Consult your OLE's documentation for the particular OLE object you are using to know what methods and properties are available.

Providing Operator Instructions Using OLE Objects with Forms

You can use existing tools in conjunction with PC-DMIS to provide you with expanded functionality. For example, suppose you want to provide an operator with detailed instructions regarding part setup or measurement. One way to do this is to embed into a custom form, using the OLE object, an external file containing these instructions. Below are some examples of how to embed instructional files into forms using some common Microsoft Office tools.

These examples demonstrate how to use a Microsoft Word file and Microsoft PowerPoint file as OLE objects inside of a form to provide instructions to an operator during measurement routine execution. These examples provide you with a taste of what you can do with OLE objects inside of your report or form. How you put this knowledge to use for your own situation is up to you.

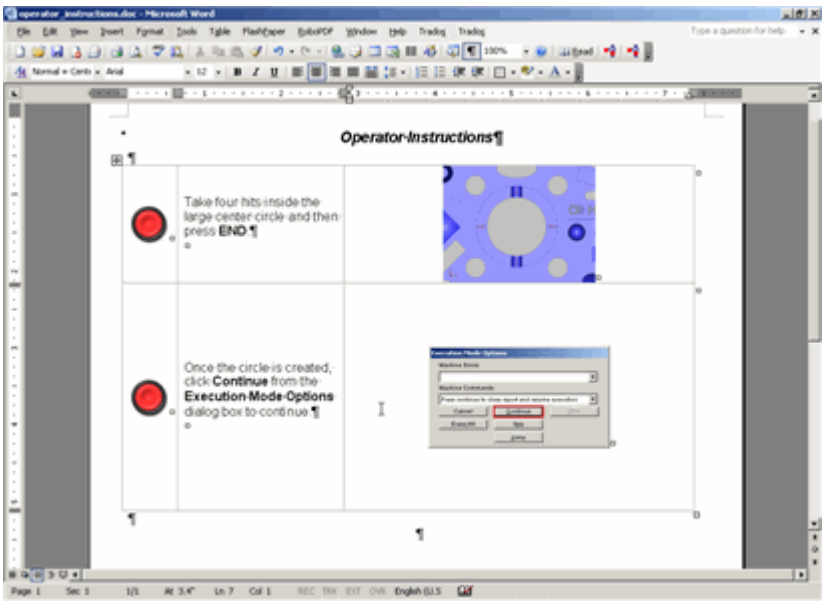
- **Providing Instructions Using a Microsoft Word OLE Object**

  One way to provide instructions to those who run your measurement routines is to use something like Microsoft Word.

  This topic and the steps below assume you have Microsoft Word installed on your computer.

  Step 1 - Create and Save the Instructions as a Word Document

  1. Create your part setup instructions inside of a Word document.
  2. Save the .doc file to a directory on your disk. Feel free to include pictures, tables, and other advanced formatting inside your .doc file. The sample doc file used for this topic looks like this:



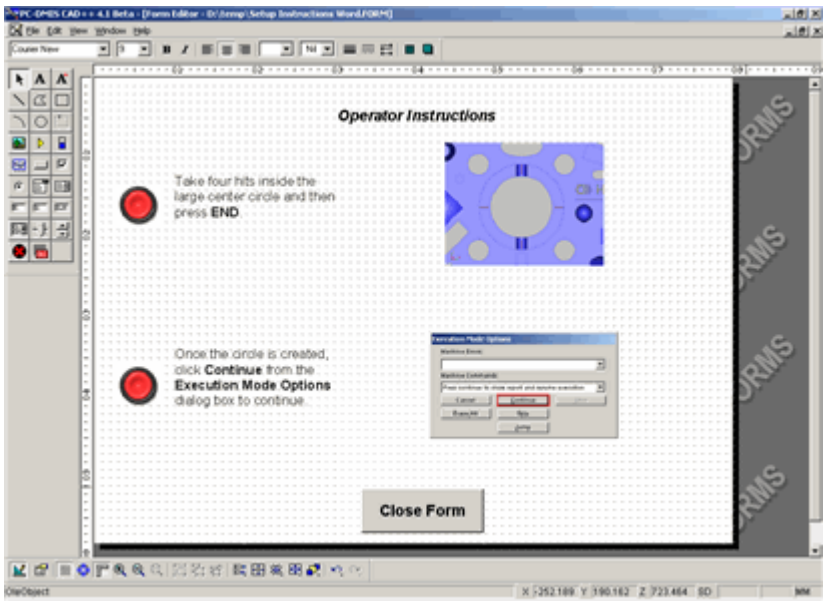
Step 2 - Create the Form

1. Select **File | Reporting | New | Form Report** to open the Form Editor.
2. If the Edit window is open, select **View | Edit Window** to close it giving you more screen space.
3. Maximize the Form Editor.
4. Size the form so that it properly houses the content of your file.
5. Add any other objects as desired. In the example form used for this topic, a **Close Form** button was added with the following properties:
   - Text = "Close Form"
   - ButtonType = OK

   When you click the button, the form closes.

Step 3 - Insert the OLE Object

1. From the **Object Bar**, click the **OLE Object** icon. Drag the object so that it fits the entire form except for a half inch margin on all sides. When you release the mouse button, the **Insert Object** dialog box opens.
2. Select the **Create from File** option.
3. In the **File** box, either type the complete pathway to the .doc file, or use the **Browse** button to locate it.
4. Select the **Link** check box. This maintains a link between the OLE object on your form and your .doc file, so that if you later update your instructions, PC-DMIS always uses the latest information.
5. Click **OK**. The document is embedded into your form like this:



6. Save the form and give it a name of your choice.

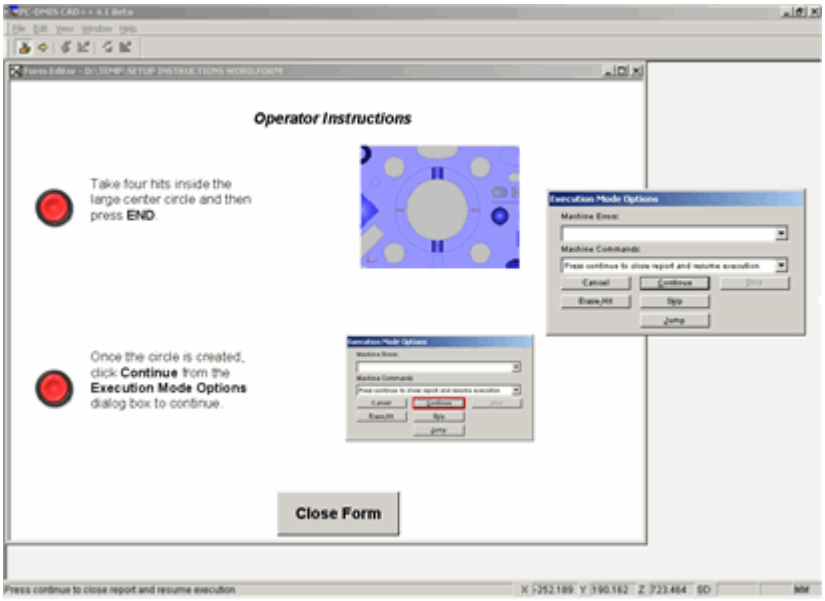
> The **Insert Object** dialog box is the same dialog box that appears if you choose to insert an external object into the Edit window from the **Insert | Report Command | External Object** menu option. If you need more information on this dialog box, consult the "Inserting External Objects" topic from the "Inserting Report Commands" section.

Step 4 - Insert and Test the Form

1. Select **View | Edit Window** to make the Edit window visible.
2. Select **Insert | Report Command | Form**. Use the dialog box to select your saved form.
3. PC-DMIS inserts a `FORM/FILENAME` command block into your measurement routine with a pathway to the form file:

```
CS1=FORM/FILENAME = <Pathway to Form File>
   PARAM/=
   ENDFORM/
```

4. Mark the command block for execution.
5. Execute the measurement routine. When PC-DMIS reaches the `FORM/FILENAME` command block, it displays the form:



6. Click **Continue** from the **Execute Mode Options** dialog box to close the form and resume execution.

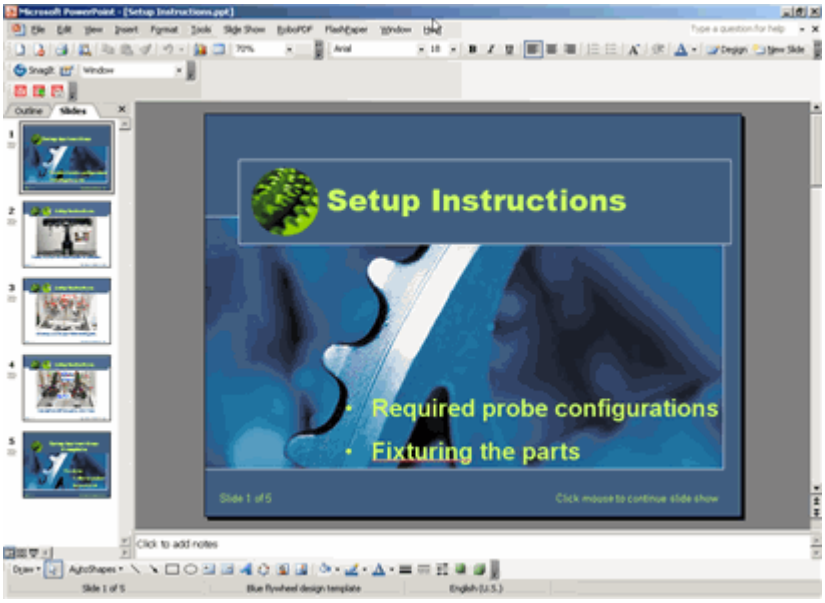
- **Providing Instructions Using a Microsoft PowerPoint OLE Object**

  This topic demonstrates how to use a Microsoft PowerPoint file (.ppt) as an OLE object inside of a form to provide detailed slide-show type instructions to an operator.

  > This topic and the steps below assume you have Microsoft PowerPoint installed on your computer.

Step 1 - Create and Save the Instructions as a PowerPoint

1. Create your part setup instructions inside of a PowerPoint file (.ppt).



2. Save the .ppt file to a directory on your disk.

Step 2 - Create the Form

1. Select **File | Reporting | New | Form Report** to open the Form Editor.
2. If the Edit window is open, select **View | Edit Window** to close it to give you more screen space.
3. Maximize the Form Editor.
4. Size the form so that it properly houses the content of your file.
5. Add any other objects as desired. In the example form used for this topic, a **Close the Form** button was added with the following properties:
    - Text = "Close the Form"
    - ButtonType = OK

    When you click the button, the form closes.

Step 3 - Insert the OLE Object

1. From the **Object Bar**, click the **OLE Object** icon. Drag the object so that it fits the entire form, except for a half inch margin on all sides. When you release the mouse button, the **Insert Object** dialog box appears.
2. Select the **Create from File** option.
3. In the **File** box, either type the complete pathway to the .ppt file, or use the **Browse** button to locate it.
4. Select the **Link** check box. This maintains a link between the OLE object on your form and your .ppt file, so that if you later update your instructions, PC-DMIS always uses the latest information.
5. Click **OK**. The PowerPoint file is embedded into your form.

6. Save the form and give it a name of your choice.

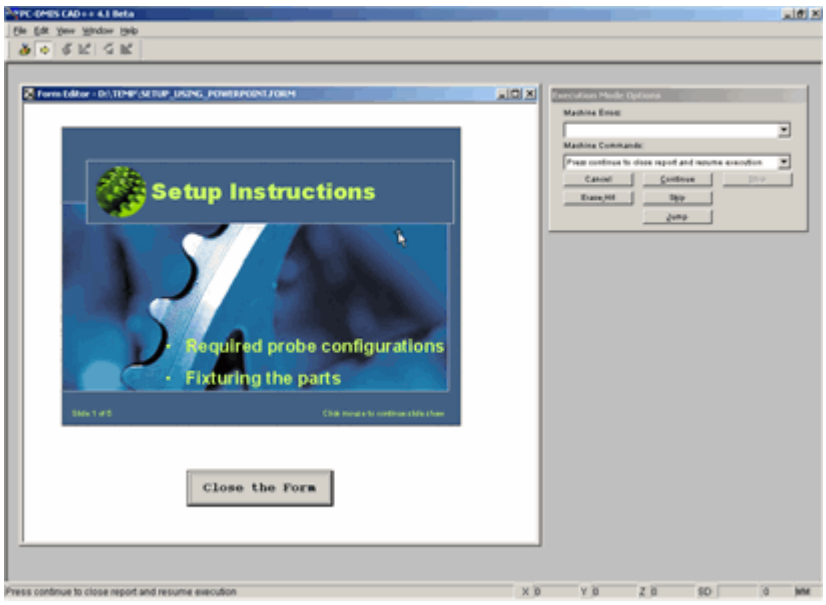
The **Insert Object** dialog box is the same dialog box that appears if you choose to insert an external object into the Edit window from the **Insert | Report Command | External Object** menu option. If you need more information on this dialog box, consult the "Inserting External Objects" topic from the "Inserting Report Commands" section.

Step 4 - Insert and Test the Form

1. Select **View | Edit Window** to make the Edit window visible.
2. Select **Insert | Report Command | Form** to show the **Insert Form** dialog box.
3. Use the **Insert Form** dialog box to select your saved form.
4. Click **Open**.
5. PC-DMIS inserts a `FORM/FILENAME` command block into your measurement routine with a pathway to the form file.

```
CS1=FORM/FILENAME= <Pathway to Form File>
   PARAM/=
   ENDFORM/
```

6. Mark the command block for execution.
7. Execute the measurement routine. When PC-DMIS reaches the `FORM/FILENAME` command block, it displays the form and the embedded PowerPoint presentation.



8. Double-click on the embedded presentation. The Microsoft PowerPoint software launches and displays the presentation. When it finishes, PowerPoint also closes.

9. Click **Continue** from the **Execute Mode Options** dialog box to close the form and resume execution.

Pointer Object

The **Pointer** object inserts a dynamic, movable, colored pointer into the form or template. The color defaults to yellow.

Along with the ability to resize the object, change colors, and change other attributes, you can cause this object to move by using these properties in conjunction with Visual BASIC code:

MaximumEq
Maximum equation (This value can be a set constant number, a value evaluated from a simple equation, or a returned value from a VBScript).

-$, $, CONST

MinimumEq
Minimum equation (This value can be a set constant number, a value evaluated from a simple equation, or a returned value from a VBScript).

-$, $, CONST

ValueEq
Value equation (This value can be a set constant number, a value evaluated from a simple equation, or a returned value from a VBScript).

-$, $, CONST

If you change the direction of the pointer, the movement of the arrow will also change to the direction specified.

PointInfo Object

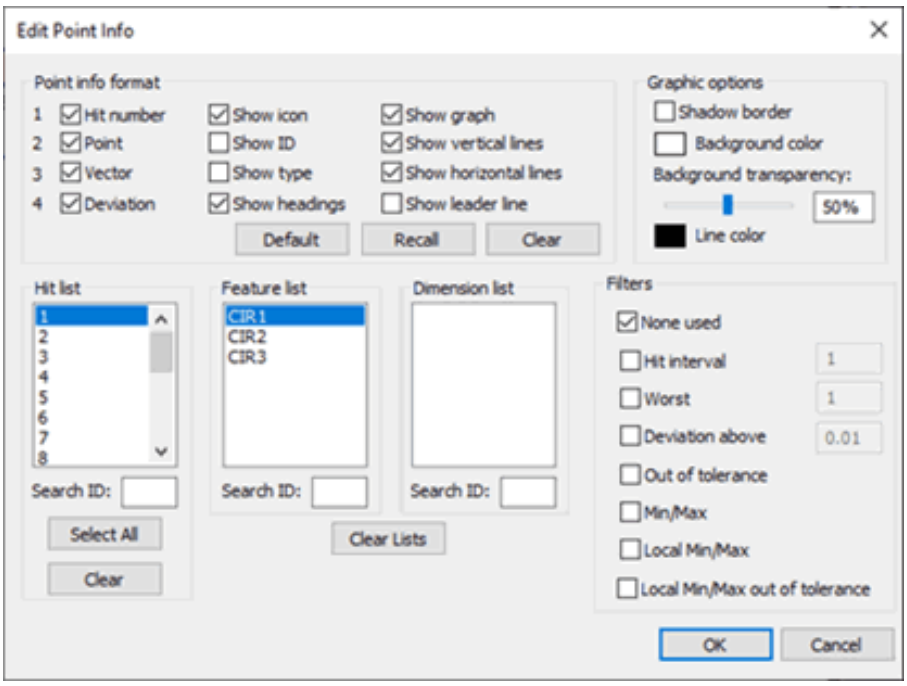
The **PointInfo** object acts as a container to hold individual point information in your report.

Using the PointInfo Object in a Label Template

Using the **Object Bar** for the Label Template editor, add and size the **PointInfo** object so that it appears as desired in your Label Template editor's display area. Save the label template. Next, use the **Rule Tree Editor** dialog box for a new or existing report template to specify under what conditions (for what dimensions) PC-DMIS will call and display that label template. See "About the Rule Tree Editor" in this chapter for information on how to do this.

Using the PointInfo Object in a Custom Report

Using the **Object Bar** for the Custom Report editor, drag or drop the **PointInfo** object into the Custom Report. PC-DMIS displays the **Point Info** dialog box allowing you to select the point to be associated with the object.



Select the feature or dimension and then a point from the dialog box, set whatever options you want, and click **OK**. PC-DMIS creates point info commands for the selected features or dimensions and closes the dialog box. PC-DMIS displays a table on your report that contains feature or dimension point information.

See "Inserting Point Info Boxes" in the "Inserting Report Commands" chapter for complete information on how to use this dialog box to display dimension information.

In a custom report, the **Analysis** object can display its own Point Info boxes as well. See "Analysis Object" for more information.

Properties specific to this object are listed below. Many of these you can set by clicking on the (Settings Dialog) property:

`DimFeatID`
Defines the feature or dimension ID containing the hits you want to display.

`HitNumber`
Defines what hit number for the information you want displayed in the point info box.

`OrderDeviation`
Defines the order of the deviation row with a value between `1-4`. A value of `1` puts the info on the top row. A value of `4` puts the info on the bottom row.

`OrderHitNum`
Same as above, except it defines the order of the hit number.

`OrderPoint`
Same as above, except it defines the order of the point row.

`OrderVector`
Same as above, except it defines the order of the vector row.

`ShowGraph`
A value of `1` displays the dimension percentage graph. A value of `0` hides the graph.

`ShowHeadings`
A value of `1` displays the heading row. A value of `0` hides the heading row.

`ShowID`
A value of `1` displays the ID of a particular feature or dimension row. A value of `0` hides the ID.

`ShowPointInfo`
A value of `1` displays the point info row. A value of `0` hides the ID. Disabled at this moment.

`ShowType`
A value of `1` displays the type of feature or dimension displayed. A value of `0` hides the type.

Polyline Object

The **Polyline** object allows you to link lines together. When you click and create the first line, a second line is automatically started at the end point of the first line. Polyline objects contain the same properties as a standard line object.

Radiobutton Object

The **Radiobutton** object inserts option buttons into the form. Option buttons are mutually exclusive. You can only have one option button selected inside your report at a time. The `ListItems` property allows you to define a set of option buttons.

Along with the ability to resize the object, change colors, and change other attributes, you can further customize this object by using these properties:

AlignTextLeft
If set to `YES`, this moves the text to the left of the option button like this:

Text Here ( )

If set to `NO`, this moves the text to the right of the option button like this:

( ) Text Here

Bitmap
This allows you to specify a bitmap to use for a selected option button.

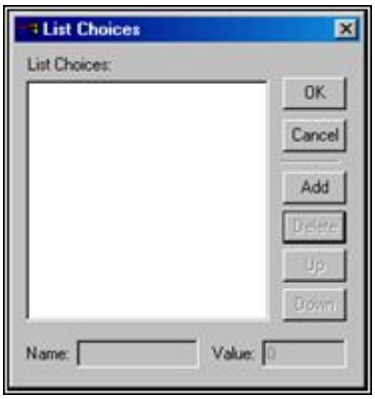
The specified bitmap must be the same shape as a standard check box.

BitmapOffState
This allows you to specify a bitmap to use for a deselected option

The specified bitmap must be the same shape as a standard option button.

ListItems
This defines a list of option buttons and its associated values (see the description on the **List Choices** dialog box below).

The `ListItems` property displays the **List Choices** dialog box.



List Choices Dialog Box

This dialog box allows you to add, rename, and delete option buttons and assign numerical values. Generally, when adding a new option, the value for that option increments automatically, so only one button is selected at a time. However, you can change the numerical values to allow the selection of groups of options with one mouse click when in run mode.

For example, suppose you have five option buttons that you've named Options A through E, and you change their assigned values to the following:

Option buttons	Value
Option A	0
Option B	0
Option C	1
Option D	2
Option E	2

When you enter run mode and select **Option A**, both **Option A** and **Option B** will be selected. This is because they're assigned the same value. Similarly, if you select **Option E**, both **Option D** and **Option E** will be selected. Only **Option C** has a unique value, so when you select it, only it is selected.

Select Object

The **Select** object isn't a traditional object that you insert into the template or form editor. Rather, it allows you to select an object already inserted into your editor. To select an object, click on the object in the report. To let you know when you select an object, PC-DMIS surrounds it with a border and small green squares. Once you select an object, you can move, resize, or edit the object.

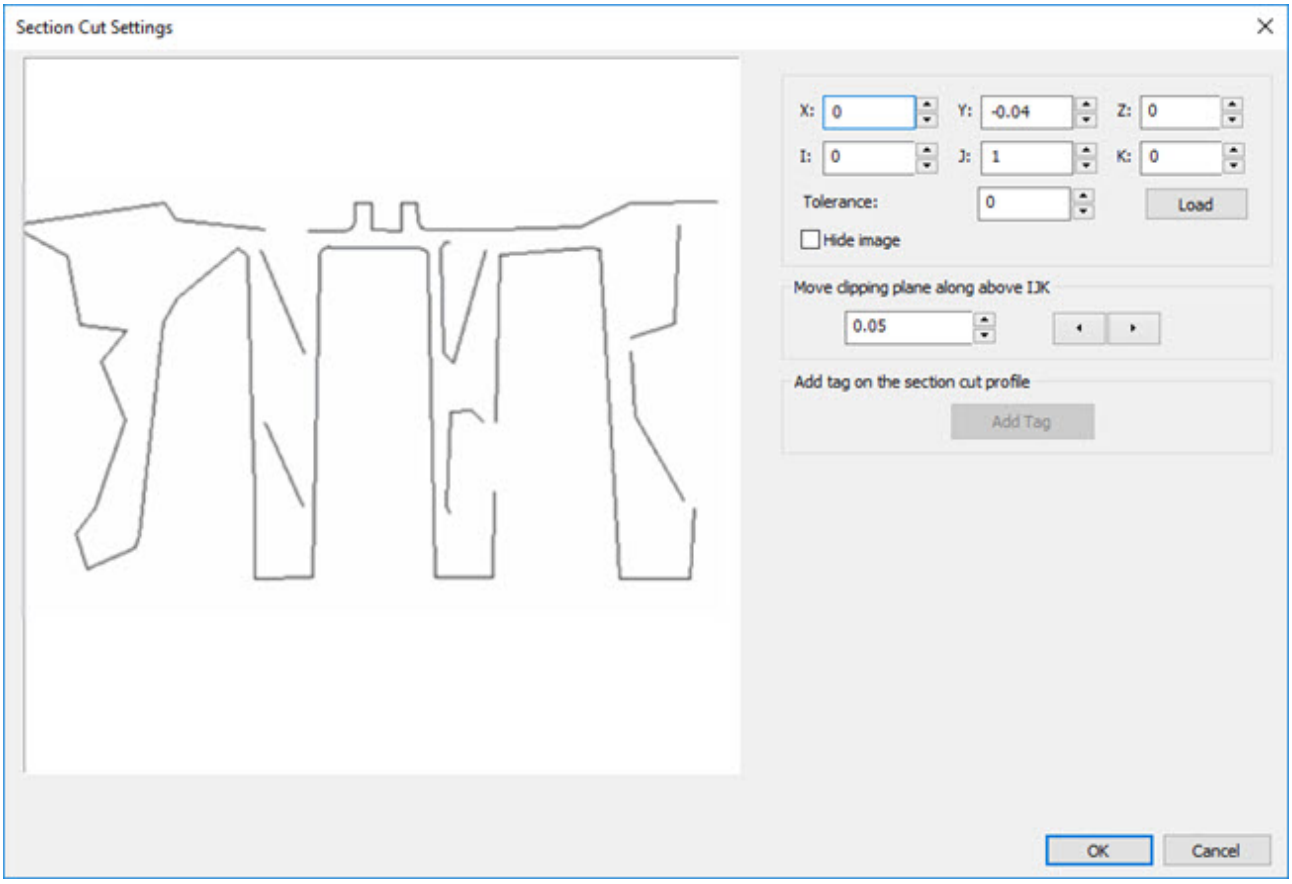
SectionCutObject

The **SectionCutObject** lets you define a section cut (cutaway view) of the CAD model. You can insert a **SectionCutObject** into the Report Template Editor as with other objects, or you can insert it into a final report page on the Report window directly. To insert this object, position the mouse pointer, and click and drag a box. When you release the button, the object appears, and—at least in the Report Template Editor—it displays "No Image!" until you move the clipping plane so that it intersects with the CAD model. You can move the clipping plane through the object's properties.

Changing the Object's Properties

If you insert the **SectionCutObject** into the Report Template Editor, right-click on it to access the object's **Properties** dialog box. You can modify the properties directly in the **Properties** dialog box or select the **(Settings Dialog)** property, and click the **...** button to use the **Section Cut Settings** dialog box to more easily modify its properties.

If you insert this object on-the-fly into a report page of the Report window, the same **Section Cut Settings** dialog box appears.



Section Cut Settings Dialog Box

You can use this dialog box to define a cutaway image of your part model that you want to show in your report.

Defining a Cutaway Image Using the Section Cut Settings Dialog Box

1. Fill out the **X**, **Y**, and **Z** boxes to define a point on the CAD model where the clipping plane intersects with the model.
2. Fill out the **I**, **J**, and **K** boxes to define the direction the plane faces.
3. Modify the **Tolerance** value as needed.
4. Click the **Load** button to see a live preview of the cutaway image in the **Section Cut Settings** dialog box.

5. Use the large left and right arrow icons to fine-tune the placement of the plane and get the exact cutaway view that you need. The preview in the dialog box updates to match the placement of the plane.

6. Reposition the image as desired. Pan the image by right-click dragging. Zoom in or out on the cutaway image by right-clicking above or below the imaginary horizontal line that splits the image view. 2D rotate the part image by holding the Ctrl key and right-click dragging.

7. Finally, place callouts onto the dialog box image by using the **Add Tag** button.

8. Click **OK** to accept your changes.

Section Cut Settings Dialog Box Items

X Y Z boxes
These boxes define a point on the CAD model where the clipping plane cuts the model.

I J K boxes
These boxes define the IJK direction vector of the clipping plane.

Tolerance box
The tolerance parameter is used to:

- Check if the polyline is closed. The start and end point distance is less than the tolerance value.
- Reduce the polyline.
- Merge polylines.

Load button
This button previews the section cut line on the CAD image as well as the section cut profile.

Hide Image check box
This check box hides the section cut profile image in the Preview window. If you click the **OK** button, PC-DMIS also hides the section cut profile image in the Report Template Editor or on the Report window's page.

Move clipping plane along above IJK area
This area contains an edit box and arrow buttons.

The edit box defines the distance that the clipping plane moves when you click the left arrow or right arrow button.

The arrow buttons move the clipping plane along the IJK vector by the specified distance with each click.

- If you have 1,0,0 then the plane moves along the X axis.

- If you have 0,1,0 then the plane moves along the Y axis.
- If you have 0,0,1 then the plane moves along the Z axis.

Add Tag button
This button allows you to place callouts on the cutaway image of the part model.

Clicking this button changes your cursor to a cross-hair icon. You can click and drag a leader line on the cutaway image in the dialog box. When you release the mouse button, a small text box appears, which allows you to type the callout text. The number of characters this text box can display is only limited by the size of the text box. Increasing the size of the box allows it to hold and display more characters.

You should place tags on the image only when the cutaway image has been completely finalized. If not, the tag is deleted with future modifications to the image.

OK and **Cancel** buttons
Clicking **OK** applies your changes to the section cut profile image and displays the image in the Report Template Editor or Report window. If your report contains a CadReportObject, the section cut line appears on the CAD image.

Clicking **Cancel** closes the dialog box without applying your changes. However, if you've added the object on-the-fly into your Report window, the SectionCutObject still exists. If desired, you can remove it by right-clicking on the object and selecting **Remove Object**.

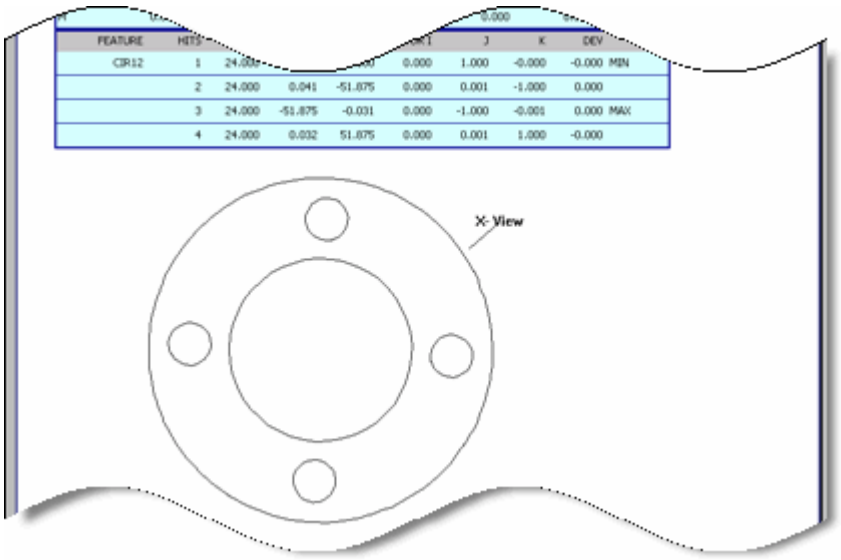
Defining On-The-Fly Section Cut Profiles

Perhaps the easiest way to use section cut profiles is to define them using an on-the-fly creation method within the final report in the Report window itself. To do this:

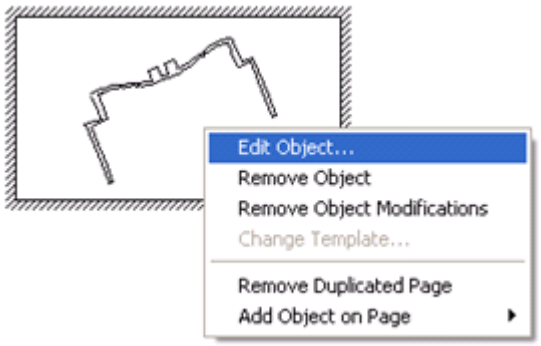
1. Right-click on the Report window. A shortcut menu appears.
2. Select the **Add Object on Page | Section Cut Profile** menu item.
3. Click and drag a box directly on the Report window with the size of the cutaway image you want. When you release the mouse button, the **Section Cut Settings** dialog box appears.
4. Use the dialog box to define the cut profile as described above. PC-DMIS inserts the section cut profile into the Report window.



Example of a section cut profile.

Modifying Section Cut Profiles in the Report Window

Right-click on the object and select **Edit Object** from the resulting shortcut menu.



Slider Object

The **Slider** object inserts a slider into your template. With a slider in your report, you can allow users to set a value from a range of continuous possible values.

Along with the ability to resize the object, and change other attributes, you can further customize this object by using these properties:

AutoTicks
Setting this to `YES` displays ticks on the slider. A tick is a short vertical/horizontal line that is placed at intervals (set by the `TickFrequency` property) along the range of the slider.

DisplayID
This determines whether or not the DisplayID gets updated when the slider gets adjusted.

HelpHotButton
Selecting `YES` shows a question mark help button next to the slider.

Clicking this help button in run mode launches the PC-DMIS Online Help.

MaximumEq
Maximum equation (This value can be a set constant number, a value evaluated from a simple equation, or a returned value from a VBScript).

```
-$, $, CONST
```

MinimumEq
Minimum equation (This value can be a set constant number, a value evaluated from a simple equation, or a returned value from a VBScript).

```
-$, $, CONST
```

Orientation
This sets the orientation of the slider.

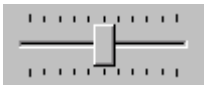
Selecting `Horizontal` sets the slider to move horizontally, side to side.

Selecting `Vertical` sets the slider to move vertically, up and down.

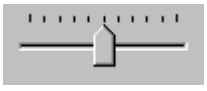
TickFrequency
This value determines the frequency that ticks are displayed. You can set a value between 2 and 200 ticks equally spaced along the range of the slider.

TickStyle
This allows you to set how ticks are displayed on a slider.

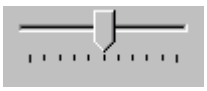
`0 - Both:` sets the ticks to above and below the slider (if a horizontal slider) or to the right and left sides (if a vertical slider).



`1 - Top/Left:` sets the ticks above the slider (if a horizontal slider) or to the left (if a vertical slider).



`2 - Bottom/Right:` sets the ticks below the slider (if a horizontal slider) or to the right (if a vertical slider).



ValueID
This is the ID of the value. You can set or get this by using the control.

Snipping Object

The **Snipping** object on the **Object Bar** puts PC-DMIS in a snipping mode. This object works with only the Custom Report Editor. In snipping mode, you can capture a section of your screen and insert it as an image into the Custom Report Editor.

To use the **Snipping** object and insert an image:

1. Click the **Snipping** object to enter snipping mode. The arrow of your pointer changes to a cross hair, and a semi-transparent white overlay covers the entire screen.
2. With your pointer, click and drag a box around the part of the screen you want in your report.
3. Release the mouse button to capture that part of the screen as an image. PC-DMIS inserts the image as an object with the name of Snipping1 into the Custom Report Editor. Additional captures are named Snipping2, Snipping 3, and so on.

The properties for this object are described in the "Common Properties" topic.

Spinner Object

The **Spinner** object inserts a spinner control into your template. You can set this control to work with an edit box, allowing you to select a numerical value by cycling through a range of numbers. The range of numbers is set using the `MinimumEQ` and `MaximumEQ` properties.

Along with the ability to resize the object vertically, and change other attributes, you can further customize this object by using these properties:

DecimalBase
This sets the base of the spinner to either decimal based (select `YES`) or hexadecimal based (select `NO`).

EditBuddy
Selecting `YES` associates the spinner to the edit control immediately preceding the

spinner in the tab order. You can view the tab order by selecting an object in edit mode and pressing Shift + Enter.

IncrAccelerator
This value determines the amount to increment or decrement the spinner each time you click an arrow. The default is `1`.

MaximumEq
Maximum equation (This value can be a set constant number, a value evaluated from a simple equation, or a returned value from a VBScript).

```
-$, $, CONST
```

MinimumEq
Minimum equation (This value can be a set constant number, a value evaluated from a simple equation, or a returned value from a VBScript).

```
-$, $, CONST
```

Orientation
This sets the orientation of the spinner control.

Selecting `Horizontal` rotates the orientation of the spinner arrows to point horizontally.

Selecting `Vertical` rotates the orientation of the spinner arrows to point vertically.

WrapAround
If incrementing or decrementing the list of values and you come to the minimum or maximum value, you can set this property to `YES`, and your report will wrap to the beginning or end of the list.

TextReportObject

The **TextReportObject** object allows you to insert a container for your textual report data into your report template. When you insert this object, PC-DMIS initially displays a box filled with some sample report data, which is useful for design purposes. Once your template gets applied to a report, your actual report data is used.

```
PART NAME  : PL54A.1
REV NUMBER :
SER NUMBER :
STATS COUNT : 1

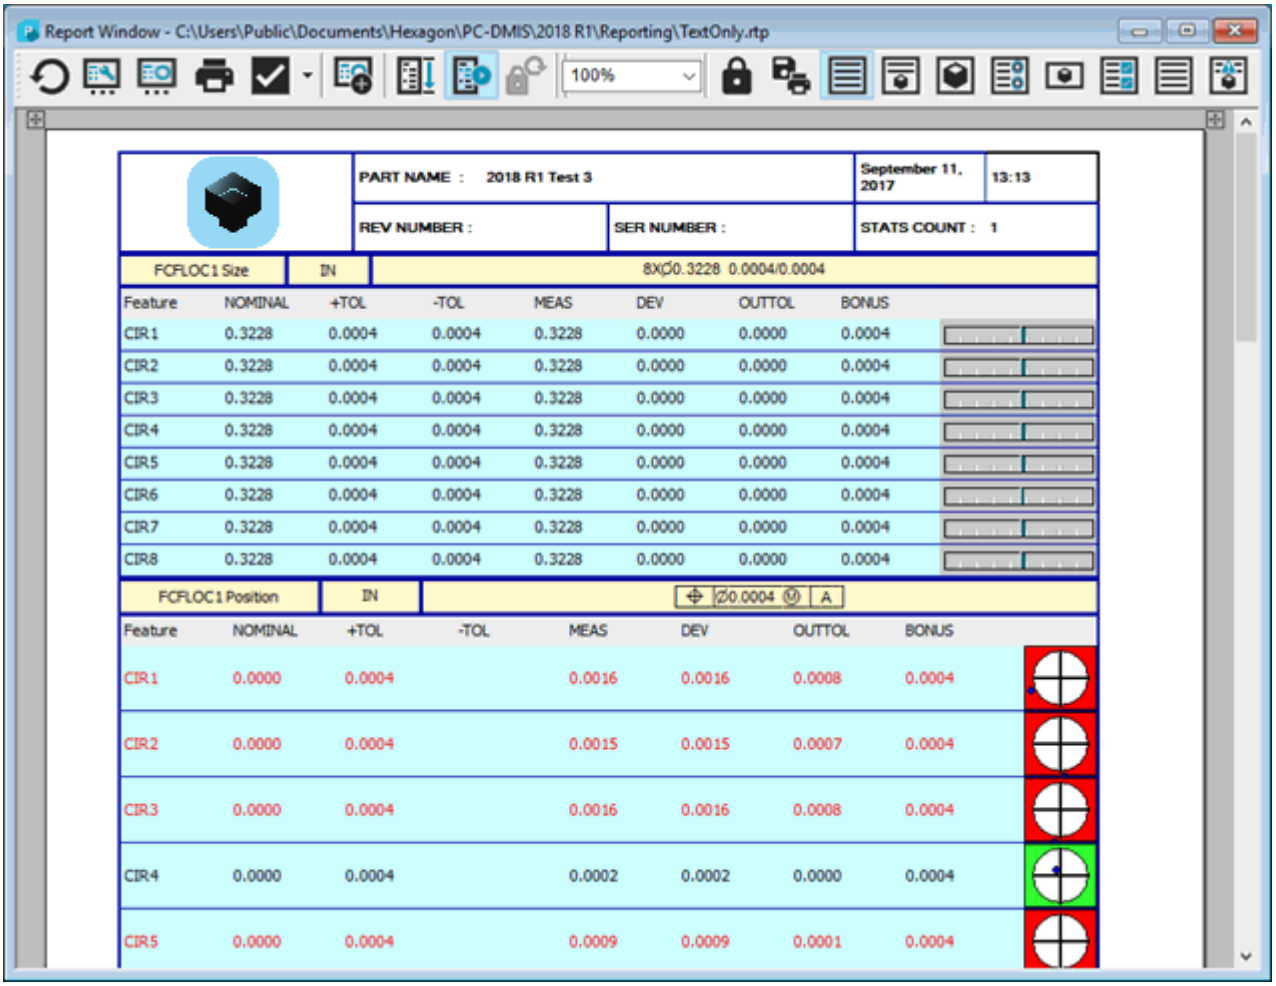
A TextReportObject with Sample Report Data



A sample Report window showing actual report data

You can change an inserted TextReportObject's display by selecting the object, right-clicking on it, and editing its properties.

Properties specific to this object include:

Colors
Lets you change the colors of the text displayed. By default, PC-DMIS causes this object to use the same color scheme you used in the Edit window's Command Mode.

When you click this property, PC-DMIS displays a message box asking if you want to create an independent color set. Click **Yes** to access the **Color Editor** dialog box. You can then use this editor to define a new color scheme for the selected TextReportObject.

> See "Defining Edit Window Colors" in "Setting Your Preferences" for information on how to use the **Color Editor**.

Report Header After PRINT
This property determines how PC-DMIS handles a report header *after* a `PRINT/REPORT` command. For information, see the "Header after Print Command" area in the "Edit Text Reporting" topic.

RuleTree
Accesses the **Rules Tree Editor** for this object. This property allows you to create rules to determine when and how expressions or label templates are used in the object.

Label templates and expressions let you control the report data that appears in this object. See "About the Rule Tree Editor".

ShowAlignments
Shows or hides alignments in your report.

ShowComments
Shows or hides comments in your report.

ShowDimensions
Determines which dimensions get displayed in your report.

> `All` - Shows all dimensions.
> `None` - None of the dimensions are shown.
> `Out of Tolerance` - Shows only out of tolerance dimensions.
> `Within Limits` - Shows only dimensions within tolerance limits.

ShowFeatures
Shows or hides features in your report.

ShowHeaderFooter
Shows or hides the report's header and footer information.

ShowMoves
Shows or hides move commands in your report.

ShowScreenCaptures
Shows or hides screen captures in your report.

Text Object

The **Text** object allows you to insert textual labels, descriptions, and markings into your template. This is helpful in making your report more meaningful. You can change an inserted text object's display by selecting the text object, right-clicking on it, and editing its properties.

The properties for this object are described in the "Common Properties" topic.

TextVar Object

The **TextVar** object allows you to insert dynamic, numerical text into your template. This object differs from the **Text** object by deleting the TEXT property and adding these 2 properties:

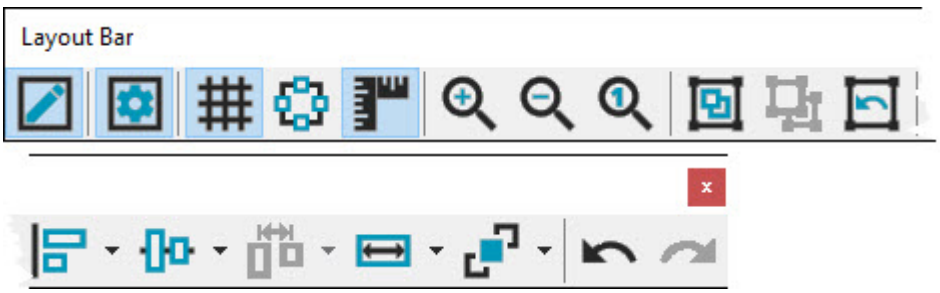
ValueEq
Value equation (This value can be a set constant number, a value evaluated from a simple equation, or a returned value from a VBScript). The value is formatted and displayed at run time.

