling a Digital Rack

You can disable a Digital Rack without removing it from your environment. This is useful when the rack is physically disconnected or when you do not want the machine to use it temporarily.

To disable a Digital Rack, right-click it in the 3D scene and select **Switch Off**. To enable it again, select **Switch On**.

A disabled Digital Rack remains on the CMM table and retains its position, alignment, modules, and probe assembly assignments. You do not have to set it up again when you enable it.

Digital Rack calibration requires a valid license. If you do not have a valid license, Environment Builder displays the message "Digital Rack calibration requires a valid license."

Aligning a Travel Rack

To align a travel rack:

1. Select the travel rack and start the alignment.
2. On the **Select your alignment steps** page, select the steps you want to run:
    - **Mount point definition**
    - **Y-Axis alignment**
    - **Port calibration**
3. Follow the prompts for each selected step. Environment Builder asks you to:
    - Confirm that the rack is clear of tools and other objects and is properly adjusted and mounted.
    - Select the angle for the alignment.
    - Confirm whether the port Y positions have already been adjusted.
    - Move the machine to a safe position before defining the mount point.
    - Move the probe down in Z and adjust Y if needed.
    - Position the sensor down at the wrist when required by the step.

    When the machine is about to move in DCC mode, make sure that the surrounding area is clear and that no personnel are near the machine.
4. If a step fails, clear the machine error and either continue the alignment or abort it.
5. When all selected steps finish, Environment Builder displays "Alignment Completed" and returns you to the **Racks** page.

Creating Auto Features

Creating Auto Features: Introduction

PC-DMIS provides a library of functions and routines to facilitate the automatic measurement of parts. These functions and routines allow PC-DMIS to easily program for measurement a variety of part features and then add them into the measurement routine as "Auto Features". In many cases, this automatic feature recognition is as simple as single-clicking with your mouse on the appropriate feature in the Graphic Display window. While Auto features have their history in sheet metal measurement or in the measurement of other thin-walled materials using PC-DMIS's Direct Computer Control (DCC), today you can use them in both DCC Mode and Manual Mode to measure parts constructed from a variety of materials.

To work with Auto features, select the appropriate feature type from the **Insert | Feature | Auto** submenu. PC-DMIS opens the **Auto Feature** dialog box for the selected feature type. You can then interact with this dialog box to create the necessary Auto features.

The main topics in this chapter include:

- Graphical Representation of Auto feature and QuickFeature Vectors
- Using the ArcReductionAngle Setting
- Quick Ways to Create Auto Features
- Creating QuickFeatures
- Using the Measurement Strategy Widget
- The Auto Feature Dialog Box
- Inserting Auto Features
- Auto Feature Field Definitions
- Setting Up Relative Measure

Depending on your specific version of PC-DMIS, the Auto Feature functionality may only be accessible as an added option to your basic PC-DMIS geometric software package. Consult your PC-DMIS vendor to determine if your version supports this functionality.

Graphical Representation of Auto Feature and QuickFeature Vectors

Vector colors and the dialog box labels associated with the vectors are color-coded for easy identification.

PC-DMIS uses the following colors for both the vector graphical display as well as the respective dialog box label.

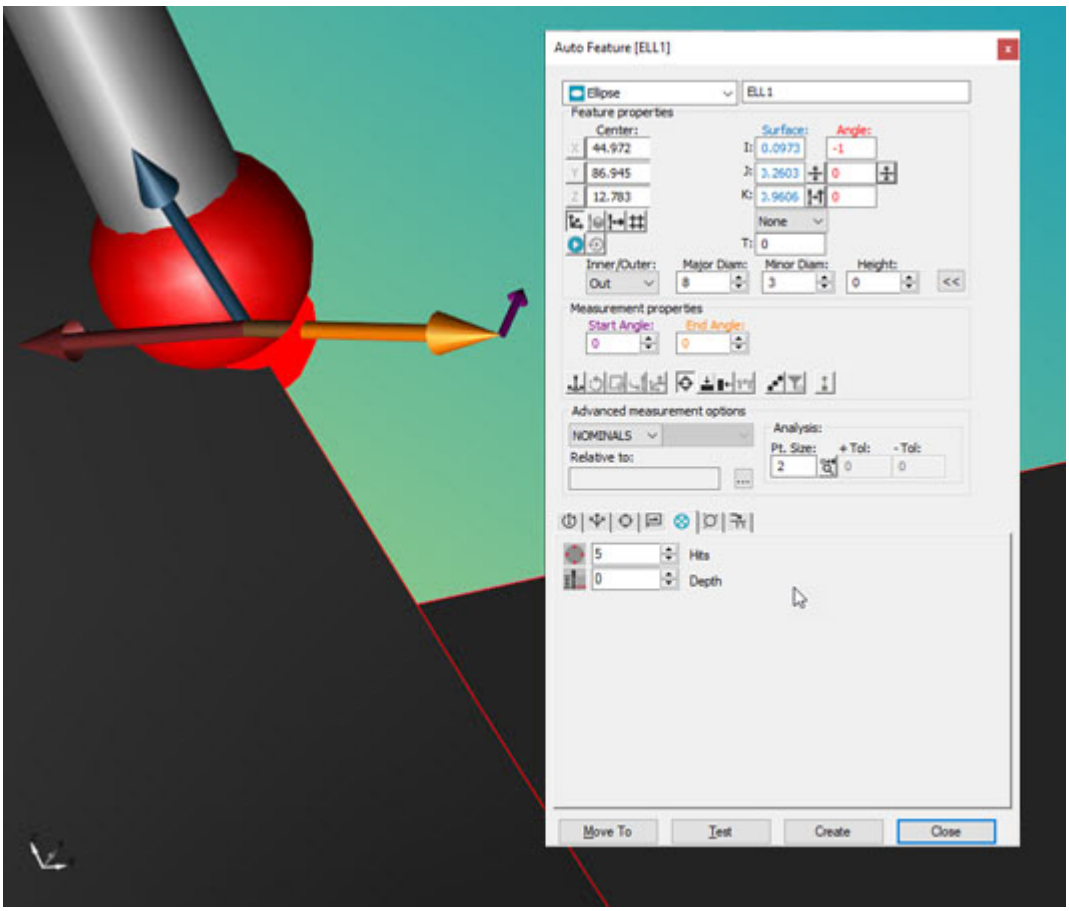
Auto Features

- **Blue** - Auto feature Surface vectors
- **Green** - Auto feature Edge vectors
- **Orange** - Auto feature End Angle vectors
- **Purple** - Auto feature Start Angle vectors
- **Red** - Auto feature Angle and Line vectors

QuickFeatures

- **Light Blue** - QuickFeature Surface vectors
- **Light Green** - QuickFeature Edge vectors
- **Light Red** - QuickFeature Angle/Line vectors

An example of the Ellipse Auto feature showing the Surface vector, Angle vector, Start Angle vector, and End Angle vector is shown below.



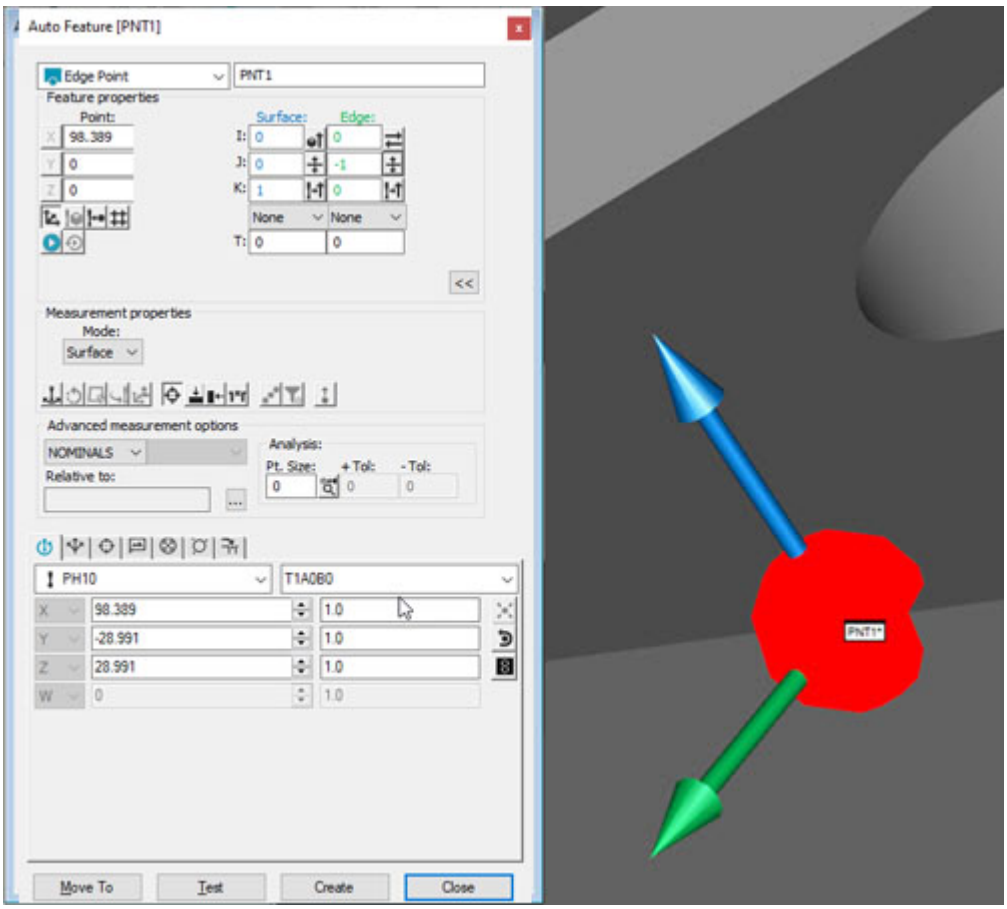
Example showing an ellipse auto feature and its associated vectors.

You can easily determine each vector by associating its color in the Graphic Display window with the labels in the dialog box.

The **Auto Feature** dialog box for the Edge Point example below shows the Surface vector color as blue and the Edge vector color as green. The Surface and Edge labels in the respective dialog boxes are colored accordingly.

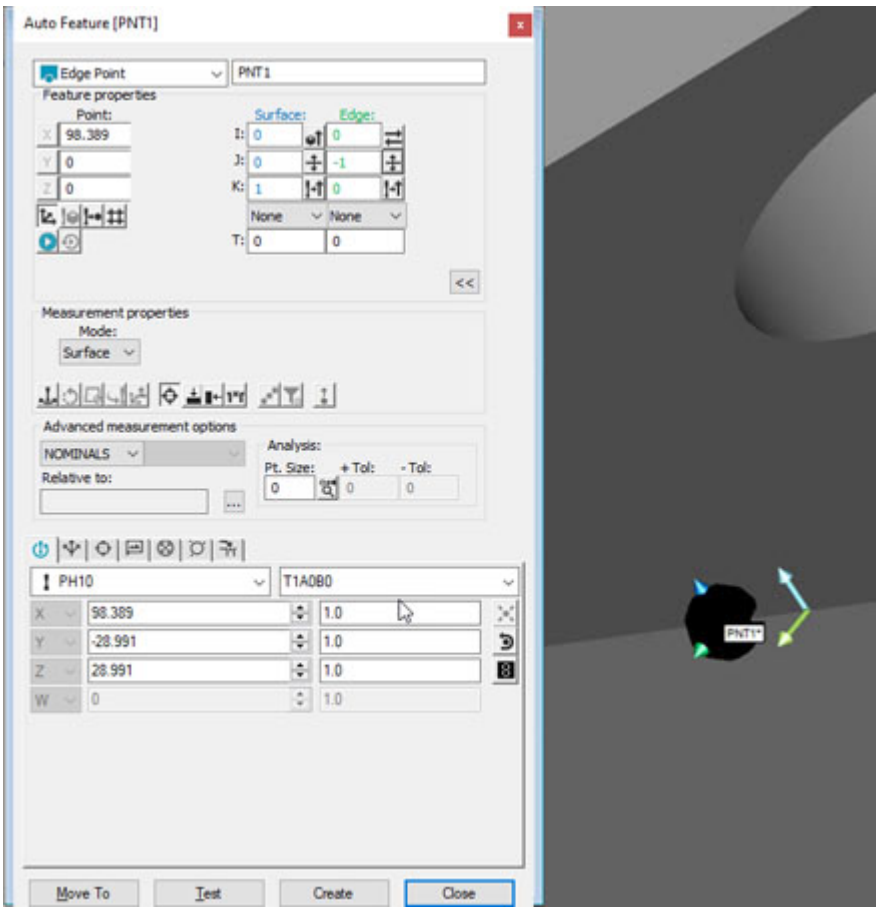
Standardized Vector Sizing

The size of the vectors is set by the **Pt. Size** value entered in the **Analysis** section of the respective dialog. For example, the image below shows the vector size for an Edge Point Auto feature when the **Pt. Size** value is set to 5.



Example of an edge point auto feature with the Pt. Size set to 5.

If the **Pt. Size** value is set to 0 (zero), the vectors are a fixed value and do not auto-scale. This is true for both the Auto features and QuickFeature modes as shown below.



Example of an edge point auto feature with the Pt. Size set to 0 (zero).

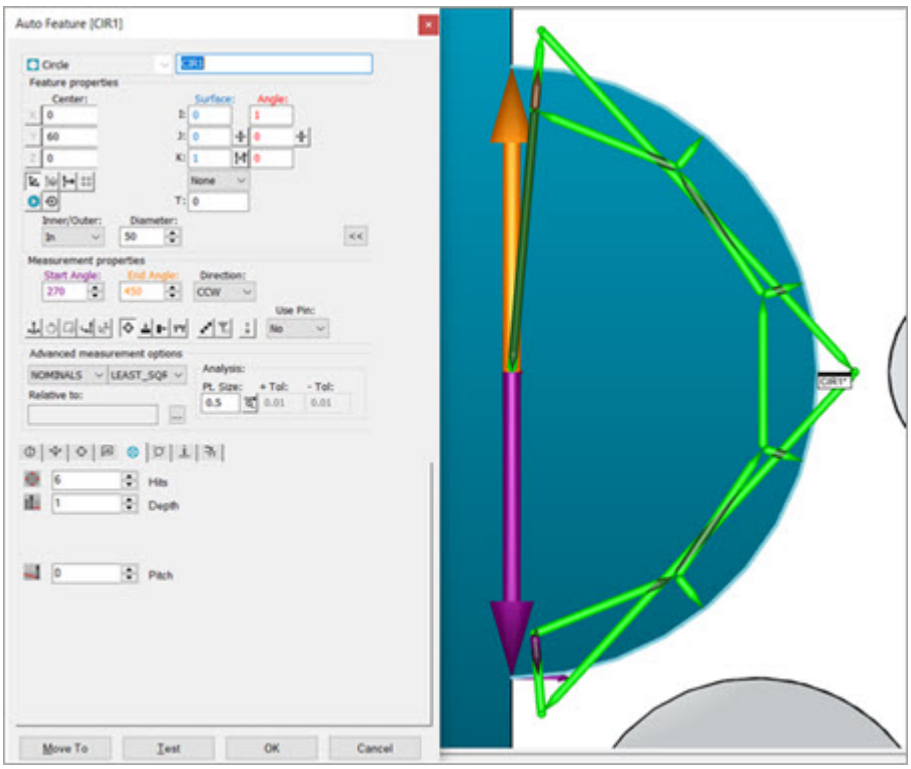
Using the ArcReductionAngle Setting

In the machining process, there is a possibility (based on the tip diameter and/or the part's shape or even in the machining process itself) that the edge of the feature being machined comes out rounded in some way or just roughly machined in the start and end areas. If this is a reoccurring issue, you can define a default arc reduction angle on those features.

The `ArcReductionAngle` setting in the PC-DMIS Settings Editor application allows you to move the first and last probed points away from the edges of a partial hole (or boss). The default value for this setting is 2 degrees but you can set it to a value that works for you. This works for Auto Circle, Auto Cone, and Auto Cylinder feature types.