```
-$, $, CONST
```

Format
This formats the numerical value using 'C' language standards. However, you should use only the numeric portion. For example, the format `%5.2lf` becomes 5.2, `%5d` becomes 5. One exception to this is when using BOOLEAN variables, the $ string gets converted into NO or YES.

To use this object edit the **ValueEq** property so that it's set to display a variable number value.

The Layout Bar



The **Layout Bar** gives you the tools you need to effectively arrange, organize, and display your objects inside the edit mode grid. The following topics discuss the functionality of each icon.

Edit

The **Edit** icon places the template into run mode. The Report Template and Label Template editors always remain in edit mode. This icon only functions when working with the Form Editor.

Property Sheet

The **Property Sheet** icon displays the properties for the selected object in the **Property Sheet** dialog box. The **Property Sheet** dialog box enables you to change the properties for a selected object. To change the object whose properties you're looking at, choose a different existing object from the list at the top of the **Property Sheet** dialog box.

For complete information on properties, see "About Object Properties".

Toggle Grid

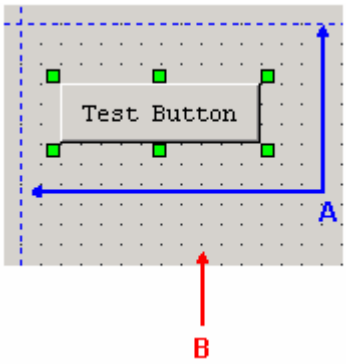
The **Toggle Grid** icon shows or hides the available grid. In edit mode, the grid helps you size objects precisely, because it contains a dot every tenth of an inch. For more information, see "Working with the Grid" below.

Working with the Grid

When working in a form or template editor, PC-DMIS can display or hide a grid on the background of your form or template in these ways:

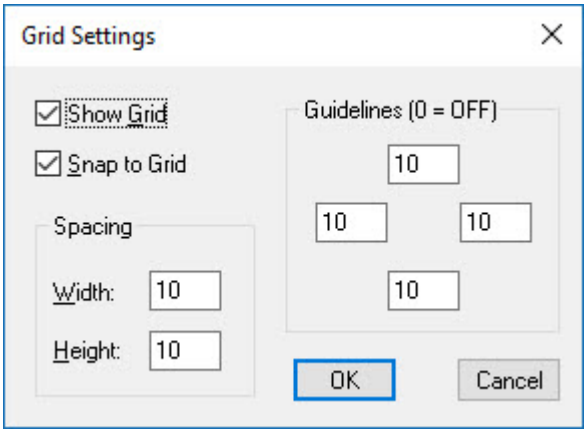
- Click the **Toggle Grid** icon ( ) from the **Layout Bar**.
- Press Ctrl + G.

You can use this grid as a tool for the accurate placing and sizing of objects. It also helps you control a template's margin guidelines.



A - Guidelines
B - Grid markings
Example showing the default grid's markings and guidelines

Select **Edit | Layout | Grid Settings** to access the **Grid Settings** dialog box.



Grid Settings Dialog Box

You can then use this dialog box to customize the grid. A description of the controls in this dialog box follows:

Show Grid check box
The **Show Grid** check box toggles the display of the grid.

Snap to Grid check box
The **Snap to Grid** check box determines whether controls placed on the grid get moved, or snapped, to the nearest grid location.

Spacing area
The **Spacing** area sets the amount of spacing between the grid markings. The smaller you set these numbers, the closer together the grid markings are.

Guidelines area
The **Guidelines** area allows you to determine the location of the top, left, right, and bottom margin guidelines for the template editor.

The value in each of these boxes sets the distance in grid markings to where the guideline is set. Setting the value to zero removes the guideline completely.

You cannot place objects beyond these guidelines.

View Snap Points

The **View Snap Points** icon shows the snap points on each object. Snap points are useful in tying objects together with lines. For example, you can create a line between a text box description pointing to an object, such as a circle, by using a line to connect snap points on the text box description and the circle object. Then, like a leader line, when you move the circle to a new location, the attached line stretches and shrinks to accommodate the new position of the circle.

To use snap points as described in the above example, follow these steps:

1. Create a circle object.
2. Create a line object.
3. In edit mode, select the **View Snap Points** icon from the **Layout Bar**. You will notice that objects on the grid that have an area display blue-colored points. These blue points are snap points.

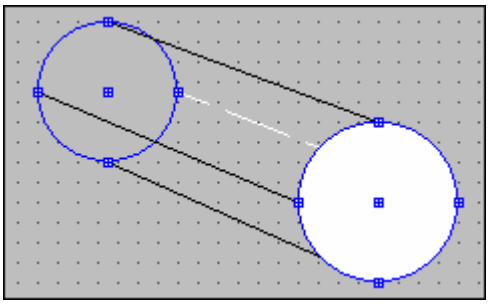
   
   Example of a circle with five snap points.
4. Select the line and drag one end of it until the end rests directly on the desired snap point of the circle. Try moving the circle object. The line is attached to the circle object's snap point.
5. Create a text object for a description for the circle and edit it with a brief description.
6. Select the other end of the line and drag it until it rests on one of the snap points of the text object.
7. Now select and drag either the text box description or the circle object. Notice that the line object gets longer or shorter and moves so that there's always a straight line between the used snap points of the two objects.

To detach objects attached to a snap point, simply drag the attached end of the object off of the snap point.

Snap Points vs. Leader Line objects

Most of the time you will probably use the **Leader Line** object instead of snap points. It has nearly all the same functionality as snap points and is easier to use (see the "Leader Line Object" topic). One advantage snap points have over the **Leader Line** object, is their

ability to support more than one line between objects and their ability to fit the connecting line exactly to a snap point. For example, with snap points, you can create a more complex shape directly in the edit mode, as shown here:



Example of a cylinder constructed from four lines fitted to snap points on two filled circles.

Supported Objects

Only Line and Polyline objects can attach to objects that have snap points. Below are the objects that have snap points:

- Text
- TextVar
- Border
- Ellipse
- Bitmap
- Dimension Color Key
- Histogram
- Feature Text
- Dimension Info
- Point Info

Viewing Attached Objects

On complex pages with a lot of objects, you may find it useful to use the **View | Route** menu option to see the chain of objects connected to the currently selected object. This menu option selects all objects connected in some way by snap points to the currently selected object.

Toggle Ruler

The **Toggle Ruler** icon allows you to turn on or off the ruler located on the top and left sides of the grid. The ruler shows the size of the grid in inches or centimeters. It also displays your cursor's position along the grid's horizontal axis (top ruler) and vertical axis

(side ruler). You can switch between Inches or Centimeters by right-clicking on the ruler and selecting the desired option from the shortcut menu.

Zoom In or Out

These icons allow you to zoom in or out of your Hyper report and then restore the original view:

Zoom In - This zooms in on your report by 100 percent per click. You can click this icon at most five times to get a 500 percent zoom.

Zoom Out - This zooms out of your report by 100 percent per click if you're already zoomed in. If you haven't zoomed in at all, you will only be able to zoom out by 100 percent one time.

Zoom 1:1 - This restores the size of your report to the original 1 to 1 zoom size.

No matter what you zoom to, PC-DMIS restores the original zoom whenever you activate a control that has an "activated" or "deactivated" mode (for example, double-clicking on the CadReportObject or GridControlObject). When you leave these controls and return to the editing environment, the zoom size goes back to what it was.

Group

The **Group** icon allows you to select multiple objects and group them together. Once grouped, the editor will show the grouped objects as one object.

To group multiple objects, either hold down the SHIFT button and select all objects in the group, or box-select all objects and then click the **Group** icon.

Ungroup

The **Ungroup** icon restores object in a group to their individual ungrouped states. To do this, select a grouped object and click **Ungroup**.

Regroup

The **Regroup** icon regroups the last ungrouped set of objects without your having to reselect the individual objects.

Align Edges

The **Align Edges** icon lets you arrange a set of selected objects along their left, right, top, or bottom edges:

Align Left - Aligns the selected objects along their left edges.

Align Right - Aligns the selected objects along their right edges.

Align Top - Aligns the selected objects along their top edges.

Align Bottom - Aligns the selected objects along their bottom edges.

Align Center

The **Align Center** button provides additional buttons that let you center selected objects either horizontally or vertically:

Center Vertically - Centers the selected objects vertically along the horizontal axis.

Center Horizontally - Centers the selected objects horizontally along the vertical axis.

Space

The **Space** icon provides you with these additional icons that allow you to equally space selected objects either horizontally or vertically:

Space Across - Equally spaces selected objects along the horizontal axis

Space Down - Equally spaces selected objects along the vertical axis

Make Same Size

The **Make Same Size** icon provides you with these additional icons that allow you to equalize the width, the height, or both the width and height of all selected objects:

Make Same Width - Equally sizes the widths of the selected objects

Make Same Height - Equally sizes the heights of the selected objects

Make Same Size - Equally sizes both the widths and the heights of the selected objects

To Front or Back

The **To Front or Back** icon provides you with additional icons that allow you to place a selected object (or objects) in front or in back of other objects. This is helpful when you have multiple objects on top of each other, and you want certain objects to be visible. The available icons include the following:

Bring to Front - Moves the selected objects in front of all other objects so that it is shown on top.

Send to Back - Moves the selected objects behind all other objects so that it is shown beneath.

Notes on Drawing Levels

Moving objects in front of or behind other objects is subject to an internal drawing level used by the different objects. This means you can only bring objects in front of other objects of the same drawing level or in front of a higher drawing level. Here is the drawing order:

CADReportObject - Drawing level 5

This object is drawn behind all objects of a lower drawing level. It can be drawn in front of other level 5 objects.

AnalysisWindow - Drawing level 4

This object can be drawn in front of level 4 or 5 objects.

Leader Line - Drawing level 3

This object can be drawn in front of level 3, 4, or 5 objects.

All other reporting objects - Drawing level 2

These objects can be drawn in front of level 3, 4, or 5 objects.

You can move objects of the same level in front of or in back of each other, but you cannot, for example, bring a CADReportObject in front of a Label Object. This type of sorting is only used by PC-DMIS version 4.x and higher reporting templates or reports. Legacy (HyperView) reports do not use a sort method.

Undo (Action)

The **Undo** icon undoes the last action you took in the editor.

Redo (Action)

The **Redo** icon redoes the last action that was undone when you clicked the **Undo** icon.

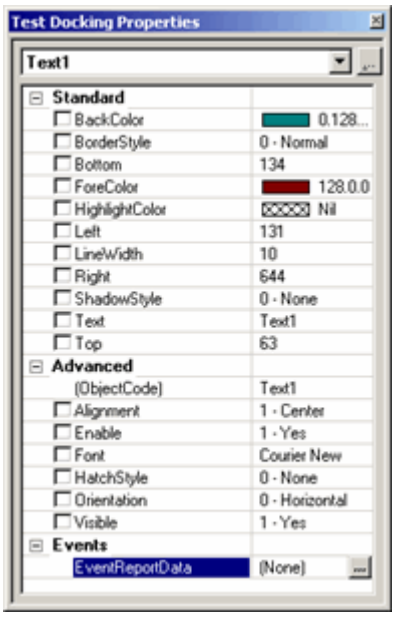
About Object Properties

Each object that you add to a template or form has a set of properties (or attributes) that control the object's position, size, colors, font, text, name, and so on. Each object also has a set of event handler functions that PC-DMIS triggers when certain events occur. For example, an event can occur when you click or double-click the mouse on that object.

You can use the **Properties** dialog box to view and modify properties and event handlers. Another name for this dialog box is "property sheet".

Viewing an Object's Properties

To view the **Properties** dialog box, select an object (single-click within its boundaries) and then right-click. This is an example of a property sheet that shows the text object **Text1** and its various properties:



Properties Dialog Box

Viewing Object Properties

A list appears at the top of the **Properties** dialog box. This list contains an entry for each object in your template or form. It also contains some objects that always exist and you cannot delete, such as the main editing area. In the Report editor, the main editing area is called the **Page**. In the Label Editor and the Form Editor, it is called **The Frame/The View**.

To view the properties for an object in your form or template, select a different object from this list. If you have a report template with more than one section, this list shows only the objects in the current section.

For report templates, you can access an additional object called **Report** only from this list. It has two properties in the **Advanced** category that you can use to specify your own external executable (an .exe file) to collect user-assigned properties. These properties are **Template Selection Program** and **Measurement Routine Execution Program**. PC-DMIS runs the specified measurement routines while you select a template and execute a measurement routine, respectively.

Property Organization

Each object's properties are in three main categories:

- **Standard** - These properties control color, position, and line styles.
- **Advanced** - These properties control whether the object is enabled or visible.
- **Events** - These properties enable you to use the BASIC language to code specific instructions when events occur.

To expand a category, click the **+** symbol to the left of the category. To collapse a category, click the - symbol.

ActiveX and OLE objects have an additional section. For more information, see "ActiveX Object" and "OLE Object".

For descriptions of properties, see "Common Properties". If that topic does not contain a description of a property, view object-specific documentation in "The Object Bar".

For more information on events, see "About Events and Visual Basic Code".

Name Identifier

When you insert an object into a template or form, PC-DMIS automatically assigns a unique name identifier to the object's **ObjectCode** property. Subsequent objects of the same type have the same name, with an incremented numerical value behind it. For example, the editor automatically names your first **Text** object "Text1". It names subsequent **Text** objects "Text2", "Text3", and so on.

You can change this value to a different name. If you change it, ensure that you give it a unique name. If you modify that object's name identifier, you must also update any BASIC scripting that uses an object's code.

Changing Property Values

To modify a property, select it and then click its value. If a list appears, select a new value. You can also type a new value in an editable field.

Expressions as Property Values

Some property values can hold reporting expressions instead of a constant value, just as a cell from a **GridControlObject** can hold expressions. Remember to preface the expression with an equal sign (=). For example, suppose that you have a **Text** object in a label template, and you also want it to display the current feature's ID instead of other text. In the **Text** property, type "=ID". When PC-DMIS executes the measurement routine, the object pulls the feature's name from PC-DMIS and displays it in that **Text** object.

Common Properties

The following are some common properties used on various objects. They make up the core set of properties for many other objects. Properties specific to an object are documented in that object's documentation. Events properties are detailed in the "About Events" topic.

Common Standard and Advanced Properties

Accelerator
This allows you to define the letter to use in conjunction with the Alt key to create an accelerator for the control. The letter or symbol defined should be unique from those used for other accelerators (including the accelerators on the menu bar). This is used with most form controls.

Alignment
Text alignment within the text object’s defining rectangle.

AnchorSnaps
Field that allows you to create, delete, or modify snap points in the **Enter Snap Points** dialog box. Snap points are found on the ellipse, rectangle, text box, or bitmap image objects.

You can connect **Line** or **Polyline** objects to an object's snap points by dragging the tip of the line onto the displayed blue snap point.

Once connected, when you drag the object to a new location, the resulting line remains connected to the snap point, rotating, elongating, and shrinking as necessary. This feature is helpful when you need to create a "leader-line" that constantly points to an object that you'll frequently be moving.

To display snap points, from the **Layout** toolbar, click the **View Snap Points** icon .

Auto Size
This determines whether or not the object sizes itself automatically based on the length of the text it contains.

> If this is set to `YES` and `Word Break` is set to `NO`, then the text object automatically adjusts its width.
>
> If this is set to `YES` and `Word Break` is set to `YES`, then the text object automatically adjusts its height.

BackColor
Background color of the object. This color is used to fill the object's defining rectangle.

`Nil` - This stands for no value. It means the background will be transparent, allowing other colors of objects behind this object to show through. By default, anything with a BackColor property is set to `Nil`.

Setting the color to `Nil` sets the color to RGB(255,255,254) which is then made transparent within the Report window.

If you try to specify a color of RGB(255,255,254), PC-DMIS automatically sets it to RGB(255,255,255), a non-transparent color. This does not affect how the object is displayed.

Be aware that if your label has a bitmap image that uses the color RGB(255,255,254), PC-DMIS sets that color to transparent inside the Report window.

BorderStyle
Style of border drawn around the object.

Bottom
Distance, in pixels, of the bottom of the object's rectangle from the top of the template or form.

CursorPointer
Cursor displayed when the user drags the mouse over the object.

Enable
Enable or disable the object. A disabled object may still be visible, but does not respond to user input.

Font
Font used for text rendered in the object.

ForeColor
Foreground color of the object. In the case of the text object, specifies the text color.

Group
This is used with form objects, such as buttons, check boxes, radio buttons and so on.

HatchStyle
This sets the type of pattern (or hash) to use with the object. Available patterns are:

Horizontal

Vertical

Diagonal

Reverse Diagonal

Cross

Diagonal Cross

Objects that use this include: Border, Ellipse, Histogram, TextVar

HelpContextID
This is the context ID of a specific help topic to call. This is often used in conjunction with the Help button type which invokes WinHelp( ).

Layer
This assigns the current object to the selected layer.

Left
Distance, in pixels, of the left side of the object’s rectangle from the left side of the template or form.

LineStyle
This changes the objects line style (or border style) to `Solid`, `Dash`, `Dot`, `Dash-dot`, and `Dash-dot-dot`.

LineWidth
This sets the line's (or border's) width in pixels.

(Object Code)
Unique name that identifies an object in a template or form. Whenever you need to access a property or method of an object using the BASIC language, use the following syntax:

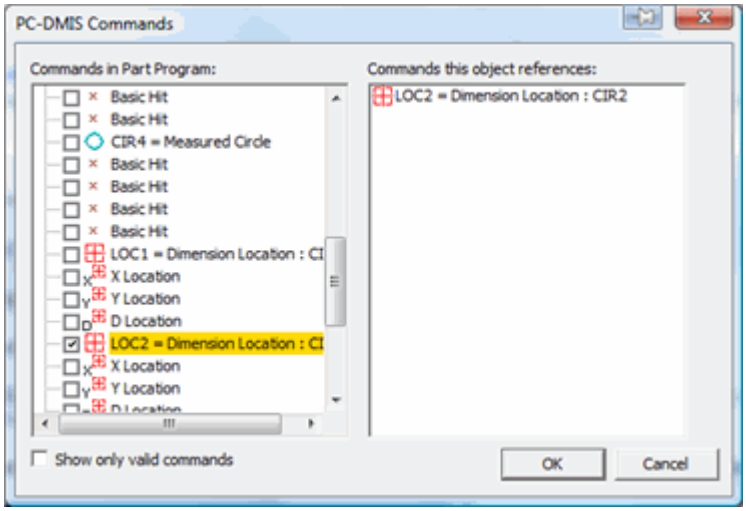
{Object Code}.{property or method name}

Orientation
Orientation of the text inside the object. Horizontal text flows from left to right. Vertical Up flows from bottom to top. Vertical Down flows from top to bottom.

Padding
This property adds pixels of white space around the text by the given amount.

PC-DMIS Commands
(Appears only for objects added to the Custom Report Editor)

Adds or Removes command references to existing objects in your report. Select an object in your report, and select this property. The **PC-DMIS Commands** dialog box appears.



PC-DMIS Commands Dialog Box

By default, all the commands in your measurement routine appear in the expandable and collapsible list on the left. However, for some objects, namely the Label object, GridControlObject, Analysis object, and DimensionHistogram object, some commands may not be valid. In those cases they are disabled in the list. You can choose to hide any disabled commands in the left-hand list by selecting the **Show only valid commands** check box.

The right-hand list displays all the commands referenced by the object.

1. Select the commands from the left-hand list that you want the selected object to reference. PC-DMIS displays them in the right-hand list if the object supports taking multiple commands. However, in most cases, you can only select one command.

2. Click **OK**. The dialog box closes and PC-DMIS now references the new command in the selected object.

This essentially provides an alternate approach to updating an object to use different data from the measurement routine. See "Dragging and Dropping Information into a Custom Report" for the usual way of updating objects.

For the CADReportObject or the AnalysisObject, features whose check boxes are marked are added to the object. Features whose check boxes are cleared are removed from the object. If nothing is marked, PC-DMIS displays items according to the `HideAllPointsonReport` and `HideAllMeasuredFeaturesOnReport` entries in the **Reporting** section of the PC-DMIS Settings Editor.

For objects that support multiple commands (such as the GridControlObject), this dialog box lets you change the order of referenced commands.

PC-DMIS References
(Appears only for objects added to the Custom Report Editor)

Tracks the commands referenced by the selected reporting object. During report generation, for each command, PC-DMIS checks the command references of each object. If that object indicates that it has a reference to the command being processed, PC-DMIS sends the command data to that object.

Most objects only support one command at a time, but some objects can support data from multiple commands (such as the GridControlObject). If you drag and drop commands into the Custom Report Editor, PC-DMIS takes care of managing the references for you internally. You should only need to use this property if you decide to have manual control over which commands are referenced for some reason.

PenWidth
Width of the pen used to draw the object. In the case of the text object, the pen width only affects the border drawn around the text.

Right
Distance, in pixels, of the right side of the object’s rectangle from the left side of the template or form.

ShadowStyle
This sets the location of the 3D shadow on the resulting object. Available locations are:

`Top/Left`, `Bottom/Right`, or `None`

Tag
Place holder that stores user-defined data.

Text
Text appearing in the text object. You can also type an ampersand symbol (&) in front of any alphanumeric character in this field to create a shortcut key (shown as an underlined character). Once defined, you can press the key along with the Alt key in run mode to cause that control to immediately have the focus. If you plan on using a lot of shortcut keys, you can ensure they are unique by using the **Edit | Layout | Check Mnemonics** menu item in edit mode.

Tabstop
This determines if pressing the Tab key cycles to the object. This is used with form objects, such as buttons, check boxes, radio buttons and so on.

ToolTipText
Text displayed when you move the mouse over the object inside run mode.

Top
Distance, in pixels, of the top of the object's rectangle from the top of the template or form.

ValueID
This contains the value of the ID, or on supported objects it contains the `CurPage` and `NumPages` variables. You get and set this property using the control. This is used with most of the form objects.

Visible
Visibility state of the object. A value of `1` corresponds to visible, `0` to hidden.

Word Break
Determines whether or not the text object can hold more than one line of text. If set to `YES`, then PC-DMIS wraps text strings that exceed the width of the object container within the object container. If set to `NO`, then text strings remain on a single line.

TheFrame/TheView Properties

The main editing areas in the Label Template Editor and Form Editor contain a special object called **TheFrame/TheView**. This object also contains properties that you can access and set just as with any other object.

- Properties that are followed by a single asterisk (*) are used in the Label Template Editor only.
- Properties that are followed by two asterisks (**) are used in the Form Editor only.
- All other properties are used in both the Label Template Editor and the Form Editor.

Height
Defines the height, in pixels, of the main editing area.

Horizontal Positioning **
Sets the horizontal position of the form within the window when executed.

LocalDecls
Declares variables with a scope that is available to your entire form or label.

LocalVariables **
See the "Declare Global Variables Using the LocalVariables Property" topic.

MaximizeBox **
If set to **Yes**, this property displays a **Maximize** icon in the upper-right corner of the form. You can click this icon in Run mode or during execution to maximize your form window to fill the available space.

If MaximizeBox is set to **Yes** but MinimizeBox is set to **No**, then the **Minimize** icon still appears but is unavailable for selection.

MinimizeBox **
If set to **Yes**, this property displays a **Minimize** icon in the upper-right corner of the form. You can click this icon during run mode or during execution to minimize your form window to the taskbar.

If MinimizeBox is set to **Yes** but MaximizeBox is set to **No**, then the **Maximize** icon still appears but is unavailable for selection.

Page Orientation *
Sets the label to one of the predefined standard orientations, either **Portrait** or **Landscape**.

Page Size *
Sets the label to one of the page sizes available on your default printer. You may see items such as Letter, A4, or one of several other sizes depending on your type of printer.

ReportLock **
Determines whether PC-DMIS can clear data from a form. If this is set to **Yes**, PC-DMIS does not clear data from the form. If it's set to **No**, PC-DMIS clears data from the form that is collected over time.

Supported Command Types *
Displays the **Supported Command Types** dialog box. With this dialog box, you can define the commands that should use this label template. Then in the Report window, when you right-click on a label and select the **Change Report** menu item, PC-DMIS only displays those labels that support the selected command type.

ToolTipText
See the "Common Properties" topic.

Vertical Positioning **
Sets the vertical position of the form within the window when executed.

Width
Defines the width, in pixels, of the main editing area.

Section and Page Properties

The main editing areas in the Report Template Editor and the Custom Report Editor are special objects called the **Section** and the **Page**, respectively. These objects contain properties that you can access and set just as with any other object.

Command Set
Defines how commands get processed within the current section (**Page** tab).

All Commands - The setting processes the entire command set in the current section (**Page** tab). This is the default value.

Continue from Previous Section - This setting continues to process the command set from the previous section, continuing where the last section stopped processing.

Same as Previous Section - This setting causes the section (**Page** tab) to take exactly the same command set as the previous section. The head section and all subsequent sections with this setting form a mini-group. All subsequent sections in the mini group create one page with the head page.

(Form Name)
Defines the name of the page.

Height
Defines the height, in pixels, of the main editing area.

LocalDecls
Provides a window for you to declare variables local to this object. Once declared, you can use these variables in events that affect the object. This type of declaration lets you give the variable a value in one event and then check that value in a different event. The variable is safe from accidental modification since it is invisible to other objects in the report or form.

LocalVariables
See the "Declare Global Variables Using the LocalVariables Property" topic.

Maximum Number Of Pages
Defines the maximum number of report pages that use the design of the current **Page** tab.

For example, if you set this value to 2, but you have easily enough dimensions in your measurement routine to fill five pages, the section does not process commands once the number of pages for that section reaches the specified maximum of two pages. The current process command needs a newly-created section (**Page** tab) to display additional information.

The default value of 0 means there is no maximum and so all pages are displayed.

ToolTipText
Common Properties

Width
Defines the width, in pixels, of the main editing area.

Examples of "Command Set" and "Maximum Number of Pages" Properties

In the following examples, suppose that your report template has four sections named A, B, C, and D, and that each one contains a TextReportObject. Additionally, suppose that your measurement routine has enough dimensions to display three pages of dimensions per section. For each example, a table details the property settings.

Example 1

Sections	Maximum Number of Pages	Command Set
A	0	All Commands
B	0	All Commands
C	0	All Commands
D	0	All Commands

In this example, PC-DMIS displays the pages in the final report like this:

A1,A2,A3,B1,B2,B3,C1,C2,C3,D1,D2,D3

Example 2

Sections	Maximum Number of Pages	Command Set
A	1	All Commands
B	0	All Commands
C	0	All Commands
D	1	All Commands

In this example, PC-DMIS displays the pages in the final report like this:

A1,B1,B2,B3,C1,C2,C3,D1

Example 3

Sections	Maximum Number of Pages	Command Set
A	1	All Commands
B	0	All Commands
C	0	Same As Previous Section
D	1	All Commands

In this example, PC-DMIS displays the pages in the final report like this:

A1,B1,C1,B2,C2,B3,C3,D1

Example 4

Sections	Maximum Number of Pages	Command Set
A	1	All Commands
B	0	Continue From Previous Section
C	0	Same As Previous Section
D	1	All Commands

In this example, PC-DMIS displays the pages in the final report like this:

A1,B2,C2,B3,C3,D1

Working with User Assigned Properties

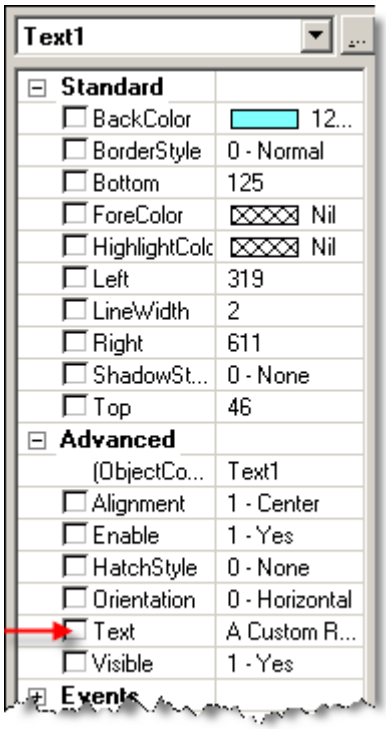
In the Report Template Editor, the **Properties** dialog box contains the ability to make a property user definable. This allows you to let measurement routine operators change object properties at runtime.

For example, suppose you want your report title to change dynamically according to whatever the current measurement routine operator wants. You can add an interactive approach such as this to your reports by using this functionality.

To Make a Property User Assigned

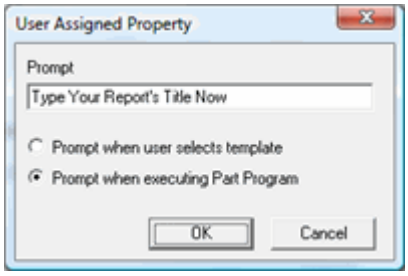
1. Select an object in one of the editors. For the example above, you would select a **Text** object.

2. Right-click on the object. This causes the property sheet for that object to appear on the right side of the editor. On the left side of the property sheet, you will see check boxes next to most properties. These check boxes determine what properties you can make user definable.



Example of a text object's property sheet with its user-definable check boxes on the left.

3. Select the check box next to the property that you want to make definable. For the example above, you would select the **Text** property for a **Text** object. A **User Assigned Property** dialog box appears, asking you to determine the message that will prompt the user for the property value and when the user should be prompted.



User Assigned Property Dialog Box

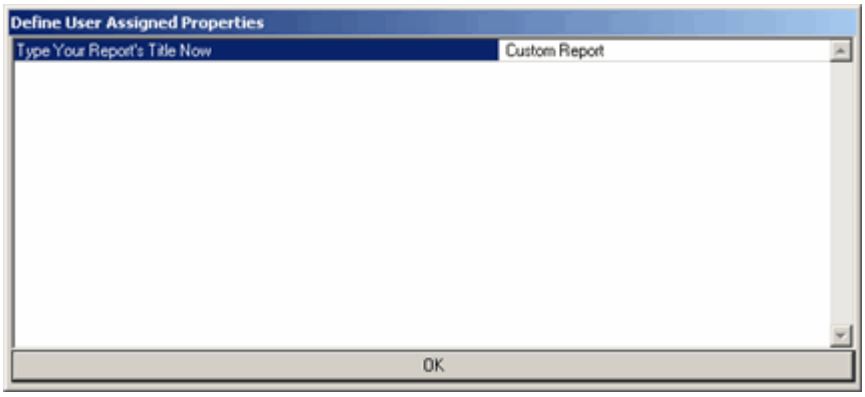
4. In the **Prompt** box, type the prompt the user will receive, and then select from one of the two option buttons when the user will receive the prompt. You can choose to prompt the user either during template selection or measurement routine execution.

5. Click **OK**. The **User Assigned Property** dialog box closes.

6. Save the report template and return to your measurement routine.

7. To test this, use the Report window and click the **Template Selection** icon. Select the report template from the dialog box and then execute your measurement routine.

8. At some time during the previous step, PC-DMIS will display the **Define User Assigned Properties** dialog box to prompt you for the properties' values according to the option button you selected in the **User Assigned Property** dialog box.

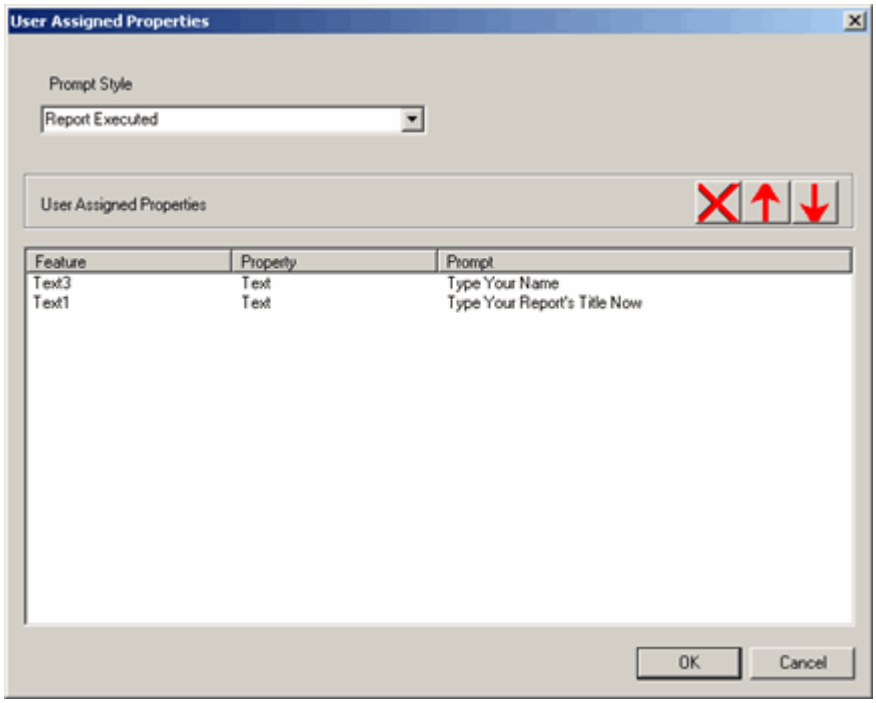


Define User Assigned Properties Dialog Box

To View and Manipulate all Your User Assigned Properties

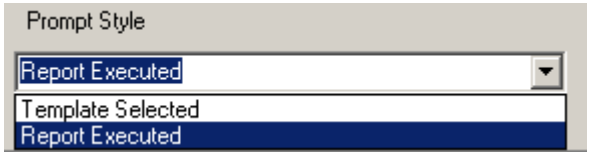
1. Access a report or label template that has user definable properties.

2. Select **Edit | User Assignable Properties**. The **User Assigned Properties** dialog box appears. This dialog box shows those properties that will be presented during template selection or measurement routine execution.



User Assigned Properties Dialog Box

3. Select an item from the **Prompt Style** drop-down list to filter what gets displayed in this dialog. The user assigned properties appear in the list box below. The list box tracks all the properties, what objects they belong to, and their prompts.



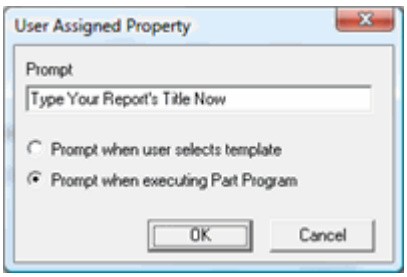
- *To remove a property*, select the property and click the red X. That object's property will no longer be user definable and will use the default value already defined in the template.

  Delete Property Button

- *To reorder a property*, select the property that you want to move and then click the red up or down arrows. This will move the selected property up or down in the list.

  Up and Down Arrow Buttons

- *To change a property's prompt or when the prompt should appear*, double-click on the property in the **Feature** column. PC-DMIS displays the **User Assigned Property** dialog box, allowing you to make the change.



User Assigned Property Dialog Box

If you selected **Prompt when user selects template** from the **User Assigned Property** dialog box, PC-DMIS will only prompt you once for any user assigned values. Thereafter, for that measurement routine, PC-DMIS will automatically use the initial property value until you clear out all template associated data. See the "Clearing Template Associated Data" topic in this chapter.

If you selected **Prompt when report is executed** then PC-DMIS automatically displays the **Define User Assigned Properties** dialog box each time the measurement routine executes.

Clearing Template Associated Data

The **File | Reporting | Clear Template Associated Data** menu item removes the following items used in the current measurement routine with the current selected report template:

- Any user-assigned property values. By clearing these, PC-DMIS will again prompt you for values to any user assigned properties in the current template.
- Table customizations on labels.
- Label placement customizations around **CADReportObject** objects.
- Changes to the rotation or zoom factor of any **CADReportObject** objects.
- Any other object modifications, additions, or page duplications.

About Events and Visual Basic Code

This section assumes that you have at least some background with the Visual Basic programming language. If you need to learn Visual Basic, please consult a book or other external resource on the subject.

The **Events** section on the **Properties** dialog box contains a list of event handler functions that your template or form object supports. An event handler function is called whenever

the event implied by the name of the function occurs for the given object. When that function gets called, any Visual Basic code inside that function gets executed.

Available Event Handler Functions

EventClick
Called when the mouse is clicked on the object.

EventDblClick
Called when the mouse is double-clicked on the object.

EventDragDrop
Called when a "draggable" item is dropped onto the object.

EventDragEnter
Called when a draggable item is initially dragged onto the object.

EventDragOver
Called when a draggable item is dragged over the object.

EventInitialize
Called when the form first enters into run mode before any other handlers are called on the object.

EventMouseDown
Called when a mouse button is clicked down while over the object. If you press the Shift key, parameters passed to the function indicate which button is pressed as well as the pointer's coordinates at the moment you clicked the mouse button.

EventMouseMove
Called when the mouse pointer passes over the object. If you press the Shift key, parameters passed to the function indicate which button is pressed as well as the pointer's coordinates when you move the pointer over the object.

EventMouseUp
Called when you release the mouse button over the object. If you press the Shift key, parameters passed to the function indicate which button is pressed as well as the pointer's coordinates at the moment you release the mouse button.

EventPumpData
This is a widely used handler function in the Form Editor. **EventPumpData** is called whenever BASIC variables that may affect the object change value. Your code can also force **EventPumpData** to be called on individual objects (or on all objects in a report) when you wish an object to update itself. Basically, any code that an object needs to reinitialize itself based on variable values or the state of other objects should occur in **EventPumpData**.

EventTerminate
Called when the report is being closed or when you toggle from Run mode to Edit mode in the Form Editor.

This handler function is only available for the **Section** editing environments.

EventReportData
This is another most widely used handler function in the Report and Label Template editors. It gets called whenever report data gets plugged into the current template.

Its primary function is to let you create your own ActiveX controls that get placed into a label. For example, PC-DMIS's best fit and feature analysis controls use this event to send data to the ActiveX control from the command. To see this, open the label named best_fit_analysis.lbl, click on the ActiveX control inside the label, and then look at the BASIC code inside its event handler. A single line passes data from the command into the control.

With data passed to your own ActiveX control, you can then use automation commands to extract and manipulate the data.

For details on PC-DMIS Basic, see the "PC-DMIS Basic" topic in the PC-DMIS Basic documentation.

For details on PC-DMIS Automation Object Library, see the "PC-DMIS Object Library" topic in the PC-DMIS Automation Objects documentation.

This event gets called once for each command when applying the report template or during measurement routine execution.

Adding Code to Event Handlers

In order to add BASIC language code to any of the event handlers:

1. Click on the function’s entry from the list of event handlers. A Mini Visual BASIC language editor opens, with the opening and closing statements of the subroutine already filled in.
2. Type additional BASIC language statements code into the editor.
3. Click **OK**.
4. Test your code.
    - *If you are using the Form Editor*, press Ctrl + E to enter Run mode to test your form.
    - *If you are using one of the template editors*, apply the template to a report and redraw the report to test your code. To do this, use the **Redraw Report** icon from the **Reporting** toolbar.

Since you don't interact with clickable buttons, lists, fields, or other interactive elements when you use a report, the only event handler function available is the **EventReportData** function.

Event Example 1: Calling Code on an EventClick Event

This event example uses a **Button** object in the Form Editor.

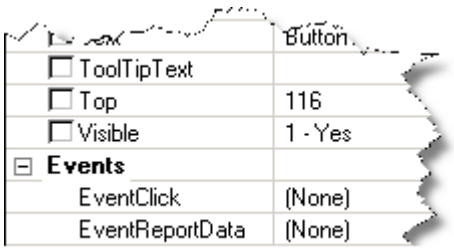
1. Select **File | Reporting | New | Form Report** to open the Form Editor.

2. First, insert a button into your form by clicking on the **Button** icon ( ) on the **Object** toolbar and then dragging out a rectangle for the button onto the form.

3. Make sure that the button is selected (highlighted).

4. Right-click on the button to bring up the dialog box that shows the button's properties.

5. If the list is not expanded, click on the **+** sign next to the **Events** section to expand the list. You should see a list of all of the available event handler functions for the button object.

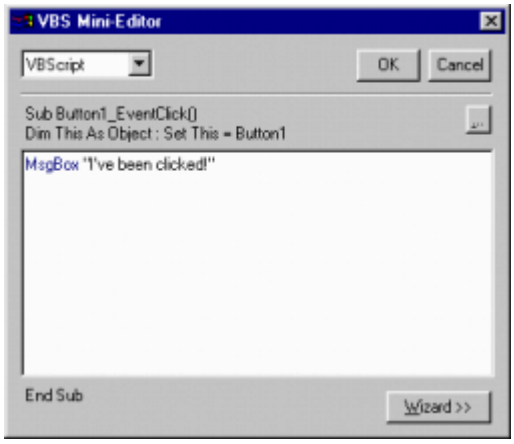


Example of a button object's events.

6. Double-click the **EventClick** function in the list. A Visual BASIC Editor entitled **VBS Mini-Editor** opens.

7. Add the following code to the **EventClick** function inside the VBS Mini Editor:

```
MsgBox  "I've been clicked."
```



8. Click the **OK** button in the upper right-hand corner of the **VBS Mini-Editor**. Close the **Property Sheet**.
9. Save the report by selecting **File | Save**. You are now ready to test the report in run mode.
10. Switch to run mode (press CTRL + E).
11. Click on the button you created. A message box with the text **I've been clicked!** should appear.

This simple example illustrates the basics of scriptable forms and event handlers.

Event Example 2: Modify Object Properties on Triggered Event

This exercise follows the above exercise, you should have completed it first. This example also uses the Form Editor.

Suppose you want to modify the properties of another object (say the text in a text object) when the button has been clicked.

1. In the Form Editor, switch back to edit mode (press Ctrl + E).
2. Create a new text object.
3. Open the text object's properties (select and then right mouse click).

4. Make sure that the text item's **Object Code** property reads "Text1". The **Object Code** property is the name that is used to refer to that object from BASIC code.
5. If not expanded, click on the **+** sign next to the **Events** section to expand the list.
6. Double-click on the **EventInitialize** handler function. The **VBS Mini-Editor** opens.
7. Add the following code to the **EventInitialize** function:
   ```
   Set This  = Text1
   ```
8. Press the Enter key to get to a new line. On the next line, type this code:
   This.Text = "The button has not yet been clicked"
9. Click the **OK** button to close the editor.
10. Once the object Text1 has been set up as described, open the property sheet for the button object added in the prior exercise.
11. Click the **Events** tab.
12. Double-click on the **EventClick** function.
13. Replace the basic code you added in the previous example with the following two lines:
    Line 1: `MsgBox  "I've been clicked, and am about to modify Text1's text"`

    Line 2: `Text1.Text  = "The button was clicked."`
14. Click the **OK** button to close the **VBS Mini-Editor**.
15. Close the **Property Sheet**.
16. Switch to run mode (press Ctrl + E). The code you added to Text1's **EventInitialize** function sets Text1 to initially read "The button has not yet been clicked".
17. Now try to click the button. The "**I've been clicked, and am about to modify Text1's text**" message should appear. As soon as you close the message box, Text1's text should be modified to read "**The button was clicked.**".

This example illustrates how the properties of any object in a form may be accessed from Basic code via the **ObjectCode.property_name** syntax.

Access Object Methods

Many of the objects support various methods in addition to their properties. You can access these methods from BASIC code via the **ObjectCode.method_name** syntax. This means you can see what properties and methods are available for any given object by typing the object's Object Code in the **VBS Mini-Editor** followed by a period. As soon as

the period is typed, a mini wizard pops up showing the available methods and properties for that object.

- A property is a routine that modifies how an object appears or behaves. This is similar to an adjective in a language.
- A method is a routine or function that performs an action. This is similar to a verb in a language.

So if you had a text object named "Text1" and you type "Text1" followed by a period, PC-DMIS shows a list of available methods or properties for a text object.

Variables declared within an event handler function (via the BASIC Dim **var_name** as **var_type** syntax) are in scope only during that event handler function. There will likely be situations where you want to declare variables, functions, or subroutines that are accessible from all BASIC code in a template or form—variables with global scope for a particular report. The template and form editors provide a place to make these declarations.

Declare Global Variables Using the LocalVariables Property

If you wish to declare global variables of any of the standard data types (String, Integer, Double, etc.) and have them show up in the Basic Wizard, you can use the **LocalVariables** property of **TheFrame/TheView or Section**.

To use the **LocalVariables** property:

1. Select then right-click an object to display the **Property Sheet** for **The Frame/The View**.
2. Select the **Settings** tab.
3. Scroll down to the **LocalVariables** property.
4. Double-click the **LocalVariables** property to display the **Local Variables** dialog box.

Local Variables Dialog Box

The **Local Variables** dialog box allows local variables of any of the basic types to be added, removed, named, and initial values to be set. Again, these variables are global to

this template or form and are accessible from any of the BASIC code written for this template or form. They also appear in the **Local Variables** area of the **Script Wizard**.

The name "LocalVariables" is something of a misnomer, since variables declared in the **Local Variables** dialog box actually have a global scope to that particular template or form. It indicates that the variables declared here are "local" to this particular template or form and cannot be accessed on other forms. Nevertheless, they are set as global variables, available to other routines elsewhere in the template or form they are defined from.

Declare/Define Variables, Functions, or Subroutines

To declare and/or define variables, functions, or subroutines that are to be accessible from all BASIC code in a report, use the LocalDecls property of **TheFrame/TheView** found on the PC-DMIS tab of the Property Sheet.

To do this:

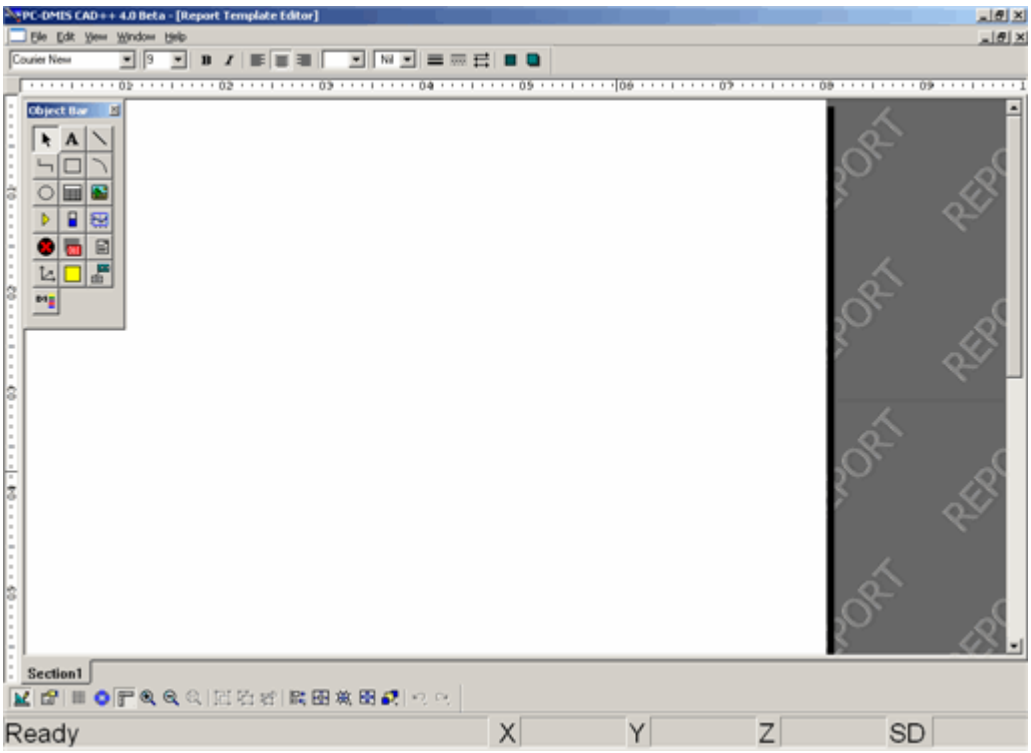
1. Open the Property Sheet for an object.
2. Select **TheFrame/TheView** from the list.
3. Click the **PC-DMIS** tab.
4. Double-click the **LocalDecls** item on the property sheet to display the **VBS Mini-Editor**.

You may add any BASIC code you wish to this window, including variable declarations and functions, or subroutine definitions. Any variables, functions, or subroutines declared here will be global, but will not appear in the **Script Wizard**.

Understanding the Report Template Editor

To access the Report Template Editor, select **File | Reporting | New | Report Template**. To open an existing report template, select **File | Reporting | Edit | Report Template**.

PC-DMIS displays the Report Template Editor in a new window.



Report Template Editor

The Report Template Editor acts as a work area. It enables you to drag, size, and place various objects, and set their properties. You place your objects on top of the white area, called the template or section. If you have worked with legacy (HyperView) reporting in previous versions of PC-DMIS, you will feel at home with this editor since it essentially functions much the same way and contains many of the same user interface elements.

With the template approach to reporting, you cannot place the Report or Label template editors into run mode. They only open in edit mode and cannot be switched. Run mode still functions with the Form Editor.

Run Mode - This mode only works with the Form Editor. In Run Mode you can run (or execute) your form, testing it for how it would look or behave in an actual measurement routine execution environment.

Edit Mode - This is the default mode for all the reporting editors and is the only mode for the Report and Label template editors.

You can switch between run and edit modes by pressing CTRL + E.

The editor contains the following elements:

- The Menu bar
- The Font Bar (toolbar)
- The Object Bar (toolbar)
- The Layout Bar (toolbar)
- Object Property Sheets

- Sections
- Working with the Grid

About Sections

Sample Sections

Sections make up the main editing area in a report template. These tabbed, scrollable areas in the Report Template Editor are where you can insert objects into your current report template. Sections give you greater control over when objects appear in your report.

With the Report Template Editor, you can add additional sections to your template and create powerful multi-section reports. Sections, however, are not the same as pages. Objects inserted into one section will not appear in other sections, but will appear in multiple pages of the same section. This approach lessens the complexity of creating report items like headers and titles that you want to remain static.

For example, you can choose to place a description of the report and author data on the first section of your template, a **TextReportObject** onto the second section, and a **CadReportObject** onto the third section. Then, depending on the length of your report data, each section in your report may spawn up to several pages.

Sections are *only* used in the Report Template Editor. Before PC-DMIS version 4.0, the main editing area for HyperView reports was called "TheFrame/TheView". This name is still used in the Form Editor and the Label Template Editor where sections are not used. For the Report Template Editor, the editor's "Section" is where you place your reporting objects.

To Add a New Section

1. Make sure your Report Template Editor window is maximized.
2. Scroll to the very bottom of your template.
3. Right-click on the **Section1** tab.
4. Select **Add Tab** from the shortcut menu. PC-DMIS inserts a new section, **Section2**, into your template. Your template should now have two sections, like this.

To Delete a Section

1. Make sure your Report Template Editor window is maximized.
2. Scroll to the very bottom of your template.
3. Right-click on the section tab you want to delete.
4. Select **Delete** from the shortcut menu. PC-DMIS deletes the section.

To Modify a Section's Properties

1. Make sure your Report Template Editor window is maximized.
2. Scroll to the very bottom of your template.
3. Right-click on the section itself. The **Properties** dialog box appears.
4. Modify the properties as desired. To rename a section, rename the section's **FormCode** property.

Spanning Command Sets Across Sections to Control Page Layout and Output Collated Pages

Two section (Page) object properties provide a way to span a command set from one report template section to another. This enables you to create different pages with different layouts while using the same command set. You can also use these properties to output the report as collated pages. See the "Section and Page Properties" topic for information and examples on the **Command Set** and **Maximum Number of Pages** properties.

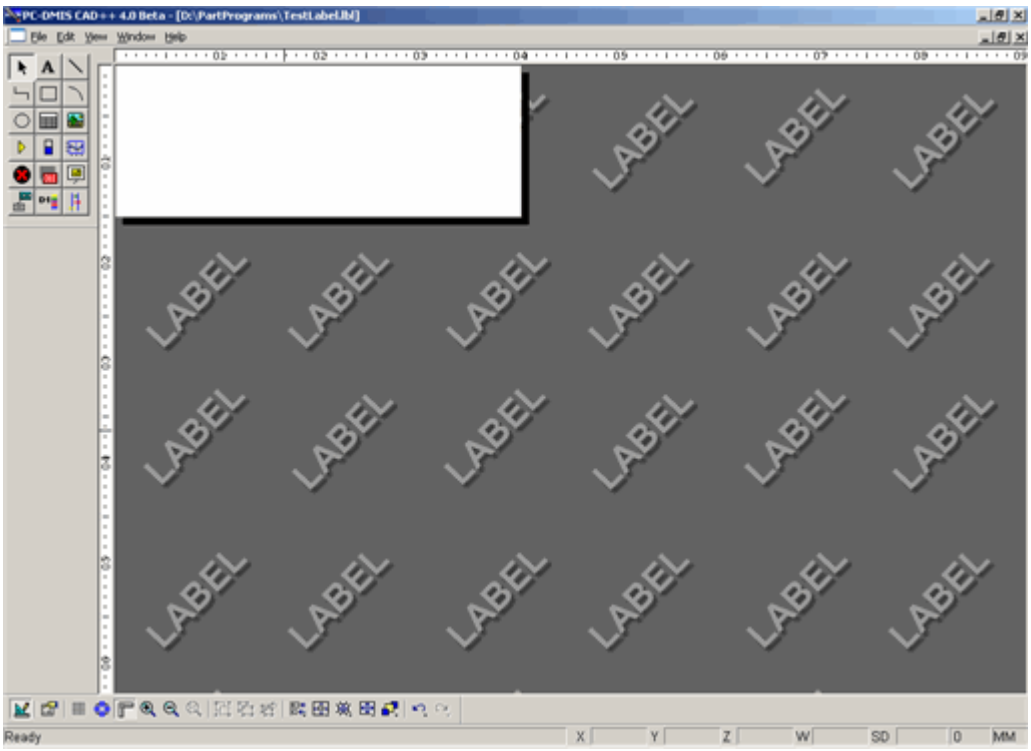
Properties Specific to Sections

See "Section and Page Properties".

About the Label Template Editor

To access the Label Template Editor, select **File | Reporting | New | Label Template**. To open an existing label template, select **File | Reporting | Edit | Label Template**.

PC-DMIS displays the Label Template Editor in a new window.



Label Template Editor

This editor is similar to the Report Template Editor and the Form Editor. With the exception of some differences in its **Object Bar**, the user interface is essentially the same. While you can technically put any object from the Label Template Editor's Object Bar into a label template, you will generally work with the GridControlObject. The label template is the white and sizable box on top of the "LABEL" background.

With the new template approach to reporting, you cannot place the Report or Label template editors into run mode. They only open in edit mode and cannot be switched. Run mode still functions with the Form Editor.

> **Run Mode** - This mode only works with the Form Editor. In run mode, you can run (or execute) your form. This enables you to test how it would look or behave in an actual measurement routine execution environment.
>
> **Edit Mode** - This is the default mode for all the reporting editors and is the only mode for the Report and Label template editors.
>
> To switch between run and edit modes, press CTRL+E.

The editor contains the following elements:

- The Menu bar
- The Font Bar (toolbar)
- The Object Bar (toolbar)
- The Layout Bar (toolbar)

- Object Property Sheets

About the Custom Report Editor

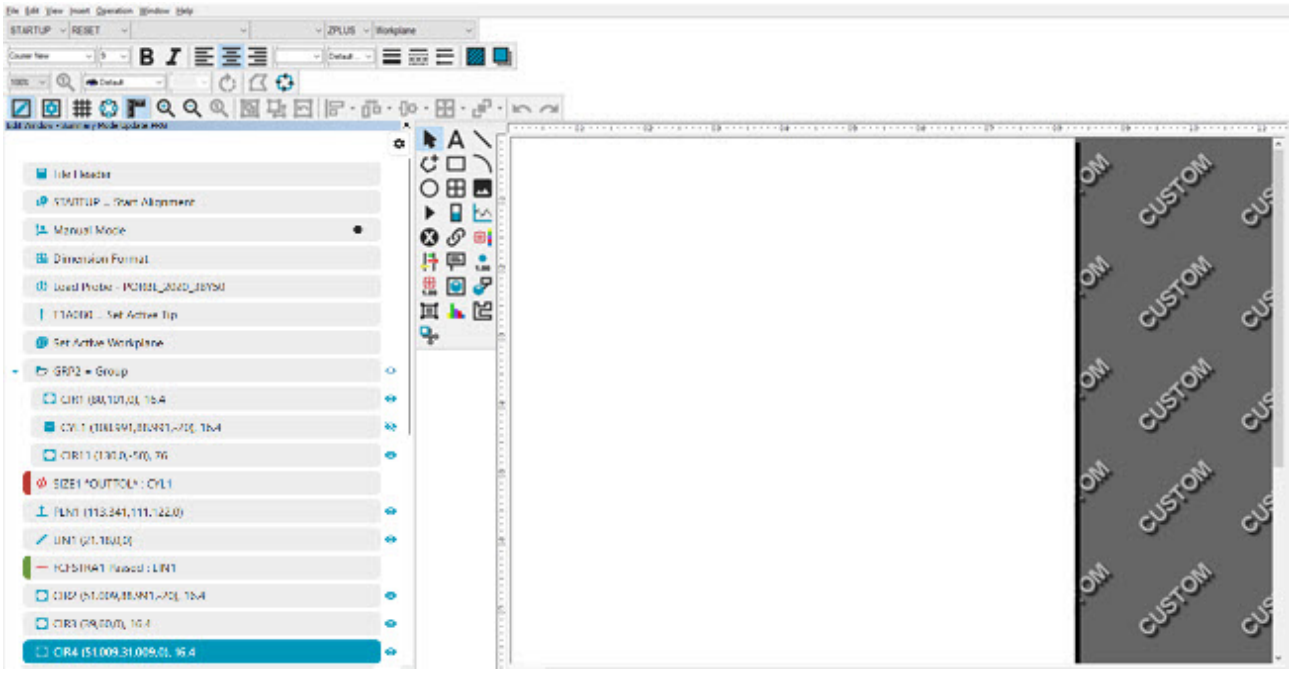
To access the Custom Report Editor, select **File | Reporting | New | Custom Report**. To open an existing custom report for your current measurement routine, select **File | Reporting | Edit | Custom Report**.

You can access a slimmed down version of this editor from the Report window's **Reporting** toolbar. This lets you edit a report without leaving the usual PC-DMIS menu structure.

You can access this editor through either of these options:

- Click **Custom Report selection dialog** ( ) and then click **Blank Report** and then **Open**.
- Click **Edit report** ( ).

PC-DMIS displays the Custom Report Editor with the Edit window placed into Summary Mode next to it.



Custom Report Editor with the Summary Mode to its left

This editor is similar to the Report Template Editor, Label Template Editor, and Form Editor. With the exception of some differences in its **Object Bar**, the user interface is essentially the same.

The custom report is the white and sizable area on top of the "CUSTOM" background. Note that when you use this editor, you do not create a template, but create the actual report that appears in the Report window. When you create a new custom report, this editor opens side by side with the Edit window set in Summary Mode. This allows you to drag the desired objects from Summary Mode onto your Custom Report. See "Creating Custom Reports".

With the Custom Report Editor, you cannot place the Report or Label template editors into Run mode as you did with the HyperView editor. The Custom Report Editor only opens in Edit mode and cannot be switched to Run mode. Run mode functions only with the HyperView editor or the Form Editor.

The editor contains the following elements:

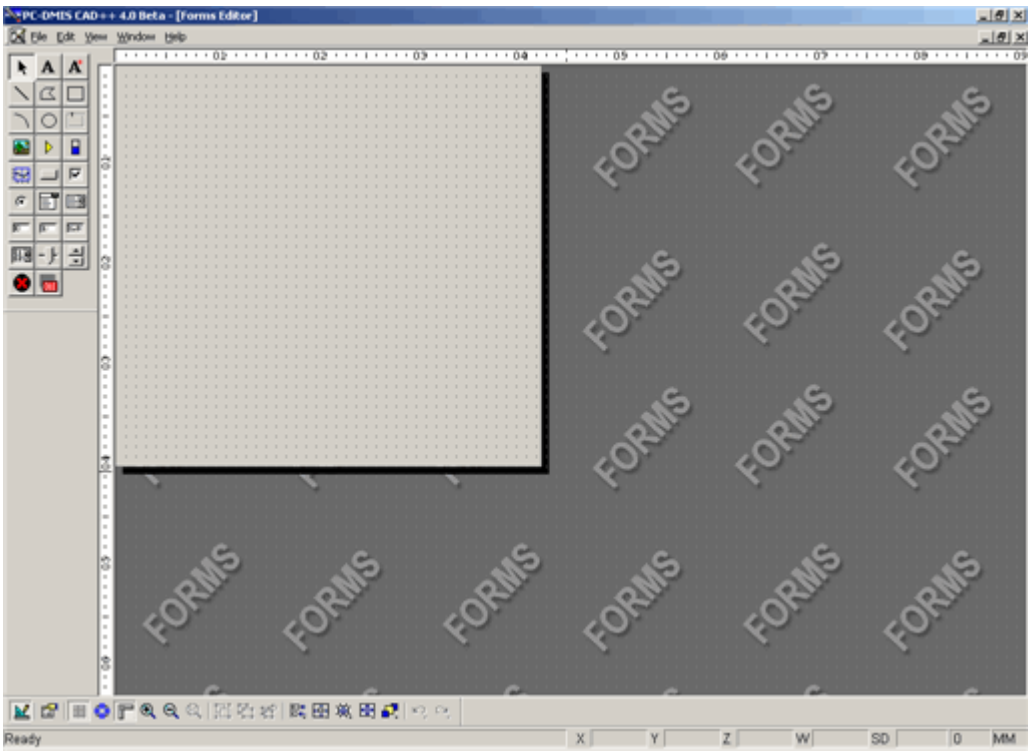
- The Menu bar
- The Font Bar (toolbar)
- The Object Bar (toolbar)
- The Layout Bar (toolbar)
- Object Property Sheets

Understanding the Form Editor

To create a new form in the Form Editor, select **File | Reporting | New | Form Report**.

To open an existing form in the Form Editor, select **File | Reporting | Edit | Form Report**.

PC-DMIS displays the Form Editor in a new window.



Form Editor

The Form Editor acts as a work area. It enables you to drag, size, and place various interactive form objects, such as buttons, list boxes, edit boxes, and so forth, and set their properties.

Objects are placed on the gray and sizable area, called a form. If you have worked with HyperView reporting in previous versions of PC-DMIS, you will feel at home with this editor since it essentially functions much the same way and contains many of the same user interface elements.

With the new template approach to reporting, only the Form Editor can use the run-mode capability. The Report and Label template editors do not use it.

> **Run Mode** - This mode only works with the Form Editor. In run mode, you can run (or execute) your form. This enables you to test how it would look or behave in an actual measurement routine execution environment.
>
> **Edit Mode** - This is the default mode for all the reporting editors. It is the only mode for the Report and Label template editors.
>
> To switch between run and edit modes, press CTRL+E.

The editor contains the following elements:

- The Menu bar
- The Font Bar (toolbar)
- The Object Bar (toolbar)
- The Layout Bar (toolbar)

- Object Property Sheets
- Object Sheet

Creating Templates

While PC-DMIS comes with some pre-designed templates that fit most users' needs, you can delve into the powerful template editors to create your own report and label templates. You can also use the Form Editor to create a more interactive approach to execution and reporting.

There are several report templates (.rtp) and label templates (.lbl) that ship with PC-DMIS.

File location: C:\Users\Public\Public Documents\Hexagon\PC-DMIS\2026.2\Reporting

For more information, see "Using Standard Reports".

The following topics discuss how to use the report template and label template editors to create your own templates.

Are you new to template reporting? Follow the "Creating a Report Template" and "Creating Label Templates" tutorials.

In addition to creating your own templates, you can download custom templates from: Hexagon Support. If you need further support for custom templates, contact your regional office or headquarters.

About Reports and Report Templates

A report template is not a report, but a description for a report. The template describes what data PC-DMIS should use to create a report, where it will go, and what it will look like. You can use report templates for more than one measurement routine to standardize the look and feel of several reports.

You create templates inside of the Report Template Editor. Report template files have an .rtp filename extension and are created inside the PC-DMIS report template editor.

You can make report template files as simple or as complex as you like. A simple report template might contain a single **TextReportObject**, while a complex report template might contain several different objects, bitmap images, shapes, or even items that use the reporting expression language and scripting to detail exactly what appears from the report data.

Do not confuse the report template's filename extension, **.rtp** with the older HyperView report filename extension, **.rpt**. These are completely different file formats.

Report Template Selection Precedence

PC-DMIS selects the report template based on this order of precedence:

1. The default report template assigned to the current measurement routine. You can define a default report template for each measurement routine by clicking the **Set this report as default template** button in the **Reporting** toolbar. For details on this button or the **Reporting** toolbar, see the "Reporting Toolbar" topic.
2. The report template specified as the default report template in the Settings Editor, if one exists. For details, see the "DefaultReportTemplate" topic in the Settings Editor documentation.
3. The TEXTONLY.RTP file.
4. The default.rtp file.

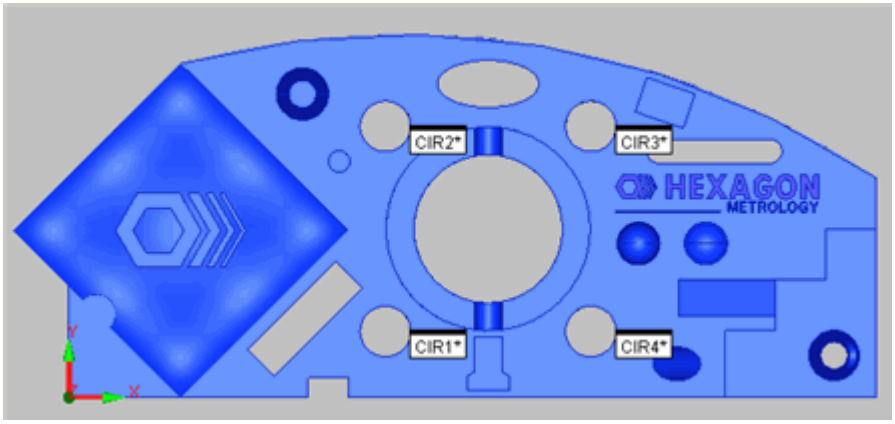
For information on the TEXTONLY.rtp and default.rtp template files, see the "Using Standard Reports" and "Viewing a Legacy Text Report" topics.

Tutorial - Creating a Report Template

This topic walks you through a very basic tutorial that creates a simple report template with a few objects and some labels. This should give you a basic overview of how things work together so that you can create and use your own report templates.

In order to give you a good foundation on how to use the template editors, this tutorial shows how to create a report template from scratch. However, in practical use, you will most likely find it much easier to customize one of the standard templates to suit your needs.

Before you begin this tutorial, create a simple measurement routine that can measure four circles on a simple part. This tutorial uses the Hexagon test block (Hexblock_Wireframe_Surface.igs).



Example of four circles to be measured.

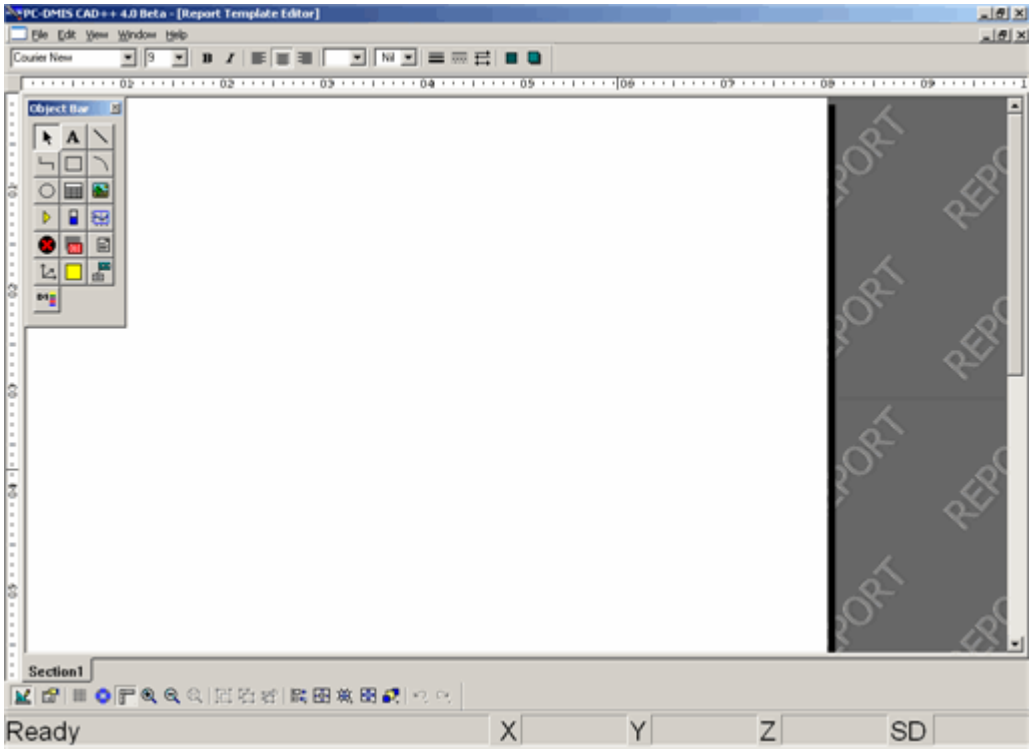
Step 1: Create a Blank Report Template

1. Select **File | Reporting | New | Report Template** to access the Report Template Editor. A blank report template automatically appears.

2. To hide any unused toolbars, right-click on the toolbar area and remove them.

3. To hide any unused PC-DMIS windows, select the open window from the **View** menu.

4. Click the maximize button on the editor's window to maximize the template editor. You should see the words "REPORT" on the background of the editor, and your editor should have a "Section1" tab at the bottom. Your Report Template Editor should now look something like this:



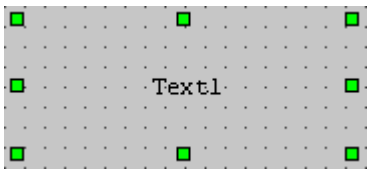
Report Template Editor

When working with one of the template editors, you may find it helpful to hide your usual PC-DMIS toolbars and windows, thereby freeing up some screen space. If you work frequently with templates, you may want to create a stored screen layout for your template. For information on layouts, see the "Window Layouts Toolbar" topic in the "Using Toolbars" chapter.

In addition, you may find it useful to create your own toolbar with the **File | Reporting** commands on it. For information on how to create custom toolbars, see the "Customizing Toolbars" topic in the "Customizing the User Interface" chapter.

Step 2: Insert and Format a Text Object for a Section Title

1. From the **Object Bar**, click on a **Text** object.
2. Insert it into the report by dragging a rectangle onto the current section. When you release the mouse, the object is selected, as shown by small green squares, called handles, at each corner of the object.



A sample text object with handles.

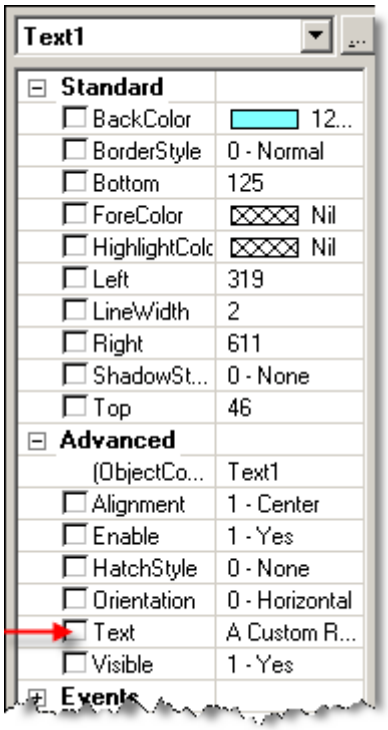
3. Select the **Text** object you inserted, and drag the green handles so that it has a height of 1 inch and a length of 6 inches. Use the **Ruler Bars** on the top and left border of the editor as needed. Select **View | Ruler Bars** if the rulers aren't available.
4. Right-click on the **Text** object.
5. Select the **BackColor** property and change it to a light blue color (0.255.255).
6. Click the **ForeColor** property and change it to a dark blue color (0.0.128).
7. Select the **BorderStyle** property and change it to **Normal**.
8. Click the **LineWidth** property and change the value to 5.
9. Click the **Text** property and change it to "A Custom Report".
10. Click the **Font** property. The **Font** dialog box appears.
11. Change the **Size** to 20, the **Font Style** to Bold, and the **Font** to Arial.
12. Click **OK**.

You have formatted your text object. It should look similar to this:

Step 3: Make Properties User Assignable

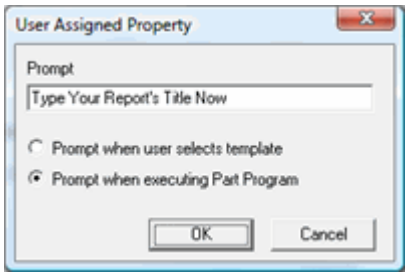
1. Select the **Text** object you created in the previous step.

2. Right-click on the object. This causes the **Properties** dialog box for that object to appear on the right side of the editor. On the left side of the dialog box you will see check boxes next to most properties. These check boxes determine what properties you can make user definable.



A sample property sheet for a text object with user-defined check boxes on the left.

3. Select the check box to the left of the **Text** property. A **User Assigned Property** dialog box opens, asking you to determine the message that will prompt the user for the property value and when the user should be prompted.



User Assigned Property Dialog Box

4. In the **Prompt** box, type "Type Your Report's Title Now".

5. Select the **Prompt when executing Measurement Routine** option.

6. Click **OK**. The **User Assigned Property** dialog box closes.

7. Select the check box to the left of the **BackColor** property. In the resulting dialog box, type "Choose Your Background Color Now" for the prompt, and once more, choose the **Prompt when executing Measurement Routine** option.

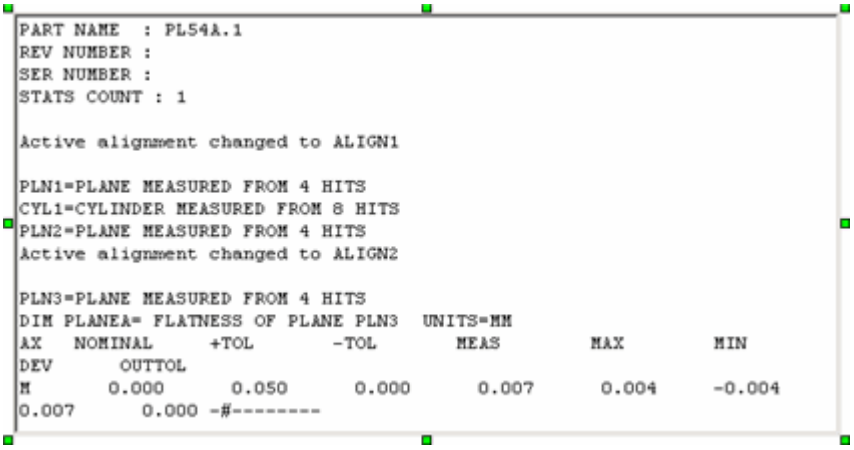
8. Click **OK**. The **User Assigned Property** dialog box closes.

In this step, you selected two properties and made them "user assignable". This means whoever executes your measurement routine will be able to set these properties.

Step 4: Add a TextReportObject

1. From the editor's **Object Bar**, click on the **TextReportObject** *icon* . Your mouse pointer changes from an arrow pointer to a cross.

2. Add the **TextReportObject** on the template by dragging a box on your template's section. PC-DMIS automatically adds some default filler report text. When you apply this template to your report, PC-DMIS uses your actual report data. This filler text simply helps you understand what your design will look like. Your object should look something like this:



A sample TextReportObject.

3. Size the object so that it's close to the width of the **Text** object you added earlier. To size the object, click and drag one of the green boxes (or "handles") that surround the object.

4. Select the **Text** object you added earlier. Hold down the Shift key and select the **TextReportObject**. This selects both objects.

5. With both selected, use the **Layout Bar**, and click the appropriate **Make Same Size** and **Align Center** icons to make the objects the same width and to align them so that they are centered in between the left and right sides of the editor.

Your template should now have a **TextReportObject** on the first section.

Step 5: Add a New Section to the Template

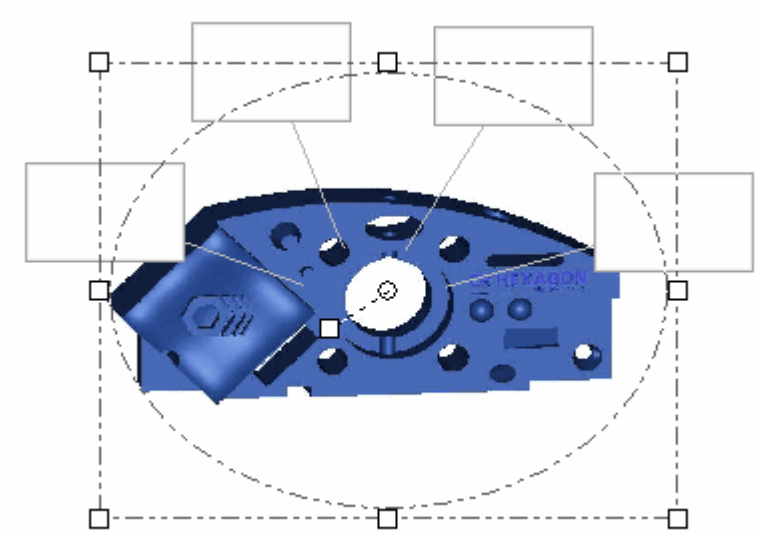
1. Maximize your Report Template Editor window.

2. Scroll to the very bottom of your template.
3. Right-click on the **Section1** tab.
4. Select **Add Tab** from the shortcut menu. PC-DMIS inserts a new section, **Section2**, into your template.

Your template should now have two sections, like this:

Step 6: Add a CADReportObject

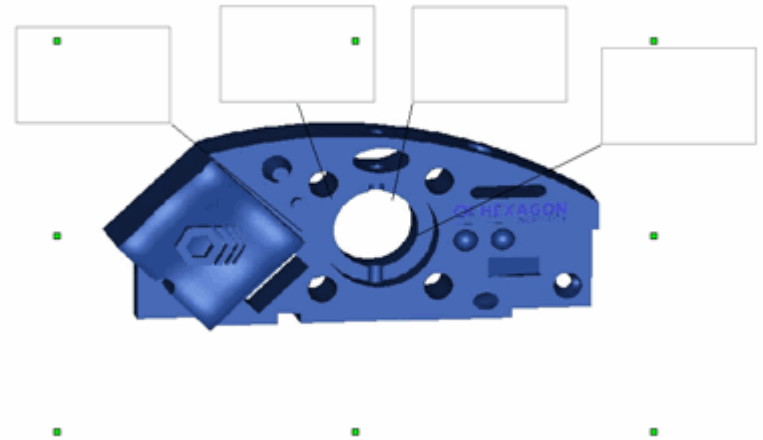
1. Click on the **Section2** tab to make that the active section.
2. From the editor's **Object Bar**, click the **CADReportObject** *icon* . Your mouse pointer changes from an arrow to a cross.
3. Drag a box on your template's section to add the **CADReportObject** on the template. Size the box so that it measures about six inches wide and four inches tall. Click and drag one of the green boxes surrounding the object to resize it.
4. When you finish drawing the box, PC-DMIS automatically displays the **Label Layout Wizard**. This wizard shows a fake part surrounded by some fake labels. These dummy items are simply design aids while working in the template editor. You can use this wizard to set up labels around your part. For in-depth information, see the "The Label Layout Wizard" topic. When you apply this template to your report, PC-DMIS uses your actual CAD drawing and label information.
5. Change the **Label Count** box number of labels to 4.
6. Change the **Layout Style** to **Elliptical Packed**.
7. Click on the small, square, white handle in the middle of the CAD drawing, and drag the square clockwise or counterclockwise to rotate the labels along the elliptical path.
8. Rotate the labels until all four are above the CAD drawing and the **Layout Preview** area of the **Label Layout Wizard** looks like this:



Layout Preview area showing four labels elliptically packed above the CAD drawing.

9. Click **OK**. PC-DMIS inserts the object into **Section2**.

Your **Section2** layout should now contain a CADReportObject looking something like this:



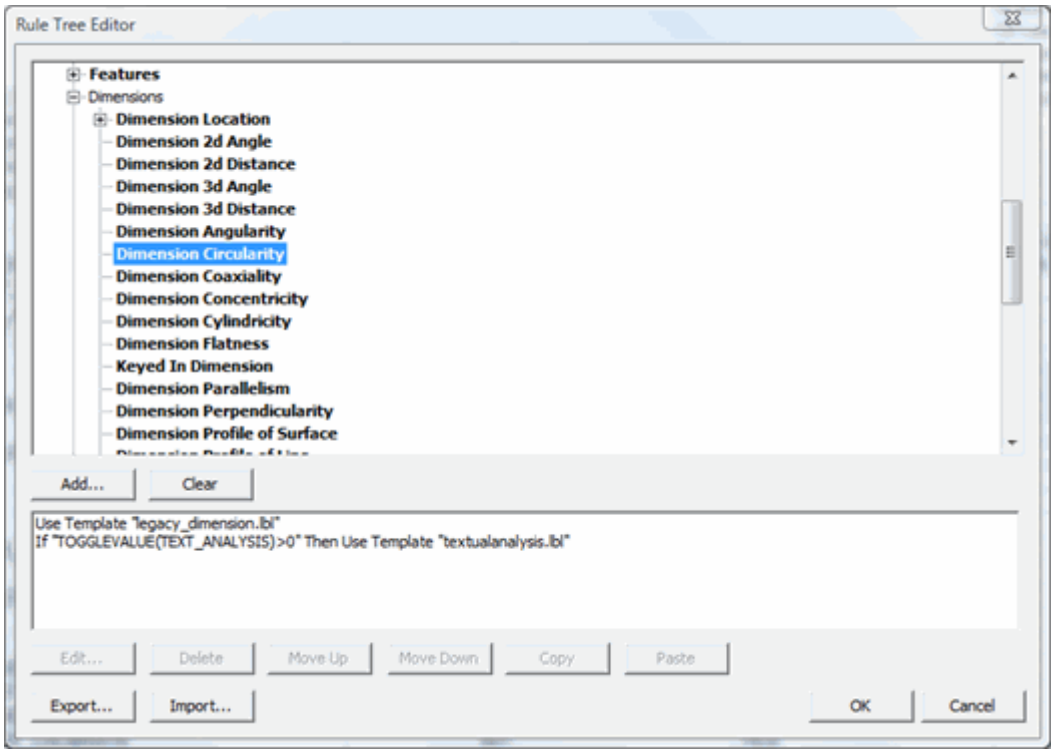
Example of a CAD report object showing the four dummy labels above the dummy part.

Step 7: Define What Measurement Information Should Appear

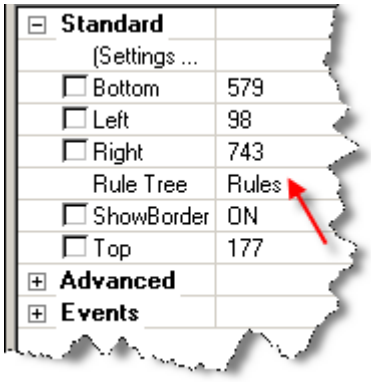
1. Click on the **Section1** tab and right-click on the **TextReportObject** you inserted earlier.
2. From the **Properties** dialog box, change these properties:
    - ShowAlignments - OFF
    - ShowComments - OFF
    - ShowDimensions - None
    - ShowFeatures - ON
    - ShowHeaderFooter - OFF

- ShowMoves - OFF
- ShowScreenCaptures - OFF

3. Click on the **Section2** tab.
4. Right-click on the **CADReportObject** you added into **Section2**. The right part of the screen displays a docked **Properties Sheet** dialog box. This dialog box contains various properties specific to the selected object.
5. Click on **Rules** in the **Rules Tree** property. The **Rule Tree Editor** appears:



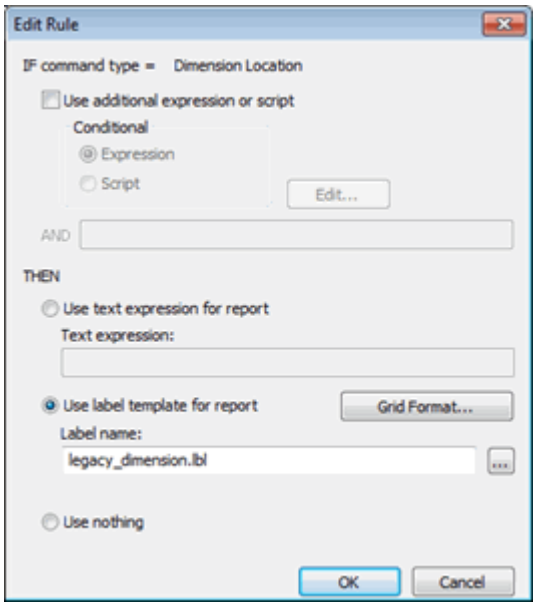
Rule Tree Editor Dialog Box



Rules Tree Property Option

6. Expand the **Features** heading. A list of features appears.
7. Expand the **Circles** heading. A list of various circle features appears.

8. Click the **Measured Circle** item, and then click the **Add** button. This tells PC-DMIS you are adding a rule that you want the template to follow. The **Edit Rule** dialog box appears. This dialog box allows you to make decisions for your report template. In this case, you are telling your report template to do something when it encounters measured circles in the measurement routine's report data.



Edit Rule Dialog Box

9. Select the **Use Label Template for Report** option. The **Label Name** box becomes available for edit.

10. Click the **...** button to open the **Open** dialog box that allows you to select a label template file.

11. Navigate to where you installed PC-DMIS, and open the Reporting sub-directory. Select the *summary.lbl* label, and click **Open**. In the **Edit Rule** dialog box, PC-DMIS displays the name of the template you selected. See "About Labels and Label Templates" for information and a tutorial on creating labels.

12. Click **OK** to close the **Edit Rule** dialog box and apply the rule. You will notice that the **Measured Circle** item in the list has a bold font to indicate that a rule exists for that feature type.

13. Click **OK** to close the **Rule Tree Editor** dialog box.

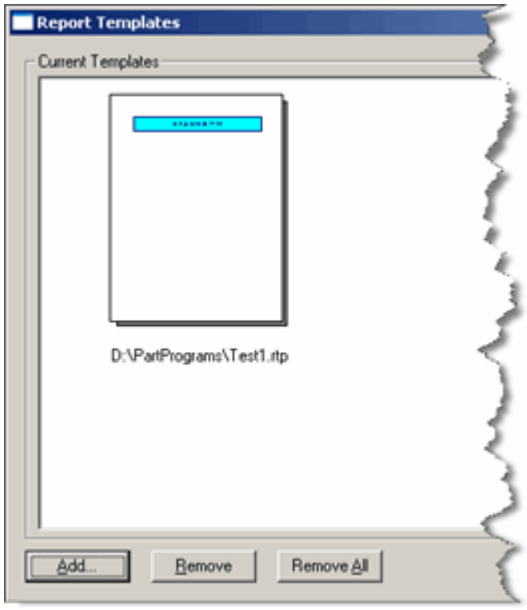
You have created a rule that tells PC-DMIS to use the *summary.lbl* label template to display summary information about the measured circle feature type.

Step 8: Save and Test the Template

1. Inside the Report Template Editor, select **File | Save**. In the **Save As** dialog box, save the template as **test1.rtp**.

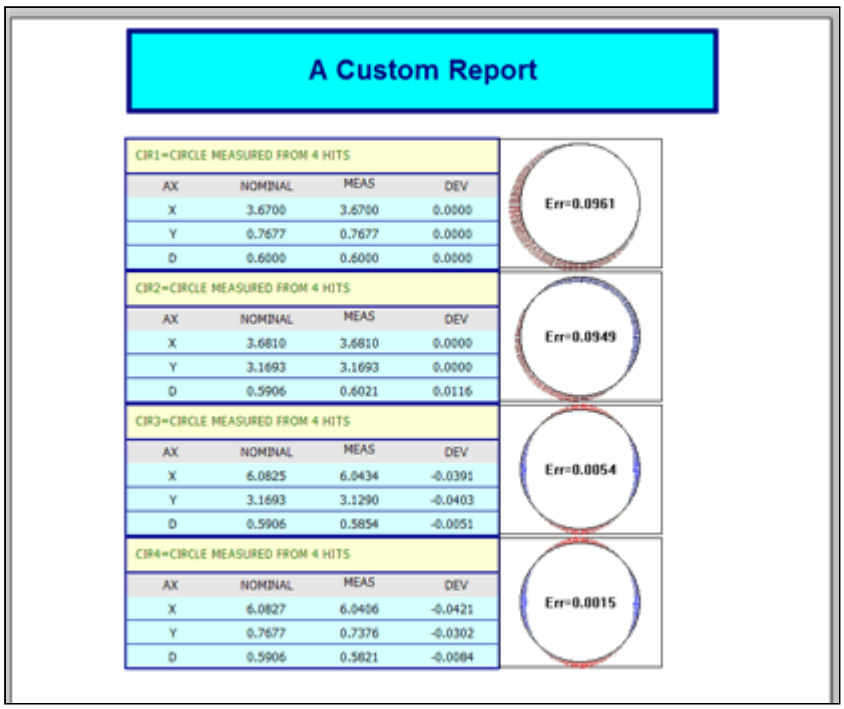
2. Select **File | Close** to close the Report Template Editor.

3. Select **View | Report Window**. The Report window opens, showing the default report template.
4. From the **Reporting** toolbar on the Report window, click the **Template Selection Dialog** *icon* . The **Report Templates** dialog box opens.
5. Click the **Add** button to add your report to the **Report Templates** dialog box.
6. Navigate to and select test1.rtp, then click **Open**. PC-DMIS adds a thumbnail view of your report into the **Report Templates** dialog box.



Report Templates dialog box showing Test1.rtp

7. Select your template's thumbnail icon, and click **Open**. PC-DMIS opens the Report window using your newly created template. It should look something like this:



Report Window Showing Report Data Using the Test1.rtp Report Template

8. Finally, execute your measurement routine. The first time you execute the measurement routine using this report template, PC-DMIS displays a **Define User Assigned Properties** dialog box, asking you to give the report a new title and to set the background color.

9. Set these properties as desired, and click **OK**. The dialog box closes and PC-DMIS runs your measurement routine.

10. When execution finishes, PC-DMIS shows the report data with the new template.

Congratulations! You have finished the Custom Report Template tutorial.

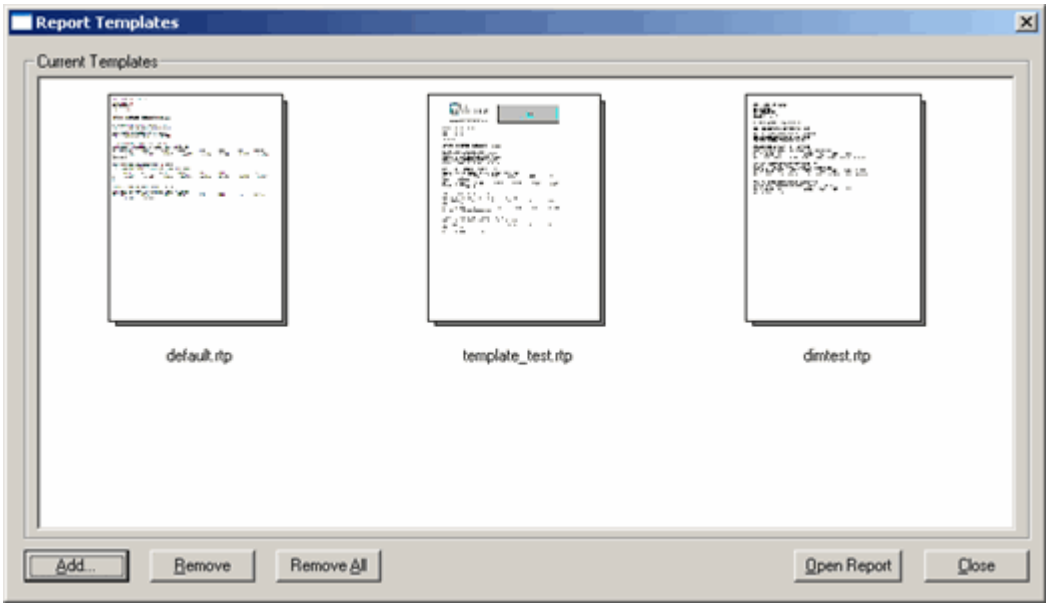
Applying or Removing a Report Template

To apply a report template to your measurement results, or to remove a report template, you must first access the **Report Templates** dialog box:

To Access the Report Templates dialog box:

1. Select **View | Report Window** to access the Report window.

2. From the **Report** toolbar on the Report window, click the **Template Selection** icon . The **Report Templates** dialog box appears showing available report templates as .rtp files:



Report Templates Dialog Box

You can use this dialog box to manage your report templates.

To Add a Report Template:

1. From the **Report Templates** dialog box, click the **Add** button. A standard **Open** dialog box appears.
2. Navigate to the report template file, select it, and click **Open**.
3. PC-DMIS adds the template, and a thumbnail picture of the template will appear in the **Report Templates** dialog box.
4. Your dialog box might contain few or many templates. To resize the dialog box to better suit your needs, drag the dialog box's edge to a new location.

To Remove a Report Template:

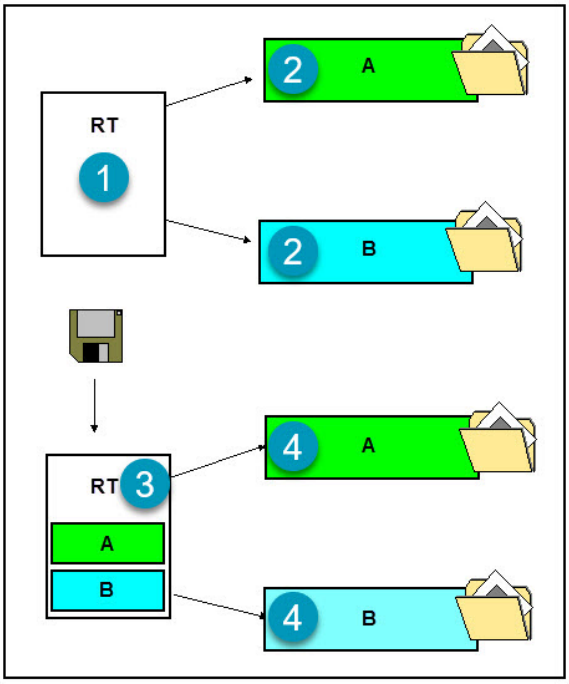
1. From the **Report Templates** dialog box, select a template.
2. Click the **Remove** button (to remove all templates, click **Remove All**).
3. PC-DMIS removes the report template from the **Report Templates** dialog box.

Removing report templates doesn't delete them. It merely removes them from this dialog box. You can always add them later using the **Add** button.

The templates listed in the **Report Templates** dialog box are different for each user account on the Windows operating system.

Sharing Report Templates

You can easily share a report template with other users. When you save a report template, PC-DMIS automatically saves a copy of any associated label templates into the report template itself. This way, if you want to share a report template, you don't have to worry about sending all the associated label templates along with it. Even so, the report template will always check for the actual label template file in the directory first. If it finds the actual label template file, it will use that. If the actual label template file doesn't exist as expected, then the report template will use the copied version of the label template file that is stored with the report template itself.



1 - In this example, the report template calls two label templates, label A and label B.

2 - The label template files (files with a .lbl filename extension) are stored in the Reporting directory (C:\Users\Public\Documents\Hexagon\PC-DMIS\\Reporting).

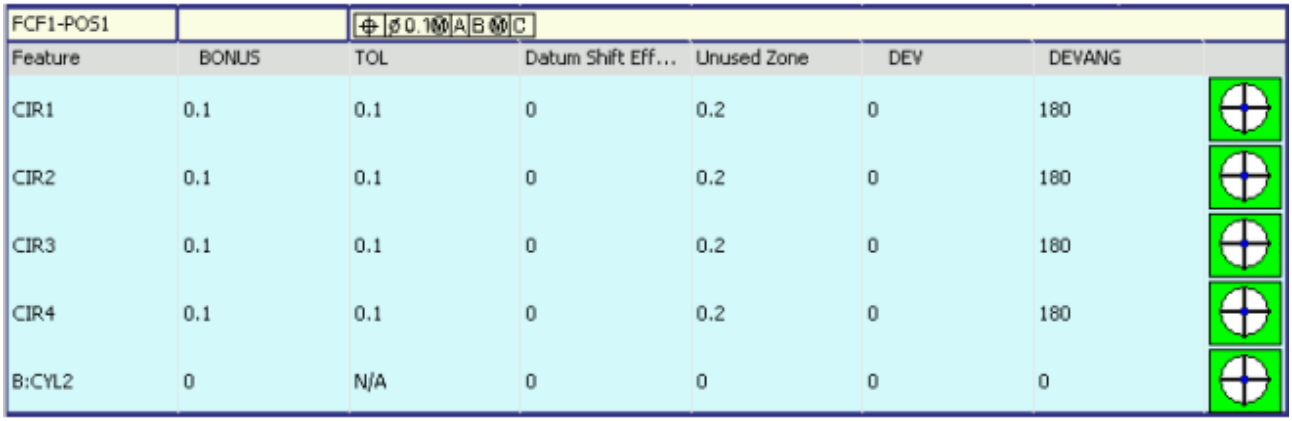
3 - When you save the report template, copies of the label templates are stored within the report template.

4 - When used, the Report template first looks for any label template files and uses those if found. If none is found, it then uses the copied label templates.

About Labels and Label Templates

A label template essentially acts like a mini-report template that you associate with a specific command (or commands) in the report. This gives you a lot of freedom with data

that you can include in your report. For example you can display labels for dimensions, labels for measured features, for Auto features, and so forth.



FCF1-POS1		⌖ ⌀0.1Ⓜ A B Ⓜ C				
Feature	BONUS	TOL	Datum Shift Eff...	Unused Zone	DEV	DEVANG
CIR1	0.1	0.1	0	0.2	0	180
CIR2	0.1	0.1	0	0.2	0	180
CIR3	0.1	0.1	0	0.2	0	180
CIR4	0.1	0.1	0	0.2	0	180
B:CYL2	0	N/A	0	0	0	0

Example of a label showing a position table with a Feature Control Frame (FCF).

PC-DMIS ships with several standard labels that you can associate with objects in your Report templates. However, as with Report templates, you can create your own label templates as well. Label templates can contain any object from the Label Template Editor's **Object Bar**, but they usually contain the **GridControlObject** or the **Graph** object.

You can use the Label Template Editor to create label templates.

Tutorial - Creating Label Templates

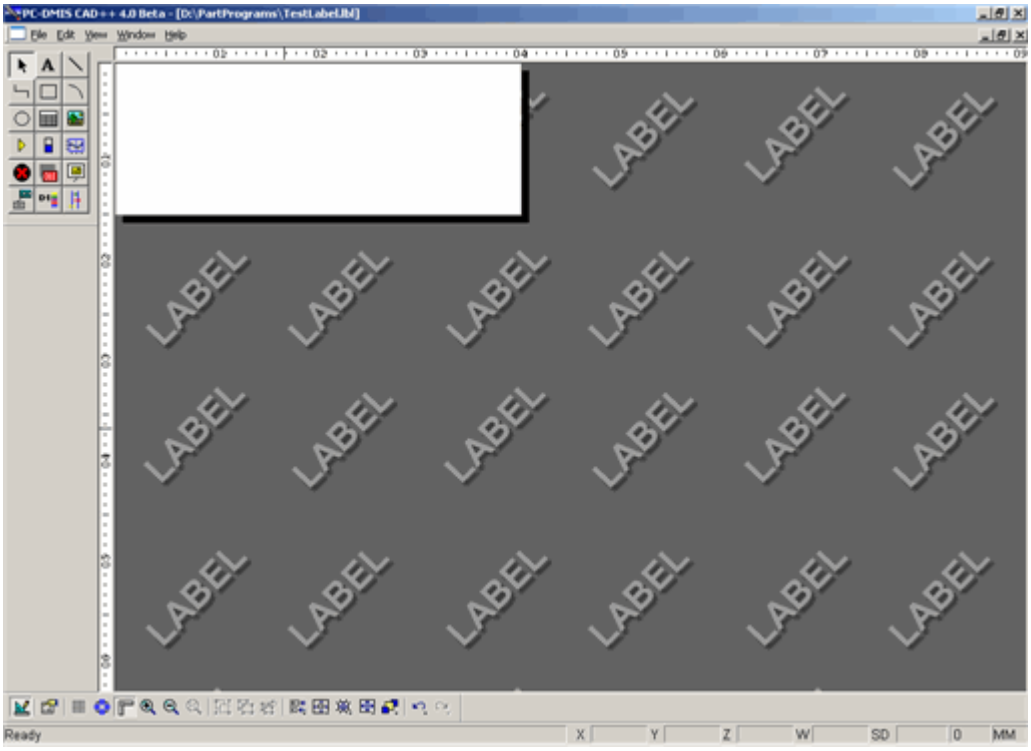
This topic walks you through a basic tutorial to create a simple label template with a few objects and a **GridControlObject**. This provides you with a basic overview of how label templates work and how to use them to display custom information in your reports.

> This tutorial builds on skills you learned in the "Creating a Custom Report Template" tutorial; be sure to complete that section first.

Step 1: Create a Blank Label Template

1. Select **File | Reporting | New | Label Template** to access the Label Template Editor. A blank label template automatically appears.
2. To hide any unused toolbars, right-click on the toolbar area and remove them.
3. To hide any unused PC-DMIS windows, select the open window from the **View** menu.
4. To maximize the template editor, click the Edit window's *maximize button* . You should see the words "LABEL" on the background of the editor.
5. Size **The Frame/The View** in the label template editing area to four inches wide and one and a half inches high. To do this, click and drag the bottom right hand corner of the label template with your mouse. Use the rulers as a guide.

You have created a blank label template. When finished with this step, it should look something like this:



Label Template Editor

When working with one of the template editors, you may find it helpful to hide your usual PC-DMIS toolbars and windows, thereby freeing up some screen space. If you work frequently with templates, you may want to create a stored screen layout for your template. For information on layouts, see the "Window Layouts Toolbar" topic in the "Using Toolbars" chapter.

Step 2: Add a CommandTextObject and Static Information into the Template

1. Click the **CommandTextObject** *icon* . The pointer changes to a cross-hair.
2. With your mouse pointer, drag a box so that it stretches about three inches wide by one half inches high. PC-DMIS inserts a CommandTextObject into your label template. Right-click on it to access the **Properties** dialog box.
3. Click the **Colors** property. If PC-DMIS asks if you want to define a color set independent from the default application colors, click **Yes**.
4. The **Color Editor** opens. PC-DMIS uses this editor to define Edit window colors. However, in this case, it only affects the current CommandTextObject.
5. Under **Background Color**, click **Edit**. A standard **Color** dialog box opens.
6. Give the object's background color a dark blue color. To do this, change the values in the **Red**, **Green**, **Blue** boxes to 0, 0, 128 respectively. Click **OK**.

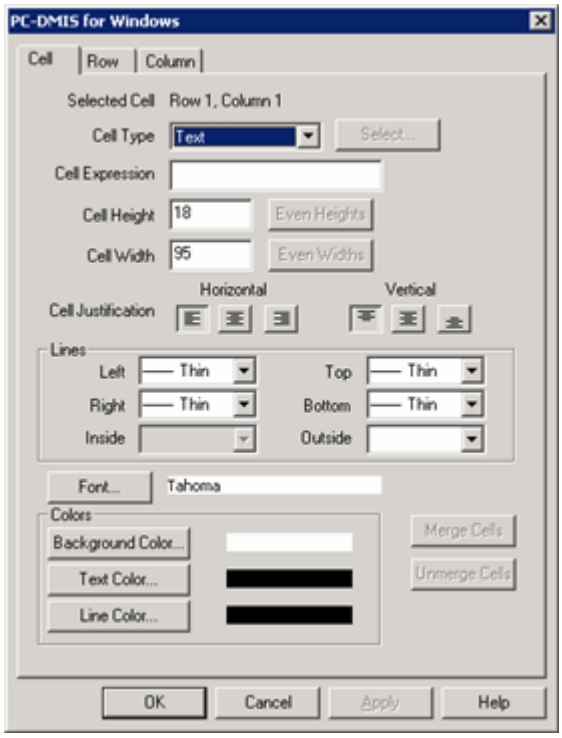
7. In the **Unmarked** box, click **Edit**. A standard **Color** dialog box opens.
8. Select white, and then click **OK**. If PC-DMIS asks if you want to change the item's children, click **No**.
9. Use a bitmap image of a circle (or use the Ellipse object to draw a circle) and place it in the top right of the canvas.

You have added the **CommandTextObject** and a static **Bitmap** or **Ellipse** object for a circle shape into the label template. At the end of this step, your label template should looks something like this:

Label Template showing the CommandTextObject and a static Bitmap object

Step 3: Insert and Format a GridControlObject

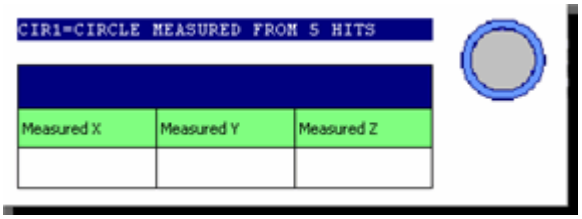
1. Click the **GridControlObject** *icon* . The pointer changes to a cross-hair.
2. With the pointer, drag a box for this object under the previously inserted CommandTextObject, so that it has the same width.
3. Size the height so that it nearly fills the rest of the canvas. When inserted, the grid shows several rows and columns.
4. Access the object's properties, and then change the **Columns** and **Rows** properties to 3 each.
5. Select the object and select a cell. To do this, double-click on the first cell in the top row. It will highlight the cell in a blue background to show that you have selected it.
6. Select the entire top row. To do this, with the first cell selected, press the Shift key, and then click on the last cell in that row. PC-DMIS highlights the entire row.
7. Right-click the GridControlObject. The object's dialog box appears. This dialog box lets you control the formatting of the selected cells as well as insert text and expressions.



The GridControlObject's dialog box

8. Click the **Merge** button to merge the selected cells.
9. Set the background color for the merged cell. Click the **Background color** button to open the **Color** dialog box. Choose a dark blue color and click **OK**.
10. Set the text color for the merged cell. Click the **Text color** button, and select white in the same way.
11. To create headings, select the first cell in the second row, and right-click to bring up the dialog box. In the **Cell Expression** box, type "Measured X". Close the dialog box, and repeat the process on the second cell, typing "Measured Y". Finally, repeat it again for the last cell, typing "Measured Z".
12. Select the entire second row. Right-click and use the dialog box to select a light green background color.
13. Under **Cell Justification**, under **Vertical**, click the *middle button* to vertically center the text in their cells.
14. Click **OK** to close the dialog box and then deselect the object.

You have inserted a GridControlObject and learned how to change the number of rows and columns. You learned how to add text into a cell and how to format the grid by using this object's special dialog box. When finished with this step, your label template should look something like this:

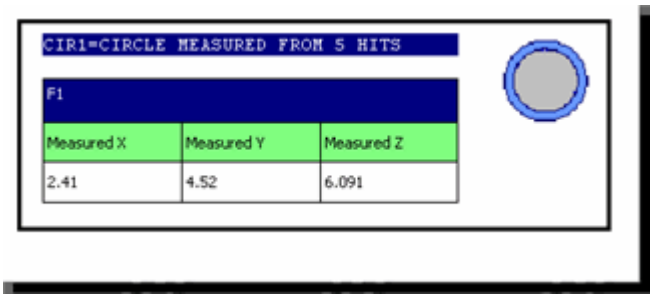


Label showing the inserted and formatted GridControlObject

Step 4: Add Expressions Into the GridControlObject

1. Select the GridControlObject's first row.
2. Once it's selected, type "=ID" directly into the cell. This is an expression that tells PC-DMIS you want to display the feature's ID in the cell.
3. Select the first cell in the third row and type "=MEAS_X"
4. Select the second cell and type "=MEAS_Y".
5. Select the third cell and type "=MEAS_Z". These expressions tell PC-DMIS you want to display the feature's X, Y, and Z values. When you deselect the object, PC-DMIS displays the expression values from the filler text used by the object. See "About Report Expressions" for information on expressions.
6. With the **Border** object, draw a border object around the label. You may need to resize the label to close to four and a half inches wide by two inches high.
7. Right-click the border, and give it a line width of 2.
8. Adjust the location of the contents so they are within the border.

You have added some report expressions into your label template and then drew a border around the template prior to testing it. When you finish this step your template should look something like this:



Label showing the results of the expressions

Step 5: Save and Test the Label Template

1. Select **File | Save** to save the label template. In the **Save As** dialog box, name the template "TestLabel.lbl".
2. Select **File | Close** to close down this template editor.
3. Select **File | Reporting | Edit | Report Template** and then select the **Test1.rtp** template file you created from the previous tutorial.

4. Select the TextReportObject you inserted into the first section of the report template and then access its properties.

5. Use the **Rules Tree Editor** and the **Edit Rule** dialog boxes to create a rule that will display TestLabel.lbl in that TextReportObject object for all measured circles. If you can't remember how to create rules, follow the procedure in the "Defining a Rule topic".

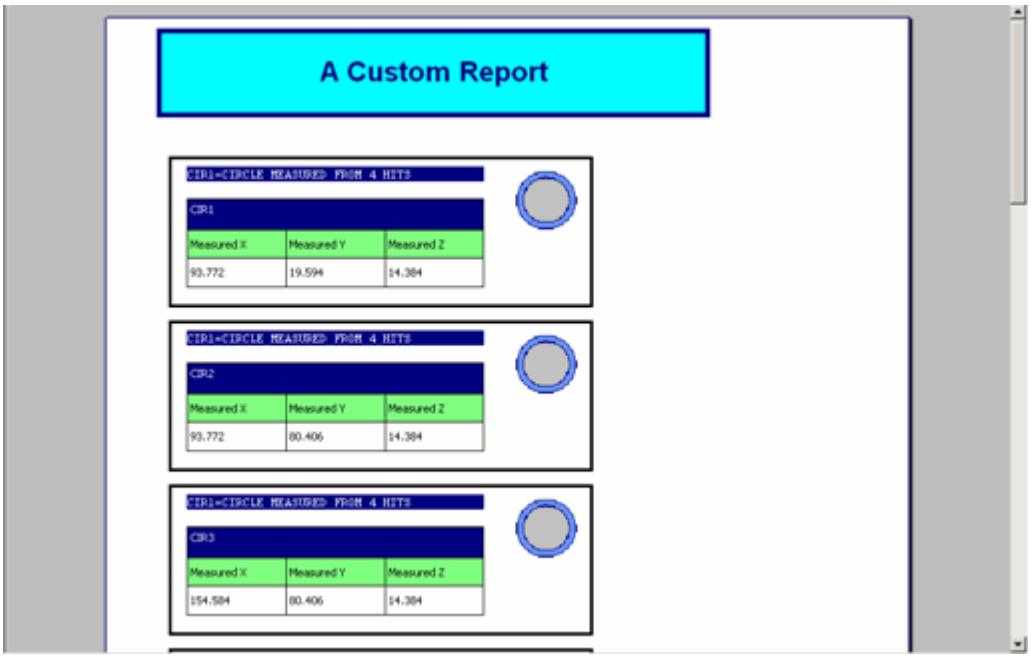
6. Select **File | Save** to save the report template.

7. Select **File | Close** to close it.

8. Execute the measurement routine and apply the template.

9. Select **View | Report window** to display the final report.

After you save and test your label template, it should look something like this:



Report window example showing the newly created label. Notice the measured X,Y, and Z center point data for each circle feature.

Step 6: Create a Repeating Row

So far, your label displays the XYZ of your circles' centers. Suppose, however, you wanted to get individual hit data instead. You can do this using repeating rows.

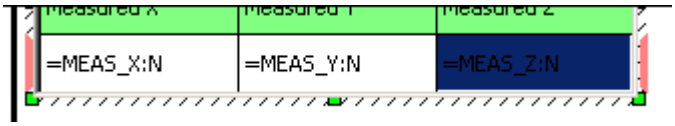
1. Select **File | Reporting | Edit | Label Template**. Select TestLabel.lbl from the dialog box and click **Open**. PC-DMIS loads the Label Template Editor and displays TestLabel.lbl.

2. Access the GridControlObject.

3. Select the first cell in the third row. Once you select it, right-click to bring up the GridControlObject's dialog box.

4. Click the **Row** tab.

5. Select the **Repeating Group** check box. This tells PC-DMIS that you want to make that row repeatable. The **Repeat Expression** dialog box becomes available. Notice that the row, at this point, contains orange markers on the left and right sides. This indicates that the row is a repeating row.



A row showing orange markers

6. Type "=N_HITS" in the **Repeat Expression** box. This tells PC-DMIS to get the total number of hits in the feature and to repeat the row for each available hit.

7. Click the **Cell** tab. You should see "=MEAS_X" in the **Cell Expression** box. Append ":N" to the expression so that it reads, "=MEAS_X:N". This tells PC-DMIS to repeat the expression in that cell for each available hit.

8. Select the other two cells in the row, and modify them so that they have the ":N" code added as well: "=MEAS_Y:N" and "=MEAS_Z:N".

9. Because the labels will expand to include all the data passed into the GridControlObject, when the row repeats, you do not need to adjust the label's size for this.

10. Click **OK** to close the GridControlObject's dialog box.

11. Save the label template and access the Report window. Click the **Redraw the Report** icon from the **Reporting toolbar** to see your latest changes. Notice that instead of displaying the center point data for the circles, PC-DMIS displays individual hits.

You have learned how to create a basic repeating row to count and display several items of data without needing to create different report templates with different row configurations.

Step 7: Use the Columns Tab to Define Columns

1. Access the TestLabel.lbl label template, and select the existing GridControlObject.

2. Select its first row and then right-click it to bring up the GridControlObject's dialog box.

3. Click the **Unmerge Cells** button. The single cell making up the first row now becomes three cells.

4. Delete the "=ID" expression text in the first cell. You don't really need this expression in your final label template because the CommandTextObject displays it automatically.

5. Use the **Background Color** and **Text Color** buttons to change the cell's background color to white and its text to black.

6. Delete the inside column lines in the first row. To do this, select the first cell, access the dialog box, in the **Cell** tab, in the **Lines** area, change the line value of the **Right** list from **Thin** to **None**. Repeat this for the middle cell as well.

7. Click **OK** to close the GridControlObject's dialog box. While your label template may appear to have its cells merged, in reality, column lines in those cells are merely hidden.

8. Select the left cell in the first row and access the dialog box.

9. Click the **Column** tab. In the **Column** list box, type "Measured X". Click **OK** to close the GridControlObject's dialog box.

10. Repeat this for the middle and right cells, typing "Measured Y" and "Measured Z" respectively. You will use these column headings to control each columns visibility and ordering later on.

11. Select the CommandTextObject you added to the template earlier, and drag it down so that it rests on top of the GridControlObject's first row.

12. Modify the location or size of the Ellipse or circle Bitmap object you created earlier so that it's centered along the right side of the GridControlObject.

13. Select and then drag the top line of the Border object down so that it's just above the GridControlObject.

14. Drag a box around all the objects in the label to select them all. Then drag those objects up to the top and to the left as far as they will go on the label's canvas.

15. Right-click to access the GridControlObject's properties.

16. Type "TestTableFormat" in the **Table Format** property, and press the Tab key.

17. Save and close your label template.

In this step, you learned how to unmerge cells, set cell line properties, insert column headings, and select and move multiple objects. Defining column headings will let you control the visibility and ordering of your columns on the fly. When you have finished this step, your label template should look something like this:

Step 8: Define a Grid Format Table

1. Open the report template, Test1.rtp, in the Report Template Editor.
2. Select the TextReportObject, and right-click to access the **Properties** dialog box.
3. In the **Rules Tree** property, click **Rules** to open the **Rule Tree Editor** dialog box.
4. Use the Rule Tree Editor and navigate to the rule you created earlier.
5. Select the rule and click **Edit** to open the **Edit Rule** dialog box.
6. Click the **Grid Format** button. The **Table Format Properties** dialog box opens.
7. In the **New Table Name** box, type "TestTableFormat", and click **Add Table**.
8. Under the **Columns** list in the edit box, type "Measured X", and then click **Add Column**.
9. Add columns for "Measured Y" and "Measured Z" in this same manner.
10. Click **OK** on the various dialog boxes until your return to the Report Template Editor.
11. Select **File | Save** to save the report template.
12. Select **File | Close** to close the Report Template Editor.

In this step, you tied the GridControlObject's columns to the TestTableFormat table in the **Table Format Properties** dialog box by adding columns with the exact same name and naming the table the same name you gave the **Table Format** property. Since you haven't changed the order or visibility at this point, the newly created table in the dialog box should look like this:

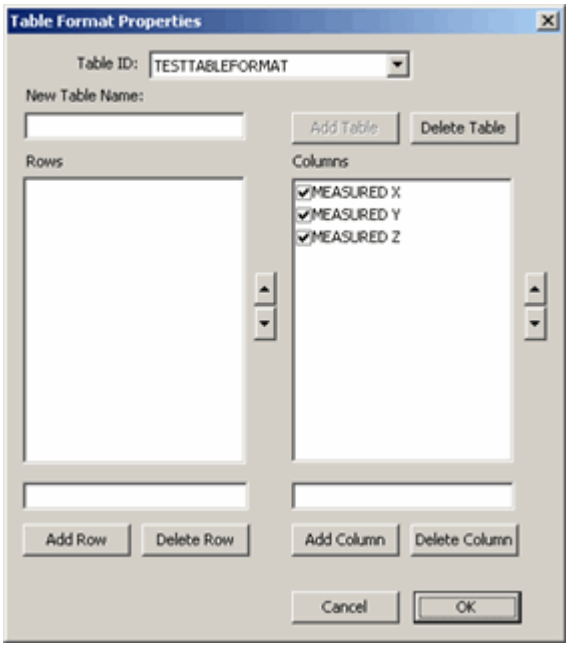


Table Format Properties dialog box showing the newly created TestTableFormat table

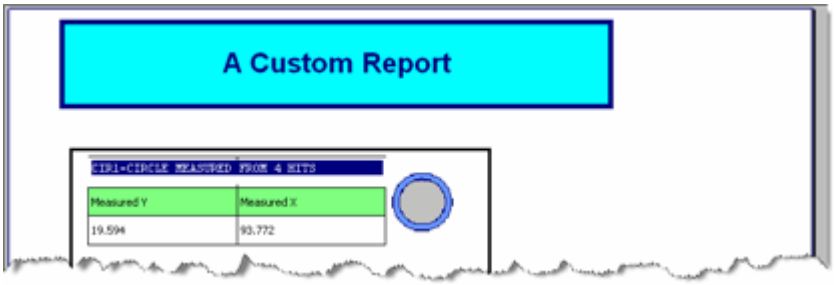
Step 9: Use Table/Format Command to Control Column Visibility and Order

1. If the Edit window is not visible, select **View | Edit Window** to display the Edit window.
2. Place the Edit window in Command Mode.
3. Select **Insert | Report Command | Table Format**. The **Table Format Properties** dialog box opens.
4. From the **Table ID** list, select the **TESTTABLEFORMAT** table. The **Columns** area shows the columns available to this custom table format.
5. Clear the **Measured Z** box to hide that column in the final report.
6. Select **Measured Y** and click the up arrow icon next to the **Columns** area to reorder the **Measured Y** column so that it gets displayed first in the report.
7. Click **OK**. PC-DMIS inserts a `TABLE/FORMAT` command into the Edit window. This command controls the visibility and order of your columns.