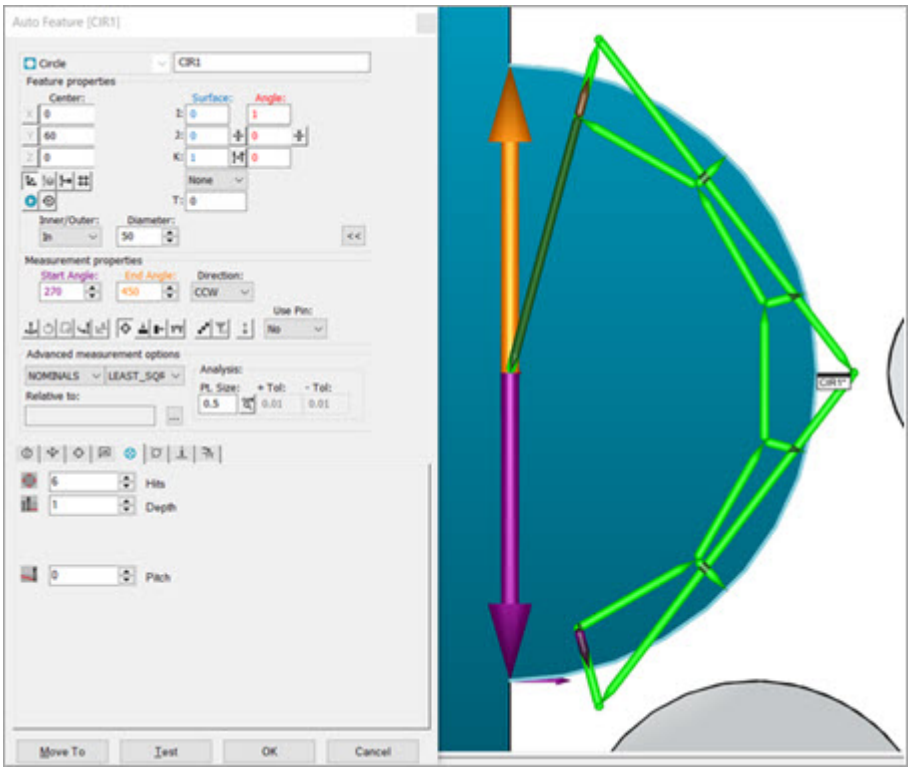
It is important to note that, even on existing measurement routines, if you make a change to this setting, you must restart the measurement routine to allow the change to take effect.

For example, in the images below, you can see the difference when you set the `ArcReductionAngle` value to 5 compared with a value of 15.



Example of a semi-circle feature with the ArcReductionAngle value set to 5.

When you run your measurement routine with this setting and you defined the measurement of this feature to measure from 0 to 180 degrees, PC-DMIS would actually measure this feature between 5 and 175 degrees.



Example of a semi-circle feature with the ArcReductionAngle value set to 15.

When you run your measurement routine with this setting and you defined the measurement of this feature to measure from 0 to 180 degrees, PC-DMIS would actually measure this feature between 15 and 165 degrees.

Quick Ways to Create Auto Features

In addition to entering values to create your auto features, the following modes are also available:

- Box selection - Click and then drag to box-select several CAD elements. Once you click **Create**, PC-DMIS creates, at once, multiple Auto features from the selected set of features.
- Single-Click selection - Click once on a supported CAD element to populate the **Auto Feature** dialog box with the appropriate nominal values.
- QuickFeature selection - Depending on the CAD element, press Shift or Ctrl + Shift, and then position your mouse pointer over a CAD element. Once PC-DMIS highlights the feature, click on the CAD element to create the associated Auto feature. For details on how to create QuickFeatures, see "Creating QuickFeatures".

Box-Selecting to Create Multiple Auto Features

You can draw a box on top of a CAD image to automatically create multiple Auto features for these supported feature types:

- Auto Vector Point
- Auto Surface Point
- Auto Edge Point
- Auto High Point
- Auto Circle
- Auto Cylinder

To Box-Select and Create Features

To use the box-select method to create multiple auto features of either the circle or cylinder Auto feature types, follow this procedure:

1. Import the CAD model that has the Auto features you want to box-select.
2. Rotate the part and select either wireframe or solid to select a view that best shows the features you want to include.

3. Access the **Auto Feature** dialog box (**Insert | Feature | Auto**) for either circle or cylinder Auto features.

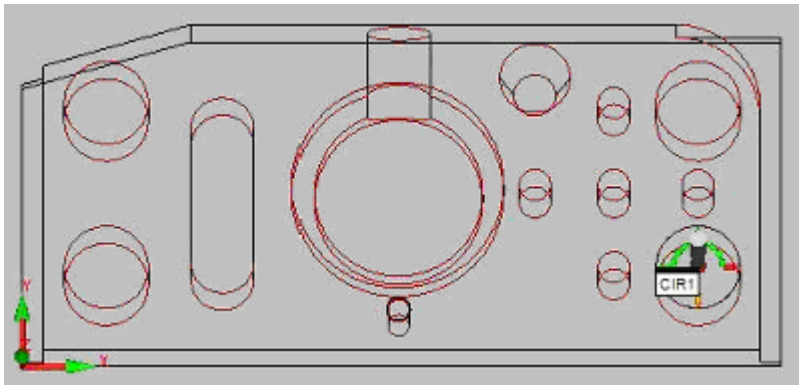
4. With the dialog box open, click the mouse, and drag a box around those feature types for which you want to create Auto features. Release the mouse button. PC-DMIS displays the **CAD Select** dialog box, showing the number of objects selected.

5. Click **Create**. Based on the objects selected, PC-DMIS generates multiple Auto features of the selected type.

Box-Selecting Details

- Box-selecting only works on objects visible in the Graphic Display window. This prevents unseen objects from being used in the creation of features.

- Models with little or no wireframe geometry should be slightly tilted (or rotated) in the Graphic Display window so that the desired surfaces and features are visible as shown below.

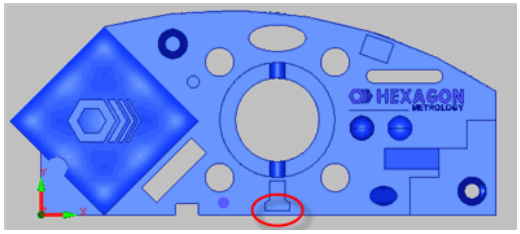


Example of a slightly rotated part.

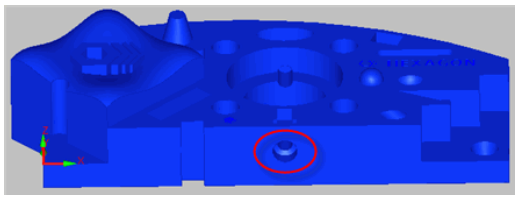
- Because of tessellation and display accuracy, the bleeding of underlying surfaces and curves may result in extra unexpected objects used to create the features. While PC-DMIS attempts to minimize this bleeding by comparing the selected objects with each other to determine the minimum number of pixels necessary to be considered a valid selection, this is not a foolproof method, and some mostly hidden objects may get selected in order to minimize the likelihood of eliminating a valid object.

- When creating the features from the selected objects, objects with vectors perpendicular to the current view are mostly ignored. For example, using the Hexagon block displayed in Z+ with the entire model box-selected, PC-DMIS will not generate a feature for the front bore that intersects the center bore.

  Selecting in the Z+ view, this circle's vector is perpendicular to the workplane and therefore PC-DMIS would not generate a circle for it.



If you tilted the part and then box-selected, PC-DMIS would select this feature.

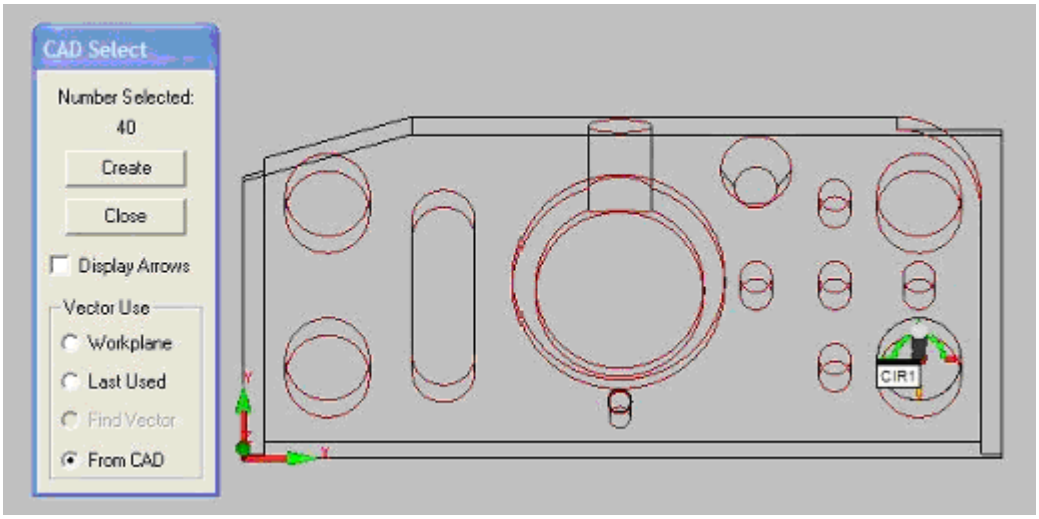


- PC-DMIS performs filtering routines to ensure that it doesn't use the same CAD object to create another feature in the same position.
- As PC-DMIS generates the features after you click **Create**, you can see each item's information displayed in the Status bar.

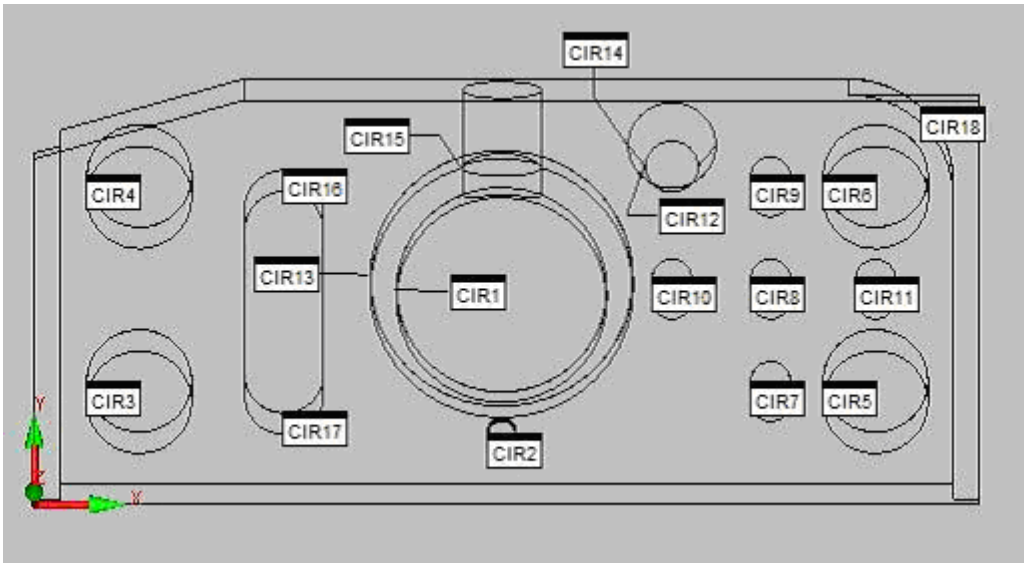
Example 1: Box-Selecting Auto Circles with Wireframe Data

This example uses the Brown and Sharpe wireframe block (Bsbwire.igs) with auto circles:

If you box-select the entire model, which is not in a complete Z+ orientation, you will notice that the top and bottom circles and arcs are selected because they are the visible objects which also satisfy the Auto Circle CAD filter logic.



Click **Create** from the CAD Select dialog box. You will get something like this:



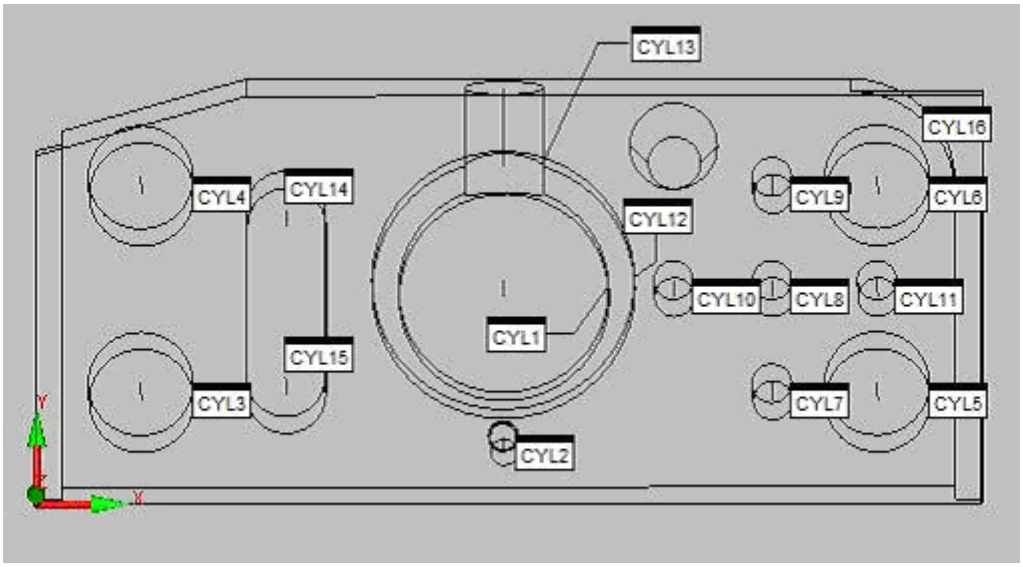
Notice that:

- Circles and arcs of the same diameter and vector are merged into a single feature. So, the top and bottom circles for the two center bores are merged into only two features, CIR1 and CIR13 (as were all the other features computed using the top and bottom circles and arcs). For the cone feature, however, since the diameters are different PC-DMIS creates two features (CIR12 and CIR14).
- A circle gets created for the back bore, CIR15. This is because the model was rotated slightly. If the view had remained entirely in a Z+ orientation, then CIR15 would not have been created.

Example 2: Box-Selecting Auto Cylinders with Wireframe Data

This example uses the Brown and Sharpe wireframe block (Bsbwire.igs) with auto cylinders:

If you do the same as in Example 1, but you use auto cylinders instead, you will get something like this:

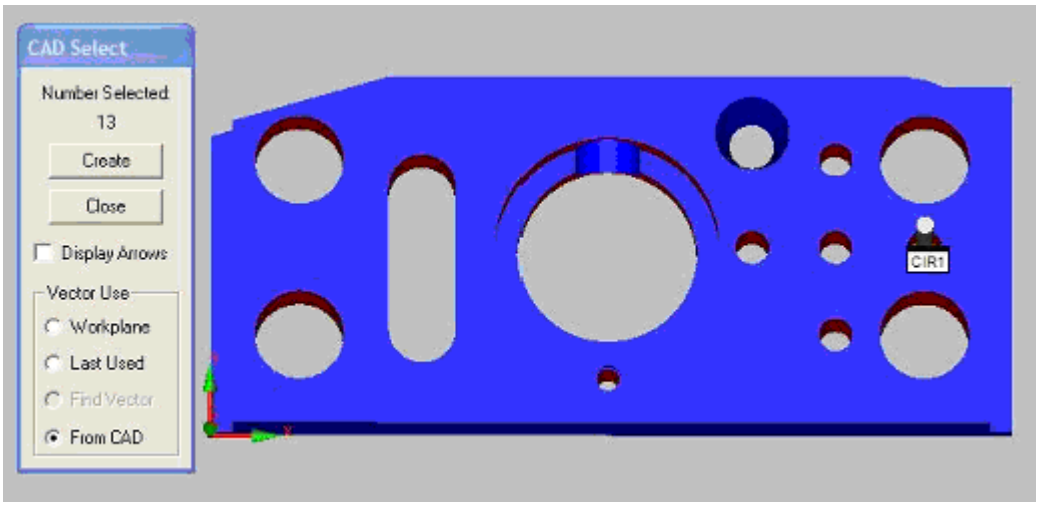


Notice that no cylinder was created at the cone feature because a cylinder must have length and must be the same diameter.

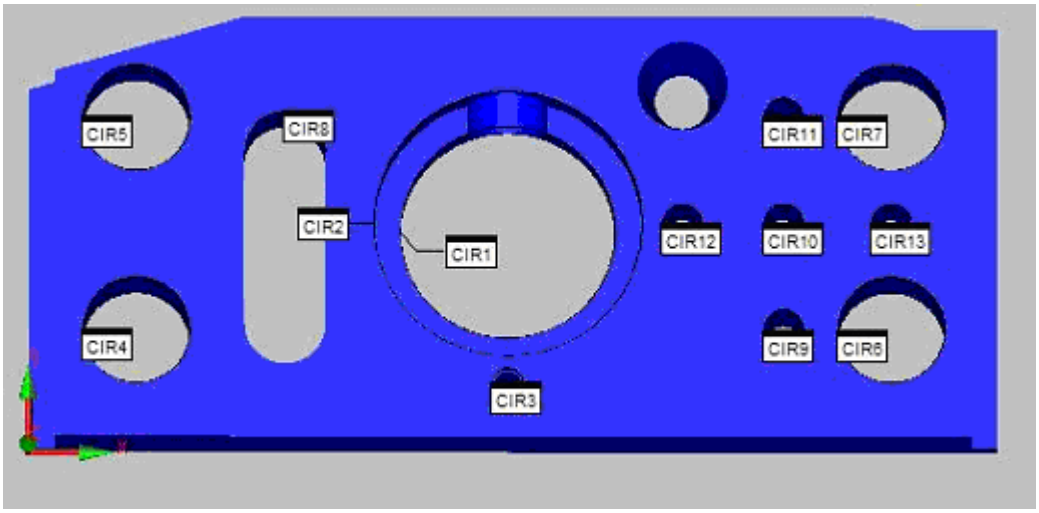
Example 3: Box-Selecting Auto Circles or Cylinders with Surface Data

This example uses the Brown and Sharpe solid block (Bsbsolid.igs) with auto circles and cylinders.