```
TABLE/FORMAT,TESTTABLEFORMAT
COLUMN/ORDER,MEASURED Y,MEASURED X, ,
ROW/ORDER
```

8. Save and execute your measurement routine. When PC-DMIS runs, notice that the order of the Measured X and Measured Y values have changed, and the Z column is hidden

In this final step, you learned how to insert and use a `TABLE/FORMAT` command to define the order and visibility of the columns in the label template. Your finished report should look something like this:



Finished report showing only the Measured Y and X columns

Using Labels in Reports

To use labels with your reports, you need to open a report template and add at least one of these objects:

- Label
- TextReportObject
- CadReportObject

Once an object exists, right-click on it to access its **Properties** dialog box. Finally, use the **Rules Tree Editor** to define rules that use one or more label templates.

When you apply your report template, PC-DMIS follows the rules you specified and uses the chosen label templates.

Understanding Stand-Alone Label Ordering

If you use stand-alone Label objects in your report template, be aware that, by default, PC-DMIS fills them with measured data in the report in front-to-back order. To illustrate this, when you add stand-alone labels, PC-DMIS defines each label by a progressive alphanumeric ID (Label1, Label2 …LabelN where N indicates the final label number). While label IDs don't control the order in which the labels are filled, they are discussed here to more easily illustrate how ordering takes place. During report creation, assuming you haven't modified the label IDs in any way, LabelN is activated and filled first, while Label1 is activated and filled last.

This only happens with stand-alone labels, not with labels used within the TextReportObject or CadReportObject.

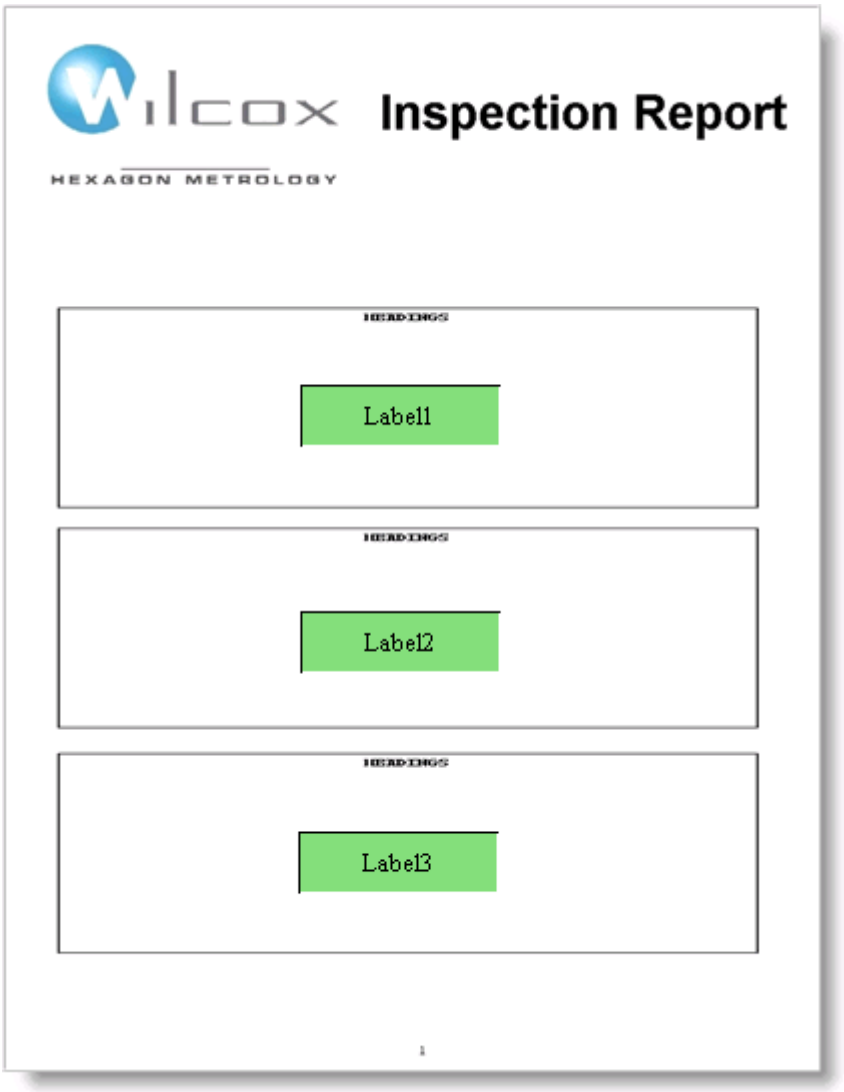
Changing Stand-Alone Label Ordering

Since PC-DMIS may not initially fill the labels in the order you would like, you can change the drawing order of the labels to determine which labels are filled first with menu items located on the **Edit | Order** submenu.

You can also click the **To Front or Back** icon on the **Layout Bar**, and then click the **Bring to Front** or **Send to Back** button.

After you change the drawing order, PC-DMIS fills the top most drawn label first and the bottom most drawn label last.

For example, suppose you have three large labels that fill up a single section with Label1 at the top, Label2 in the middle, and Label3 at the bottom.



A sample report template with three large labels

Initially, it fills up Label3 first, then Label2, and then Label1. To guarantee that PC-DMIS displays your data in measurement routine order, you can change the drawing order of the labels, like this:

1. Select Label1 and choose **Edit | Order | Bring to Front**.
2. Select Label2 and choose **Edit | Order | Sent to Back**.
3. Select Label3 and choose **Edit | Order | Send to Back**.

Arranging Labels in the Report Window

When the report template receives measurement routine data, it has to size the labels dynamically to fit that data. So, these labels may not be in the best location or may overlap other labels after measurement routine execution. However, you can modify where to put labels, by selecting a label and then dragging it to a new location.

You can select a label in one of these ways.

- Double-click on the label.
- Press the Ctrl key and left-click the label.
- Drag a box around the label.

The latter two methods are used to select multiple labels as well.

Using the Table Format Command

The `TABLE/FORMAT` Edit window command lets you control a **GridControlObject's** column and row ordering and visibility on the fly from within your measurement routine. This means you don't have to use the Label Template Editor to create different variations of the same label template if you only want to reorder or hide certain rows or columns. Instead, you can simply insert this command into your measurement routine to determine how to display the **GridControlObject** in the label template.

For this command to work properly, you must set the value of the **GridControlObject's** `TableFormat` property to the exact same table format name defined in the **Grid Format** button of the **Edit Rule** dialog box.

Inserting the Command

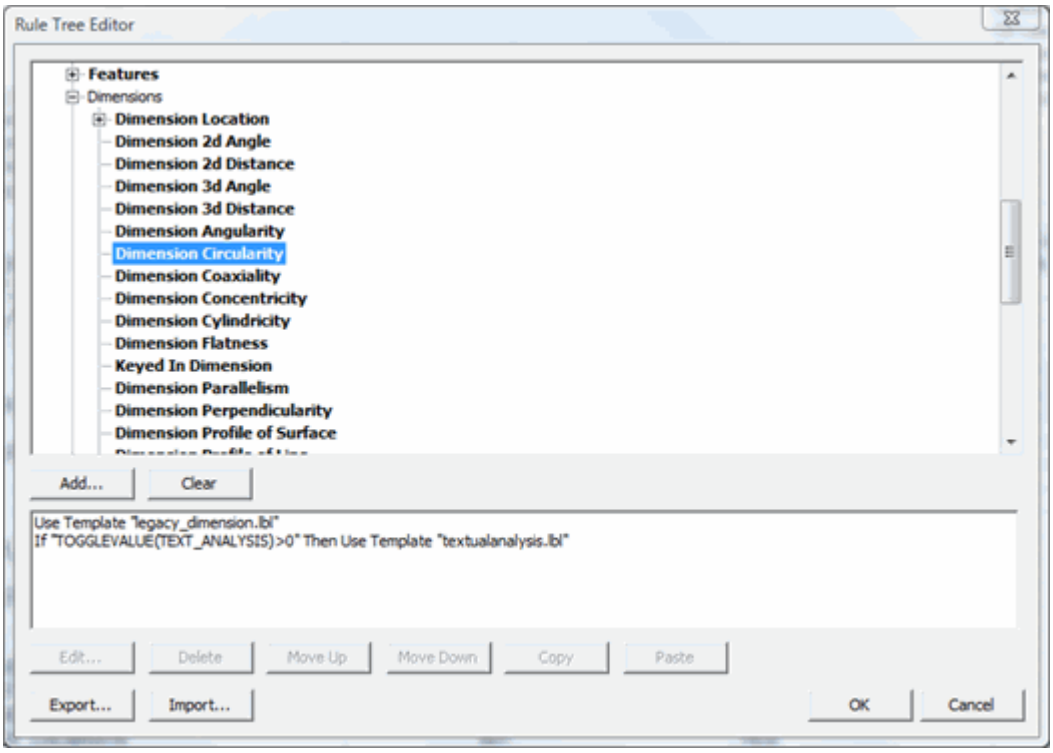
To insert this command, select **Insert | Report Command | Table Format**. The **Table Format Properties** dialog box appears. This dialog box, like the dialog box used in the **Rules Tree Editor**, also controls the visibility and ordering of rows and columns for label templates using the **GridControlObject**. When you finish manipulating the rows and

columns, click **OK**, and PC-DMIS inserts the `TABLE/FORMAT` command into the Edit window.

An inserted `TABLE/FORMAT` command takes precedence over any ordering you may have already defined with the **Edit Rule** dialog box's **Grid Format** button.

About the Rule Tree Editor

The **Rule Tree Editor** dialog box lets you define rules–or conditions and responses–that certain objects follow when displaying report information. For example, you may only want to show roundness dimension information for circle features in your report, even though your measurement routine contains many other features. You can do this by using this editor. In your report template, you might add a **CadReportObject** and then access the **Rule Tree Editor** for that object. Inside the editor, you can then specify a circle feature type and then select a label template that is programmed to display roundness data.



Rule Tree Editor Dialog Box

Supported Objects:

The **Rule Tree Editor** works with these objects available from the Report Template Editor:

- TextReportObject
- CadReportObject
- Label Object

It also works with **Page** object available within the **Custom Report Editor**. Only these objects can access data from a measurement routine using the **Rule Tree Editor**.

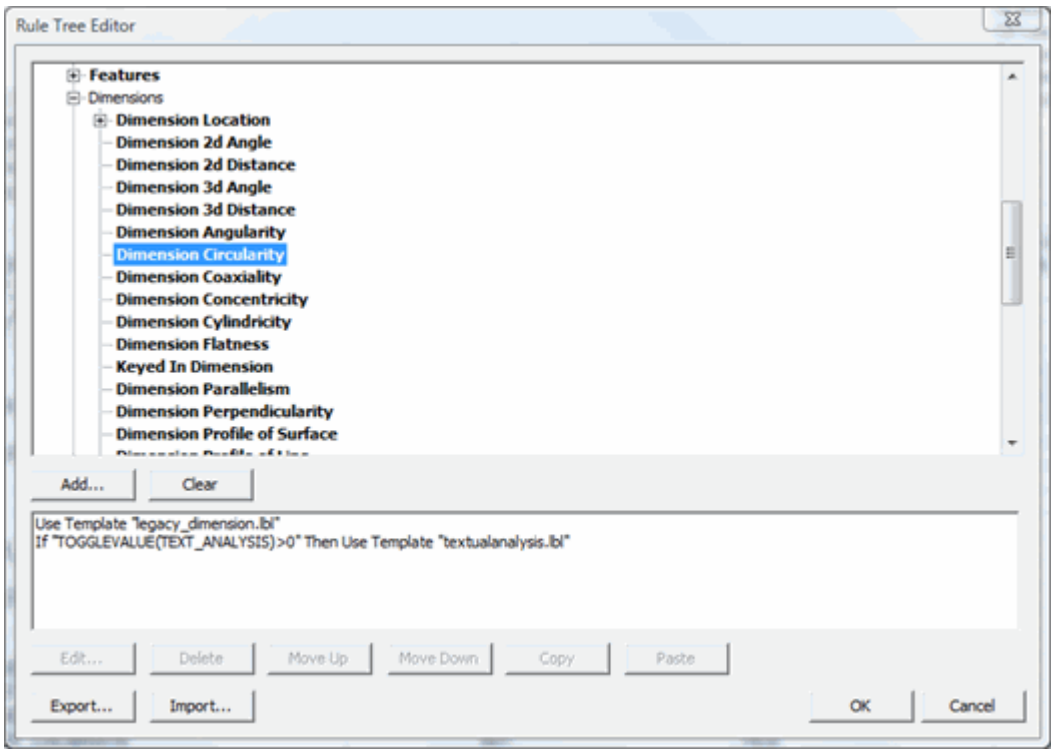
Accessing the Rule Tree Editor:

1. Insert a supported object into your report template, or select the **Page** object in the **Custom Report Editor**.
2. Right-click on the object.
3. Click on **Rules** next to the **RuleTree** property to open the **Rule Tree Editor** dialog box.

Defining a Rule in the Rule Tree Editor

To define a rule using the **Rule Tree Editor** dialog box, follow these steps:

1. Select **File | Reporting | New | Report Template** to open the Report Template Editor.
2. Add a **TextReportObject**, **CadReportObject**, or **Label** object to the template.
3. Right-click the object to open the **Properties** dialog box.
4. Select the **Rules Tree** property to open the **Rule Tree Editor** dialog box. The dialog box lists various items that make up a measurement routine. To expand an item, click the plus (+) symbol to view more specific items or commands. Some standalone items that are not inside expanding lists include:

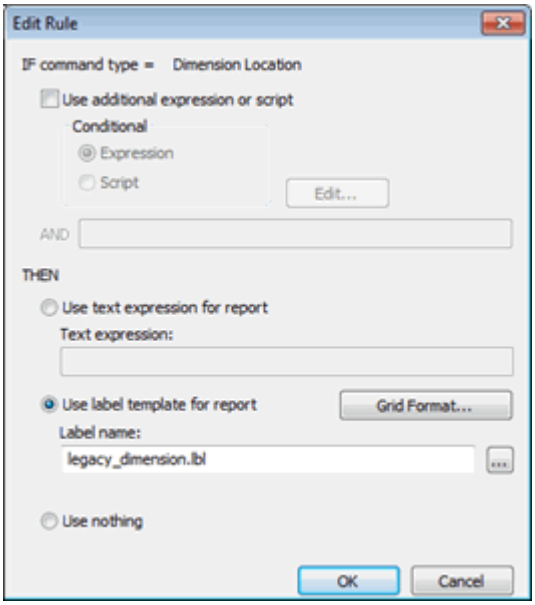


Rule Tree Editor Dialog Box

- **Top of First Page in Section** - You can use this item to display a label or text expression at the top of the first page in the current section of the report.

- **Bottom of Last Page in Section** - You can use this item to display a label or text expression at the bottom of the last page of the current section.
- **File Header** - You can use this item to replace the standard report header (such as PART NAME, REV NUMBER, SER NUMBER, and STATS COUNT) with a custom label or text expression. The File Header appears on the first page of the current section of the report.

5. Define the conditions to be met:
   - From the list, select an item to define as a condition.
   - Click **Add** to open the **Edit Rule** dialog box.



Edit Rule Dialog Box

   - If you want to define another condition, you can choose either a reporting language expression or a BASIC script. To do this, select the **Use Additional Expression or Script** check box, and then in the **Conditional** area, select either the **Expression** or **Script** option.
     - If you select **Expression**, type the condition in the **Conditional Expression** box. For example, to create a rule for a measured circle, you can test any circle data type field values to determine whether to display a label. Suppose you want to display a label only if the measured circle has less than four hits. In the **Conditional Expression** box, type:

       ```
       N_HITS < 4
       ```

       If this condition is evaluated as TRUE, PC-DMIS uses the associated label. You do not need to include the entire IF statement. The IF statement is already understood and evaluated in this box.

- If you selected **Script**, click the **Edit** button to create your BASIC script. A **VBS Mini-editor** appears where you can type your code. The script must return TRUE for the condition to be met. When finished, right-click and select **Check Syntax**, then click **OK**. PC-DMIS automatically stores the script with the defined rule.

If the rule is deleted, the script is lost. To prevent this, store your script in a separate text file.

6. Define a label, an expression, or nothing to display if the conditions are met. In the **Edit Rule** dialog box, select one of the following:

- **Use text expression for report**
  - *If you use a text expression*, type a simple text message or define an expression in the **Text Expression** box. For example, whenever PC-DMIS measures a circle, you can type static text, such as:

```
"We just measured a circle!"
```

  - You can also use expressions to include information about the circle, such as:

```
"We just measured a circle! It had " +  N_HITS  + " hits!"
```

- **Use label template for report**
  - *If you use a label template*, select a label template. This field also accepts expressions, provided they evaluate to a label template name. If you use an expression, precede it with the "=" symbol. If desired, click the **Grid Format** button to open the **Table Format Properties** dialog box. Use this dialog box to define a grid format for your report. A grid format lets you reorder or hide your columns and rows without creating a brand-new label template. Defining a grid format also lets you use the `TABLE/FORMAT` Edit window command to control row and column ordering from within the measurement routine. For details on how to define a grid format, see the "Using the Table Format Properties Dialog Box" topic in the PC-DMIS Core documentation.

- **Use nothing**
  - *If you use nothing*, then PC-DMIS displays nothing for that condition. You may find this useful if you don't want to output anything for a specific feature, command, or condition. **Use nothing** only applies to the TextReportObject.

7. After you fill out the **Edit Rule** dialog box, click **OK**. PC-DMIS displays the item in bold and adds its rule at the bottom of the **Rule Tree Editor** dialog box.

8. Organize your rules. You can create multiple rules for a given command type. If a command has more than one rule, PC-DMIS evaluates them in the order they appear. To change the evaluation order, select a rule and click **Move Up** or **Move Down** in the **Rule Tree Editor** dialog box.

    - To copy and paste rules, use the **Copy** and **Paste** buttons. You can copy rules to another item, multiple items, or an entirely different tree. For details on how to copy and paste rules, see the "Copying and Pasting Rules" topic in the PC-DMIS Core documentation.

    - To remove rules from an item, click **Delete** or **Clear**. To remove rules from multiple items, select them and click **Clear**. For details on clearing rules, see "Clearing Rules" topic in the PC-DMIS Core documentation.

9. Click **OK** to save your changes in the **Rule Tree Editor**.

10. Test the rule.

    - Save the report template.

    - Apply the report template to the report data using the **Reporting** toolbar in the Report window.

    - Execute the measurement routine.

A rule assigned to a child element always overrides one assigned to a parent element. A rule assigned to a parent node applies to each child element unless the child element has its own rule.

Importing and Exporting Rules

If you work in a collaborative environment, you will probably want to share rules that are created from different report templates with each other. Using the **Rules Tree Editor** dialog box, you can easily do this and import someone else's rules by using the **Import** button, or you can share your own rules with someone else by using the **Export** button.

A rules file has a ".rul" filename extension.

Importing a Rules File:

1. Access the **Rules Tree Editor** dialog box.

2. Click the **Import** button. An **Open** dialog box appears.

3. Navigate to the directory containing the rules file (.rul) you want to import.

4. Click **Open**. PC-DMIS imports the rule file into the **Rules Tree Editor**.
5. Click **OK** to save the imported rule.

Exporting to a Rules File:

1. Access the Rules Tree Editor dialog box.
2. Click the **Export** button. A **Save As** dialog box appears.
3. Navigate to the directory where you want to store the rules (.rul) file.
4. Type a name for the file In the **Filename** box.
5. Click **Save**. All rules associated with that object get exported. Someone else can now import and use your exported rules file.

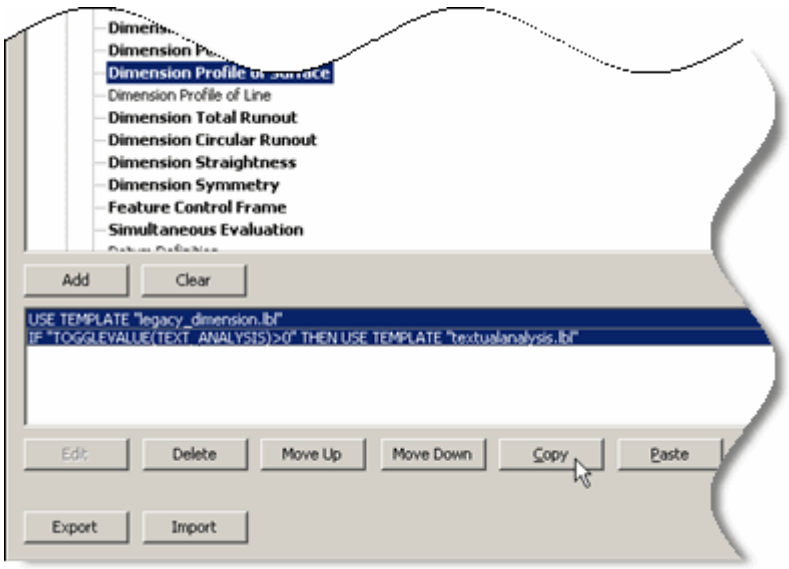
Copying and Pasting Rules

The Rule Tree Editor contains **Copy** and **Paste** buttons so that you can copy and paste rules between the current **Rule Tree Editor** and a **Rules Tree Editor** for a different object or to a different item within the same **Rule Tree Editor**.

A copied rule is not stored in the Windows Clipboard; so you cannot copy and paste a rule outside of the specific context discussed here.

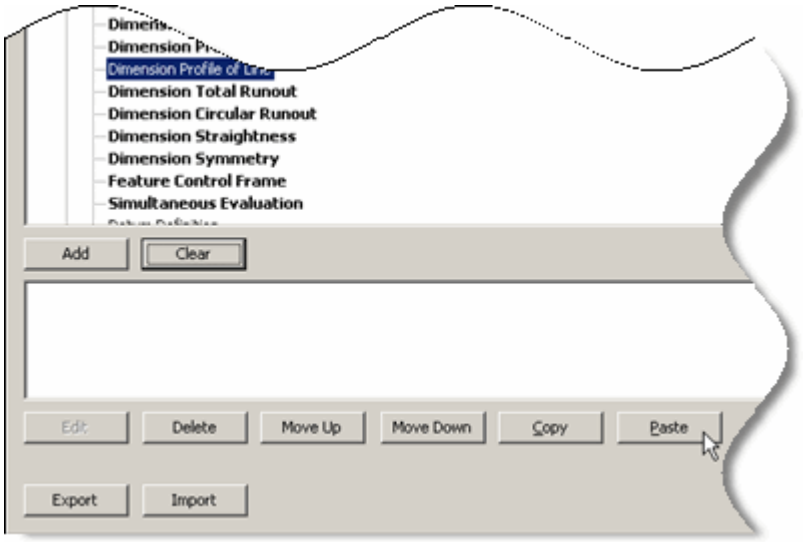
To Copy and Paste Rules:

1. Select a single item from the **Rule Tree Editor**. If you select more than one item from the tree editor, the **Copy** button will never become enabled.
2. Select one or more rules from the rule list box. The **Copy** button becomes enabled for selection.



Example showing the copying of two rules.

3. Click **Copy**.
4. Select and highlight one or more items from a rule tree. Hold down the CTRL key while clicking to select multiple items. The **Paste** button becomes available.

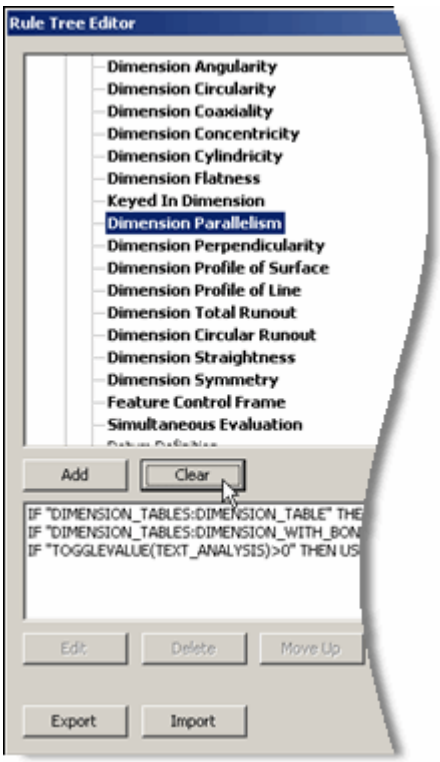


Example showing the pasting of copied rules into an empty item.

5. Click **Paste** to paste the copied rule(s) into the selected item(s). Note that if you paste a copied rule or rules into an item that already contains one or more rules, the existing rules are not overwritten by the new rules, but the new rules are instead appended to the existing list. You can click **Paste** multiple times into several different rule tree items.
6. Click **OK** on the **Rule Tree Editor** to save your changes.

Clearing Rules

The **Clear** button removes any rules associated with one or more selected items from the Rule Tree Editor. You can select more than one item by pressing the CTRL key while selecting additional items.



Example showing the clearing of rules for a selected item.

Using the Table Format Properties Dialog Box

The **Table Format** dialog box works with a **GridControlObject's** defined column and row names, which enables you to control the visibility and order of columns and labels in a **GridControlObject** in a label template. To access this dialog box, from the **Edit Rule** dialog box, click the **Grid Format** button. For information on the **Edit Rule** dialog box and the **Grid Format** button, see "Defining a Rule in the Rule Tree Editor".

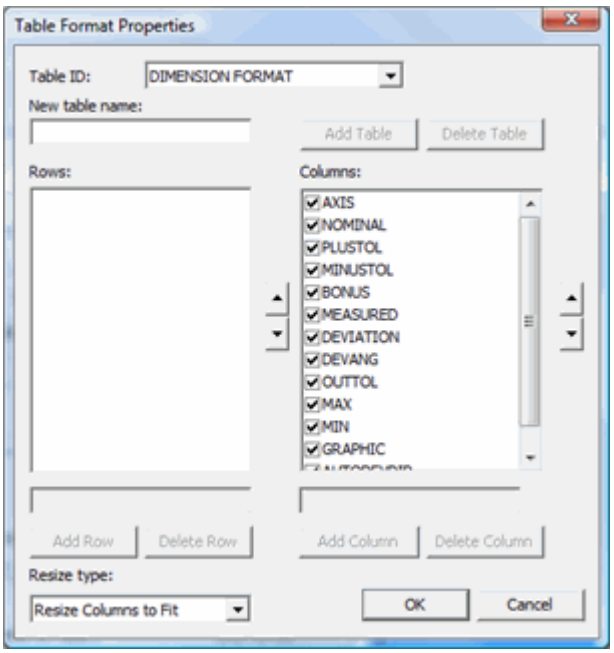


Table Format Properties Dialog Box

This dialog box contains different table formats. A table format simply defines how you want named rows and columns to appear in your final report. This dialog box lets you change the order and visibility state of all existing table formats. You can also use this dialog box to create your own custom table formats.

For the pre-existing table formats, the only thing you can modify is their visibility state and the order of their rows or columns. You cannot delete these table formats nor change what rows or columns they have.

To use table formats, you must first use a label template with a **GridControlObject** that has its columns or rows already named.

The following properties are available:

Table ID
Lists all available table formats.

New Table Name
Defines a new table format.

Add Table
Adds the new table format. This button only becomes enabled when you type a name in the **New Table Name** box.

Delete Table
Deletes the selected custom table format. This button only becomes enabled when you select a custom table from the **Table ID** list.

Rows
Lists the rows and columns in your table format. You can reorder them by clicking the up and down arrows.

Add Row/Column
Adds a row or column name to the **Rows** or **Columns** area. You can only add to custom table formats.

Delete Row/Column
Deletes the selected row or column from the **Rows** or **Columns** area. You can only delete items from custom table formats.

Resize Type
Determines what the table will when you show or hide columns. The list contains three items:

Resize Grid - This retains existing column sizes and resizes the grid to fit the new width.

Resize Columns to Fit - This retains the grid's existing width and resizes each column equally to fit that width.

Hide Text - This doesn't resize the grid or the columns. It simply hides the text.

Cancel
Closes the dialog box without applying any changes.

OK
Uses the selected table format for the rule in the **Rule Tree Editor** or for the `TABLE/FORMAT` command in the Edit window.

To name a column or row in a GridControlObject:

1. In the Label Template Editor, select the **GridControlObject**.
2. Double-click on the first cell in a column or row.
3. Right-click to access the property editor.
4. Click either the **Cell** or **Column** tab.
5. In the **Row Label** box or **Column Label** box enter a value. You can select from the list or type a custom value. Custom labels can only show up on custom table formats.

To reorder columns or rows:

1. Select a table format from the **Table ID** list.
2. Its rows or columns already appear.
3. In the **Rows** or **Columns** area, select the row or column you want to reorder, then click the up or down arrow buttons to either send that item either up or down in the list. Items higher in the list get displayed before others.

To show/hide columns or rows:

1. Select a table format from the **Table ID** list. Its rows or columns already appear.
2. In the **Rows** or **Columns** area, clear the check box to the left of the row or column name to hide that item in the label. Select the check box to show it in the label.

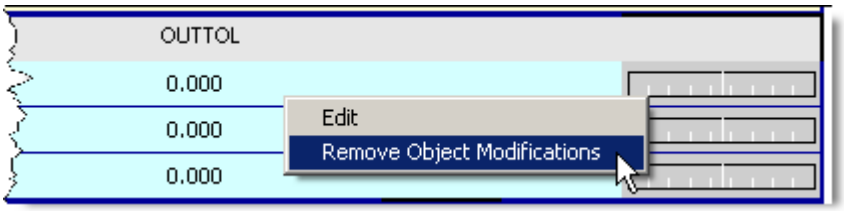
To create a custom table format:

1. In the **New Table Name** box, type a name.
2. Click the **Add Table** button. The custom table appears in the **Table ID** list and remains until you delete it.
3. In the **Add Row** or **Add Column** box, type a name that matches a row or column label name you gave to the **GridControlObject**.
4. Click **Add Row** or **Add Column** to add that item to the table.

5. Continue adding row or columns and deleting or rearranging them as desired until the table format contains the information you want.

Removing your Modifications

To quickly remove a modification, right-click on the desired report object (a TextReportObject, CADReportObject, or Label object), and select the **Remove Object Modifications** button.

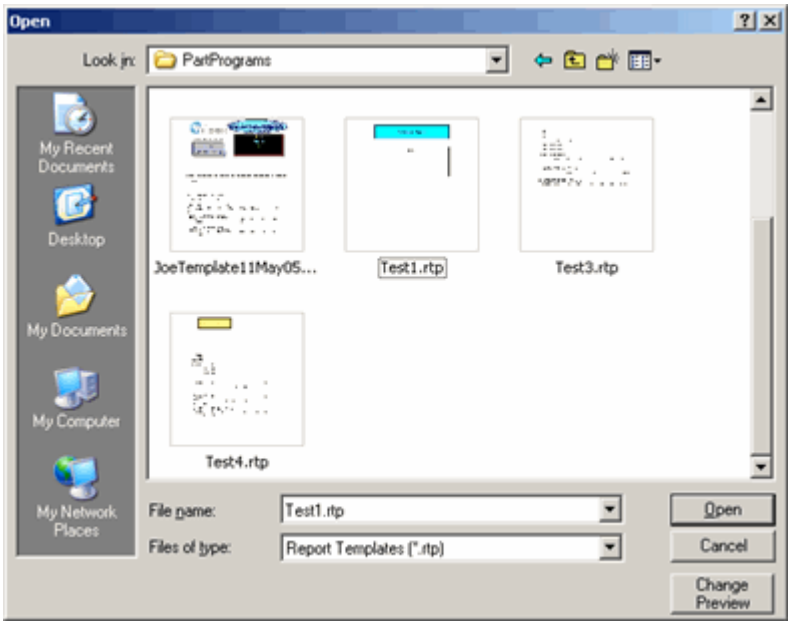


PC-DMIS returns the report object back to its default state.

Changing a Template's Preview Thumbnail Icon

Whenever you create a report or label template, PC-DMIS automatically creates a thumbnail-sized preview of that template based on what appears on the template's initial page or section.

This thumbnail preview appears whenever you attempt to edit a template and access the **Open** dialog box (**File | Reporting | Edit | Report Template** or **Label Template**).



A sample Open dialog box showing several report template preview icons

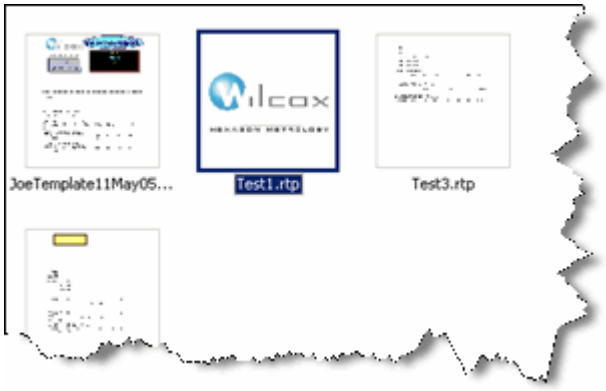
If you want to use a custom image file instead of the default generated preview for a template, you can do this within the **Open** dialog box.

To Change a Template's Preview Thumbnail:

1. Select the template file from the **Open** dialog box.
2. Click the **Change Preview** button to open the **Template Image Selection** dialog box.

Template Image Selection Dialog Box

3. Select the **Select Image from File** option button.
4. Click **OK**. Another **Open** dialog box opens allowing you to select a preexisting image file.
5. Navigate to the directory containing either a .bmp or .jpeg file, select the image file, and click **Open**. PC-DMIS uses the selected image for your preview.



Example of a Test1.rtp file with a bitmap preview image.

Saving a Template or Form to an Earlier Version

You can save your report templates, label templates, or forms so that they are backwards compatible with earlier PC-DMIS versions that also support template reporting.

To do this:

1. Open the desired report or label template inside its respective editing environment (the Report Template editor, the Label Template editor, or the Form Editor).
2. Select the **File | Save As** menu item to open the **Save As** dialog box.

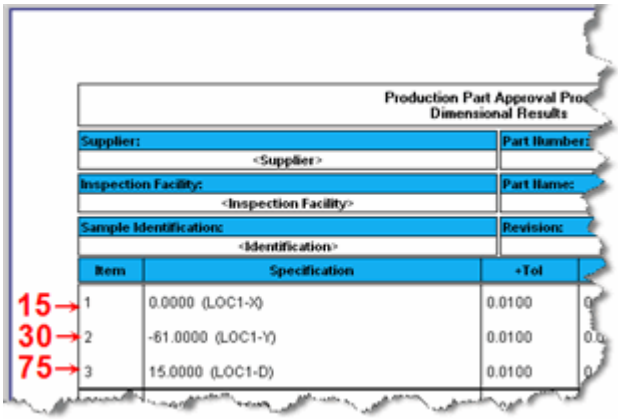
3. Near the bottom of the dialog box, use the list under the **Save as type** list to specify the version. The earliest version you can save these items back to is version 4.2 MR2. Select the desired version and click **Save**.

If you use the **File | Save** menu item, PC-DMIS automatically saves the item to your current running version of PC-DMIS, even if it was saved to an earlier version previously.

Tutorial - Customizing a Report Template

Most of the time, you won't need to create a brand-new report template from scratch, but instead will want to create a new template based on an existing template that ships with PC-DMIS.

For example, suppose that you have ballooned (or numbered) prints, and you want the ballooned numbers to appear in your final report, such as in the **Item** column in the PPAP report (as shown below).



How do you get ballooned data into the PPAP template?

Perhaps feature #15 on the print is the X dimension for a hole, feature #30 is the Y dimension, and feature #75 is the hole's diameter. How do you get this information into the **Item** column in your final report? One way is to configure the PPAP and label templates to pull the information from variables in your measurement routine.

This tutorial shows you how to make copies of the PPAP report and label templates. It then demonstrates how to modify them so that the information that appears under the **Item** heading displays variables taken from your measurement routine, instead of the normal sequential list of numbers that appears in the PPAP report.

This tutorial uses skills learned in the "Creating a Report Template" and "Creating Label Templates" tutorials. You should complete those tutorials first so that you have a proper foundation for this tutorial.

Step 1: Copy the PPAP Report and Label Template

The first thing you need to do is create copies of all the components used to generate the PPAP report. These include both the report template and the underlying label templates.

1. In the Report Template Editor, open the PPAP.RTP report template.
2. Select **File | Save As**.
3. Name the report template "BALLOON_PPAP.RTP".
4. Close the Report Template Editor.
5. In the Label Template Editor, open these templates, select **File | Save As** on each one, and save them with a "BALLOON_" filename prefix as shown in this table:

Existing Label Template	Save As Filename
PPAP_DIMENSION.LBL	BALLOON_PPAP_DIMENSION.LBL
PPAP_DIMENSION_TRUE_POSITION.LBL	BALLOON_PPAP_DIMENSION_TRUE_POSITION.LBL
PPAP_SizeTolerance.LBL	BALLOON_PPAP_SizeTolerance.LBL
PPAP_GEOTOL_SIZE.LBL	BALLOON_PPAP_GEOTOL_SIZE.LBL
PPAP_GEOTOL_SEGMENT1.LBL	BALLOON_PPAP_GEOTOL_SEGMENT1.LBL
PPAP_GEOTOL_SEGMENT2.LBL	BALLOON_PPAP_GEOTOL_SEGMENT2.LBL
PPAP_GEOTOL_SEGMENT3.LBL	BALLOON_PPAP_GEOTOL_SEGMENT3.LBL
PPAP_GEOTOL_SEGMENT4.LBL	BALLOON_PPAP_GEOTOL_SEGMENT4.LBL
PPAP_GEOTOL_SEGMENT5.LBL	BALLOON_PPAP_GEOTOL_SEGMENT5.LBL
PPAP_TRUE_POSITION_INBETWEEN.LBL	BALLOON_PPAP_TRUE_POSITION_INBETWEEN.LBL

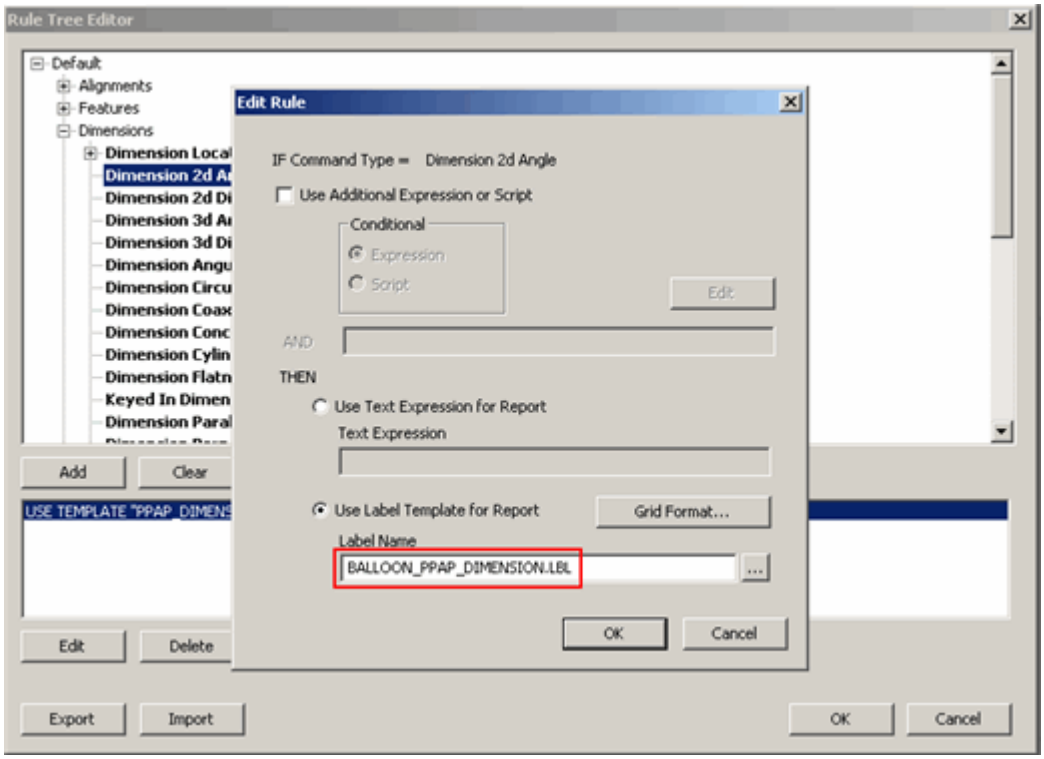
You should now have copies of all the report and label templates used with the PPAP report. You will customize these copies in subsequent steps.

Step 2: Modify Rules in the Report Template

Now that you have created copies of the report and label templates, you need to modify the rules on the new report template so that the newly saved BALLOON label templates are used instead of the usual PPAP labels.

1. In the Report Template Editor, open the BALLOON_PPAP.RTP report template.
2. Access **TextReportObject1** on the template and right-click on it to access the properties for the object.
3. In the **Properties** dialog box, click **Rules** to access the **Rule Tree Editor**.
4. Expand the **Dimensions** list in the **Rule Tree Editor**. You see several dimensions in boldface font indicating that a rule is applied to that dimension type.
5. Select each boldface item in the **Dimensions** list, and modify its existing rule or rules so that the corresponding label templates with the "BALLOON_" prefix are used instead.

Existing Label Templates Used	New Label Templates to Use
PPAP_DIMENSION.LBL	BALLOON_PPAP_DIMENSION.LBL
PPAP_DIMENSION_TRUE_POSITION.LBL	BALLOON_PPAP_DIMENSION_TRUE_POSITION.LBL
PPAP_SizeTolerance.LBL	BALLOON_PPAP_SizeTolerance.LBL
PPAP_GEOTOL_SIZE.LBL	BALLOON_PPAP_GEOTOL_SIZE.LBL
PPAP_GEOTOL_SEGMENT1.LBL	BALLOON_PPAP_GEOTOL_SEGMENT1.LBL
PPAP_GEOTOL_SEGMENT2.LBL	BALLOON_PPAP_GEOTOL_SEGMENT2.LBL
PPAP_GEOTOL_SEGMENT3.LBL	BALLOON_PPAP_GEOTOL_SEGMENT3.LBL
PPAP_GEOTOL_SEGMENT4.LBL	BALLOON_PPAP_GEOTOL_SEGMENT4.LBL
PPAP_GEOTOL_SEGMENT5.LBL	BALLOON_PPAP_GEOTOL_SEGMENT5.LBL
PPAP_TRUE_POSITION_INBETWEEN.LBL	BALLOON_PPAP_TRUE_POSITION_INBETWEEN.LBL



Changing the Label Template

6. Save the report template.

You have modified your existing rules to use the label templates with the "BALLOON_" prefix to format and display your report data.

Step 3: Add ASSIGN Statements into your Measurement Routine

Now that the rules are modified, the next thing you need to do is insert ASSIGN statements into your measurement routine for each ballooned item. Prior to each dimension in your measurement routine, add ASSIGN statements for each characteristic you will display in that dimension. For example, at the beginning of this topic, we suggested that feature #15 on the print was the X dimension for a hole, feature #30 the Y dimension, and feature #75 the hole's diameter. If you had a LOCATION dimension to display the X, Y, and D values (three characteristics), you would insert these three ASSIGN statements prior to your dimension:

```
ASSIGN/V1[1]=15
ASSIGN/V1[2]=30
ASSIGN/V1[3]=75
```

These statements create an array of multiple values for the V1 variable.

Apply similar ASSIGN statements before each dimension in your measurement routine.

- If your dimension displays only one characteristic, then you would only put one ASSIGN/V1[#] before that dimension statement.

- If your dimension displays ten characteristics (for example, a Geometric Tolerance Position), then you would need ten ASSIGN statements for the ten elements in your array:

```
ASSIGN/V1[1]=2
ASSIGN/V1[2]=4
ASSIGN/V1[3]=6
ASSIGN/V1[4]=24
... and so on until ...
ASSIGN/V1[10]=76
```

In most cases, you must use the same variable name for all ASSIGN statements for all dimensions. This tutorial uses the variable V1. The exception is for a Position legacy dimension. For this dimension type, you can use V1[1], V1[2], and other variables for the XYZ axis. However, for diameters of features and datums, and the position callout, you should use unique variables, perhaps V2[1], V2[2], and V3[1] respectively. Also be aware that the variable can only take number characters. Alphabetic characters show only zeros in the report.

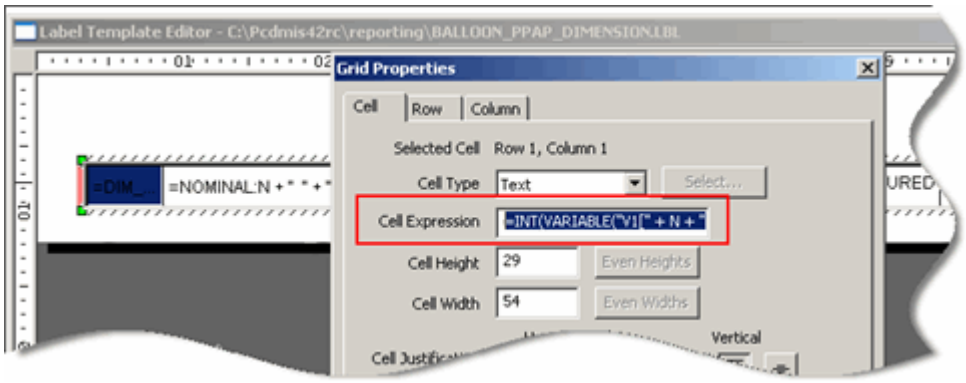
When you've finished adding in the ASSIGN statements, your measurement routine is finished and ready to execute. The only thing left to do is modify your label templates to read in the variable's array of values for each dimension.

Step 4: Modify Label Templates to Read Variables

In this step, you open each applicable label template and configure it so that it reads the array of values for the variable.

1. Inside the Label Template Editor, with the exception of BALLOON_PPAP_DIMENSION_TRUE_POSITION.LBL, open the other label templates with the "BALLOON_" prefix given earlier.
2. Access the GridControlObject and access the contents of the first cell.
3. Modify the expression there to read as follows:

```
= INT ( VARIABLE ("V1["+N+"]",ID:N))
```



4. Save each label template.
5. Finally, open BALLOON_PPAP_DIMENSION_TRUE_POSITION.LBL. Since this template has more than one row in the GridControlObject, you need to specify more than just the V1 variable.
    - *For the XYZ axis*, you can use the V1 variable in your expression:

      ```
      = INT ( VARIABLE ("V1["+N+"]",ID:N))
      ```

    - *For diameters of datums and features*, you need it to use the unique variable used earlier (such as V2):

      ```
      = INT ( VARIABLE ("V2["+N+"]",ID:N))
      ```

    - *For the position callout,* use another unique variable used earlier (such as V3):

      ```
      = INT ( VARIABLE ("V3["+N+"]",ID:N))
      ```

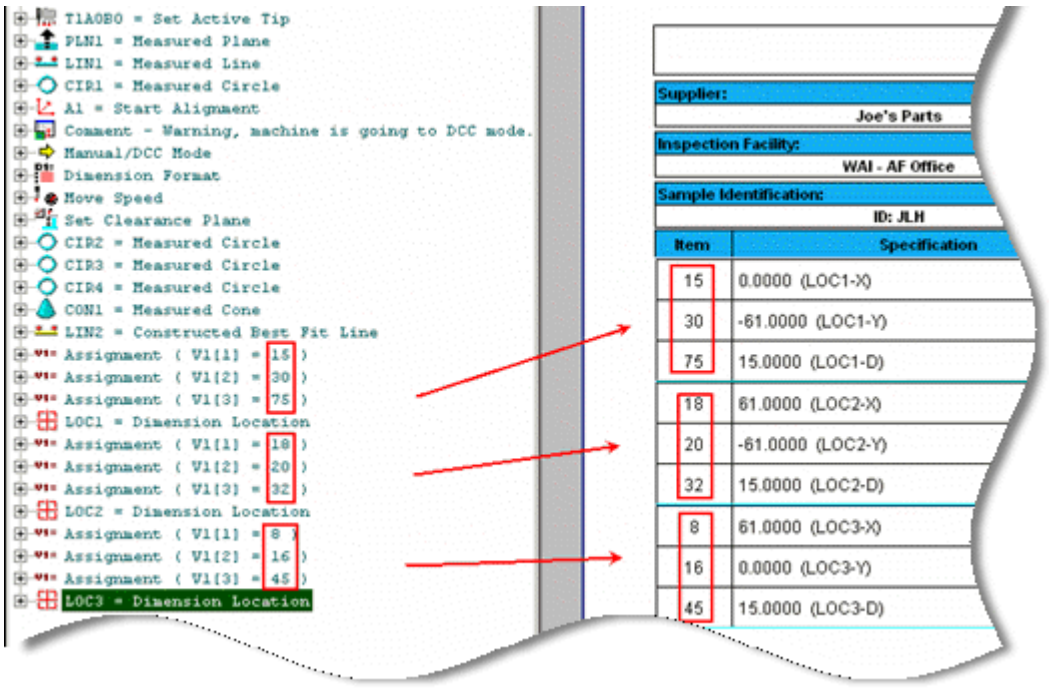
As the report increments through each dimension (using :N), the variable array is called with "V1[" + N + "]", and the Nth element of the V1 array is displayed. You are now ready for the final step of executing and viewing your results.

Step 5: Execute and View Results

In this final step, you define the report template to use in the Report window, execute your measurement routine, and view your final results.

1. Save all your changes made to this point.
2. Access the Report window, and load the BALLOON_PPAP.RPT template.
3. Execute your measurement routine. You may also need to click the **Redraw the Report** icon from the Reporting toolbar after execution.

The Report window shows your final report. It should be similar to this, where the numbered prints inside your PPAP report appear:



Final Report Showing Custom Numbered Items inside of a PPAP Report

Creating Forms

The Form Editor (**File | Reporting | New | Form Report**) lets you build interactive forms and dialog boxes and activate them when a measurement routine gets executed. These interactive forms use the Visual BASIC language. Forms, mixed with a good understanding of the Visual BASIC language and PC-DMIS automation, can give power and flexibility to your measurement routines.

Forms play an active part in reporting because whenever you use a form to control what gets executed, you indirectly control what ends up in your report.

This section, however, does not attempt to cover everything that you can do with forms. Instead, it covers how to use create and use forms in general, and in a reporting sense, how to get information from the user and into a report using standard PC-DMIS commands.

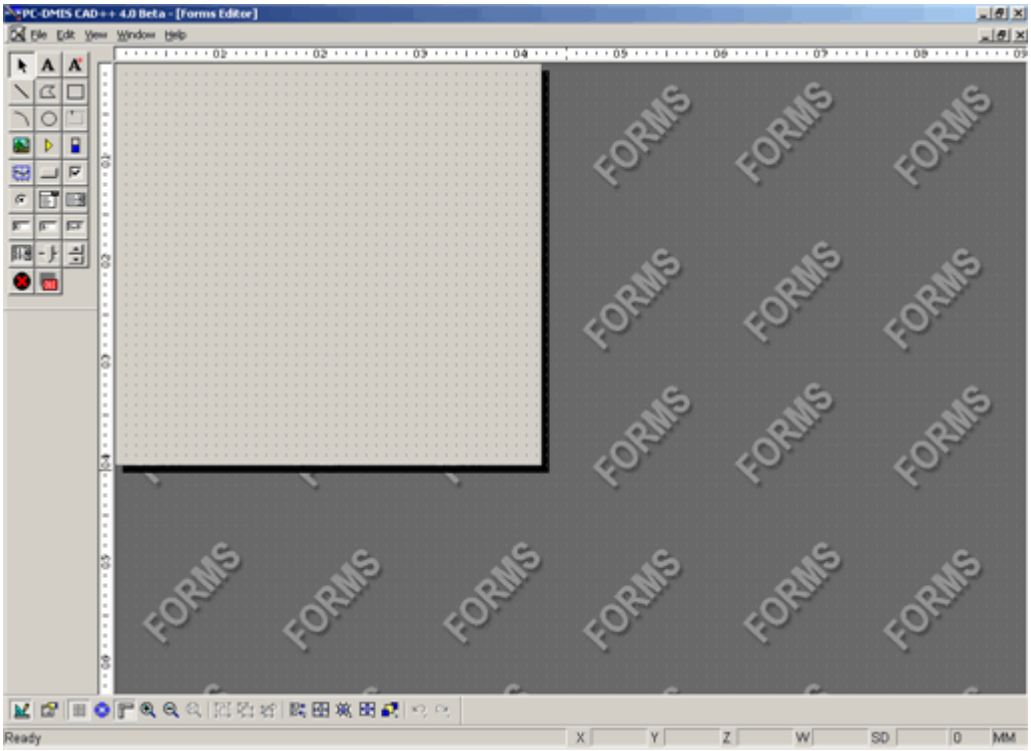
Forms can also be used in a non-reporting role as a way to provide useful instructions to operators. See "Providing Operator Instructions Using OLE Objects with Forms" for some examples on how to do this.

Understanding the Form Editor

To create a new form in the Form Editor, select **File | Reporting | New | Form Report**.

To open an existing form in the Form Editor, select **File | Reporting | Edit | Form Report**.

PC-DMIS displays the Form Editor in a new window.



Form Editor

The Form Editor acts as a work area. It enables you to drag, size, and place various interactive form objects, such as buttons, list boxes, edit boxes, and so forth, and set their properties.

Objects are placed on the gray and sizable area, called a form. If you have worked with HyperView reporting in previous versions of PC-DMIS, you will feel at home with this editor since it essentially functions much the same way and contains many of the same user interface elements.

With the new template approach to reporting, only the Form Editor can use the run-mode capability. The Report and Label template editors do not use it.

> **Run Mode** - This mode only works with the Form Editor. In run mode, you can run (or execute) your form. This enables you to test how it would look or behave in an actual measurement routine execution environment.
>
> **Edit Mode** - This is the default mode for all the reporting editors. It is the only mode for the Report and Label template editors.
>
> To switch between run and edit modes, press CTRL+E.

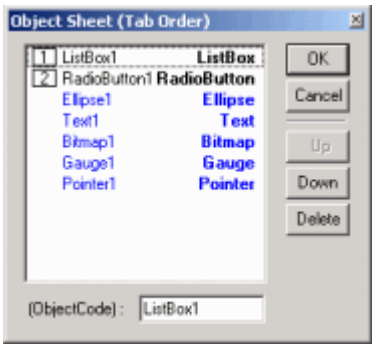
The editor contains the following elements:

- The Menu bar
- The Font Bar (toolbar)
- The Object Bar (toolbar)

- The Layout Bar (toolbar)
- Object Property Sheets
- Object Sheet

Object Sheet

The Form Editor's **Edit | Layout | Objects** menu item displays the **Object Sheet** dialog box.



Object Sheet Dialog Box

You can use this dialog box to set the tab order for objects and controls typically used on dialog boxes by simply changing the order an object appears in this dialog box.

When you press TAB in run mode, PC-DMIS will jump to the next object defined in this dialog box, giving it the focus. Only some objects are affected by the TAB key. Pressing TAB only works on those objects that have a number to the left of them in the **Object Sheet** dialog box.

Tutorial - Creating Forms

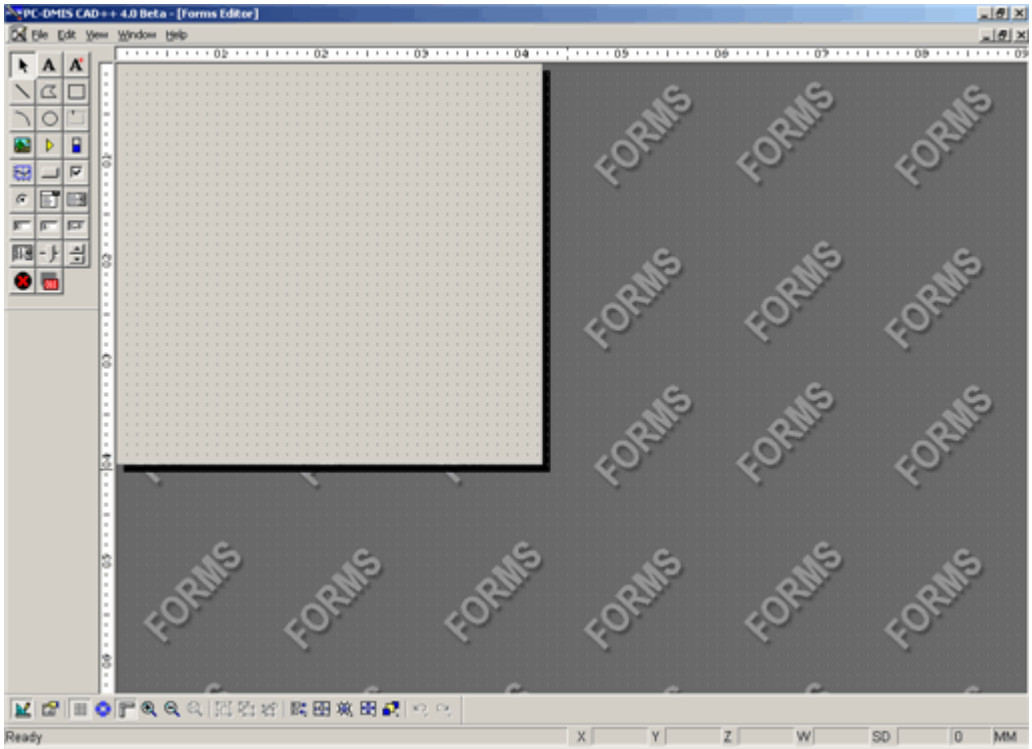
This topic walks you through a basic tutorial that will create a simple form with some interactive dialog box controls that, when executed, allows you to select a user name from a list and then choose to measure only certain features. The information you select will then appear in a final report.

While you can certainly duplicate aspects of this by using certain Edit window commands, this tutorial will give you an idea of what's possible with the Form Editor, some imagination, and a little programming skill.

This tutorial uses files you created in the "Creating a Custom Report Template" and "Creating Label Templates" tutorials. If you haven't already done so, complete those tutorials first.

Step 1: Preparing the Work Environment

1. In this tutorial you will switch between the Form Editor and the Edit window, so first prepare the Edit window.
    - Right-click on your Edit window and select **Docking View** from the shortcut menu to undock it.
    - Select the maximize button so that it fills the screen.
    - Place the Edit window into Command Mode.
2. Select **File | Reporting | New | Form Report** to open the Form Editor.
3. To hide any unused toolbars, right-click on the toolbar area and remove them.
4. To hide any unused PC-DMIS windows, select the open window from the **View** menu. Keep the Edit window open.
5. To maximize the Form Editor, click the *maximize button* in the upper right corner of the editor's window. You should see the words "FORMS" on the background of the editor. Your Form Editor should now look something like this:



Form Editor

When working with the Form Editor, you may find it helpful to hide your usual PC-DMIS toolbars and windows, thereby freeing up some screen space. If you work frequently with this editor, you may want to create a stored screen layout for your template. For information on layouts, see the "Window Layouts Toolbar" topic in the "Using Toolbars" chapter.

Step 2: Create the Form

1. Drag the **TheFrame/TheView's** gray background so that it is five inches wide by six inches tall.

2. Add a **Border** object, and drag the border so that it fits just within the form's area. Set the border's properties so that it has a **LineWidth** value of 3 and a **ForeColor** of dark blue (0.0.128).

3. Add a **Bitmap** object in the top of the form. The **Bitmap Dialog** opens. Use the **Load** button to navigate to a bitmap file of your choice, such as a corporate logo. Size and position the bitmap so that it's within the top 1.5 inches of the form.

4. Add a **RadioButton** object under the Bitmap object. Access the RadioButton's properties, and click on the **ListItems** value. The **List Choices** dialog box opens. This dialog box lets you create a list of option buttons for the object.

    - Select the existing **RadioButton1** item from the **List Choices** box. In the **Name** box, change the name to "CIRCLE 1". The index **Value** should already display 0.

    - Click the **Add** button to add three more items. Then change the newly added items to read "CIRCLE 2", "CIRCLE 3", and "CIRCLE 4". They should have index values of 1, 2, and 3 respectively. The **List Choices** dialog box, should look like this:

    
    List Choices dialog box showing four options with index values ranging from 0 to 3.

    - Click **OK** when finished.

5. Rename the RadioButton object by changing the **(ObjectCode)** value from "RadioButton1" to "optMeasure".

6. Add a **Frame** object and drag it around your RadioButton object. Change the Frame's **Text** property to read "Select What to Measure".

7. Add an **EditBox** object to the right of the RadioButton object, and rename it from "EditBox1" to "txtMeasure".

8. Add a **Text** object (Text1) under the RadioButton object, and set its **Text** property to read "Select User:".

9. Add a **ComboBox** to the right of the Text object, and rename it from "ComboBox1" to "cboUsers". This control will contain a list of users.

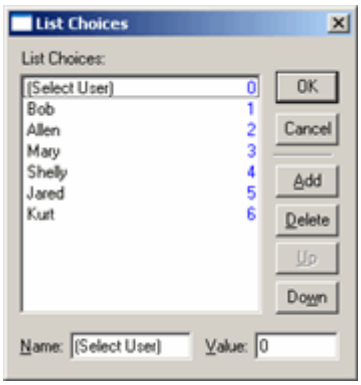
    - Click on the **ListItems** value to add the list of users. This accesses the **List Choices** dialog box again.

    - Click **Add**. PC-DMIS inserts "(None)" under **List Choices**.

    - Change the name of the first item in the list from "(None)" to "[Select a User]", and give it an index **Value** of 0.

    - Continue to use this dialog box as you did before to add five or six user names. This tutorial used "Bob", "Allen", "Mary", "Shelly", "Jared", and "Kurt".

    - Use the **Up** or **Down** buttons as desired to change where an item appears in the list. The dialog box, when finished, should look something like this:



List Choices dialog box showing a list of user names for the ComboBox.

    - Click **OK**. Your ComboBox object now contains those list items.

10. Add an **EditBox** object to the right of the ComboBox, and rename it from "EditBox2" to "txtUser".

11. Add another **Text** object (Text2) under the object that reads "Select User", and set its **Text** property to read "Type a Report Description:".

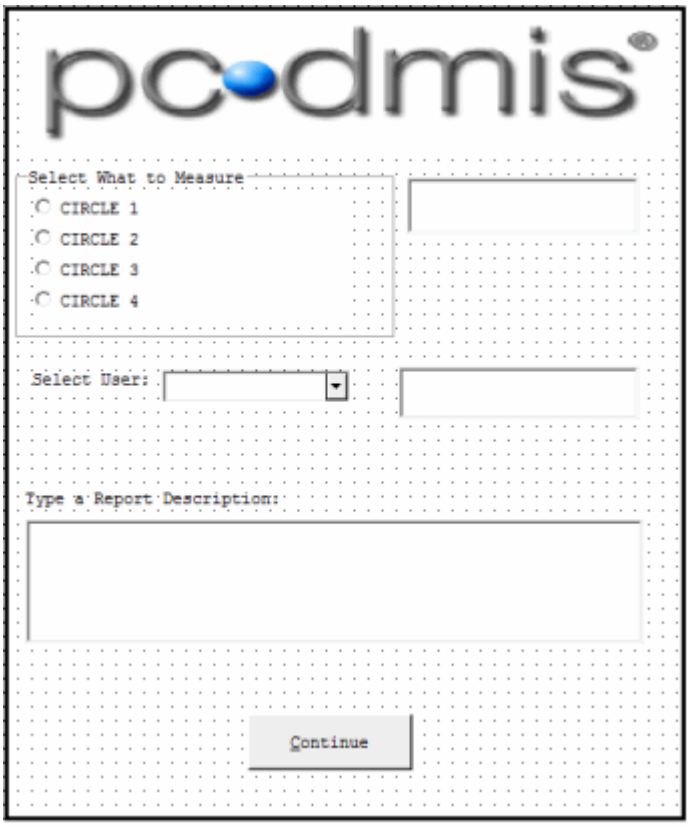
12. Add another **EditBox** object to the right of the above Text object, and rename it from "EditBox3" to "txtDescription".

13. Add a **Button** object to the bottom of the form, and rename it from "Button1" to "cmdContinue". Change its Text property to read "&Continue". The ampersand symbol lets you define whatever character follows it as a shortcut character to be used with Alt. So, pressing Alt + C on your form in Run Mode will act as if you clicked the **Continue** button.

14. Select **File | Save** to save the form. Give it the name "TestForm.Form" and save it in a directory of your choice.

15. Press Ctrl + E to test your form in Run mode. There's no code tied to any of the controls so nothing much happens if you click on anything, but you'll add that next. When finished, press Ctrl + E again to return to Edit mode.

In this step, you have completed the basic form, adding various controls and assigning items to lists. It should look something like this:



Form with the various form controls added

Step 3: Add Code to the RadioButton Control

1. Select the RadioButton object, **optMeasure**, and access its properties.

2. Click on the **EventChange** event. The **VBS Mini Editor** appears. This small code window lets you type Visual BASIC code statements that will run whenever you select a new value from the list of option buttons.

3. In the code window, type this code:

```
Dim intIndex As Integer
intIndex=optMeasure.Index
Select Case intIndex
Case 0
   txtMeasure.Text="Circle 1"
Case 1
   txtMeasure.Text="Circle 2"
Case 2
   txtMeasure.Text="Circle 3"
Case 3
   txtMeasure.Text="Circle 4"
End Select
```

4. Click **OK**. The mini editor closes.
5. Select **File | Save** to save the form.
6. Test your report by pressing Ctrl + E and entering Run mode. Select a feature to measure.

This code runs when you select a feature to measure from the list. It looks at what gets selected from the list of option buttons, and sets the **Text** property of txtMeasure to display a text string of "CIRCLE 1", "CIRCLE 2", and so on. Press Ctrl + E to return to Edit mode.

Step 4: Add Code to the ComboBox Control

1. Select the ComboBox object, **cboUsers**, and access its properties.
2. Click on the **EventChange** event. The **VBS Mini Editor** opens.
3. In this code window, type this code:

```
txtUser.Text=cboUsers.TextValue
```

4. Click **OK**. The mini editor closes.
5. Select **File | Save** to save the form.
6. Press Ctrl + E to enter Run mode to test your report. Select a user.

This code runs when you select a user from the list. It looks at the text value of the selected list item, and sets the **Text** property of txtUser to display a text string of the selected user. Press Ctrl + E to return to Edit mode.

Step 5: Add Code to the Continue button

1. Select the Button object, **cmdContinue**, and access its properties.
2. Click on the **EventClick** event. The **VBS Mini Editor** opens.
3. In this code window, type this code:

```
   If cboUsers.Value>0 And Len(txtDescription.Text)>0
And Len(txtMeasure.Text)>0 Then
      TheView.Cancel
   Else
      MsgBox "Please fill out the entire form before
continuing."
   End If
```

4. Click **OK**. The mini editor closes.
5. Select **File | Save** to save the form.
6. Press Ctrl + E to enter Run mode to test your report. Click the **Continue** button.

This code runs when you click the **Continue** button. It checks to make sure the form is all the way filled out, and if it is, it closes the Form Editor. If not, it displays a message telling the user to fill out what's missing.

- The Len ( ) function tests the length (or the number of characters) for the text string in the edit boxes, making sure something is there.
- The cboUsers.Value > 0 code checks to make sure a user name gets selected from the list.

Step 6: Assign Edit Window Variables to Hold Form PropertiesStep 6: Assign Edit Window Variables to Hold Form Properties

Now that you have defined your form, you need a way to pass data back and forth, between the Edit window and the form.

1. If you haven't already done so, save your form.
2. From the **Window** menu select **Edit Window** to make the Edit window come to the front.
3. Make sure it is in Command Mode.
4. After each Circle feature insert a Location dimension for that circle.

5. Near the top, before the Circle features, define variables that you will assign to work with the form. To do this, type this code in the Edit window *before* the measured Circle features:

```
ASSIGN/STR_DESCRIPTION=""
ASSIGN/STR_USER=""
ASSIGN/STR_MEASURE=""
```

6. Place your cursor immediately after these statements, and select **Insert | Report Command | Form**. An **Insert Form** dialog box opens. Navigate to where you stored "TestForm.FORM", select it, and click **Open**.

7. PC-DMIS inserts a `FORM/FILENAME` command block into the Edit window with a pathway to the selected form file. PC-DMIS runs this form when you mark and execute this command. It then waits until you close the form before it continues execution of the Edit window.

> Notice that this command contains a `PARAM/=` statement, or a "parameter". These parameters let you pass values back and forth between the PC-DMIS Edit window variable and the form control properties.

8. Click just before the left side of the equals sign in the `PARAM/=` statement, and type "TXTDESCRIPTION.TEXT". Click on the right side of the equals sign, and type "STR_DESCRIPTION". Press Enter. Another `PARAM/=` statement appears.

> Remember that **txtDescription** is the name you gave the EditBox object in your form that holds a user-entered description of the report.
>
> During execution, the **Text** property of **txtDescription** initially takes the value of whatever `STR_DESCRIPTION` holds. In this case, it would take an empty string. After you close the form, it passes whatever value the form has back into `STR_DESCRIPTION` .

9. Continue to define parameters in this way for both the `STR_USER` and `STR_MEASURE` variables, tying them to the **txtUser** and **txtMeasure** objects' **Text** properties respectively.

10. Save your changes to the Edit window. When finished, your `FORM/FILENAME` command block, should look something like this.