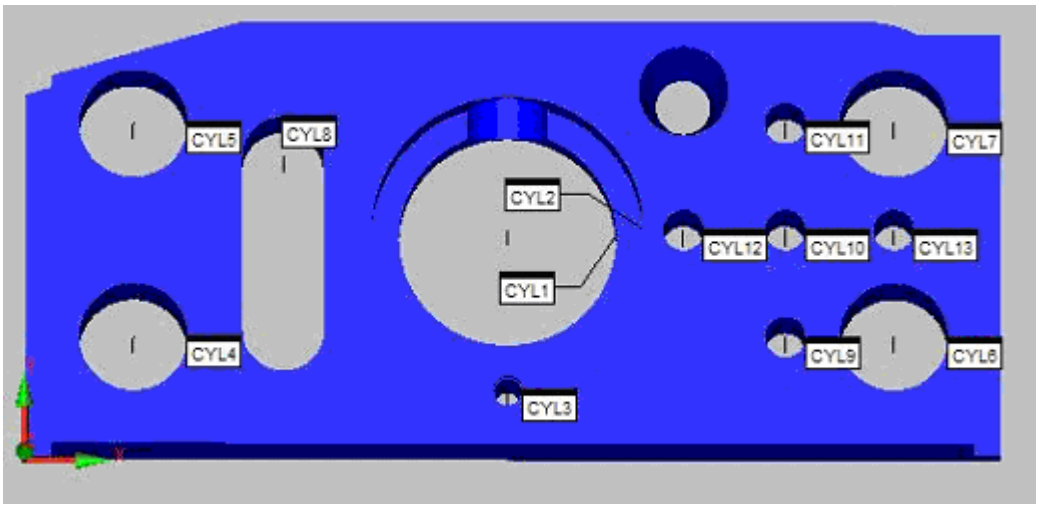
If you box-select to create features with a model that only has surface data (no wireframe data), the model needs to be slightly rotated in the view so that the desired surfaces are visible, like this:



Once you click **Create** and PC-DMIS generates the features from the selected objects, you get something like this:



Example showing circle features.



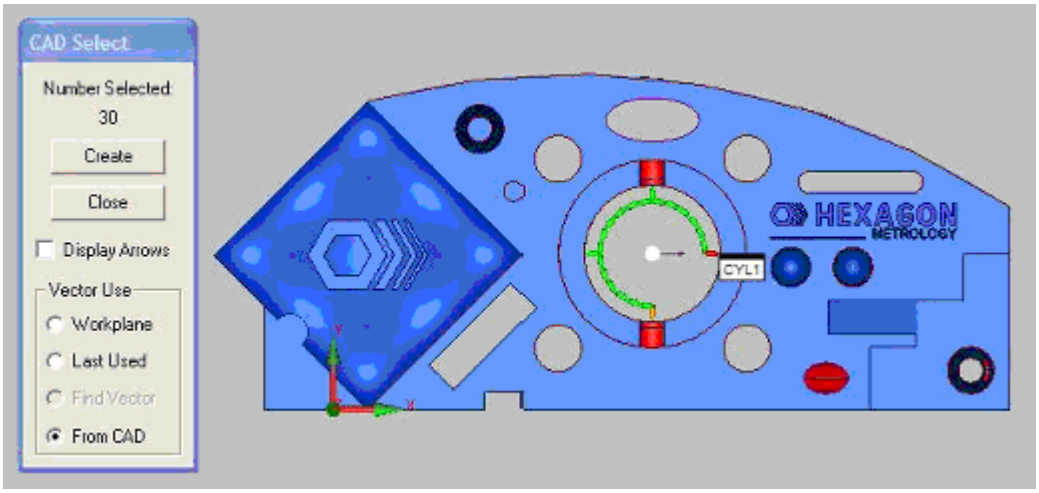
Example showing cylinder features.

Notice that because of the tilting, you do not get a circle or cylinder feature at one end of the slot, nor at the top right outer diameter (OD) cylinder.

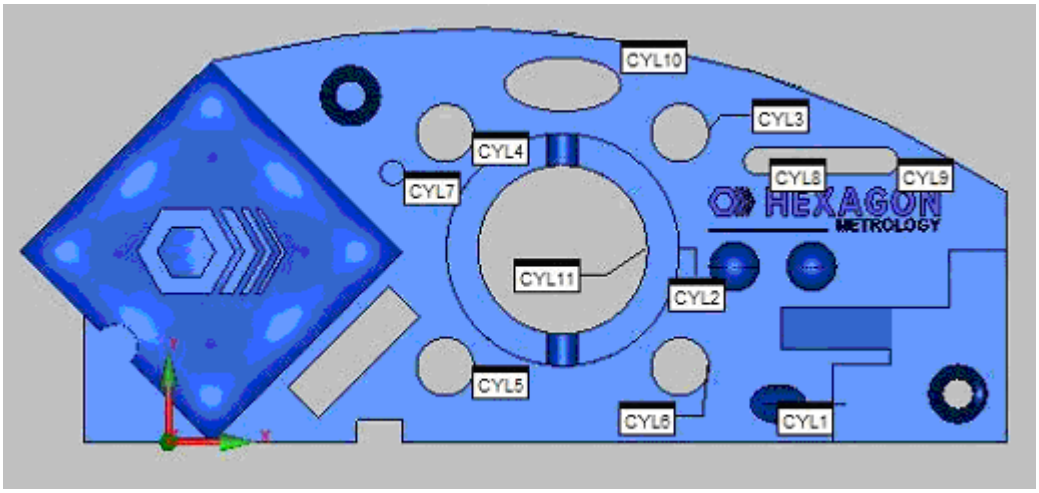
Example 4: Box-Selecting Auto Cylinders with Both Wireframe and Surface Data

This example uses the Hexagon model that ships with PC-DMIS (Hexblock_Wireframe_Surface.igs) with Auto Cylinders.

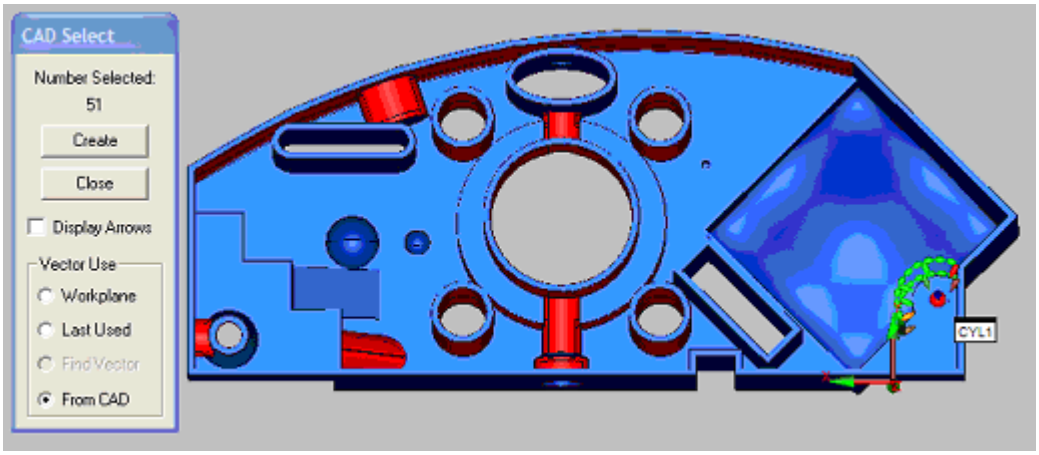
Put the model into a Z+ orientation and box-select the entire model.



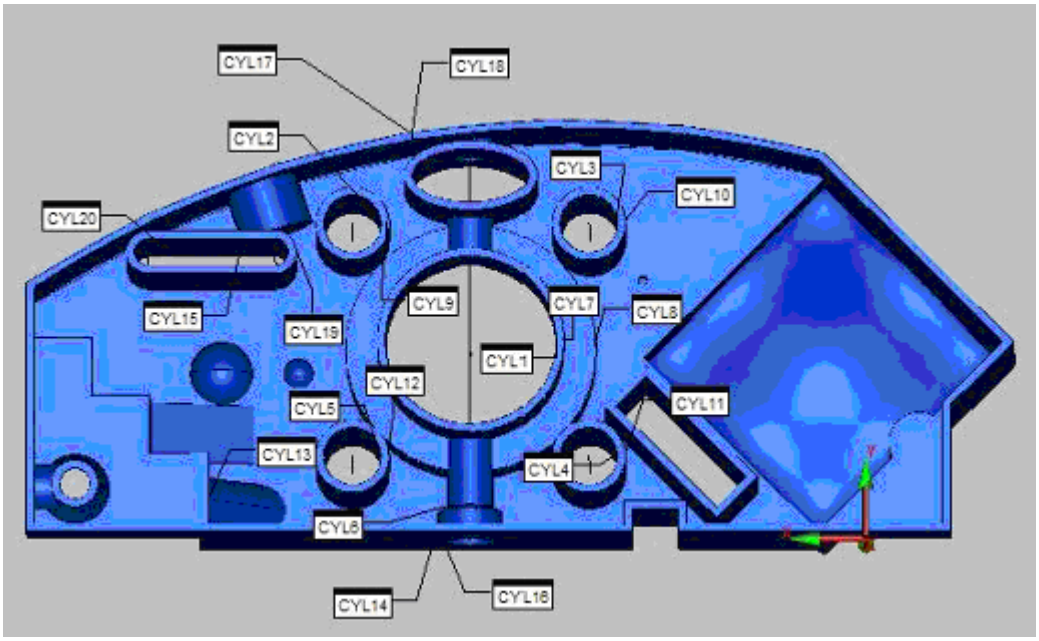
Click **Create** to see the following:



If you flip the part over to a Z- orientation, tilt the part slightly, and then box-select, PC-DMIS shows something like this:



Click **Create** to display something like this:



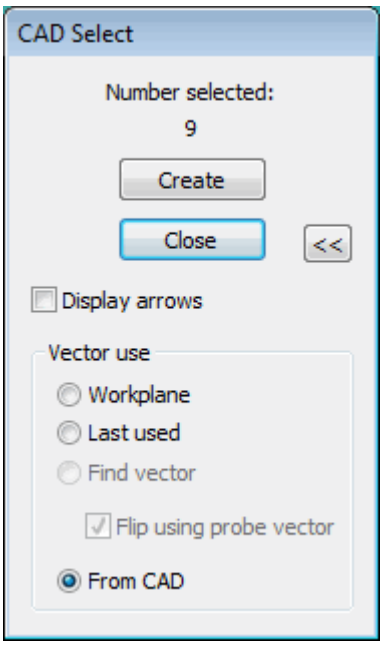
Notice that PC-DMIS generated both an inner diameter (ID) and outer diameter (OD) cylinder feature for most of the cylinders on the part, such as the top right CYL3 and CYL10.

With point features, if the model has defined the points as CAD elements, you can box-select them with QuickFeatures. For more information, see "Creating QuickFeatures".

Understanding the CAD Select Dialog Box

You can use the **CAD select** dialog box to create multiple Auto features at once. The **CAD Select** dialog box appears after you drag a box (box-select) on a CAD model. You must have the **Auto Feature** dialog box open to a supported feature type (for the supported feature types, see the "Box Selecting to Create Multiple Auto Features" topic), and you must box-select CAD elements of the feature type displayed in the dialog box. If you meet these conditions, the **CAD select** dialog box displays the number of selected CAD elements that match the selected Auto feature type.

For points or cylinder CAD elements, once the **CAD Select** dialog box opens, you can deselect and select highlighted elements if you click on them. For circle elements, however, once you deselect a circle, you cannot click on it again to re-select it.



CAD Select Dialog Box

Create - This button creates Auto features of the selected type from the selected CAD elements (currently for points, circles, cylinders, or cones). PC-DMIS closes the **CAD Select** dialog box, and from each box-selected element, PC-DMIS generates the appropriate feature. The **Vector use** area in the advanced portion of the dialog box determines the vector method.

Close - Closes this dialog box and cancels the box selection.

>> or **<<** - Shows or hides the advanced items on the dialog box. These advanced items control the features' vectors and are most often needed for imported DES models:

Display arrows - This check box displays or hides colored arrows showing the direction of vectors used by the methods in the **Vector Use** area.

The **Vector use** area lets you choose the methods PC-DMIS should use to determine the vectors for the nearly-created Auto features.

- **Workplane** - This method uses the vector of the currently active workplane as the vector for each individual feature.
- **Last used** - This method uses the last vector that was placed in the dialog box for the Auto feature. This lets you specify one vector to be used for all the selected features.
- **From CAD** - This method uses the vector that is specified by the CAD feature. This method becomes available if vector data is available for each feature.
- **Find vector** - This method finds the vector using the CAD surface data that is closest to the feature. This method is only available if surface data is available.

- **Flip using probe vector** - During the CAD import process, some types of CAD (usually IGES) may have some surface normal vectors that incorrectly point into the part instead of out of the part. This method flips the selected features' vectors so that they point out of the surface, using the probe vector to help indicate the correct vector direction. That option becomes available when you box-select feature types that may have surfaces with incorrect normal vectors.

'Multi-Clicking' and 'Single-Clicking' Auto Feature Creation

In older versions of PC-DMIS, you often had to provide multiple mouse clicks for PC-DMIS to generate an Auto feature. Over the years, PC-DMIS has continually increased its capability to select auto features on the screen with less and less mouse clicks.

The following table lists the Auto features you can select with a single mouse click in both Curve Mode and Surface Mode. It also shows the number of clicks required for features that do not support single-click selection.

Auto Feature Type	Curve Mode	Surface Mode
Angle Point	No (2 Clicks)	Yes
Circle	Yes	Yes
Cone	Yes	Yes
Corner Point	Yes	Yes
Cylinder	Yes	Yes
Ellipse	Yes	Yes
Edge Point	No (2 Clicks)	Yes
High Point	Yes	Yes
Line	No (2 Clicks)	No (2 Clicks)
Notch	Yes	Yes
Plane	Yes	Yes
Polygon	Yes	Yes
Round Slot	Yes	Yes
Square Slot	Yes	Yes
Sphere	Yes	Yes

Surface Point	Yes	Yes
Vector Point	Yes	Yes

Using Single-Click Mode

- **Angle Point Features**

  With the **Auto Feature** dialog box open, click once near but not on the intersection of the two surfaces. In Surface Mode, PC-DMIS generates the point at the angle where the two surfaces meet.

- **Circle Features**

  With the **Auto Feature** dialog box open, click once on the planar surface that contains the circle for a hole, on the feature's wall, or on a cylindrical end of a stud.

  - The edge closest to the mouse-click determines whether the circle feature is a hole or a stud. (See Note B.) However, due to how the CAD is sometimes defined, PC-DMIS cannot always determine this on its own.
  - If the circle has a length (depth) like a cylinder, then PC-DMIS uses the circle closest to where you clicked the mouse to define the center position.
  - PC-DMIS automatically fills in the dialog box and determines the circle's vector.

  For details on how to create single-point circle features with PC-DMIS Portable, see "Creating Single-Point Circle Features" topic in the PC-DMIS Portable documentation.

- **Cone Features**

  With the **Auto Feature** dialog box open, click once on the planar surface that contains the cone's hole, on the feature's wall, or on a conical end of a cone.

  - The edge closest to the mouse-click determines whether the cone feature is an inner cone or an outer cone. (See Note B). However, due to how the CAD is sometimes defined, PC-DMIS cannot always determine this on its own.
  - The vector of the cone points away from its apex.
  - PC-DMIS automatically fills in the dialog box and determines the center point. Inner cones use the larger radius for the center point. Outer cones

use the smaller radius. PC-DMIS does this to avoid shank collisions when measuring the cone.

- **Cylinder Features**

  With the **Auto Feature** dialog box open, click once on the planar surface that contains the cylinder, on the feature's wall, or on a cylindrical end of an outer cylinder.

  - The edge closest to the mouse-click determines whether the circle feature is a hole or a stud. (See Note B). However, due to how the CAD is sometimes defined, PC-DMIS cannot always determine this on its own.
  - PC-DMIS automatically fills in the dialog box and determines the cylinder's vector. It uses the center location of the cylinder end closest to where you mouse-clicked.

- **Edge Point Features**

  With the **Auto Feature** dialog box open, click once anywhere. PC-DMIS automatically populates the dialog box.

  - If you are using Surface Mode, PC-DMIS generates the edge on the nearest edge where you clicked.
  - If you are in Wireframe Mode, PC-DMIS selects only the edge. A second click is required to create the edge point on the wire.

- **Ellipse Features**

  Same as Round Slot.

- **Notch Features**

  With the **Auto Feature** dialog box open, click once close to the back edge of the notch. When you single-click to create a notch feature, the software always defines it as an inner notch. PC-DMIS automatically fills in the dialog box.

- **Polygon Features**

  With the **Auto Feature** dialog box open, click once on a polygon feature that contains five or more sides. PC-DMIS automatically fills in the dialog box and determines the starting side by the edge closest to the mouse click.