```
CS7         =FORM/FILENAME=D:\PARTPROGRAMS\TESTFORM.FORM
             PARAM/TXTDESCRIPTION.TEXT=STR_DESCRIPTION
             PARAM/TXTMEASURE.TEXT=STR_MEASURE
             PARAM/TXTUSER.TEXT=STR_USER
             PARAM/=
             ENDFORM/
```

Step 7: Add Edit Window Conditional Code to Control MeasurementStep 7: Add Edit Window Conditional Code to Control Measurement

When you created your form, you created a list of option buttons (using the RadioButton object) to control what exactly gets measured. You now need to add conditional statements into the Edit window too, so that the proper feature gets measured according to what gets selected from the form.

1. In the Edit window, place your cursor right before the first CIR1 feature and press Enter. Your cursor should be in a blank line above the CIR1 feature.
2. Select **Insert | Flow Control Command | Control Pairs | If / End If**. PC-DMIS inserts an IF / END IF conditional statement into the Edit window:

   ```
   IF/0

   END_IF/
   ```

3. Define the condition. Highlight the default value of 0 and type:

   ```
   STR_MEASURE=="Circle 1"
   ```

4. Press the Enter key.
5. Select the entire CIR1 feature and the location dimension following it, and select **Edit | Cut**. Then select **Edit | Paste** to move it onto a blank line after the `IF/ STR_MEASURE == "Circle 1"` line but before the `END_IF/` line. Your first conditional block should look like this:

   ```
   IF/STR_MEASURE=="Circle 1"
      CIR1 feature goes here...
      Location dimension goes here...
   END_IF/
   ```

Remember that `STR_MEASURE` , after execution, will hold the value of the **txtMeasure** object's **Text** property. According to the form code, this is either:

"Circle 1", "Circle 2", "Circle 3", or "Circle 4".

This first line checks the variable value of `STR_MEASURE` and if it matches the string value of "Circle 1" then it measures the CIR1 feature. If not, it skips and goes to whatever follows the END_IF/ statement.

6. Continue repeating the above steps, defining conditional statements for the other circle features as well. When finished, your Edit window code should look something like this:

```
            ASSIGN/STR_DESCRIPTION=""
            ASSIGN/STR_USER=""
            ASSIGN/STR_MEASURE=""
CS7        =FORM/FILENAME=D:
\PARTPROGRAMS\TESTFORM.FORM
            PARAM/TXTDESCRIPTION.TEXT=STR_DESCRIPTIO
N
            PARAM/TXTMEASURE.TEXT=STR_MEASURE
            PARAM/TXTUSER.TEXT=STR_USER
            PARAM/=
            ENDFORM/
            IF/STR_MEASURE=="Circle 1"
CIR1       =FEAT/CIRCLE...
DIM LOC1 LOCATION OF CIRCLE CIR1
            END_IF/
            IF/STR_MEASURE=="Circle 2"
CIR2       =FEAT/CIRCLE...
DIM LOC2 LOCATION OF CIRCLE CIR2
            END_IF/
            IF/STR_MEASURE=="Circle 3"
CIR3       =FEAT/CIRCLE...
DIM LOC3 LOCATION OF CIRCLE CIR3
            END_IF/
            IF/STR_MEASURE=="Circle 4"
CIR4       =FEAT/CIRCLE...
DIM LOC4 LOCATION OF CIRCLE CIR4
            END_IF/
```

Step 8: Add Finishing Touches

Now, you need to apply some finishing touches. First, you need to tell PC-DMIS to send the values of our form to the final report in the Report window with report comments. Then you need to make some objects invisible on the form.

1. In the Edit window, type these commands immediately following the `FORM/FILENAME` command block.

```
COMMENT/REPT,
"User: "+STR_USER
COMMENT/REPT,
"Report Description: "+STR_DESCRIPTION
COMMENT/REPT,
"Measure Routine: "+STR_MEASURE
```

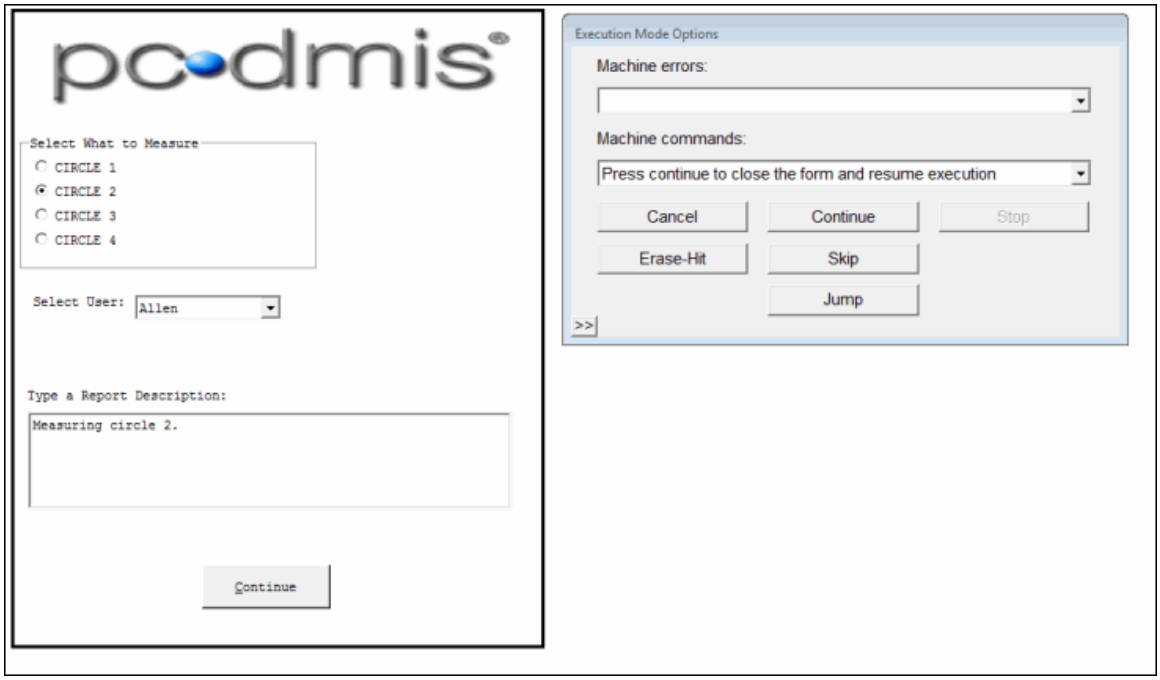
> After you insert a PC-DMIS comment, to type additional PC-DMIS commands in Command Mode, you must first press Enter *twice* after the `COMMENT` command. This tells PC-DMIS that you no longer want to add text to the comment but are ready to add a new command.

2. Select **Window | Form Editor** to go back to the Form Editor.
3. Right-click to access the **Properties** dialog box. Select **txtMeasure** from the drop-down list. PC-DMIS selects the object.
4. Click **Advanced** and set the **Visible** property to NO.
5. Select **txtUser** from the drop-down list. PC-DMIS selects the object.
6. Click **Advanced** and set the **Visible** property to NO. Since a user doesn't need to see these values and the only reason we used them was to pass a value back to PC-DMIS, setting this property to NO makes these objects invisible during execution.
7. Save your form.
8. Close the Form editor.

Step 9: Execute the Measurement Routine

1. Select **View | Report Window** and use the **Template Selection Dialog** toolbar icon to set the report to use the default standard report template, TextOnly.rtp.
2. Return to the Edit window. Mark the entire Edit window, save your measurement routine, and then select **File | Execute** to test your measurement routine.

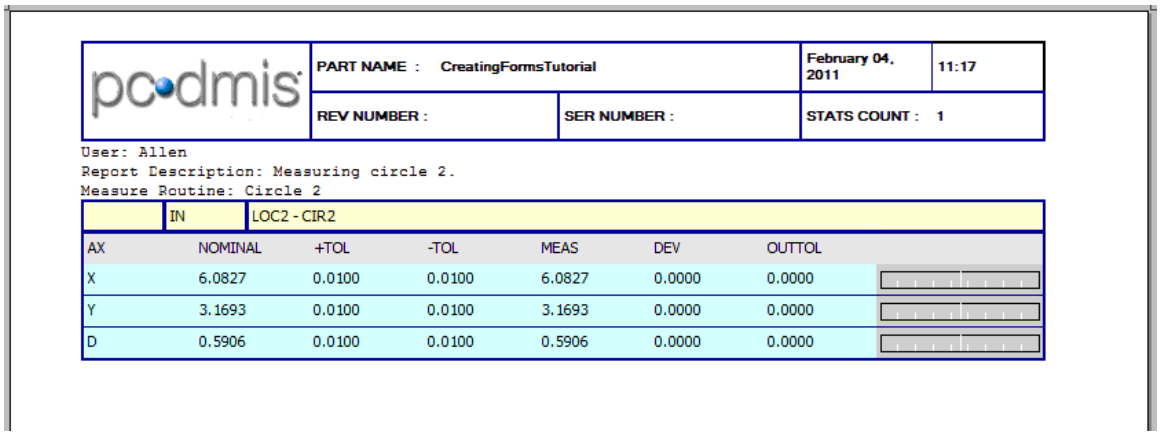
3. When PC-DMIS reaches the `FORM/FILENAME` command, it runs the form and pauses execution until you finish filling it out.



4. Fill out the form and click the **Continue** button. PC-DMIS passes the values from the form back into the PC-DMIS variables.

5. The conditional statements check the value of the `STR_MEASURE` variable and execute the appropriate Circle feature accordingly.

6. PC-DMIS prints the report comments and the measured results for the measured feature to the Report window.



Using Forms with Reports

Forms usually only modify reports indirectly. For example, you may have a form that controls whether or not certain features get executed. In this case, the final report isn't modified directly, but indirectly because reports always show what gets executed anyway.

You can however use the `FORM/FILENAME` command to pass parameters back and forth between the Edit window and a form's objects, and use Comments to cause those parameters to appear in a final report. See the "Creating Forms" tutorial and the "Inserting a FORM Command" topic for examples of this type of forms use.

Additionally, after getting the values from a form into the Edit window, you can also use the `REPORT/TEMPLATE` command to pass parameters from the Edit window into a report template in the same way that you use the `FORM/FILENAME` command.

Select **Insert | Report Command | Template Report** to insert a `REPORT/TEMPLATE` command, then assign parameter values to modify object properties in the report template. See the "Creating Forms" tutorial on how to do this, using the `FORM/FILENAME` command as a guide, but instead of selecting a .FORM filename, select a Report Template (.rtp filename). Also, see the "Embedding HyperView Reports or Report Templates in a Measurement Routine" topic.

Creating Custom Reports

Custom reports provide a flexible and easy-to-use approach to creating reports for your measurement results. This is most useful when you need to generate a report quickly and simply for a specific measurement routine, but you don't need the power available to the template-based approach. Since custom reports do not use any report template, and instead utilize your current measurement routine's data directly, custom reports are generally easier to create and customize, but they lack the power and scope of template reporting.

Advantages of Custom Reporting:

- You can place the data anywhere on the page and in any order.
- You can combine the data from multiple commands as a single element on the report.
- You can generate the reports by unique drag-and-drop method.
- The report editor uses the actual data from the measurement routine, not the dummy data. This makes customizing the report much simpler.

Disadvantages of Custom Reporting:

- You are creating a single report, not a template, and this report is tied to your measurement routine. While you can import the structure of the report to use with other measurement routines, the reusability is not as great as with report templates designed with specific rules.
- It isn't as extensible as template reporting. Suppose you add a new feature or dimension later to your measurement routine. For it to show up, you will need to drag and drop the new item into your report editor.

The following topics provide you with a tutorial that walks you through how to create, view, and print your first custom report. Procedural topics will also be provided for quick access should you need them later.

About the Custom Report Editor

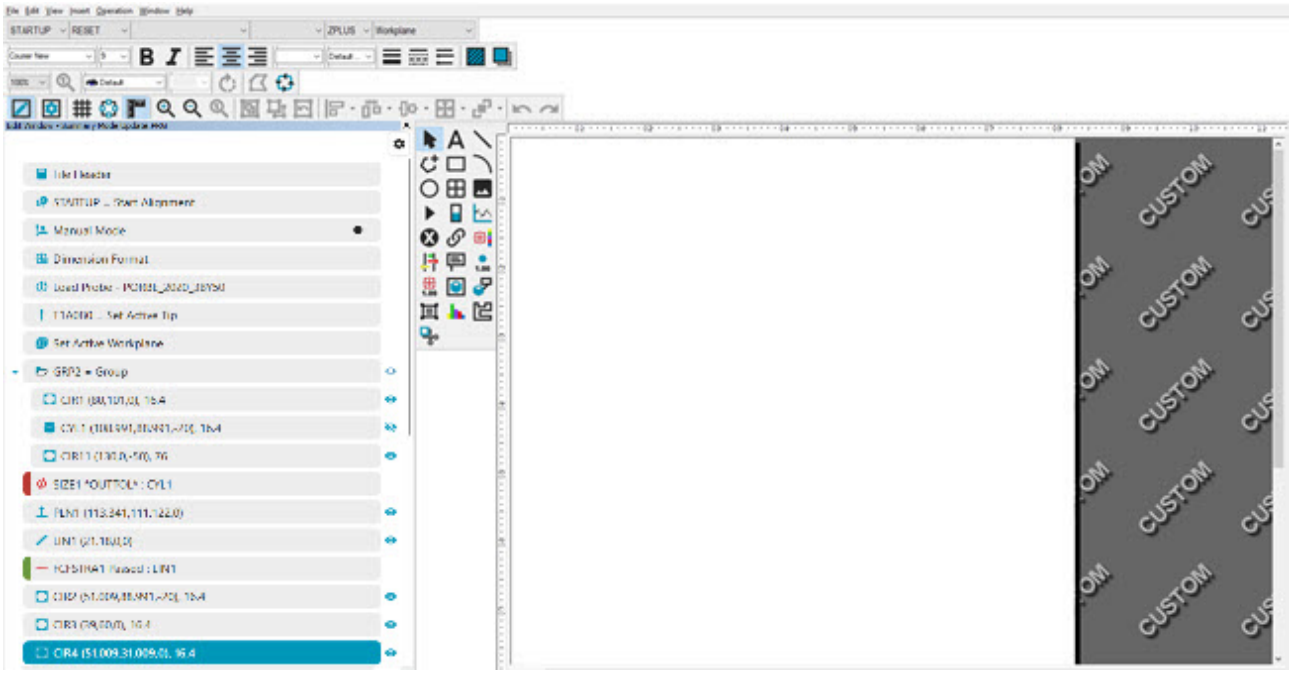
To access the Custom Report Editor, select **File | Reporting | New | Custom Report**. To open an existing custom report for your current measurement routine, select **File | Reporting | Edit | Custom Report**.

You can access a slimmed down version of this editor from the Report window's **Reporting** toolbar. This lets you edit a report without leaving the usual PC-DMIS menu structure.

You can access this editor through either of these options:

- Click **Custom Report selection dialog** ( ) and then click **Blank Report** and then **Open**.
- Click **Edit report** ( ).

PC-DMIS displays the Custom Report Editor with the Edit window placed into Summary Mode next to it.



Custom Report Editor with the Summary Mode to its left

This editor is similar to the Report Template Editor, Label Template Editor, and Form Editor. With the exception of some differences in its **Object Bar**, the user interface is essentially the same.

The custom report is the white and sizable area on top of the "CUSTOM" background. Note that when you use this editor, you do not create a template, but create the actual report that appears in the Report window. When you create a new custom report, this editor opens side by side with the Edit window set in Summary Mode. This allows you to drag the desired objects from Summary Mode onto your Custom Report. See "Creating Custom Reports".

With the Custom Report Editor, you cannot place the Report or Label template editors into Run mode as you did with the HyperView editor. The Custom Report Editor only opens in Edit mode and cannot be switched to Run mode. Run mode functions only with the HyperView editor or the Form Editor.

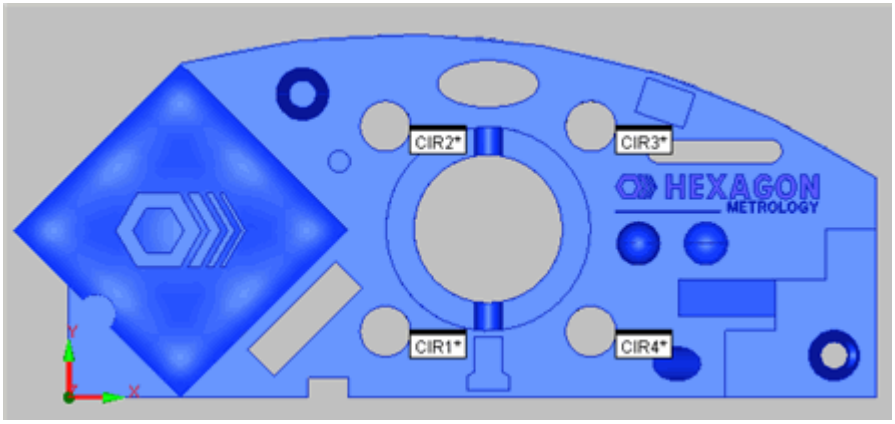
The editor contains the following elements:

- The Menu bar
- The Font Bar (toolbar)
- The Object Bar (toolbar)
- The Layout Bar (toolbar)
- Object Property Sheets

Tutorial - Creating a Custom Report

This topic walks you through a very basic tutorial that will result in you creating a simple custom report. This should give you a basic overview of how to create custom reports within the Custom Report Editor and how they interact with existing label templates so you can later create and use your own custom reports.

Before you begin this tutorial, create a simple measurement routine that has four measured circles on a simple part and four Circularity dimensions, one for each circle. This tutorial uses the Hexagon test block (Hexblock_Wireframe_Surface.igs).



Example showing the four circles.

Step 1: Setting Up the Work Environment

In this tutorial you will use the Edit window in Summary Mode along with the Custom Reporting Editor.

1. Select **File | Reporting | New | Custom Report** from the menu bar to show both the Custom Report Editor and Summary Mode next to it.

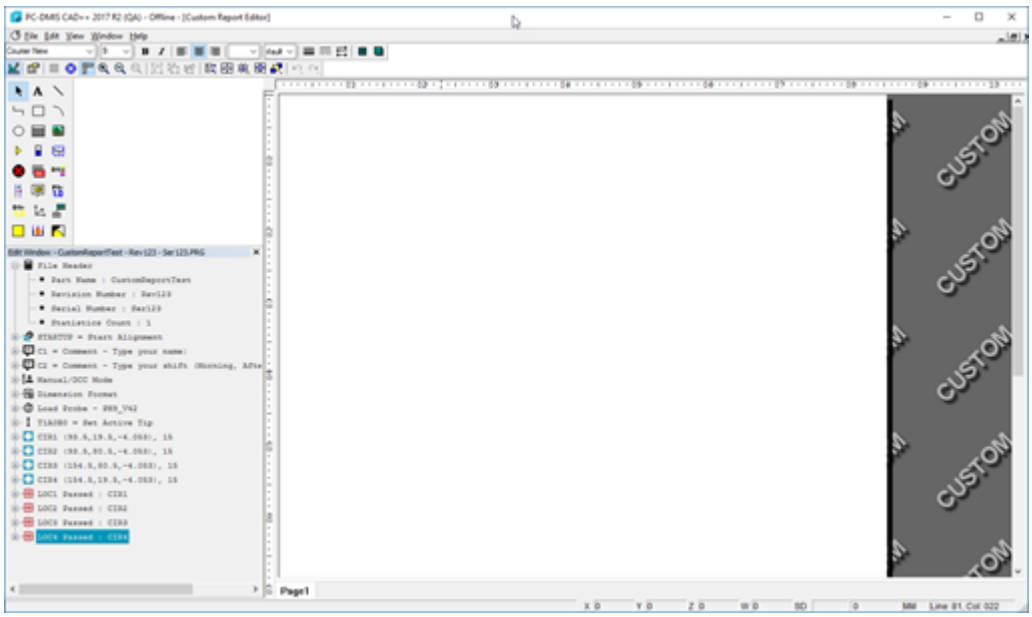
   > You can also create a new report from the **Custom Report Selection dialog** icon ( ) on the Report window's **Reporting** toolbar. From the dialog box that appears, click **Blank Report** and then **Open** to create the blank report.

2. To hide any unused toolbars, right-click on the toolbar area and remove them.

3. To hide any unused PC-DMIS windows, select the open window from the **View** menu. Keep the Edit window open.

4. To maximize the Custom Report Editor, click the maximize button in the upper right corner of the editor's window. You should see the words "CUSTOM" on the background of the editor.

5. Drag the Edit window underneath the Custom Report Editor's **Object Bar**. Your work environment should now look something like this:



When working with the Custom Report Editor, you may find it helpful to hide your usual PC-DMIS toolbars and windows, thereby freeing up some screen space. If you work frequently with this editor, you may want to create a stored screen layout for it. For information on layouts, see the "Window Layouts Toolbar" topic in the "Using Toolbars" chapter.

Step 2: Dragging, Dropping, and Positioning Objects

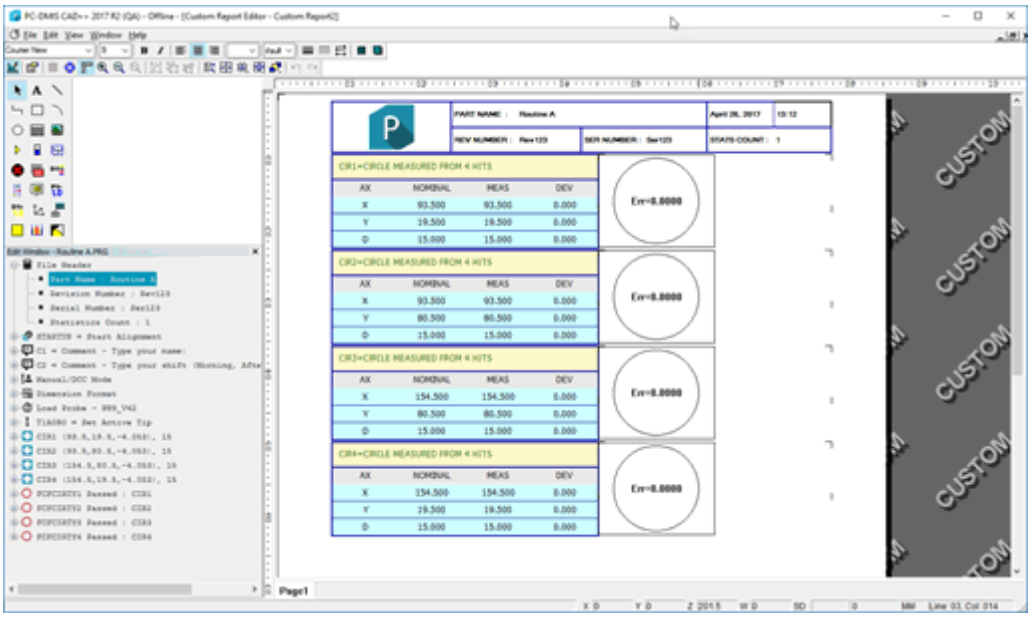
In this step, you will drag the report items into the Custom Report Editor.

1. From the Edit window in Summary Mode, select **File Header**, and drag it out onto the editor. You will notice a transparent image of that item's icon as you drag it out onto the work area.
2. Release the mouse button. PC-DMIS creates a File Header object in the editor.
3. Drag and drop CIR1 and CIR2 onto your report. Don't worry about positioning them properly. For now, just drop them into any empty space on the first page of the report.
4. In the Report Editor, select the **File Header** object already in your report, and drag it to a place near the top of the report and center it horizontally on the page.
5. Next, select the label object for CIR1, and drag it so that the top edge is just under the bottom edge of the File Header object. Try to align their left sides as well.
6. Repeat this step for CIR2.
7. Now, drag the CIR3 feature from the Edit window to the bottom of the label used for CIR2. Notice that as you move your mouse over the various labels already in the editor, green handles appear around the labels. When the blue arrow appears just below CIR2, release the mouse. The feature is dropped into the editor below CIR2, and the label object for it becomes automatically aligned with the object above it.

8. Repeat the above step for CIR4, attaching it just below CIR3.

9. Select **File | Save**. A dialog box will appear, which allows you to save your report. Choose any name and click **Save**.

Your Custom Report Editor should look something like this:



Step 3: Using Multiple Pages

In this step, you will work with multiple pages. You will add two additional pages and modify one page to support a different page size. Then you will rearrange the pages.

1. In the Report Editor, at the bottom of the page, right-click on the **Page1** tab and select **Add Tab**. A new page appears, called **Page2**.

2. Right-click on that page. The **Properties** dialog box appears.

3. Change **Height** to 850, and press the Tab key.

4. Change **Width** to 1100, and press the Tab key. Changing these two properties essentially formats the page for Landscape printing.

5. Create a third page, **Page3**.

6. Right-click on **Page2**, and click **Move Right**. Notice how this moves the **Page2** tab to the right of **Page3**.

7. Right-click on **Page3**, and click **Move Left**. Your pages are now reordered to show **Page3**, followed by **Page1**, followed by **Page2**. In this way, you can rearrange your pages.

8. Save your report.

Your report now has three pages, and their order has been changed.

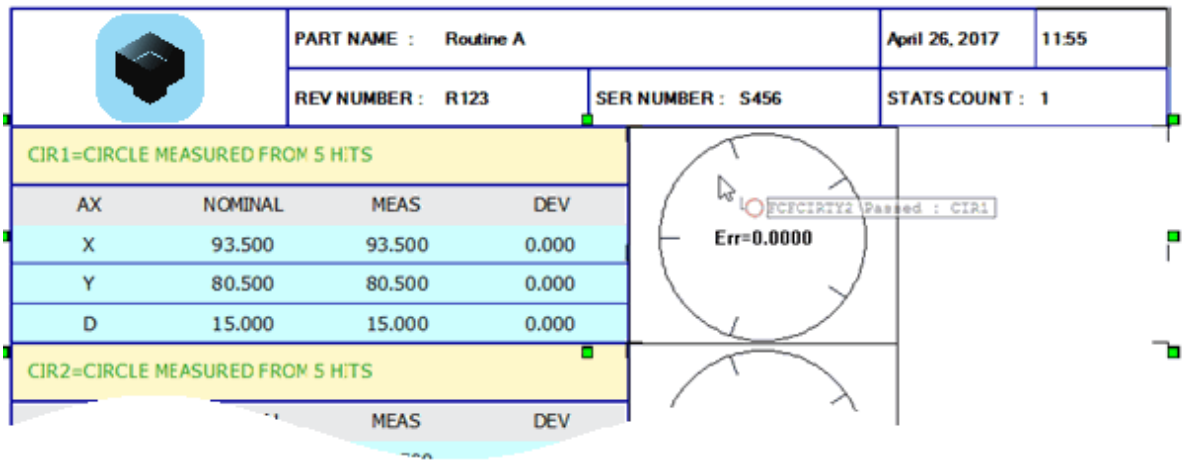
Step 4: Dropping onto Other Objects

This step demonstrates how you can replace existing label objects with new label objects and how to use the **CADReportObject** inside a custom report.

1. In the Custom Report Editor, select the **Page1** tab. To replace any object in your report, drag and drop any other item of a similar type on top of it. For example, you can drop any item that uses labels on top of any existing label in your editor.

2. Select the label in your report for the CIR1 feature. You should already have four Circularity dimensions. If not, create them now, one for each circle feature.

3. Drag the Circularity dimension for the CIR1 feature from your Edit window and drop it on top of the feature label already in your report editor for CIR1, like this:



Example of the label object updated with a new label object.

4. If the updated object moved, reposition it.

5. Drag the other dimensions on top of their respective feature labels in the editor. PC-DMIS updates all the labels accordingly, so that they look something like this:

	PART NAME : Routine A				April 26, 2017	13:12
	REV NUMBER : Rev123		SER NUMBER : Ser123		STATS COUNT : 1	
FCFCIRTY1	MM			0.01		
Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
CIR1	0.000	0.010		0.000	0.000	0.000
FCFCIRTY2	MM			0.01		
Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
CIR2	0.000	0.010		0.000	0.000	0.000
FCFCIRTY3	MM			0.01		
Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
CIR3	0.000	0.010		0.000	0.000	0.000
FCFCIRTY4	MM			0.01		
Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
CIR4	0.000	0.010		0.000	0.000	0.000

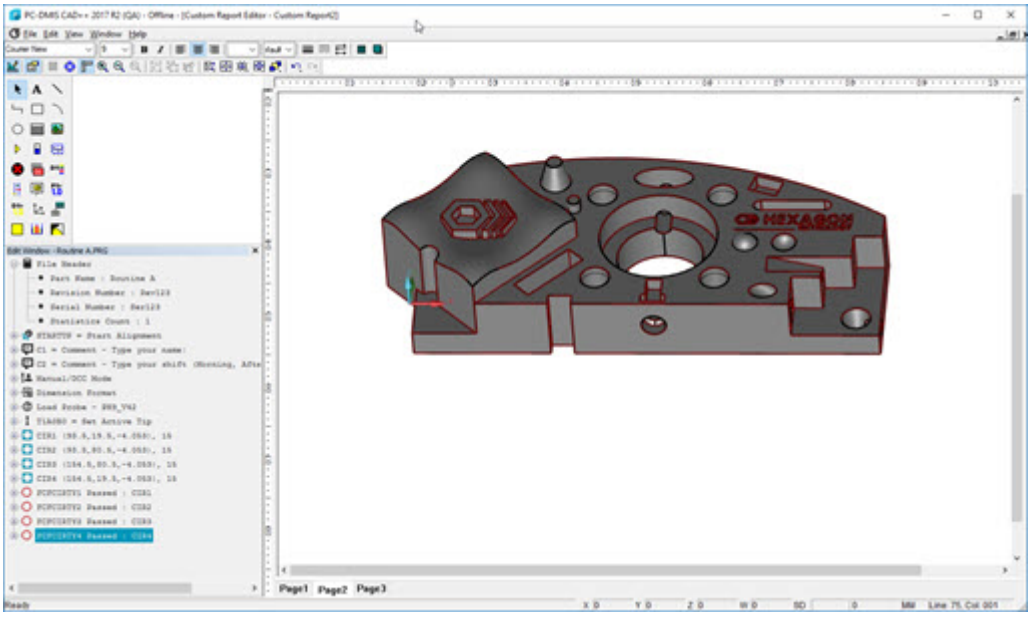
Report Editor showing the four dimension labels.

6. Now, click on the **Page2** tab. Drag a **CADReportObject** from the **Object Bar** onto that page, and size it so it fills the page.

7. Drag the four dimensions one at a time on top of the **CADReportObject**. For this object, notice PC-DMIS does not replace it with a label object for the dimension. Instead, PC-DMIS automatically creates the appropriate labels and leader-lines on top of the **CADReportObject** for the dimensions.

8. Save your report.

Page1 now has dimension labels instead of feature labels, and the **CADReportObject** in **Page2** should look something like this:

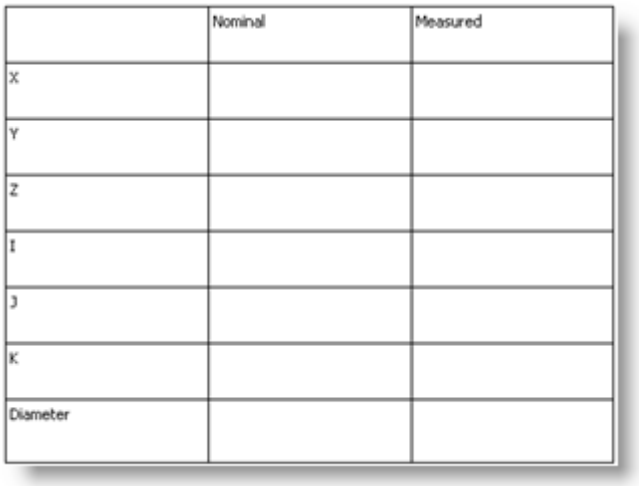


Step 5: Inserting Data Items

In this step, you will insert a **GridControlObject** and get it ready to display values from the Edit window.

1. Click on the **Page3** tab.

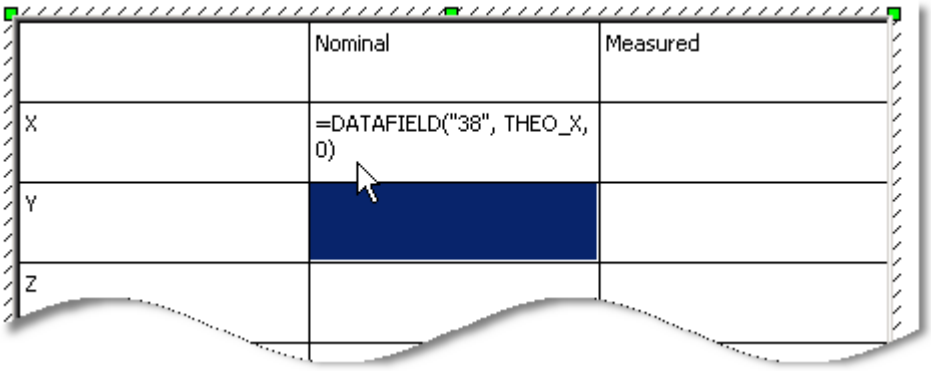
2. Click on the **GridControlObject** icon, and drag the object onto the page.
3. Access the **Properties** dialog box, and set **NumRows** to 8 and **NumCols** to 3.
4. In the first row, the middle cell, double-click, and then type "Nominal". In the right cell, do the same, and type "Measured".
5. Starting with the first row, and first column, and then moving down through the other rows, type "X", "Y", "Z", "I","J" ,"K", and "Diameter". This fills in rows 2 through 8 in column 1. Your GridControlObject should look like this:



A GridControlObject with Static Text

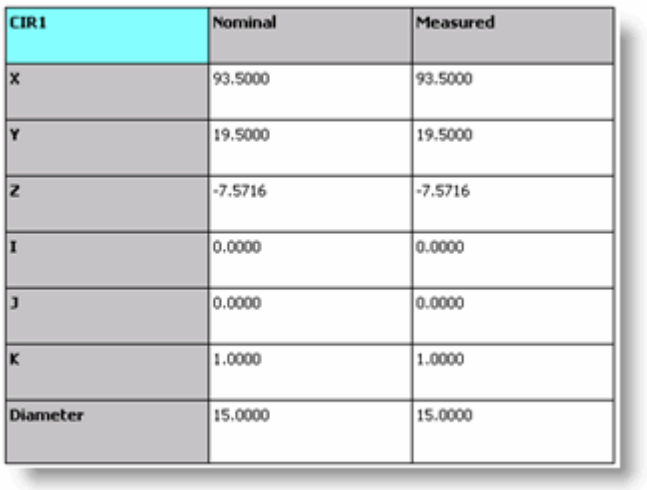
> Remember when typing information into a cell, you must click in another cell or press the Tab key for the value to actually be displayed.

6. Double-click on the item to type the expression in the cell. This cell dynamically displays the data which means the information is not hard coded. If the value changes, PC-DMIS updates the data in your report to match.



Example of the data item's expression.

7. Finally, apply some text and background formatting of your choice to row 1 and column 1, and then save your report. The **GridControlObject** should look similar to this:



CIR1	Nominal	Measured
X	93.5000	93.5000
Y	19.5000	19.5000
Z	-7.5716	-7.5716
I	0.0000	0.0000
J	0.0000	0.0000
K	1.0000	1.0000
Diameter	15.0000	15.0000

A Sample GridControlObject containing data items.

8. Select **File | Close** to close the Custom Report Editor.

   Your values may differ based on the part and circles measured.

Step 6: Viewing, Updating, and Printing your Report

This final step explains how to load your custom report into the Report window, how to view it, how to update a report from a measurement routine that changes, and finally how to print it.

1. Select **View | Report Window** to access the Report window.
2. From the Report window's **Reporting** toolbar, select **Custom Report Selection Dialog** . A dialog box appears and shows all custom reports.
3. Select your report and click **Open**. Your report appears in the Report window.
4. Next, you will update your report. Select **File | Reporting | Edit | Custom Report**. A dialog box appears and shows all the reports you've created for your current measurement routine.
5. Select your report and click **Open**. Your report opens inside the Custom Report Editor.
6. Go ahead and make any change to your report in the editor, and then save your report again.
7. To get the newly-updated report to appear in the Report window, re-execute your measurement routine, or click the **Redraw** icon from the **Reporting** toolbar.
8. Finally, you need to print your report. Select the **File | Printing | Report Window Print Setup** menu item. The **Output Configuration** dialog box appears.
9. Select the **Report** tab. In the **Output Options** section, mark the **Printer** check box to send the report to your printing device.

10. From the Report window's **Reporting** toolbar, click the **Print** icon. PC-DMIS prints your report.

In this step, you've loaded an existing report into the Report window, updated it, and then sent it to your printer.

Congratulations! You've successfully completed the Creating a Custom Report tutorial.

Custom Report Generation

To create a new custom report, follow these steps:

1. Select **File | Reporting | New | Custom Report** to open the **Custom Report Editor** and show the Edit window in Summary Mode.
2. Drag items from the Edit window and drop them into the editor.

> PC-DMIS automatically uses the labels defined by the current **Page** object's rule set to display the objects. If you drop an object and it doesn't have an associated label, an **Open** dialog box appears so that you can choose a label defined for the dropped item.

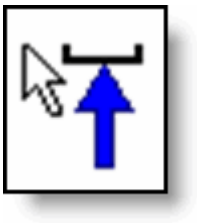
3. Add and configure additional objects from the editor's **Object Bar** as needed.
4. Position report elements as desired.
5. Select **File | Save** to save your report. A dialog box opens to allow you to specify the name of your report.

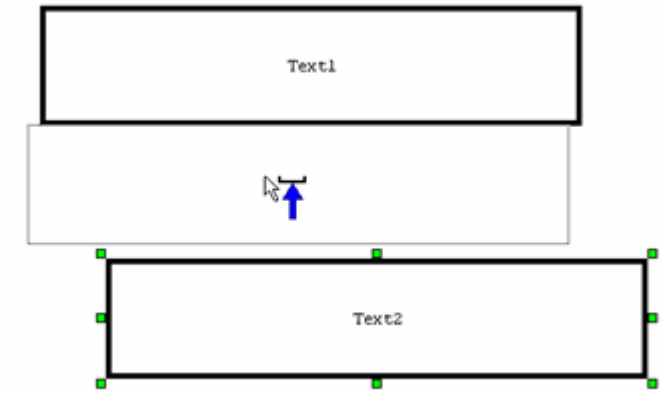
> Another way you can create a new custom report is to use the **Reporting** toolbar. (For information on the Reporting toolbar, see "Reporting Toolbar".)
>
> 1. From Report window's **Reporting** toolbar, click the **Custom Report Selection dialog** button ( ).
> 2. Double-click on **Blank Report** to create a new blank custom report.
> 3. Edit the report as usual.
> 4. Click the **Edit report** button ( ) to close edit mode and follow the prompt to save your report.

Positioning Report Objects

Inside the Custom Report Editor (**File | Reporting | New | Custom Report**), you can position objects by dragging objects where you want them or by using the appropriate alignment icons from the editor's **Layout Bar**.

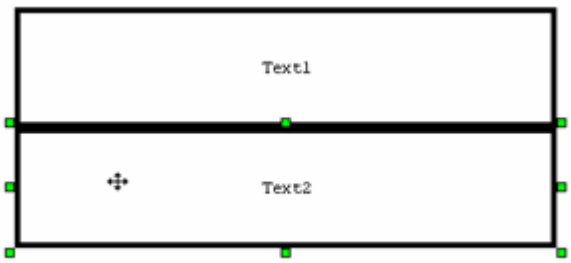
In addition, PC-DMIS provides a useful tool to essentially snap an object below an object above it. To do this, slowly drag an object so that its top and left edges are more or less aligned with another object's bottom and left edges. Your mouse pointer will change to include a small blue arrow: This arrow indicates that the object's left side you are positioning will be aligned with the object's left side above it.





Example showing the object's alignment using the blue arrow.

When this arrow appears, you can release you mouse button, and the object you are dragging will align itself to the other object:



Example showing the aligned objects.

The blue arrow can also help with dropping an object precisely under another object. Simply drag the object over an existing object until green handles appear around the existing object, then drag the mouse slightly under that object until the blue arrow appears.

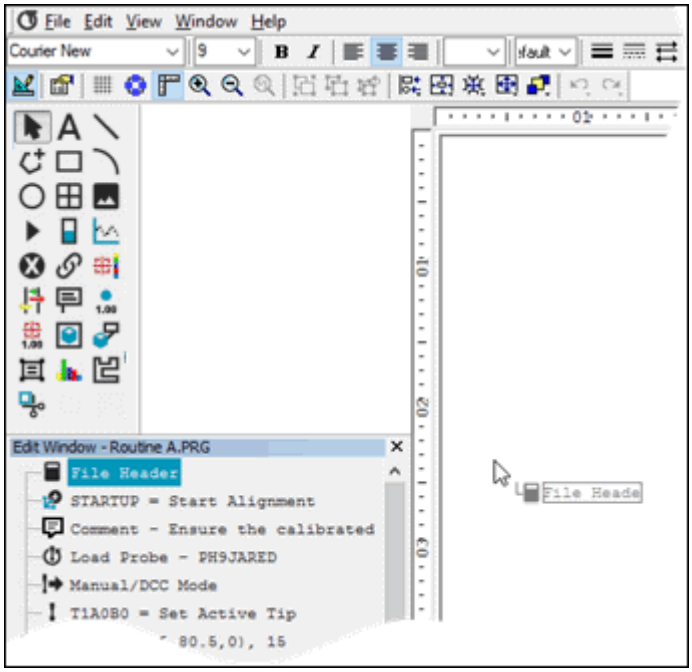
Release the mouse when it appears, and the dropped object will appear aligned to the other object.

This allows you to create a list of objects without white space in between, useful when aligning a list of labels containing your feature or dimension data.

Dragging and Dropping Information into a Custom Report

As the "Custom Report Generation" topic describes, you can drag features and other items from the Edit window in Summary Mode into the Custom Report Editor (**File | Reporting | New | Custom Report**).

You cannot drag the command properties from the Edit window in Summary Mode into the Custom Report Editor.



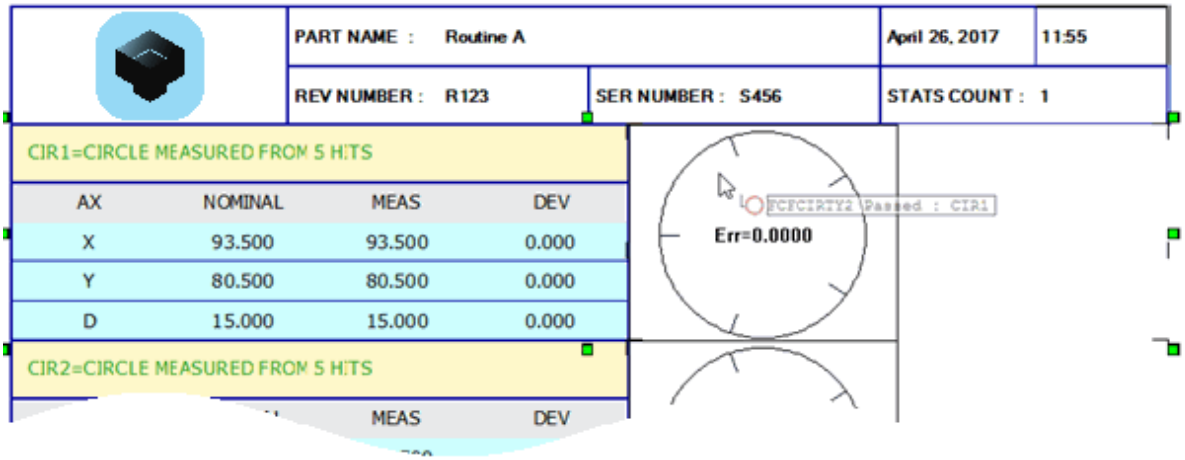
Example of dragging a File Header object onto the editing area (the Page object)

When you drop an item into the editor, the appropriate label for that feature, as defined by the **Page** object's **Rule Tree Editor**, automatically gets created:

Example of a dropped File Header object

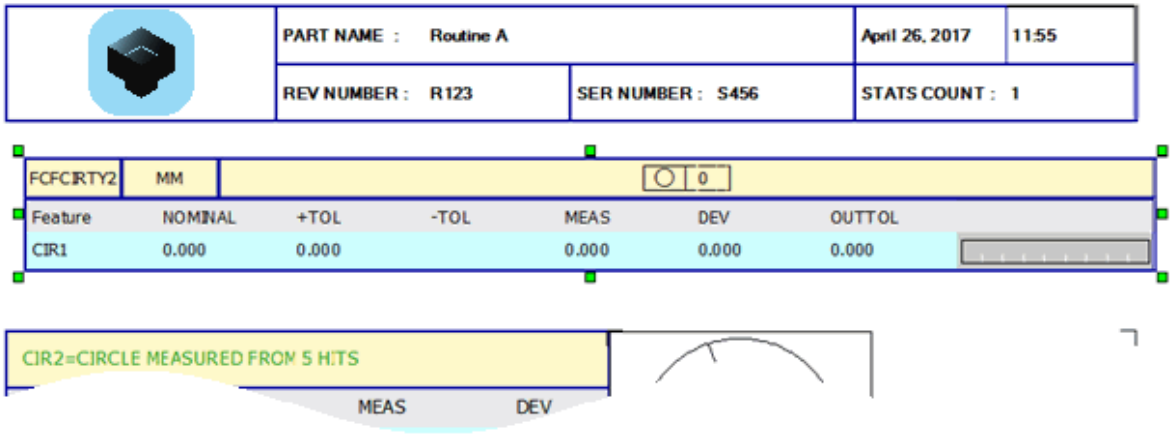
Replacing Information by Dropping on Top of Existing Labels

If you drag an item on top of an existing label, like this:



Example of dropping a Dimension on top of an existing label

PC-DMIS replaces the existing label with the dropped item:



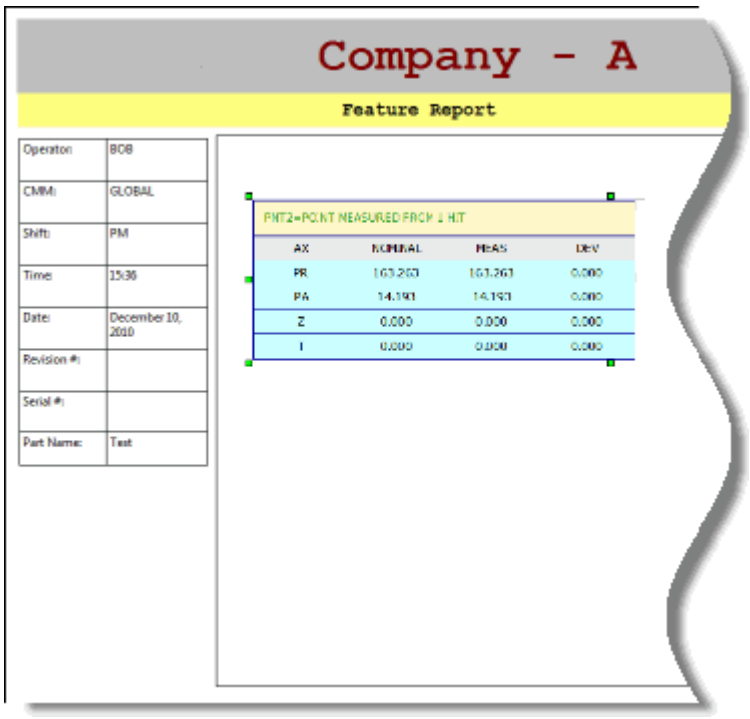
Example of the updated label

Dropping a Floating Label by using the Alt Key

If you drag an item on top of an existing label while you press the Alt key, like this:

Example of Dragging on top of a Large Page-Size Label

PC-DMIS does NOT replace the information in the label with what you dropped. Instead, it floats the new label on top of the existing label.

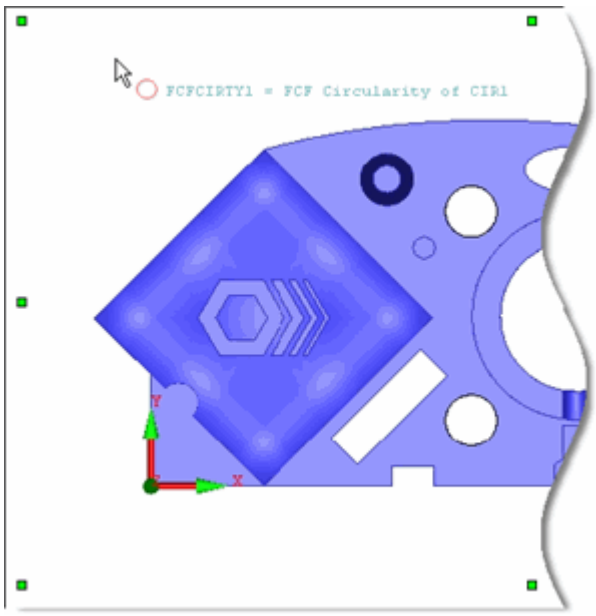


Example of dropping onto a large page-size label with Alt key pressed

You may find this useful if you have a large custom label that covers much of the page, and you want to place new labels on top of that label instead of updating it.

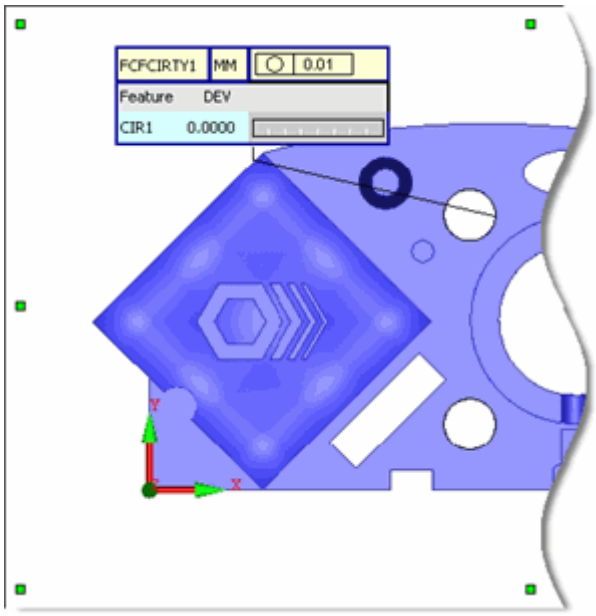
Dropping Feature or Dimension Data on a CADReportObject

If you drag a feature or dimension on top of a **CADReportObject** (CRO), like this:



Example of dropping a Dimension on top of a CRO

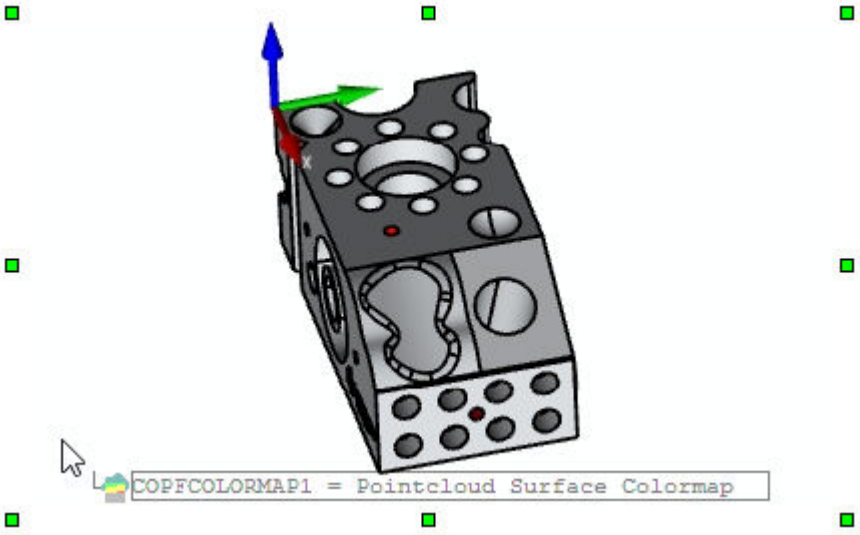
PC-DMIS adds the appropriate label object and leader-line for the dropped object on top of the CRO. The label that PC-DMIS shows depends on the label specified in the CRO's Rule Tree Editor and not the Rule Tree Editor for the **Page** object.



Example of a dropped dimension on top of a CRO

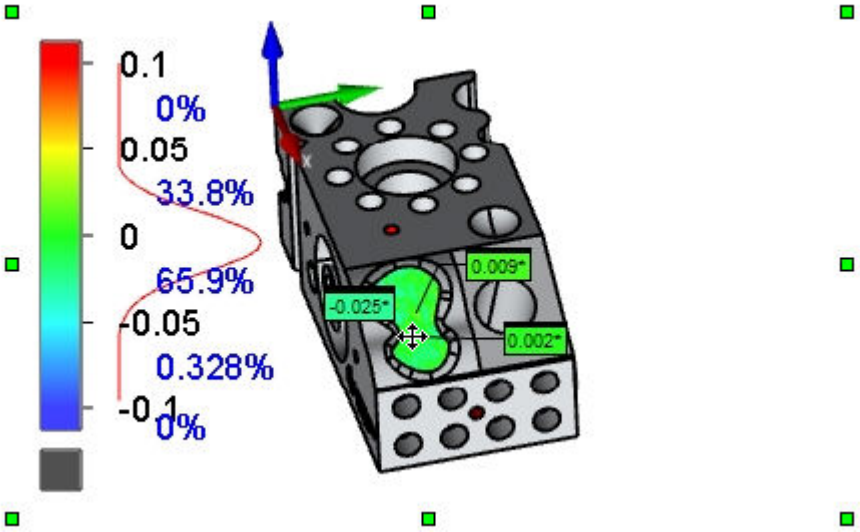
Dropping Colormaps on a CADReportObject

If you drag a colormap on top of a **CadReportObject** (CRO), like this:



Example of dropping a surface colormap onto a CRO

PC-DMIS displays the colormap on the CRO:

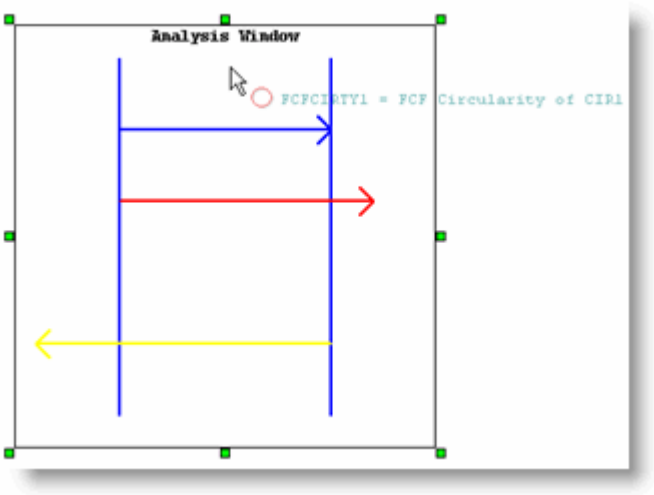


Example of dropping a surface colormap onto a CRO

For more information on using colormaps with the CRO, see "Colormaps and the CadReportObject".

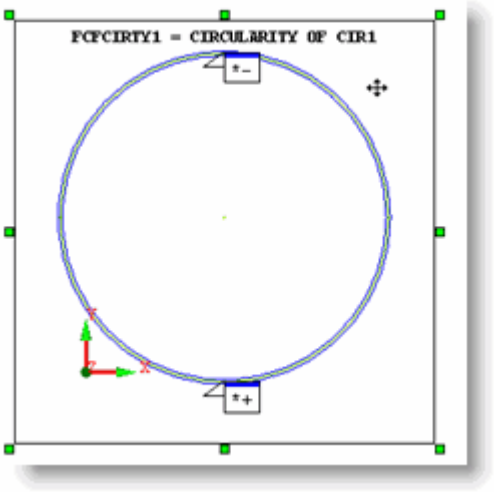
Dropping Data on an Analysis Object

If you drag a dimension on top of a **Analysis** object, like this:



Example of dropping a Dimension on top of an Analysis object

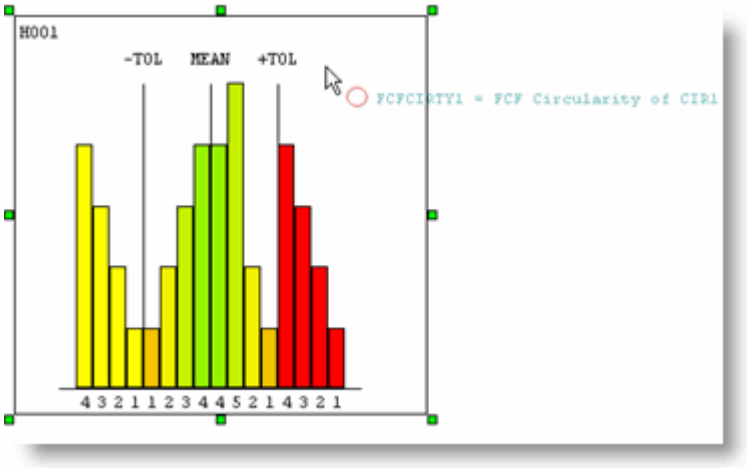
PC-DMIS displays the graphical analysis information for the dropped dimension inside the **Analysis** object.



Example of a dropped Dimension on top of an Analysis object

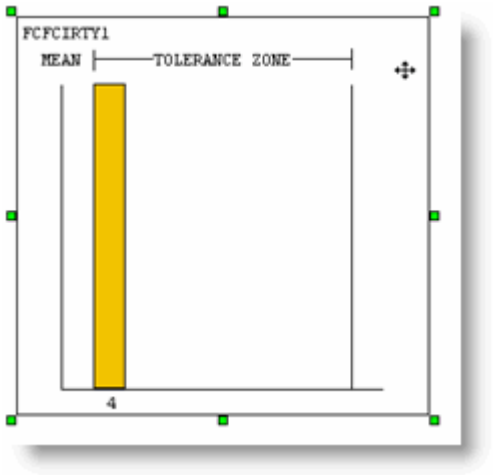
Dropping Data on a DimensionHistogram Object

If you drag a dimension on top of a **DimensionHistogram** object, like this:



Example of dropping a Dimension on top of a DimensionHistogram object

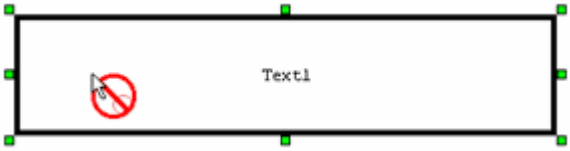
PC-DMIS displays the histogram information for the dropped dimension inside the **DimensionHistogram** object.



Example of a dropped Dimension on top of a DimensionHistogram object

Invalid Drop Areas

If you try to drop an item on top of an invalid object (for example if you drag a feature or dimension on top of a Text object), PC-DMIS changes your pointer to display a red "not allowed" symbol to show you that you cannot drop that item there.



Example of an invalid drop area for a dragged dimension

Using Shift and Ctrl Keys When Dropping

While you perform the drop of a command (such as a feature or dimension), if you hold down the Shift or Ctrl key and release the button, PC-DMIS does the following:

- Shift key - PC-DMIS inserts a CommandTextObject for that item. This lets you display the information for that item in a textual, non-table format.
- Ctrl key - PC-DMIS displays an **Open** dialog box, which enables you to select a different label template for the item.

When performing a drop of a data item, if you hold down the Ctrl key, PC-DMIS displays the evaluated expression for the data item as well as the descriptive string of text from the Summary Mode that precedes it.

Dropping Multiple Items

You can drag multiple items at once from the Edit window in Summary Mode. This is useful if you want to quickly add several items into your report.

- To select an entire list of consecutive items, click the first item, press Shift on the keyboard, and click the last item. All items between them are selected.

- To select or deselect individual items to or from your existing selection, press and hold the Ctrl key while you click on items.

Once you have selected a list of items, drag them into the editor.

Using Rules

Like template reports, custom reports use the **Rule Tree Editor** to determine what label templates should be used in your report. A default set of rules is automatically included, so you only need to change the default rules if you want to load some sort of custom label template.

To work with these rules,

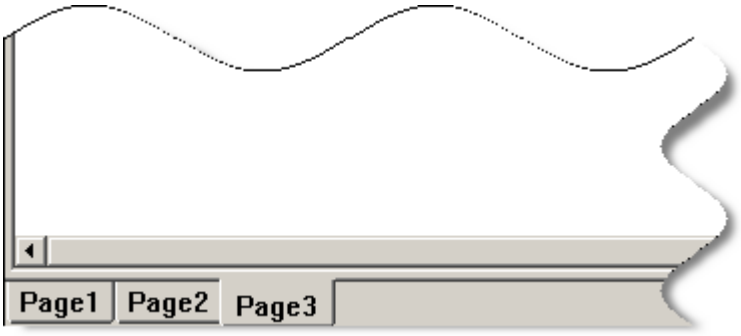
1. Right-click on the editing area (the **Page** object) in the **Custom Report Editor** (**File | Reporting | New | Custom Report**).
2. Select **Properties** from the small popup menu to open the **Properties** dialog box.
3. Click on **Rule...** in the **Rule Tree Editor** property. The **Rule Tree Editor** appears.
4. Modify the rules as desired.

For information on accessing and using the Rule Tree Editor, see "About the Rule Tree Editor".

Working with Multiple Pages

When you create a new custom report using the **Custom Report Editor** (**File |Reporting | New |Custom Report**), the editing area is blank. No objects exist in the editing area except for the editing area itself. The editing area is actually a **Page** object, and its properties can be modified as with any other object. Simply right-click on the object and select **Properties**.

Similar to **Section** tabs in the Report Template Editor, you can create multiple **Page** tabs (**Page** objects) in the **Custom Report Editor**. To do this, right-click on the tab and select **Add Tab** from the popup menu. An additional tab appears at the bottom of the editing area:



Multiple Page Tabs

This will create additional reporting pages that will later appear in the Report window. While similar to **Section** tabs, **Page** tabs reflect a single additional page in your final report, whereas a single **Section** tab may actually end up displaying multiple pages in the final report depending on any defined rules for objects in that section and the length of your measurement routine.

You can size your Page objects to meet different needs. For example, you can modify one page's properties to display its contents in a standard Portrait format and another page's properties to display its information in a Landscape format or to match printer or page settings for a specific locale.

You can easily reorder pages as well. To do this, right-click on a **Page** tab, and select either **Move Right** or **Move Left**. The tabs at the bottom of the Editing area will be reordered accordingly.

From the Report window's preview pane, you can also create and reorder pages. From that pane, you can drag and drop objects to move them from one page to another. For more information, see "Working with the Preview Pane".

Viewing and Printing Custom Reports

Custom reports are viewed and printed using the Report window.

To view your report, follow these steps:

1. Access the Report window (select **View | Report Window**).
2. From the Report window toolbar, select the **Custom Report Selection Dialog** icon . A dialog box appears showing all custom reports.
3. Select your report and click **Open**. Your report appears in the Report window.

To print your report, follow these steps:

1. Define your output using the **File | Printing | Report Window Print Setup** menu item.
2. Either execute your measurement routine or click the **Print** icon from the **Reporting** toolbar.

Editing or Deleting Custom Reports

Custom reports are not stored as a typical file. Instead, they are stored as part of the measurement routine.

Editing a Custom Report

1. In PC-DMIS, select **View | Report Window** to select the Report window.
2. From the Report window, click on the **Custom Report Selection Dialog** icon ( ).
3. Select the report to edit.
4. From the **Reporting** toolbar, click **Edit report** ( ) to place the report in edit mode. When the report is in edit mode, PC-DMIS shows the Edit window in Summary Mode. PC-DMIS also enables or shows the following reporting tools:
   - The **Save** ( ) and **Save As** ( ) buttons on the **Reporting** toolbar
   - The Font bar
   - The Layout bar
   - The Object bar
   - The **View | Report Controls** submenu
5. Use the Edit window and the above reporting tools to edit the report.
6. Click **Save** ( ) or **Save As** ( ) to save your changes.
7. Click **Edit** ( ) again to leave edit mode and restore PC-DMIS to its previous state.

Alternately, you can also edit your custom report through the older **File | Reporting | Edit | Custom Report** menu item.

Deleting a Custom Report

Because custom reports are stored in the measurement routine, you have to delete them within PC-DMIS, not through Windows Explorer.

1. In PC-DMIS, select **View | Report Window** to select the Report window.
2. Make sure the report is not in edit mode.
3. From the Report Window, click on the **Custom Report Selection Dialog** icon ( ).
4. Select the report to delete.
5. Press the Delete key on your keyboard.

Using a Custom Report from another Measurement Routine

You can use a Custom Report from another measurement routine in your current measurement routine to a certain extent.

To do this,

1. Select the **File | Reporting | Edit | Custom Report from Other Measurement Routine** menu item. An **Open** dialog box appears showing all your measurement routines.

2. Select your measurement routine and click **Open**. A **Custom Report** dialog box appears. If a report exists for the selected measurement routine, it will show up in this dialog box.

3. From the dialog box, select the report you want to use and click **Open**. PC-DMIS loads the report in the Custom Report Editor.

If a feature or item is not found in the measurement routine, the label or object will be blank.

About Report Expressions

Report Expressions are special commands that you place inside of report and label template objects to pull specific data from PC-DMIS and place them into those objects. For example, suppose that you want to insert a feature ID into a label template. You would add an object that supports expressions into your report, such as the **GridControlObject**. Then, inside of an Expression Cell of the grid, you would type "=ID".

There are four areas where you can insert report expressions:

- The Rules Tree Editor - in the **Conditional Expression** and **Text Expression** boxes
- The GridControlObject - in its grid cells
- The GridControlObject - in the **Repeat Expression** box in the **Row** tab for repeat expressions
- Property Sheet Values - on edit fields or combo boxes that take text values

Consult those topics for information on where to insert report expression code.

For available expressions, consult "Functions and Operators" and "Using Data Types to Find a Report Expression" for lists of available functions, operators, and data types.

Reporting expressions can also use many normal PC-DMIS expressions. Precede the expressions with the "=" sign when you type them in the cell. Expressions are discussed in the "Using Expressions and Variables" chapter.

Functions and Operators

The following are lists of functions and operators available to the Reporting expression language. These work the same as the PC-DMIS expression language.

The Reporting expression language does not support variables, structures, or functions like the PC-DMIS expression language does. In place of variables, a new type called DATA_TYPE has been added to the language. See "Using Data Types to Find a Report Expression" for more information. Another new difference in the Reporting language is the addition of a set of constants described in "Predefined Constants".

Remember to precede your expression with an equals sign (=). Also, make sure that the command from which you are getting your data supports the expression you want to use.

() Parentheses are used to group expressions and determine evaluation order.

Functions for Report Expressions

Items preceded with an asterisk symbol (*) are unique to the reporting expression language.

`ABS (<expression>)`
This function returns the absolute value of the input value.

`ACOS (<expression>)`
This function returns the arc-cosine for the input value. Input and result are in radians.

`ANGLEBETWEEN (<expression1>, <expression2>)`
This function returns the angle between the two inputs expression1 and expression2, which should be of type vector. Result is in degrees.

`ARRAY (<expression1>,<expression2>, & <expressionN>)`
This function creates an array out of the input values.

`ASIN (<expression>)`
This function returns the arc-sine for the input value. Input and result are in radians.

`ATAN (<expression>)`
This function returns the arc-tangent for the input value. Input and result are in radians.

`AVERAGE (<expression>)`
Same as in PC-DMIS expression language.

`COMMANDDATA (<expression1>,<expression2>)`
This expression calculates or displays information from the feature referenced by the command object from the Report Data event. This takes a single required parameter for expression1. This parameter tells PC-DMIS what feature information to display. A second optional parameter, expression2, is provided for future support but currently isn't used.

You can pass string values through expression1:

- "RMS" - This stands for Root Mean Square. It calculates the Root Mean Square value of the feature.
- "T" - This returns the T value of the feature (it is the same as the T axis on a dimension).

You can also pass expressions, like the ISOUTTOL() function, through expression1:

Suppose you have the following expression taken from the TEXTANDCAD_OOT.RTP report template that checks to see if the out-of-tolerance value is greater than zero:

```
IF "COMMANDDATA("=ISOUTTOL()","")>0" Then
Use Template "Reference_ID.lbl"
```

If so, it uses the Reference_ID.lbl label template. For more information on ISOUTTOL, see the ISOUTTOL expression description below.

`CHR (<expression>)`
This function returns the ASCII character value for the corresponding input value, which should be of type integer.

`* COLOR (<expression1>, <expression2>)`
This function makes the text value of expression1 use one of the four colors as currently defined in the color tree. 1 = Marked Color, 2 = Unmarked Color, 3 = Step Mode, and Color 4 = Error Color. See "Changing a String's Text Color".

`* GetTolColor (expression1, expression2, expression3)`
This function takes three expressions: deviation, plus tolerance, and minus

tolerance. It returns the current tolerance color as type COLORREF based on the deviation.

expression1 is the deviation as a double value, expression2 is the plus tolerance as a double value, and expression3 is the minus deviation as a double value.

You can use this returned color with the color properties of objects in reporting, such as **ForeColor** and **BackColor**, to dynamically change the color of the object to reflect the current tolerance value.

These colors are specified in the **Edit Dimension Colors** dialog box. See "Editing Dimension Colors" in the "Editing the CAD Display" chapter.

`CONCAT (<expression1>, <expression2>, & <expressionN>)`
This function concatenates all of the strings specified in expressions 1 through N together into one string.

`COS (<expression>)`
This function returns the cosine for the input value. Input and result are in radians.

`* COUNT (expression1)`
This function returns the number of instances of the data type specified in expression1 for the current command.

`CROSS (<expression1>, <expression2>)`
This function returns the cross product of expession1 and expression2, both of which should be of type vector.

`* DATAFIELD (<expression1>, <expression2>, <expression3>)`
You use this function only within the Custom Report Editor. This function returns information from a specific data field within a feature, dimension, or command. This function takes three parameters: expression1 is a string representing the unique id or id of the command, expression2 is a string representing the data type, and expression3 is the typeindex. Normally, the typeindex is 0, but in cases where a dtype occurs more than once, it will be 1 or greater.

PC-DMIS automatically creates and uses this expression when you drag and drop items from the Edit window into your custom report.

`DATEVALUE ()`
Same as in PC-DMIS expression language.

`DEG2RAD (<expression>)`
This function converts the input from degrees to radians.

`DELTA (<expression1>, <expression2>, <expression3>)`
This function generates a new point moved along the vector specified in expression2 by the distance specified in expression3 from the point specified in expression1.

`DISTANCEFROMEDGE ()`
This function retrieves the distance of the measured centroid of the command's underlying feature from the closest edge on the CAD.

- If the underlying command is a feature, this function uses the measured feature to return the distance.
- If the underlying command is a dimension, this function uses the first feature in the dimension to return the distance.

You can use this function in the Rule Tree Editor to specify different label templates based on the distances returned.

`DOT (<expression1>, <expression2>)`
This function returns the dot product of expression1 and expression2. The input values should be of type point.

`DOUBLE (<expression>)`
This function converts the input value from its current type to a double. In the case of a point, the function returns the distance of the point from the origin.

`* ELAPSEDTIME ()`
This function returns the amount of time taken for execution.

`ELEMENT (<expression1>, <expression2>, <expression3>)`
Same as in PC-DMIS expression language.

`EQUAL (<expression1>, <expression2>)`
This function tests whether two arrays are identical and returns 1 if they are identical; otherwise, it returns 0.

`<expression1> ^ <expression2>`
Same as in PC-DMIS expression language.

`EXPON (<expression>)`
Same as in PC-DMIS expression language.

`* FILENAME ()`
This function returns the full path and file name of the measurement routine.

`FORMAT (<expression1>, <expression2>)`
Same as in PC-DMIS expression language.

`* GETCOUNT (expression1)`
This function returns a long value of the number of instances that exist for the ENUM_FIELD_TYPES data type, specified in expression1. For example, a location dimension that reports in X,Y,Z, and D would return 4 for the Axis data type.

`GETFEATURESSETID (<expression1>)`

During execution, if the current command is a dimension, this function checks to see if the reference feature for this dimension is in a feature set. If it finds the reference feature in a set, it returns that set's ID as a string value with a ".lbl" extension appended to the end it. If it does not find a feature set command with the reference feature, it returns the default string value supplied in <expression1>. This default value should be a label file name that includes the .lbl extension.

For example, suppose you have the following Location dimension that references a circle named CIR1:

```
DIM LOC1= LOCATION OF CIRCLE CIR1 UNITS=IN ,$
GRAPH=OFF TEXT=OFF MULT=10.00 OUTPUT=BOTH
...
END OF DIMENSION LOC1
```

You can use the GetFeatureSetID function inside a rule to automatically determine the label that PC-DMIS displays for this dimension depending on whether or not CIR1 exists inside of a feature set.

For example, this rule automatically uses the LEGACY_DIMENSION.LBL label if it cannot find a FEAT/SET command that contains CIR1:

```
USE TEMPLATE
"=GetFeatureSetID("LEGACY_DIMENSION.LBL")"
```

If there is a FEAT/SET command, you can then change the ID for that command to match the desired label name you want to use (or change a label file name to match the ID). PC-DMIS then uses that label instead.

In this code here, notice that the FEAT/SET references CIR1. It also has its usual label identification changed to "REFERENCE_ID" and the GetFeatureSetID function returns "REFERENCE_ID.LBL":

```
REFERENCE_ID=FEAT/SET,CARTESIAN
   THEO/<0,0,0>,<0,0,1>
   ACTL/<0,0,0>,<0,0,1>
   CONSTR/SET,BASIC,CIR1,,
```

`GETTEMP (<expression1>)`
This function returns the specified temperature or threshold value. One of these string values used for expression1 determines what this function returns:

- "TEMPP" - Returns the part temperature
- "TEMPX" - Returns the X axis temperature
- "TEMPY" - Returns the Y axis temperature
- "TEMPZ" - Returns the Z axis temperature
- "REF_TEMP" - Returns the temperature compensation reference temperature
- "HIGH_THRESHOLD" - Returns the temperature compensation high threshold
- "LOW_THRESHOLD" - Returns the temperature compensation low threshold

`GETPROGRAMINFO (<string>,<optional string>)`
Same as in PC-DMIS expression language.

`IF (<expression1>, <expression2>, <expression3>)`
If expression1 evaluates to a non-zero value, the function returns the value of expression2; otherwise, the function returns the value of expression3.

`INDEX (<expression1>, <expression2>)`
Same as in PC-DMIS expression language.

`INTEGER (<expression>)`
Same as in PC-DMIS expression language.

`ISMARKEDFORARM (<expression>)`
Use this function in Multiple Arm Mode contexts. This function returns 1 if the command is marked for the arm specified in <expression>; otherwise, it returns 0. This function lets you control what is displayed in the report based on the command's executing arm.

```
=IsMarkedForArm(1)
```

would return 1 if the current command is marked for arm 1, otherwise it returns 0.

```
=IsMarkedForArm(2)
```

would return 1 if the current command is marked for arm 2, otherwise it returns 0.

```
=IsMarkedForArm(1) AND IsMarkedForArm(2)
```

would return 1 if the current command is marked for both arms, otherwise it returns 0.

`*ISOUTTOL()`
This function checks if a command is out of tolerance. This is only used with the COMMANDATA expression as discussed above.

`LEFT (<expression1>, <expression2>)`
Same as in PC-DMIS expression language.

`LEN (<expression>)`
For a string, this function returns the number of characters in the string. For an array, it returns the number of elements in the array.

`LN (<expression>)`
Same as in PC-DMIS expression language.

`* LOADSTR (<expression>)`
This function loads the string using the numerical value from the resource files. A negative numerical value causes the string to be loaded from the string's resources. See "Loading Strings from PC-DMIS" for more information.

`LOG (<expression>)`
Same as in PC-DMIS expression language.

`LOWERCASE (<expression>)`
Same as in PC-DMIS expression language.

`<expression1> < <expression2>`
Same as in PC-DMIS expression language.

`MAX (<expression>)`
Same as in PC-DMIS expression language.

`MAXINDEX ( <expression>)`
Same as in PC-DMIS expression language.

`MAXINDICES ( <expression>)`
Same as in PC-DMIS expression language.

`* MEASSCALE ()`
This function returns the re-scale factor used when measuring.

`MIN (<expression>)`
Same as in PC-DMIS expression language.

`MININDEX (<expression>)`
Same as in PC-DMIS expression language.

`MININDICES (<expression>)`
Same as in PC-DMIS expression language.

`MID (<expression1>, <expression2>, <expression3>)`
Same as in PC-DMIS expression language.

`MPOINT (<expression1>, <expression2>, <expression3>)`
Same as in PC-DMIS expression language.

`* NUMMEAS ()`
This function displays a number value that represents the number of dimensions reported.

`* NUMOUTTOL ()`
This function displays the number of reported out-of-tolerance dimensions.

`ORD (<expression>)`
Same as in PC-DMIS expression language.

`PCDMISUSERHIDDENDATAPATH ()`
Same as in PC-DMIS expression language.

`PCDMISUSERVISIBLEDATAPATH ()`
Same as in PC-DMIS expression language.

`PCDMISSYSTEMHIDDENDATAPATH ()`
Same as in PC-DMIS expression language.

`PCDMISSYSTEMVISIBLEDATAPATH ()`
Same as in PC-DMIS expression language.

`PCDMISSYSTEMREPORTINGPATH ()`
Same as in PC-DMIS expression language.

`PCDMISAPPLICATIONPATH ()`
Same as in PC-DMIS expression language.

`* PARTNAME ()`
This function displays the part name (the same as what is shown in the file header).

`* PAGE ()`
This function displays the current page number.

`* PAGES ()`
This function displays the total number of pages.

`PAGEDIMCOUNT ("ObjectID",Range)`
This function takes two parameters. If the first parameter is empty (nothing inside the quote marks), then this function returns the number of dimensions in the current page with a max deviation less than Range*Tol. The second parameter, Range, is a floating number. If the first parameter references a CadReportObject ID or a TextReportObject ID, then this returns the number of in-tolerance dimensions associated with the specified CadReportObject or TextReportObject.

For example, suppose you want to return the number of out of tolerance dimensions with CadReportObject1. You could use the following code to do this:

```
= TotalPageDimCount ("CadReportObject1") -
PageDimCount ("CadReportObject1",1.0)
```

You can also calculate the number of dimensions that contain a specific number of axes. To do this, append ":N" to the ID, where N is a number that represents the number of axes.

You can type `= PageDimCount ("CadReportObject1:4",1.0)` which return the number of dimensions associated with CadReportObject1 that contains at least four axes and that had the fourth axis within the specified tolerance of 1.0. If you do not specify the number of axes, it returns the number of dimensions associated with CadReportObject1 if all axes were within the specified tolerance of 1.0.

For Custom Reports, you can only use this function with a CADReportObject, because a TextReportObject cannot go on a Custom Report.

`RAD2DEG (<expression>)`
Same as in PC-DMIS expression language.

`REAL (<expression>)`
Same as in PC-DMIS expression language.

`* REGSETTING (<expression1>, <expression2>)`
This function displays a value of a specific entry. This function takes two parameters: expression1 determines the section, and expression2 determines the entry.

`REPORTDIMCOUNT (<"expression1">, <expression2>)`
This function acts like the PageDimCount() function except that instead of displaying the number of out of tolerance dimensions for the current page, it displays the total number of out of tolerance dimensions for the entire report. In addition, for <expression1>, you need to use CadReportObject1 or TextReportObject1 as the ID, or leave it empty (with just the quotes).

For Custom Reports, you can only use this function with a CADReportObject, because a TextReportObject cannot go on a Custom Report.

`REPORT_LABEL_AXIS (<expression1>,<expression2>, etc.)`
This function returns a string delimited by \n that describes each axis that the tolerance command outputs.

`* REPORTVALUE (<expression1>)`
This function displays the value of another object's property. It takes one parameter, shown as expression1. This should be a string value of the object's unique ID followed by a period and then the property's name. For example:
`= REPORTVALUE ("text1.text")`

`* REVNUM ()`
This function displays the revision number (the same as what is shown in the file header).

`* RGB (<expression1>, <expression2>, <expression3>, <expression4>)`
This function colors the string specified in expression1 to the color specified via the RGB values of expression2, expression3, and expression4. See "Changing a String's Text Color".

`RIGHT (<expression1>, <expression2>)`
Same as in PC-DMIS expression language.

`ROUND (<expression1>, <expression2>)`
Same as in PC-DMIS expression language.

`* SECTION ()`
This function displays the current section number.

`* SERNUM ()`
This function displays the serial number (the same as what is shown in the file header).

`SIN (<expression>)`
Same as in PC-DMIS expression language.

`SORTUP (<expression>)`
Same as in PC-DMIS expression language.

`SORTDOWN (<expression>)`
Same as in PC-DMIS expression language.

`SQRT (<expression>)`
Same as in PC-DMIS expression language.

`* STATCOUNT ()`
This function returns the statistics count (the same as in the file header).

`STR (<expression>)`
Same as in PC-DMIS expression language.

`STRING (<expression>)`
Same as in PC-DMIS expression language.

`SUM (<expression>`
Same as in PC-DMIS expression language.

`SYSTIME ()`
Same as in PC-DMIS expression language.

`SYSTEMDATE (<expression>)`
Same as in PC-DMIS expression language.

`SYSTEMTIME (<expression>)`
Same as in PC-DMIS expression language.

`* TOGGLESTR (<expression1>, <expression2>)`
This function pulls the toggle string from the resources base on the resource id value in expression1. The function uses a negative number for cases where the string should come from the strings resources. This function uses the value of expression2 to specify the substring to return. The result is the substring.

`* TOGGLESTRING (DATA_TYPE)`
If the specified data type for the given command is of type toggle string, this function returns the full toggle string.

`* TOGGLEVALUE (DATA_TYPE)`
If the specified data type for the given command is of type toggle string, this function returns the index number (or toggle value) of the toggle string.

`* TOL (<expression1>, <expression2>, <expression3>, <expression4>)`
expression1 is the string to color, expression2 is the test value, expression3 is the maximum in-tolerance value, and expression4 is the minimum in-tolerance value. If the test value is in tolerance (between the values for expression3 and expression4), then the software colors the text black. Otherwise, the software colors the text with

the error color (usually red). You can define the error color in the **Color Editor** dialog box (**Edit | Preferences | Edit Window Colors**).

For example, this code displays the text "In Tolerance" in black:

```
=TOL(" In Tolerance ",100,100.5,99.5)
```

This code displays the text "Out of Tolerance" in the error color (by default, this is red):

```
=TOL(" Out of Tolerance ",99,100.5,99.5)
```

* `TOLF (<expression1>, <expression2>, <expression3>, <expression4>, <expression5>)`
This function provides additional formatting capabilities beyond the TOL expression. The first four parameters are the same as listed in the `TOL` function above. The fifth expression determines the font, size, format, and color for an out-of-tolerance condition. It expects this syntax:

"**f:s:w:c**"

f is the name of the font to use.

s is the size of the font in points.

w is the font's formatting, and it can be done using any of these:

B or BOLD for boldface formatting.

I or ITALIC for italic formatting.

R or REGULAR for regular formatting.

BI, BOLDITALIC, IB, or ITALICBOLD for both bold and italic formatting.

c is an RGB(r,g,b) color formatting where r = red, g = green, and b = blue. Each value can be in the range of 0 to 255.

Each of these items is optional and must be separated with a colon (:) character. For example, to set only the font size, you could have ":14", but to set only the color, you would need ":::RGB(0,0,0)".

This example formats any measured dimension that is out of tolerance with an Arial font, size 12, with a boldface formatting and a red color.

```
=TOLF(DIM_MEASURED:N,DIM_OUTTOL:N,0.0,0.0,"Arial:12:B:RGB(255,0,0)"
```

`TOLEXT (<expression1>, <expression2>, <expression3>, <expression4>, <expression5>)`
This function is similar to the TOL function except you can use ExtendedDTypes.

For example:

```
=TOL(NOMINAL:N,DIM_OUTTOL:N,0.0,0.0)

=TOLEXT(REPORT_LABEL_NOMINAL:N,DIM_OUTTOL:N,"SEG=1",0.0,0.0)
```

Where `"SEG=1"` is the extended portion that PC-DMIS adds to the `REPORT_LABEL_NOMINAL` expression.

`TOTALPAGEDIMCOUNT ("ObjectID")`
This function contains one parameter. If the function is empty (nothing between the quotation marks), it returns the total number of dimensions in the current page. If you type the ID of a CadReportObject or TextReportObject in the parameter, PC-DMIS returns the total number of dimensions associated with that object.

You can use this expression `= TotalPageDimCount ("CadReportObject3") to` return the total number of dimensions associated with CadReportObject3.

You can also calculate the number of dimensions that contain a specific number of axes. To do this, append ":N" to the ID, where N is a number that represents the number of axes.

You can type `= TotalPageDimCount ("CadReportObject1:4")` to return the total number of dimensions associated with CadReportObject1 that contained at least four axes.

For Custom Reports, you can only use this function with a CADReportObject, because a TextReportObject cannot go on a Custom Report.

`TOTALREPORTDIMCOUNT ("ObjectID")`
This function is similar to the TotalPageDimCount() function with these important differences: Instead of returning the number of dimensions for the current page, it returns the total number of dimensions for the entire report. This works if there's a CadReportObject or TextReportObject. If you have an object ID as your parameter, it needs to be named CadReportObject1 or TextReportObject1.

For Custom Reports, you can only use this function with a CADReportObject, because a TextReportObject cannot go on a Custom Report.

`TRACEFIELD (<expression>)`
This function displays the given tracefield's name and value in the report. The value of the expression is a number value that represents the order of the listed tracefields

from top to bottom in your measurement routine. So to display the first listed tracefield, the code would read: `= TRACEFIELD (1)`

`UNIT (<expression>)`
Same as in PC-DMIS expression language.

`USERSTRING (<expression1>,<expression2>)`
This function pulls a custom string from a comma separated value (CSV) text file and displays that string in the label. See "Loading Strings from a Text File" for an example of this function.

`* VARIABLE (<expression1>,<expression2>)`
This function displays the defined variable's value. This function takes one or two parameters. expression1 is the string value that represents the variable's ID. expression2 is an optional ID of another command ID or UID. See "Displaying a Variable's Value" for more information.

`VECX (<expression>)`
Same as in PC-DMIS expression language.

`VECY (<expression>)`
Same as in PC-DMIS expression language.

`VECZ (<expression>)`
Same as in PC-DMIS expression language.

Operators for Report Expressions

`<expression1> == <expression2>`
Evaluates to 1 if expression1 equals expression2. Otherwise, evaluates to 0.

`<expression1> >= <expression2>`
Evaluates to 1 if expression1 is greater than or equal to expression 2. Otherwise, evaluates to 0.

`<expression1> <= <expression2>`
Evaluates to 1 if expression1 is less than or equal to expression 2. Otherwise, evaluates to 0.

`<expression1> > <expression2>`
Evaluates to 1 if expression 1 is greater than expression2. Otherwise, evaluates to 0.

`<expression1> < <expression2>`
Evaluates to 1 if expression 1 is less than expression2. Otherwise, evaluates to 0.

`<expression1> - <expression2>`
Subtracts expression2 from expression1.

`<expression1> / <expression2>`
Divides expression1 by expression2.

`<expression1> % <expression2>`
Returns the remainder from expression1 divided by expression2 if any.

`<expression1> * <expression2>`
Multiplies expression1 by expression2.

`<expression1> <> <expression2>`
Compares expression1 to expression 2. If they don't match, it evaluates to 1. If they do match, it evaluates to 0.

`-<expression>`
The unary minus operator negates the value of the operand in expression.

`!<expression>`
Logical NOT operator. This inverts the value of the variable or expression. If the <expression> evaluates to TRUE, the !<expression> evaluates to FALSE. If the <expression> evaluates to FALSE, the !<expression> evaluates to TRUE.

`<expression1>  AND  <expression2>`
Performs a binary AND operation on two numbers. Otherwise, concatenates strings or numbers together in the case of mixed types.

`<expression1>  OR  <expression2>`
Performs a binary OR operation on two numbers.

`<expression1> + <expression2>`
Adds expression1 and expression2 together.

Some Reporting Expressions Examples

The following topics provide you with a few examples of things you can do with the Reporting expression language:

- Displaying a Variable's Value
- Changing a String's Text Color
- Loading Strings from PC-DMIS
- Loading Strings from a Text File

Use the functions and operators in the "Functions and Operators" topic, to create your own Reporting expressions.

Displaying a Variable's Value

You can use the Variable() function in PC-DMIS's reporting language to display a variable's value in your report. This function has the following syntax:

Variable(<varname>, [<optional command id or uid>])

The first parameter, coerced to a string type, represents the name of the variable. You can use the second optional parameter to solve for the variable's value relative to another command.

For example, suppose you have this code in your measurement routine:

```
ASSIGN/V1=2

F1=FEAT/CIRCLE...