- **Corner Point Features**

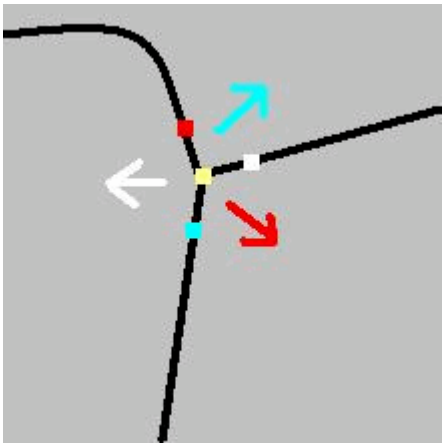
  With the **Auto Feature** dialog box open, click once near an edge that contains the corner point.

  - The closest edge to the mouse click determines the closest end point to the mouse click. This end point becomes the corner point.

- PC-DMIS automatically fills in the dialog box.

How it Works:

- PC-DMIS finds adjacent edges relative to the first edge. It tests each edge to see if it has an end point coincident to the corner point. If so, then it finds a point on that edge very near the corner point. This continues until two edges (and two points) are found that have unique vectors (ideally perpendicular) to each other and the first edge.
- Once PC-DMIS has three points near the corner point, these three points are all on different edges. Using the two different points near the corner point, and the corner point, PC-DMIS computes three planes. For example, in this image, the YELLOW corner point and the RED and WHITE points create a plane whose vector is the BLUE arrow. Similarly, the YELLOW, WHITE, and BLUE points give us the RED arrow and the YELLOW, BLUE, and RED points give us the WHITE arrow.



- **Round Slot Features**

With the **Auto Feature** dialog box open, for an inner round slot, click once on the planar surface that contains the rounded edge or the feature's wall. For an outer round slot, click on the top edge of the rounded end, away from where the curve ends, and the planar sides begin or on the feature's wall. (See Note A).

- The edge closest to the mouse click determines whether the feature is an inner round slot or an outer round slot. (See Note B). However, due to how the CAD is sometimes defined, PC-DMIS cannot always determine this on its own.
- PC-DMIS automatically fills in the dialog box and determines the slot's vector and orientation.

- **Square Slot Features**

With the **Auto Feature** dialog box open, for an inner square slot, click once on the planar surface near any edge of the slot or on the feature's wall. For an outer square slot, click on any top edge or on the feature's wall. (See Note A).

- The edge closest to the mouse click determines whether the feature is an inner square slot or an outer square slot. (See Note B). However, due to how the CAD is sometimes defined, PC-DMIS cannot always determine this on its own.
- PC-DMIS automatically fills in the dialog box and determines the slot's vector and orientation.

- **Sphere Features**

  With the **Auto Feature** dialog box open, click once on the sphere's edge. PC-DMIS automatically fills in the dialog box.

- **Surface Point Features**

  With the **Auto Feature** dialog box open, click once anywhere. PC-DMIS automatically fills in the dialog box.

- **Vector Point Features**

  With the **Auto Feature** dialog box open, click once anywhere. PC-DMIS automatically fills in the dialog box.

  - If you use Curve Mode, PC-DMIS snaps the point to the nearest wire.
  - If you use Surface Mode, PC-DMIS generates the point where you clicked.

By default, PC-DMIS attempts to interpret a single left mouse click on the part model and generate the Auto feature from that input. It momentarily displays the probe on the screen and then inserts the feature information gathered from the mouse click into the open **Auto Feature** dialog box. If, for some reason, this fails, PC-DMIS automatically switches to the older Multi-Click Mode of input (see the Multi-Click Mode information below).

If you want the animated probe to appear permanently on the screen when you click on the part model, you can use the PC-DMIS Settings Editor to locate the DisplayProbeForJustOneMoment entry in the **Option** section, and change its value to FALSE.

Temporarily Switching to Multi-Click Mode

You can temporarily switch to the Multi-Click Mode of input. To do this, with the **Auto Feature** dialog box open, take two clicks within three pixels of each other. When you take the second mouse click, PC-DMIS switches to Multi-Click Mode and draws the cross-hairs at the location of the second mouse click. This click becomes the first mouse click of the Multi-Click Mode. PC-DMIS then waits for the remaining mouse clicks needed to generate

the feature. Once the feature is generated, PC-DMIS switches back to the Single-Click Mode.

Using Multi-click Mode

Once you have switched to Multi-Click Mode, follow the instructions on the Status bar which walks you through the hits you need to take.

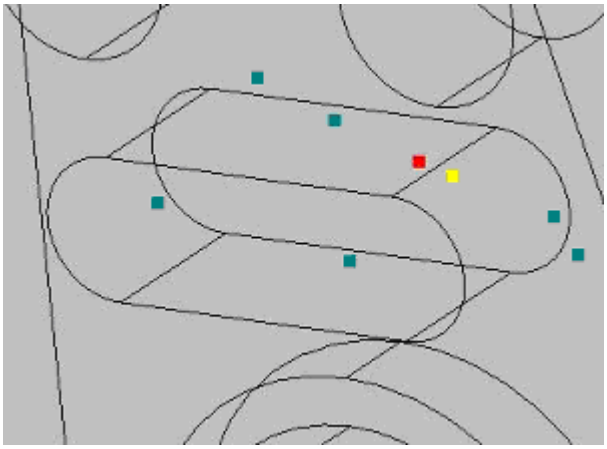
Permanently Switching to Multi-Click Mode

If you want to turn off the Single-Click Mode functionality permanently, access the PC-DMIS Settings Editor, and set the SingleClickCadSelectionDisabled entry (in the **AutoFeatures** section) to TRUE. When you restart the software, PC-DMIS enables Multi-Click Mode.

Note A

In this image:

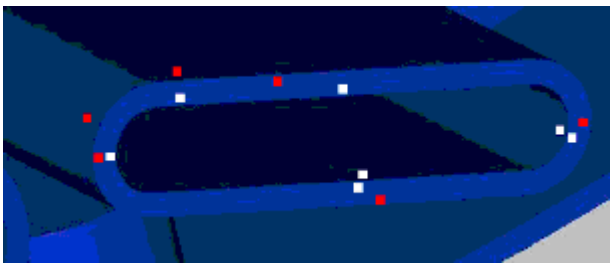
- The GREEN marks should work because the line/curve (or edge if it is a surface) that is closest to the marks is a line/curve that is in the plane that defines the slot.
- The RED mark will not work because the line (or edge if it is a surface) that is closest to the mark is a line/curve that is not in the plane that defines the slot.
- The YELLOW mark will work if the surface is a cylinder.



Note B

In this image, showing a flipped over, Z- orientation of the Hexagon model:

- The RED marks will produce an Outer Diameter (OD) feature.
- The WHITE marks will produce an Inner Diameter (ID) feature.



Creating QuickFeatures

For details on how to implement QuickFeatures in PC-DMIS Laser, see "Implementation of QuickFeatures in PC-DMIS Laser" in the PC-DMIS Laser documentation.

For details on how to implement QuickFeatures in PC-DMIS Vision, see "Implementing QuickFeatures in PC-DMIS Vision CAD View" and "Implementing QuickFeatures in PC-DMIS Vision Live View" in the PC-DMIS Vision documentation.

For details on how to use the Quick Scan functionality to create a Linear Open scan from a polyline or surface, see "Creating Quick Scans" in the "Scanning" chapter in the PC-DMIS CMM documentation.

About QuickFeatures

You can use the QuickFeatures functionality to create Auto features from gestures. These gestures are usually click or click-and-drag operations with key combinations. You perform the gestures with the mouse on the CAD model without any menu options or dialog boxes. Also, if models contain point features, and PC-DMIS is in Curve Mode, you can use QuickFeatures to box-select and create multiple point features at a time. For more information, see "Creating Vector Point Features by Box-Selecting" below.

When you create QuickFeatures, dialog boxes with feature lists (such as for constructions or dimensions) can remain open. As you add the new features into the measurement routine, PC-DMIS adds them into the feature list and automatically selects them for the current operation.

For information about the default settings and on how to use the Measurement Strategy Editor to change default settings, see "Using the Measurement Strategy Editor" topic.
By default, when you create a feature from the QuickFeature functionality and there is no other dialog box displayed, the measurement strategy widget appears. This widget lets you change a feature's main parameters. For more information, see "Using the Measurement Strategy Widget" in the next main topic.

Requirements

Your CAD model can contain either surface data or wireframe data. However, due to limitations in wireframe data, if your model is a wireframe-only model, PC-DMIS cannot create these features using the QuickFeature functionality:

- Vector Point
- Angle Point
- Plane
- Sphere

Also, QuickFeatures only function with contact Auto features.

General Process to Create QuickFeatures

You can choose to work with or without the **Auto Feature** dialog box open. However, the procedure below assumes your **Auto Feature** dialog box is not open. Also, the measurement strategy widget does not appear if you use the **Auto Feature** dialog box.

1. In the Edit window, click to define where to insert the new feature.
2. In the Graphic Display window, position your mouse pointer over the CAD element.
3. For point features (Vector, Edge, Angle, Corner), press Ctrl + Shift and click on the CAD element to create the feature.

    - Vector Point

      To create a vector point, press Shift + Ctrl and hover the pointer over the surface. An arrow that represents the surface vector (light blue) appears. Click and release the mouse button to create the feature.

      
      Example showing the vector point selection.

      You can also quickly create vector points by box-selecting them. See "Create Vector Point Features by Box-Selecting" below.

- Edge Point

  To create an edge point, press Shift + Ctrl. Hover the pointer near a surface edge where the angle between the two surfaces is 90 degrees. Arrows that represent the surface vector (light blue) and the edge vector (green) appear. Click and release the mouse button to create the feature.

  
  Example showing the edge point selection.

- Angle Point

  To create an angle point, press Shift + Ctrl and hover the pointer near a surface edge where the angle between the two surfaces is NOT 90 degrees. PC-DMIS draws arrows to highlight the angle point (the light blue arrow represents the surface 1 normal vector, and the light green arrow represents the surface 2 normal vector). Click and release the mouse button to create the feature.

  
  Example showing the angle point selection.

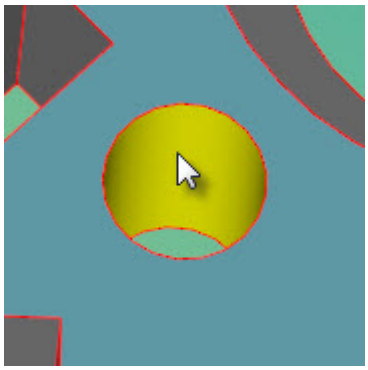
- Corner Point

  To create a corner point, press and hold Shift + Ctrl and hover the pointer over a corner. PC-DMIS draws arrows to highlight the corner point. Click and release the mouse button to create the feature.

  
  Example showing the corner point selection.

If you enable a 3D grid on the Graphic Display window, the software snaps Vector, Edge, and Angle points to the nearest intersection on the grid. For more information, see "Adding a 3D Grid" in the "Editing the CAD Display" chapter.

4. For Plane, Circle, Ellipse, Cylinder, Cone, or Sphere, press Shift and click on the CAD element to create the feature.



Example of a highlighted 3D cylinder.

For Line, Round Slot, Square Slot, Notch Slot, and Polygon feature types, follow the instructions in their respective topics below. These feature types, and other information not covered in this general procedure, are discussed below.

5. By default, the measurement strategy widget appears. You can use this widget to modify common feature properties. For information on the measurement strategy widget, see "Using the Measurement Strategy Widget" in this chapter.

6. Continue to create any other QuickFeatures you need. With each new feature you create, PC-DMIS automatically applies and accepts the previous feature. This also works with multi-QuickFeatures below.

7. Once you're done creating your features, click the green **Apply** button to accept the final feature and close the measurement strategy widget.

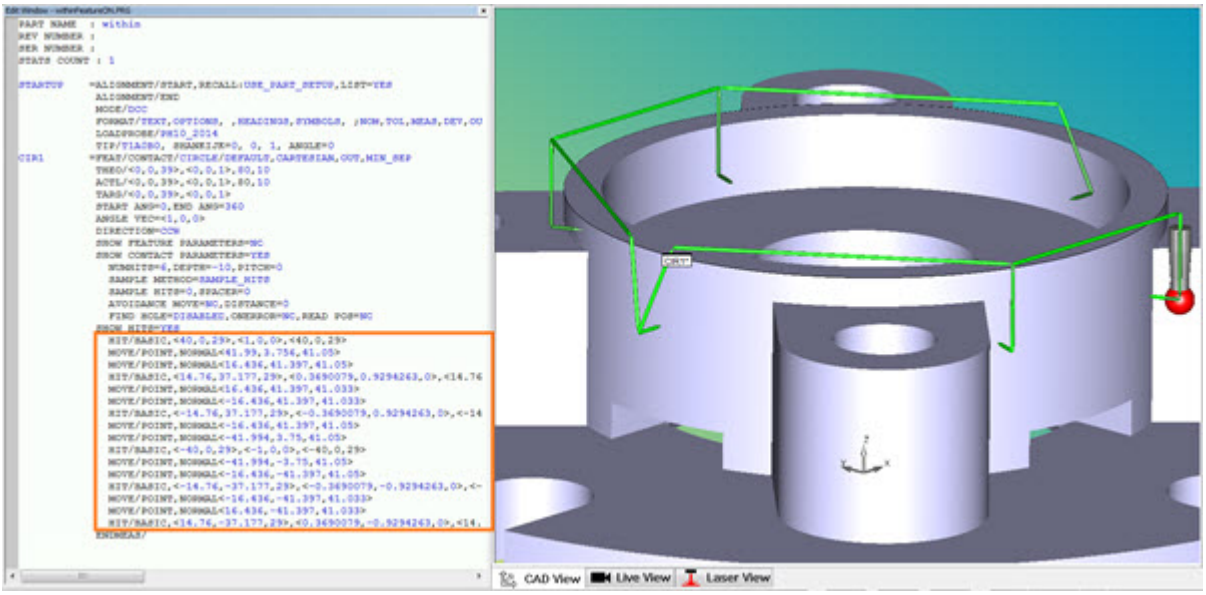
Additional Information on QuickFeatures

- You can select colinear or coplanar elements. To do this, press and hold Shift, hover the pointer over a line or plane, click and hold the mouse button, and move the pointer to a colinear or coplanar element. Once all the elements are highlighted, release the mouse button to create the feature from both elements. For an example, see "Creating Line Features" above.

- You can toggle what features are executed within the Graphic Display window. To do this, press Alt and click on the feature label to toggle its marked state. For information on how to mark features, see "Marking Commands for Execution" in the "Editing a Measurement Routine" chapter.

- You can have PC-DMIS automatically generate safe moves inside the QuickFeature. To do this, select **Operation | Graphic Display Window | Clearance Move | Within feature** prior to creating the features. If this menu option is enabled, moves (between

sample hits and among hits in the same list) are automatically computed and drawn as lines.



Example showing the Within feature option set to active.

For details on how to create clearance moves, see "Inserting Clearance Moves Automatically" in the "Inserting Move Commands" chapter.

- If you select **Operation | Graphic Display Window | Clearance Move | With Feature Creation**, PC-DMIS generates clearance moves between QuickFeatures. The **Auto Feature** dialog box must be closed.
- Automatic safe moves between features that use different probe tip angles are not supported. You must manually define these moves.
- PC-DMIS automatically updates the contents of an open **Auto Feature** dialog box. During feature creation, it retrieves the data from the feature on the CAD model.

  For a created feature, the dialog box updates to the feature you selected.

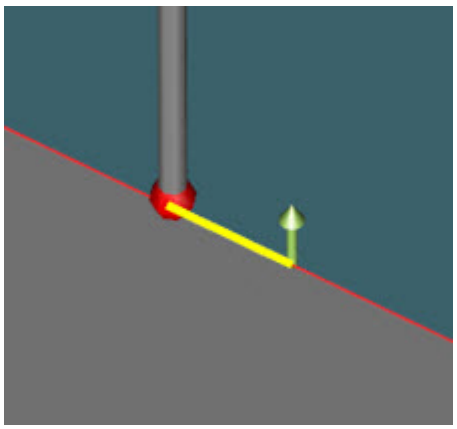
  For an edited feature, it only does this if the selected feature matches the edited one.

  In both cases, the default values for the feature come from entries.

Click the links below to show the descriptions of how to create each of the feature types.

Creating Line Features

- To create a basic line feature, position the mouse pointer near a surface edge where the angle between the two surfaces is 90 degrees. Press and hold the Shift key on your keyboard. Click and drag the pointer for a short distance along the line. PC-DMIS starts to highlight the line. An arrow representing the edge vector (green) appears.



Drag to define the length of the line and release the mouse button. PC-DMIS places the line's start point where you click the button and the end point where you release the button.

- To create a line feature from multiple, colinear, line elements, press and hold Shift, (1) hover the pointer over a line, click and drag the pointer for a short distance along the line to start to highlight it; then (2) move the pointer to another colinear element and drag to define the length of the line. Once the software highlights the elements and the line is the desired length, (3) release the mouse button to create the line feature from the line elements.