ASSIGN/V1=F1. X

COMMENT/OPER,"Some comment text"
```

For the purposes of this example, assume that the comment has a unique ID or "UID" of 245.

Now consider the following examples with the code above:

`=VARIABLE("V1")` - If there are no other statements setting the value of V1 in the report then the value may be either 0, 2, or the same as the measured centroid x value of feature F1. It all depends on which commands have already executed at the point that the report expression is evaluated and which command is currently being processed for the report.

`=VARIABLE("V1","F1")` - If this is the only feature named "F1" in the measurement routine, then the result of evaluating this expression should be 2 since V1 is assigned to 2 directly above feature F1.

`=VARIABLE("V1",245)` - In this case, the UID is used; the value of this expression on the report should be the same as F1.X.

Individual cells of a **GridControlObject** cannot acquire a variable's value from the measurement routine. In most cases, you will need to use **Text** objects.

Variables and Headers

Normally, you *cannot* display a variable's value inside your report's file header because PC-DMIS evaluates the file header before executing statements in the measurement routine. So, when the file header attempts to reference a variable that hasn't yet been

created, PC-DMIS displays a zero value. However, some options do exist to get information from your measurement routine into your header:

Option 1 - Use the tracefields instead of Variables
Use tracefields instead of variables in your measurement routine to capture the information and then use the =TRACEFIELD() function inside the desired cell in the **GridControlObject** of the header's label template to reference it. Tracefields force the template to re-evaluate the report based on the new information causing the tracefield to appear.

Advantages / Disadvantages

- **Advantages** - Relatively easy to set up.
- **Disadvantages** - You aren't actually using variables. Tracefields are used instead and have their own limitations.

Procedure

Step 1: Open the File_Header.lbl file in PC-DMIS and Modify the **GridControlObject** to hold another row of data.

1. In PC-DMIS access the label template editor (**File | Reporting | Edit | Label Template**) and open File_Header.lbl. It will appear in the label template editor. You will see the information is contained inside an object called a GridControlObject.
2. Select the **GridControlObject** and right-click on it to open the **Properties** dialog box containing the properties that make up the GridControlObject. Change **NumRows** to 3 to add another row and then press the Tab key. Notice that the background isn't tall enough to support the added row.
3. From the drop down list on the **Properties** dialog box, select **TheFrame/ TheView** and change the **Height** property to 100 and press the Tab key to accept the change.

Step 2: Add a report expression into the GridControlObject to accept a tracefield's information

1. Select the GridControlObject again.
2. If the handles (green boxes) do not yet include the newly added row, drag the green handles downward until they do.
3. Double-click to make the GridControlObject "active". This shows all the behind-the-scenes expressions.
4. Select the cell that will hold the tracefield's value and type: =TRACEFIELD(1) and then press the Tab key. This expression tells PC-DMIS to put the data for the first tracefield in that cell. For example, if you

wanted the second tracefield's data, you would use =TRACEFIELD(2). (See the attached image file below.)

5. Play around with the cells and format them as desired. The best way to do this is to select one or more cells within the grid and then right-click on it to open the **Grid Properties** dialog box.
6. Click outside the GridControlObject to deactivate it.
7. Save your changes.

Step 3: Test your changes.

1. Execute your measurement routine.
2. Access the Report window (**View | Report Window**).
3. Click the **Redraw the Report** icon on the Reporting window's toolbar.
4. The tracefield's info should now appear in the header.

Option 2 - Embed the Report Template

Embed the report template into your measurement routine sometime after the ASSIGN statements have been defined, and then send the variable's value to the label template as a parameter. Add additional rows or cells as needed and on top of the added cells, add and size a **Text** object for each variable you want to display. Finally, modify the **Text** property through a parameter of the REPORT/TEMPLATE command, like this:

```
ASSIGN/V1="A String Value to Pass"
CS1=REPORT/
TEMPLATE,FILENAME=TEXTONLY.RTP,AUTOPRINT=NO,Section=
-1
   PARAM/TEXT1.TEXT=V1
   PARAM/=
   ENDREPORT/
```

Because the label template is merged into the report template, you can modify certain parameters on the label template by referencing the report template in the above fashion.

Advantages / Disadvantages

- **Advantages** - Variables will now appear in your final report's header.
- **Disadvantages** - Somewhat difficult to set up since you need to add a **Text** object into your label template in addition to the code to embed the report template into the measurement routine. The main disadvantage to this approach, however, is that PC-DMIS generates the report twice, one after the

other (once from PC-DMIS's default functionality and again from the embedded REPORT/TEMPLATE code block).

Option 3 - Put the header information directly into the report
Instead of using a report template that refers to an external label template for the header, such as File_Header.lbl, recreate the **GridControlObject** from the header's label template directly inside your report template. Add additional rows or cells as needed and on top of the added cells, add and size a **Text** object for each variable you want to display. Then for each **Text** object use the =VARIABLE() function to pull in the variable information. For example, =VARIABLE("V1").

Make these remaining modifications inside the report template:

1. In the **TextReportObject** change the rules so that the header label isn't used.
2. Set these properties for the current section, Section1:

   Command Set = All Commands

   Maximum Number of Pages = 1
3. Add a second section, Section2, and give it a **TextReportObject** as well, again changing its rules so that a header label isn't used.
4. Set these properties for Section2:

   Command Set = Continue From Previous Section

   Maximum Number of Pages = 0 (meaning there is no maximum)

Advantages / Disadvantages

- **Advantages** - Variables will now appear in your final report's header.
- **Disadvantages** - Somewhat difficult to set up since you have to recreate the **GridControlObject** inside the report template, add **Text** objects for each variable, and add an additional report section. Additionally, any editing done to the report, such as turning on "Show Feature" or changing Dimensions to "Out of tolerance Only", needs to be done twice, once for page 1 (first section) and once for the other pages (section 2).

Option 4 - Use a generic feature to force report generation
This option uses an empty Generic feature to force the label template to re-evaluate the report and pull needed variables values into your final report.

In your measurement routine, create an empty Generic feature and give it a descriptive name such as:

```
REPORTHEADER=GENERIC/NONE,DEPENDENT,CARTESIAN,OUT,$
```

Next, modify the header label template, adding additional cells as needed to the **GridControlObject**, and then on top of the added cells, add and size a **Text** object for each variable you want to display. Now set the **Text** property for each **Text** object to use the =VARIABLE() function to pull in the variable information. In this option, however, you need to refer to the generic feature by using the extra parameter in the =VARIABLE() function. For example, =VARIABLE("V1","REPORTHEADER")

Advantages / Disadvantages

- **Advantages** - Probably the most versatile approach. Variables will now appear in your final report's header. You will not need to edit the final report twice as in Option 2.
- **Disadvantages** - Somewhat difficult to set up since you will need to include an empty Generic feature in your measurement routine, and add **Text** objects for each variable inside the label template.

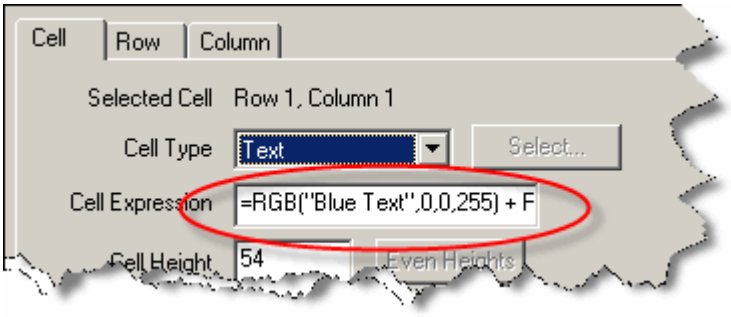
Changing a String's Text Color

Using the RGB Function

The Reporting expression language lets you use a RGB function to define an RGB (Red Green Blue) color value and apply it to a string of characters in expression text. This function takes four parameters, a string parameter, followed by comma separated RGB parameters, like this:

```
=RGB(string,R,G,B)
```

If you type this function in the **Cell Expression** box (or cell) of the GridControlObject, click **OK**, and then click outside of the object, PC-DMIS evaluates the expression and gives the text the specified color value.



Cell Expression box showing the RGB expression

For example, if you type this expression into a cell,

```
=RGB("Blue Text",0,0,255) + RGB(" Black Text",0,0,0) +
RGB(" Yellow Text",255,255,0)
```

then the words would look like this in a template editor:

Displaying a Dimension Color with RGB

For the second parameter in the RGB function, if you use a value that exceeds 255, PC-DMIS interprets that parameter as a COLORREF value instead of a standard 0 - 255 RGB value. In this case, PC-DMIS ignores the second and third parameters (although you do need to include them). You can use this approach to return the color of the dimension's axis if you use the `DIM_RPT_TOLERANCECOLOR1` data type.

For example, suppose you use this expression in a cell of a GridControlObject:

```
=RGB(NOMINAL:N,DIM_RPT_TOLERANCECOLOR1:N,0,0)
```

This grabs the nominal value of the current axis undergoing evaluation and sets the color to that axis's dimension color.

The `:N` behaves as a variable that holds the current dimension axis index so that the expression returns the color value of each axis.

You can also specify a specific axis. For example, suppose you have a dimension with three axes, X, Y, and Z.

- `DIM_RPT_TOLERANCECOLOR1:1` returns the color value for the first axis, X.
- `DIM_RPT_TOLERANCECOLOR1:2` returns the color value for the second axis Y.
- `DIM_RPT_TOLERANCECOLOR1:3` returns the color value for the third axis Z.

If you do not define the optional index (`:N`), it returns the color of the dimension itself.

Using the Color Function

The Color function takes two parameters. The first, a color parameter, is actually a number that represents one of the principle Edit window colors. The second, is the string value to which PC-DMIS applies the color.

```
=COLOR(1, "My Text")
```

The first parameter is a value of 1 to 4 and passes the Edit window color that associated with the following:

1 passes the Marked Color

2 passes the Unmarked Color

3 passes the Step Mode Color

4 passes the Error Color

These colors are defined in the Edit window's **Color Editor** dialog box (**Edit | Preferences | Edit Window Colors**). For information on this dialog box, see "Defining Edit Window Colors" in "Setting Your Preferences" for information.

Loading Strings from PC-DMIS

Similar to how you can change the text color for a cell in the "Changing Expression Text Color" topic, the Reporting expression language lets you pull strings from PC-DMIS's current running language by using this expression:

```
=LOADSTR(<integer expression>)
```

This function takes a single parameter, an integer number that corresponds to the value of a string located in resource.dll or strings.dll.

- A positive number pulls the string from the resource.dll file.
- A negative number pulls the string from the strings.dll file.

If you type this function in the **Cell Expression** box (or cell) of the GridControlObject, click **OK**, and then click outside of the object. PC-DMIS evaluates the expression and returns the string assigned to the specified integer value.

This functionality was added primarily so that the label templates that ship with PC-DMIS use string data from your current language.

Loading Strings from a Text File

With PC-DMIS, you can load custom strings from a comma separated value (CSV) text file and display them inside of a customized label. This is very handy if you need custom strings displayed in a different language. To do this, just localize the csv file and provide it to the operator.

The Syntax

The `USERSTRING` function takes two parameters:

```
=USERSTRING(<expression1>,<expression2>)
```

- The first parameter, Expression 1, is a string pathway that defines the location of the CSV file. This must be inside quotes. If the file cannot be found, due to an incorrect pathway or a lack of read permissions, the function returns, "File cannot be opened".
- The second parameter, Expression 2, is the index number in the CSV file associated with the string of text to display. If the CSV file is accessible, but you specify an index number that doesn't exist in the CSV file, the function returns, "index not found".

The CSV File

The csv file must contain on an individual line: the unique index number, then the comma, and then the string.

To define multi-line strings, use the new line character (\n).

For example, consider this sample CSV file:

```
10,The universe is your playground.
1,Place the part on the table.
3,This is a \nMulti-line string.
...
230,"Bleeding Edge. Cutting Edge."
200,Circle 6001
201,5+5
```

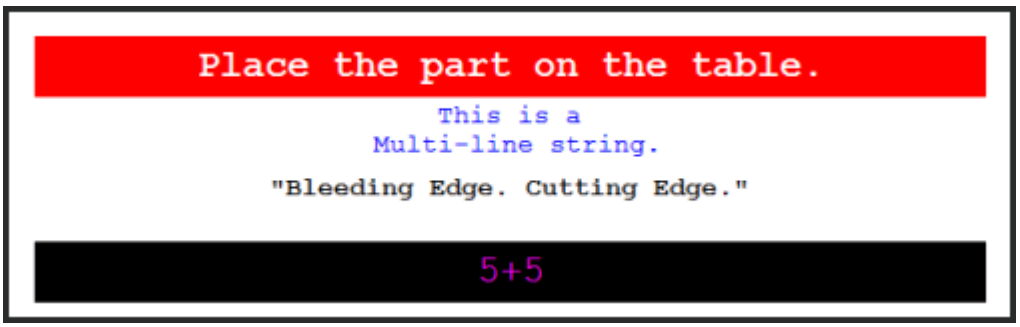
Notice that the numbers preceding each string don't need to be sequential; they only need to be unique. Quotation marks and other characters will come through as typed in the CSV file. Numbers are not mathematically evaluated.

An Example

Suppose the above CSV file was stored in your d:\temp\ directory with a file name of MyStrings.csv. If you wanted to display four different custom strings in a label, your expressions in the cells of the GridControlObject on that label might look like this:

```
=USERSTRING("d:\temp\MyStrings.csv",1)
=USERSTRING("d:\temp\MyStrings.csv",3)
=USERSTRING("d:\temp\MyStrings.csv",230)
=USERSTRING("d:\temp\MyStrings.csv",201)
```

Your label, once evaluated would look like this:



Using Data Types to Find a Report Expression

When using expressions, you usually use expressions that pull data from PC-DMIS. You need to make sure that the command or feature you associate with the label template to do this has the data you are trying to display. Data Types can help you find the correct expression to use.

For example, suppose you create a label template that has a GridControlObject, and in one of the cells you type this expression to display a feature's measured X data:

```
=MEAS_X
```

Now, if you create a report template, add a TextReportObject, and use the **Rule Tree Editor** to associate your label template with PREHIT commands, in the Report window the cell will not display anything. Why? Because the PREHIT command does not have a measured X field. To use the correct expression, you can view data types for different fields in the Edit window's Command Mode.

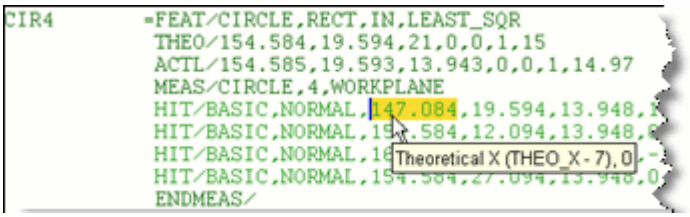
This procedure explains how to turn on and view data types:

1. Access the Edit window.
2. Place the Edit window into Command Mode.
3. Right-click on the Edit window. A shortcut menu appears.

Data Type Information Menu Option

4. Select **Change Popup Display | Data Type Information**.
5. Hover your mouse pointer over a field in a command, and PC-DMIS will display a small, yellow popup that shows that field's data type. The first part of the value in parentheses is the data type and an equivalent expression exists in the list of expressions.

Consider this example:



This data type popup shows that THEO_X is a valid expression for this command. If you typed "=THEO_X" into an appropriate location, PC-DMIS would display this feature's theoretical X value.

Using data types you can ensure that your report and label templates are using expressions supported by that command.

A List of Available Data Types

This list of data types displays the data type names in alphabetical order, their associated type numbers, descriptions, index values, and value strings as appropriate. When you use data types inside VB scripts in template events and rules, you may need to use the data type number as not all script locations accept the enumerated data type value.

Data type names followed by (Deprecated) are no longer used. They remain available so that existing measurement routines and report templates continue to open, but PC-DMIS will remove them in a future release. Do not use them in new report templates, rules, or scripts.

-A-

Number	Data Type Name	Data Type Description	Index	Value String

112	SURFVEC_I	Surface vector i		
113	SURFVEC_J	Surface vector j		
114	SURFVEC_K	Surface vector k		
546	SURFVEC_MEAS_I	Surface vector i meas		
547	SURFVEC_MEAS_J	Surface vector j meas		
548	SURFVEC_MEAS_K	Surface vector k meas		

Slot Vector Data Type

Note that SLOTVEC_I, SLOTVEC_J, and SLOTVEC_K are enumerations. They only function within the context of automation.

For an automation example using enumerations, you should use SLOTVEC_I, SLOTVEC_J, and SLOTVEC_K as shown below:

```
   FeatureCommand.PutData(LocSlotVector,FDATA_SLOT_VECTOR,FD
ATA_MEAS,FDATA_PART,"",PLANE_TOP)
   Command.PutText("0",MEAS_SLOTVEC_I,1)
   Command.PutText("1",MEAS_SLOTVEC_J,1)
   Command.PutText("0",MEAS_SLOTVEC_K,1)
```

If you're using pointers or variables directly in the Edit window via the PC-DMIS expression language, you need to use TANGVEC_IJK or ANGVEC_IJK:

- TANGIJK gets the *theoretical* IJK slot vector.

  You can also get the specific values:

  - TANGI gets the I value.
  - TANGJ gets the J value.
  - TANGK gets the K value.

- ANGIJK gets the *measured* IJK slot vector.

  You can also get the specific values:

  - ANGI gets the I value.
  - ANGJ gets the J value.
  - ANGK gets the K value.

For an expression example, to give variables V1 and V2 the theoretical and measured IJK values of the a round slot, you can use the following:

```
ASSIGN/V1=SLTR.TANGIJK
ASSIGN/V2=SLTR.ANGIJK
```

Using a Type Index to Display Specific Data

Type indexes let you pull in very specific data into your report. For example, if you had a cylinder feature with eight hits, you could use a type index to grab the second hit's measured X value. To use a type index, simply append a colon and a number to the expression to get that hit or that row of dimension data.

Type Indexes to Display Specific Data

To demonstrate how this works, if you typed:

```
=MEAS_X
```

PC-DMIS would not use a type index (the type index would default to 0) and PC-DMIS would display the measured X value of the feature's center point.

But, if you typed:

```
=MEAS_X:1
```

PC-DMIS would display the measured X value of the first hit.

If you typed:

```
=MEAS_X:2
```

PC-DMIS would retrieve the measured X value of the second hit.

Repeating Rows to Display all Data

Similar to type indexes, In the GridControlObject you can define a row as a "repeating row". With repeating rows, the character "N" evaluates to the current repeat index of the row being drawn. When you define a repeating row, you can also define a repeating row expression that, when evaluated, determines how many times the row repeats.

So, if you wanted to display all of the measured X values for all hits in a feature, you could define a single repeating row with the following expression:

```
=MEAS_X:N
```

You could then set the repeating row expression to "=N_HITS" to get the total number of hits. PC-DMIS would continue to repeat the row with subsequent hit data until the total number of hits was displayed.

Using a Prefix Number to Access Reference Feature Data

A report expression can take an optional prefix number inside curly brackets to indicate from which reference command the data should be taken.

For example, if you create a label template for a Roundness dimension, and you want to show the measured diameter on the label template, you could use this expression:

```
={1}MEAS_DIAM()
```

Notice the {1}. This indicates that the data needs to come from the first reference command (the feature) instead of the command for which the template is being created (the dimension).

If there is more than one reference feature used, the number within the curly braces represents the feature from which PC-DMIS will pull the information. For example, a Distance dimension uses two features to compute the distance. Using {1} would pull information from the first reference feature and {2} would pull it from the second reference feature.

Predefined Constants

The reporting expression language also uses some predefined constants for the type indices used with the DIMENSION_TABLES data type.

```
LINE1_SIZE_TABLE = 1
LINE2_POSITION_TABLE = 2
LINE3_POSITION_TABLE = 3
DATUM_SHIFT_TABLE = 4
SUMMARY_TABLE = 5
LINE2_ORIENTATION_TABLE = 7
LINE3_ORIENTATION_TABLE = 8
LINE2_BASIC_DIMENSION_TABLE = 9
LINE3_BASIC_DIMENSION_TABLE = 10
TRUE_POSITION_TABLE = 11
DIMENSION_TABLE = 12
DIMENSION_WITH_BONUS_TABLE = 13
```

NEWLINE

NEWLINE is used to add a carriage return to a text expression:

This expression,

```
="This is line 1" + " and this is line 2"
```

would appear as,

```
This is line 1 and this is line 2
```

on the report.

The expression,

```
="This is line 1" + NEWLINE + " and this is line 2"
```

would appears as,

```
This is line 1

and this is line 2
```

on the report.

N:

When you use repeating rows in a grid, N evaluates to the current row count in the repeating rows. This is useful when placing expressions that use a data type more than once in a repeating row.

Below is a sample grid that shows hit values in a table. N is used in the expressions for the repeating row. When the expressions for the first instance of the repeating row are evaluated, N equals 1, and so the X, Y, and Z values of the first hit are shown. When the second row is added, N equals 2, and so the X, Y, and Z values of the second hit are shown.

Hit #	Measured X	Measured Y	Measured Z
=N	=MEAS_X:N	=MEAS_Y:N	=MEAS_Z:N

Expressions Used in Standard Templates

In the various standard report and label templates, PC-DMIS uses several reporting expressions to display different pieces of information or to format the display of information. For example, consider the code behind feature.lbl, a standard label template that ships with PC-DMIS.

In this template, there are several reporting expressions (=LOADSTR, =DIM_MEASURED, =NOMINAL and so on) that determine what information PC-DMIS should display in the cells.

Common Expressions

The following list describes the most common expressions used in the various standard templates:

Some of these functions are also discussed in the "Functions and Operators" topic.

- =<Expression>:N - This expression allows you to display repeated information. See "Using a Type Index to Display Specific Data" and "Predefined Constants" for more information on repeating rows.
- =AXIS - This expression displays the current axis name (XAXIS, YAXIS, or ZAXIS).
- =DEVIATION_ANGLE - This expression displays a decimal value that represents the deviation angle in degrees of a Position dimension. PC-DMIS uses this value to draw the radial graphic for the Position dimension templates.
- =DEVPERCENT_NOM - This expression displays a decimal value that represents the percentage of the total tolerance range that marks the 0 deviation (nominal) position on the linear graphic. For a bilateral tolerance where the +/- values are equal, this value would be 50.0 (percent); the center of linear graphic represents 0 deviation. For a non-bilateral tolerance, this value would be 0.0; the leftmost side of linear graphic represents 0 deviation.
- =DEVPERCENT2 - When you set USETWODEVIATIONS to TRUE (see USETWODEVIATIONS below), this expression displays a decimal value representing the percentage of the + tolerance used by the max deviation of a bilateral profile reported as form and location. The percentage of the – tolerance used by the min deviation is given by DIM_RPT_DEVPERCENT.
- =DIM_DEVIATION - This expression displays how much a dimension deviates from the nominal.
- =DIM_OUTTOL - This expression displays the out of tolerance value for a dimension.
- =DIM_MAX - This expression displays the maximum value for the given axis among all points related to the input feature.
- =DIM_MEASURED - This expression displays a dimension's measured value.
- =DIM_MIN - This expression displays the minimum value for the given axis among all points related to the input feature.
- =DIM_RPT_DEVPERCENT - This expression displays a decimal value representing the percentage of the total tolerance range that marks the deviation of this dimension.

- =DIM_RPT_GRAPHIC - This expression displays an integer value representing the type of graphic control PC-DMIS should display for the dimension.

  0 - Report no graphic control.

  1 - Report the linear graphic control.

  2 - Report the radial graphic control.

- =DIM_RPT_ISBILATERAL - This expression determines whether or not the linear graphic represents a bilateral tolerance (+/- tolerance value) such as the size of a hole or profile reported as form and location. Examples of tolerances that are not bilateral (single tolerance value) are form tolerances such as circularity, flatness, straightness, and profile reported as form only. The value can be "0" (FALSE) or "1" (TRUE).

- =DIM_RPT_NUMZONES - This expression displays a decimal value indicating the number of tolerance zones (from 0 deviation to the maximum allowed deviation) to be drawn on the linear graphic. You can set this in the **Edit Dimension Colors** dialog box (select **Edit | Graphic Display Window | Dimension Colors**). You can assign each zone a unique color to show by the color of the linear graphic how much of the tolerance was used by the deviation of the dimension.

- =F_PLUS_TOL - This expression displays a feature's plus tolerance.

- =F_MINUS_TOL - This expression displays a feature's minus tolerance.

- =ID - This expression displays the feature or dimension ID.

- =LOADSTR - This expression loads a string from a table of stored strings within PC-DMIS. See "Loading Strings from PC-DMIS" for more information.

- =NOMINAL - This expression displays the nominal data for a feature.

- =Page() - This expression displays the current page number of the Report window.

- =Pages() - This expression displays the total number of pages of the Report window.

- =TOL - This function colors any text or expressions.

- =UNIT_TYPE - This expression displays the unit of measurement for the feature or dimension.

- =USETWODEVIATIONS - This expression determines whether or not the legacy dimension label template's linear graphic uses two deviation values. A bilateral profile reported as form and location displays how much of the + tolerance was used by the max deviation and how much of the – tolerance was used by the min deviation. The value can be "0" (FALSE) or "1" (TRUE).

Combined Expressions

You can also combine expressions or use them together with other expressions, as shown in this code string taken from the Legacy_Dimension_Cad.lbl label template:

```
=TOL(DIM_DEVIATION:N,DIM_OUTTOL:N,0.0,0.0)
```

This uses the =TOL function to display the dimension's deviation value and give it the Error color (usually red).

You can find another example in the standard report templates in PC-DMIS versions 4.2 and higher. The **Text** object at the bottom of those templates uses this combined expression in the **Text** property to display the current page number along with the total number of pages:

```
=page() + " Of " + pages()
```

Page six of a 10-page report would read as follows at the bottom of the page in the Report window:

6 Of 10

Using PC-DMIS ActiveX Controls

This series of topics provides an example of how to set up the properties of various PC-DMIS ActiveX controls and use them in a label template to display dimensional information.

- Adding an ActiveX Control
- Passing Information to an ActiveX Control
- Some PC-DMIS ActiveX Controls

The topics focus on the unique ActiveX properties for each control.

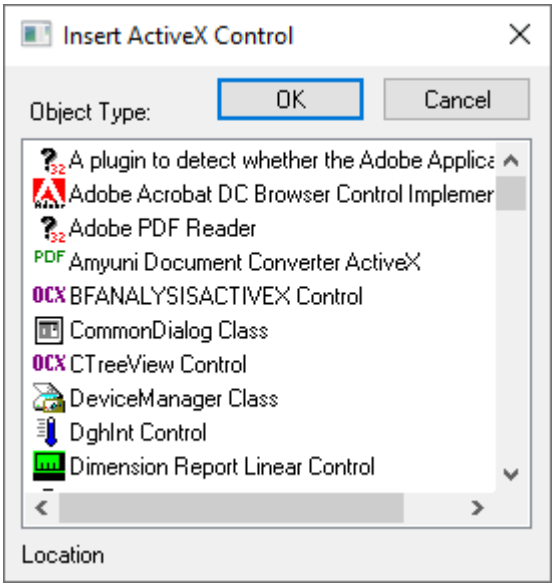
Adding an ActiveX Control

You can add an ActiveX control to a label template in the Label Template Editor in two ways:

- **ActiveX Object from Object Bar** - Click the **ActiveX** icon in the editor's Object Bar to add an ActiveX control directly to the label template. You can then define the area where the control will populate. (See the "ActiveX Object" topic.)

- **ActiveX Object from GridControlObject** - In a GridControlObject, double-click on the object to select it, and then right-click the object to show the **Grid Properties** dialog box. From that dialog box, set the **Cell Type** to **ActiveX**. This activates the **Select** button. Click **Select**. (For information, see the "GridControlObject" topic.)

Regardless of what method you use, PC-DMIS displays the **Insert ActiveX Control** dialog box.



Insert ActiveX Control Dialog Box

Select the desired control from the list and click **OK**.

This dialog box lists all the controls on your system, not just those controls added by PC-DMIS. If you want to use a third party control in a label template, you would add it in the same way.

Passing Information to an ActiveX Control

For all of the PC-DMIS ActiveX controls described here, the software passes information into the control using the EventReportData event. PC-DMIS encapsulates the specific dimensional information into an object called ReportData (see the "ReportData Object" topic in the PC-DMIS 2026.2 Automation Object Library documentation for additional information). For example, if you look at the Rule Tree Editor for the TextOnly.rtp report template, you will find for the Dimension Location item that one of the rules is:

Use Template "legacy_dimension.lbl"

The Legacy_dimension.lbl label template receives the dimensional information about the location dimension via the ReportData object. The information is now in the label but it has not yet been passed to the ActiveX control.

To understand how this information gets passed:

1. Open the legacy_dimension.lbl label template in the Label Template Editor. You will see that it contains a GridControlObject named **ActiveX12**.
2. Right-click to display the **Properties** dialog box for the object.
3. Double-click on one of the cells in this grid control to put it in edit mode.
4. Click the cell in the lower right corner. This cell uses the **Dimension Report Linear** control. Notice that the **Properties** dialog box has four categories of properties (**Standard**, **Advanced**, **Events**, **ActiveX**). Normally, objects only have three categories (**Standard**, **Advanced**, **Events**). This fourth category, **ActiveX**, is unique to ActiveX controls and is the area we will be concentrating on in the following sections.
5. Expand the **Events** section.
6. Access the **EventReportData** property. The VBA Mini Editor appears. Notice that the editor contains this line of code:

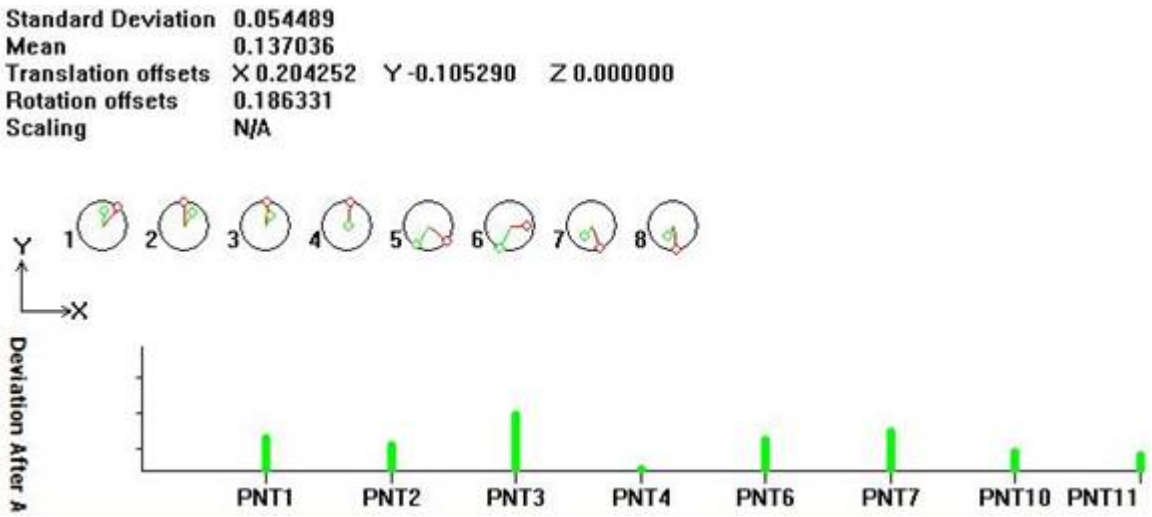
```
This.X.EventReportData ReportData
```

This code is the mechanism that passes ReportData (the dimensional information) to the ActiveX control. Therefore, whenever you add an ActiveX control to a label template, you will need to set the EventReportData property to do the same thing by using that line of code.

Some PC-DMIS ActiveX Controls

The following sections describe some PC-DMIS reporting ActiveX controls and their properties. Note that the DimAnalysisActiveX Control is not discussed here. Although it appears in the ActiveX list, it is used internally by the Analysis object in the Label Template Editor.

BFAnalysisActiveX



Property	Description	Example
AfterColor	The color of the last bar.	tbd [defaults to 65280 (Green)]
BeforeColor	The color of the first bar.	tbd [defaults to 255 (Blue)]
NumberFeatures	The number of features shown on the X axis.	tbd

`AfterColor` and `BeforeColor` take long values representing a color.

They use the following formula:

(Red * 256 * 256) + (Green * 256) + Blue.

So Red would be 16711680; that is (255 * 256 * 256) + (0 * 256) + 0; Green would be 65280; that is (0 * 256 * 256) + (255 * 256) + 0; Blue would be 255; that is, (0 * 256 * 256) + (0 * 256) + 255.

Example Label Template: BFANALYSISACTIVE1 in Best_Fit_Analysis.lbl.

Dimension Report Linear

Property	Description	Example
DeviationNominalPercent	See "Expressions Used in Standard Templates" for a description of the example expression.	=DEVPERCENT_NOM:N
DeviationPercent	See "Expressions Used in Standard Templates" for a description of the example expression.	=DIM_RPT_DEVPERCENT:N
DeviationPercent2	See "Expressions Used in Standard Templates" for a description of the example expression.	=DEVPERCENT2:N
Is Bilateral	See "Expressions Used in Standard Templates" for a description of the example expression.	=DIM_RPT_ISBILATERAL:N
UseTwoDeviations:	See "Expressions Used in Standard Templates" for a description of the example expression.	=USETWODEVIATIONS:N

Example Label Template: Bottom right cell in Legacy_Dimension.lbl.

Dimension Report Linear2

Property	Description	Example
Deviation:	See "Expressions Used in Standard Templates" for a description of the example expression.	=DIM_DEVIATION:N
Negative Tolerance:	See "Expressions Used in Standard Templates" for a description of the example expression.	=F_PLUS_TOL:N
Positive Tolerance:	See "Expressions Used in Standard Templates" for a description of the example expression.	=F_MINUS_TOL:N

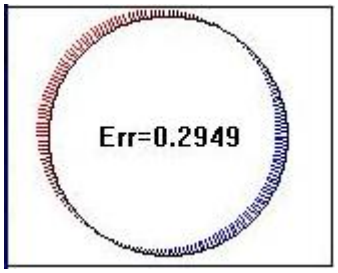
Example Label Template: Not currently used in any standard label template.

Dimension Report Radial

Property	Description	Example
Cylindrical Deviation	See "Expressions Used in Standard Templates" for a description of the example expression.	=DIM_RPT_DEVPERCENT:101
Cylindrical Deviation Angle:	See "Expressions Used in Standard Templates" for a description of the example expression.	=DEVIATION_ANGLE:101

Example Label Template: Bottom right cell in Legacy_Dimension_True_Position.lbl.

FeatureAnalysisActiveX



There are no properties to set up for this control. It uses the data passed to it in ReportData.

Example Label Template: FEATUREANALYSISA1 in Feature.lbl.

DataFileFormatControl

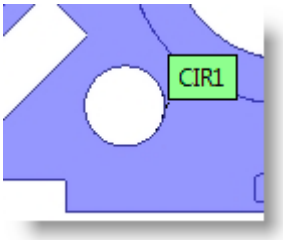
Property	Description	Example
DataFileName	The .dat file (logo.dat, elogo.dat, or header.dat) to interpret. If you use a .dat file outside of the PC-DMIS installation directory, be sure to include the full path to the file.	If you typed logo.dat, PC-DMIS would interpret the keywords inside that .dat file displaying the specified bitmap, date, time, and so forth according to the .dat file keywords in the file.

Example Label Template: None. See the "Reporting Using .DAT File Keywords" topic.

Tutorial - Using Scripting to Enhance your Report

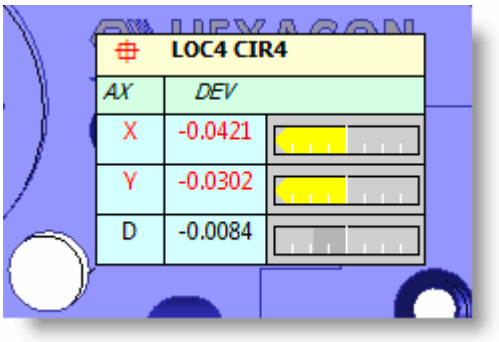
This tutorial demonstrates some of the capability available in PC-DMIS Reporting when you couple it with the power of scripting.

This tutorial shows you how to create a report template that displays a CADOnly type report, except that if the dimension is in-tolerance, a label template similar to Reference_ID.lbl is used.



A Sample in-tolerance feature.

If it is out-of-tolerance, PC-DMIS uses the Legacy_Dimension_CAD.lbl label template. Additionally, the Reference_ID.lbl-like label uses the dimension color for its background color.



A Sample out-of-tolerance feature.

This tutorial is not a complete solution since it does not cover needed modifications to labels used by Geometric Tolerance commands. For this to be a complete solution, you may want to perform similar steps to GEO_TOL_LABEL.lbl so that your Geometric Tolerance commands follow the same pattern.

Before you start the tutorial, you may want to review the "Summary of Tutorial Steps" and "Things to Know" topics below.

Summary of Tutorial Steps

1. Copy CADONLY.RTP to CADONLYREF_ID.RTP.
   CADONLYREF_ID.RTP will be the name of your new report template.

2. Copy REFERENCE_ID.LBL to REFERENCE_ID_COLOR.LBL.
   REFERENCE_ID_COLOR.LBL will be your new label template used for in-tolerance dimensions.

3. Add VB Script to REFERENCE_ID_COLOR.LBL.
   Using the Label Template Editor, you will add VB script code to the new label template, REFERENCE_ID_COLOR.LBL, to set the background color based on the dimension color.

4. Import the CAD2.RUL rules into CADONLYREF_ID.RTP.
   In this step, you will import rules contained in the .RUL file into your new report template, CADONLYREF_ID.RTP. The .RUL file contains the set of rules used by the CAD portion of the TextAndCAD report, and it uses REFERENCE_ID.LBL to display the dimension. You will modify rules that uses REFERENCE_ID.LBL to use new rules and the new label template, REFERENCE_ID_COLOR.LBL.

5. Add VB Script Code to CADONLYREF_ID.RTP
   Using the Report Template Editor, you will add script code to CADONLYREF_ID.RTP at each place in the rule tree that references REFERENCE_ID.LBL to check to see if

the dimension is in tolerance. If it is in tolerance, the code will cause it to use REFERENCE_ID_COLOR.LBL. If it is not, the code will cause it to use LEGACY_DIMENSION_CAD.LBL.

> If you are creating a new FCF_LABEL.LBL, e.g. FCF_LABEL_COLOR.LBL, at this time you would also change the Feature Control Frame rule to use FCF_LABEL_COLOR.LBL instead of FCF_LABEL.LBL if it is in-tolerance and use another label, like LINE2.LBL, if it is out-of-tolerance.

6. Modify the Rules to Use the VB Script Code for Remaining Dimensions.
   At this point the new rules will only be established for Dimension Location. In this step you will use the Copy and Paste functions inside the Rule Tree Editor so that other dimension types can use the same rules.

7. Test CADONLYREF_ID.RTP in the Report Window.
   In this step you select the CADONLYREF_ID.RTP template and test it inside the Report window. By the end of this tutorial you will have a report template that causes in-tolerance dimensions to only display the feature name with a background dimension color that matches a color from the dimension color key at the bottom of the page. Out-of-tolerance dimensions will use the LEGACY_DMENSION_CAD.LBL label.

Things to Know

- The "ReportData Object" topic in the PC-DMIS 2026.2 Automation Object Library documentation provides a description of methods for this object. This example uses several ReportData methods.
- To get Dtype information, right click on a dimension in the Edit Window. At the bottom of the displayed menu is the item "Change Pop-up Display”. Select that and then select "Data Type Information”. Now when you hover the cursor over an item in the Edit Window, a help tip displays Dtype information. For example, if you hover over an OUTTOL value, the tooltip description displays "Out tol (DIM_OUTTOL – 344), 0”. The Dtype is DIM_OUTTOL and the Dtype number is 344. This example uses the Dtype numbers. Future versions of PC-DMIS will also allow the use of the Dtype itself.
- The VBS Mini-Editor accepts the MsgBox statement. You may want to use this statement to help debug your script. Information that you display via the MsgBox statement will be displayed during report generation.
- The VBS Mini-Editor is a "mini" editor. If you are familiar with Visual Basic / Visual Studio, note that this editor and the BASIC language used do not have all of the capabilities of the larger BASIC systems.

Step 1: Copy CADONLY.RTP to CADONLYREF_ID.RTP

In this step, CADONLYREF_ID.RTP will be the name of your new report template.

Inside Windows Explorer, create a copy of the CADONLY.RTP file in your Reporting sub-directory, and rename the copy to CADONLYREF_ID.RTP.

You can find the Reporting folder at this location. This folder contains all the templates that the Report window uses:

C:\Users\Public\Documents\Hexagon\PC-DMIS\<version>\Reporting

<version> represents the PC-DMIS version. If you want to customize existing templates or create new ones, do so in that directory.

If you need to restore any modified template to its factory settings, you can copy it from the DefaultReportingTemplateBackup directory located within the PC-DMIS installation directory and paste it the above Reporting directory.

Do not modify the templates in the DefaultReportingTemplateBackup directory.

Step 2: Copy REFERENCE_ID.LBL to REFERENCE_ID_COLOR.LBL

In this step, REFERENCE_ID_COLOR.LBL will be your new label template used for in-tolerance dimensions.

From the same Reporting subdirectory, create a copy of REFERENCE_ID.LBL, and rename the copy to REFERENCE_ID_COLOR.LBL.

Step 3: Add VB Script to REFERENCE_ID_COLOR.LBL

In this step, you will use the Label Template Editor to add VB script code to the new label template, REFERENCE_ID_COLOR.LBL, to set the background color based on the dimension color.

1. Select **File | Reporting | Edit | Label Template**, and open REFERENCE_ID_COLOR.LBL. The label opens. It contains a GridControlObject with one row and one column. If you double-click on the cell, you will see an expression inside which reads:

   ```
   =REF_ID:1
   ```

   This means the label will display the ID of the reference feature.

2. Right-click on the editor to display the **Properties** dialog box.

3. Select **GridControlObject1** from the list of objects.
4. In the **Properties** dialog box, expand **Events**.
5. Click [None] to the right of the **EventReportData** property. The **VBS Mini-Editor** appears. You may need to expand the **VBS Mini Editor** to be wider so that you can see the entire Sub statement toward the top.

   You can see that the ReportData object is passed in. This is where PC-DMIS extracts information about passed in dimensions. For additional information on the ReportData object, see the "ReportData Object" topic in the PC-DMIS 2026.2 Automation Object Library documentation. Also, if you need to reference the GridControlObject, you can use "This" as a shortcut to the object.

6. Insert this code into the **VBS Mini-Editor**:

```
   Dim I As Integer
   Dim MaxIndex As Integer
   Dim MaxDev As Double
   Dim CurrentDev As Variant
   Dim Dev As Variant
   Dim PTol As Variant
   Dim MTol As Variant
   Dim iReturn As Boolean   ' Initialize Max deviation
and Max Index
   MaxDev = 0.0
   MaxIndex = 1   ' Get the number of axes for this
dimension
   ' 132 is the Dtype AXIS
   Count = ReportData.GetCount(132)   ' Loop through to
find the largest deviation
   ' When the loop is complete, MaxIndex is the index to
the
   ' largest deviation
   For I = 1 to Count
      ' 340 is the Dtype DIM_DEVIATION
      CurrentDev = ABS(ReportData.GetValue(340, I))
      If CurrentDev > MaxDev Then
         MaxDev = CurrentDev
         MaxIndex = I
      End If
   Next I   ' Using MaxIndex, acquire that axes
deviation, + Tol and - Tol
   ' 167 is Dtype F_PLUS_TOL; 168 is Dtype F_MINUS_TOL
   Dev = ReportData.GetValue(340, MaxIndex)
   PTol = ReportData.GetValue(167, MaxIndex)
   MTol = ReportData.GetValue(168, MaxIndex)   ' Use
this information to adjust the background color of the
grid cell
   iReturn = This.SetCellBackgroundColor(0, 0,
ReportData.GetTolColor(Dev,PTol,MTol))
```

Explanation of Code:

This code uses the numeric values for Dtypes. The variable MaxDev is initialized to zero and when a larger deviation is found, it is placed in MaxDev. After the For/Next loop finishes, MaxDev holds the maximum deviation for this dimension and MaxIndex holds the index to that axis. The statement `ReportData.GetCount` gets the number of axes for this dimension. The For/Next loop loops through each axis.

`ReportData.GetTolColor` gets the tolerance color for the specified deviation and tolerance values. We use MaxIndex to get the deviation and tolerance values for the axis with the largest deviation. `GetTolColor` returns the color values as a Long.

We use `"This"` to reference the `GridControlObject1` object. `SetCellBackgroundColor` sets the background color for a specific cell. Arguments 1 and 2 are the cell's row and column numbers. The first cell in a row and column of a grid control is row / column zero. The third argument is the color that you wish to be the background color for this cell. It is also a Long value.

7. Once you have added the code, click **OK**. The Mini-Editor checks for any syntax errors. If you have an error in your code, PC-DMIS displays a message at this time. If there aren't any errors, the **VBS Mini-Editor** closes.
8. Select **File | Save** to save your new copy of REFERENCE_ID_COLOR.LBL.
9. Select **File | Close**. This closes the Label Template Editor.

Step 4: Import the CAD2.RUL rules into CADONLYREF_ID.RTP

In this step, you will import rules contained in the .RUL file into your new report template, CADONLYREF_ID.RTP. The .RUL file contains the set of rules used by the CAD portion of the TextAndCAD report, and it uses REFERENCE_ID.LBL to display the dimension. You will modify rules that uses REFERENCE_ID.LBL to use new rules and the new label template, REFERENCE_ID_COLOR.LBL.

1. Select **File | Reporting | Edit | Report Template**, and open CADONLYREF_ID.RTP.
2. Display the **Properties** dialog box.
3. Select the **CadReportObject1** object from the list of objects.
4. In the **Properties** dialog box, expand the **Standard** list and click **Rules** next to the **Rule Tree** property. The **Rule Tree Editor** opens.
5. Click the **Import** button, select CAD2.RUL, and then click **Open**. Your report template now includes the same rules that are used in the CAD portion of the TextAndCAD report template.

6. In the **Rule Tree Editor**, click on **Dimension Location**, and select the rule that says **Use Template "Reference_ID.lbl"**.
7. Click **Edit**. The **Edit Rule** dialog box appears.
8. Change the **Label Name** from "Reference_ID.lbl" to "Reference_ID_Color.lbl". You can do this by typing or by clicking the **...** button and navigating to this file.

Step 5: Add VB Script Code to CADONLYREF_ID.RTP

In this step, using the **Report Template Editor**, you will add script code to CADONLYREF_ID.RTP at each place in the rule tree that references REFERENCE_ID.LBL to check to see if the dimension is in tolerance. If it is in tolerance, the code will cause it to use REFERENCE_ID_COLOR.LBL. If it is not, the code will cause it to use LEGACY_DIMENSION_CAD.LBL.

1. While still In the **Edit Rule** dialog box, click **Use Additional Expression or Script**, select the **Script** option, and then click the **Edit** button. The **VBS Mini-Editor** appears.
2. Insert the following code into the VBS Mini-Editor:

```
DimCount As Integer
DimCurrentOutTol As Variant
DimI As Integer

' iRetVal = 1 if In-Tolerance;iRetVal = 0 if Out-of-
Tolerance

iRetVal= 1

'132 = Dtype AXIS

Count= ReportData.GetCount(132)

' Loop through each axis to see if OutTol is non-zero

ForI = 1 to Count

            ' 344 = Dtype DIM_OUTTOL
            CurrentOutTol = ReportData.GetValue(344, I)
            If CurrentOutTol > 0 Then
              iRetVal = 0
              Exit For
            End If
NextI
```

Explanation of Code:

This code uses the numeric values for Dtypes. It loops through each axis of this dimension and looks at the out-of-tolerance value. The return value is initialized to 1 (True). If a non-zero out-of-tolerance value is found, it sets the return value to 0 (False).

3. Once you have added the code, click **OK**. The Mini-Editor checks for any syntax errors. If you have an error in your code, PC-DMIS displays a message at this time. If there aren't any errors, the **VBS Mini-Editor** closes.
4. Click the **Add** button to define a new rule. The **Edit Rule** dialog box appears.
5. In the **Label Name** box, select or type LEGACY_DIMENSION_CAD.LBL.
6. Again, click **Use Additional Expression or Script**, select the **Script** option, and then click the **Edit** button. The **VBS Mini-Editor** appears.
7. In the **VBS Mini-Editor**, insert the following code:

```
Dim Count As Integer
Dim CurrentOutTol As Variant
Dim I As Integer

' iRetVal = 1 if In-Tolerance; iRetVal = 0 if Out-of-
Tolerance

iRetVal = 0

' 132 = Dtype AXIS

Count = ReportData.GetCount(132)

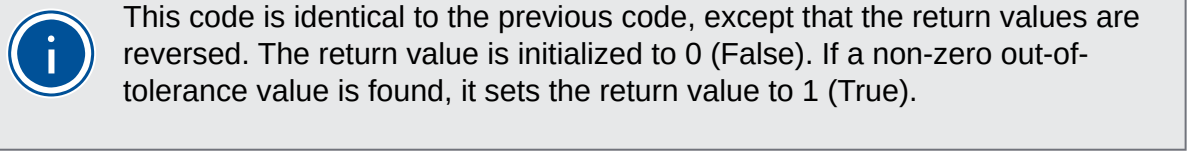
' Loop through each axis to see if OutTol is non-zero

For I = 1 to Count

            ' 344 = Dtype DIM_OUTTOL
            CurrentOutTol = ReportData.GetValue(344, I)
            If CurrentOutTol > 0 Then
              iRetVal = 1
              Exit For
            End If

Next I
```

Explanation of Code:



8. Once you have added the code, click **OK**. The **VBS Mini-Editor** checks for any syntax errors. If you have an error in your code, PC-DMIS displays a message at this time. If there aren't any errors, the **VBS Mini-Editor** closes.

9. Click **OK** to close the **Edit Rule dialog box.**

Step 6: Modify the Rules to Use the VB Script Code for Remaining Dimensions

In this step you will use the **Copy** and **Paste** functions inside the **Rule Tree Editor** so that the other legacy dimension types can use the same rules.

At this point, the **Rule Tree Editor** is open and the **Dimension Location** is selected.

1. Click and highlight both rules for the selected dimension.

2. Click the **Copy** button.

3. Go through each legacy dimension in the rule tree, and check to see if it has this rule: Use Template "Reference_Id.lbl".

4. If it does, select the rule, and click the **Paste** button. This adds the copied rules to the selected dimension type.

5. Once you have modified all the dimension types to use the new rules, click **OK** to close the **Rule Tree Editor**.

6. Select **File | Save** to save your new copy of CADONLYREF_ID.RTP.

7. Select **File | Close**. This closes the Label Template Editor.

Step 7: Test CADONLYREF_ID.RTP in the Report Window

In this step you select the CADONLYREF_ID.RTP template and test it inside the Report window.

1. Ensure that your measurement routine uses legacy dimensions.

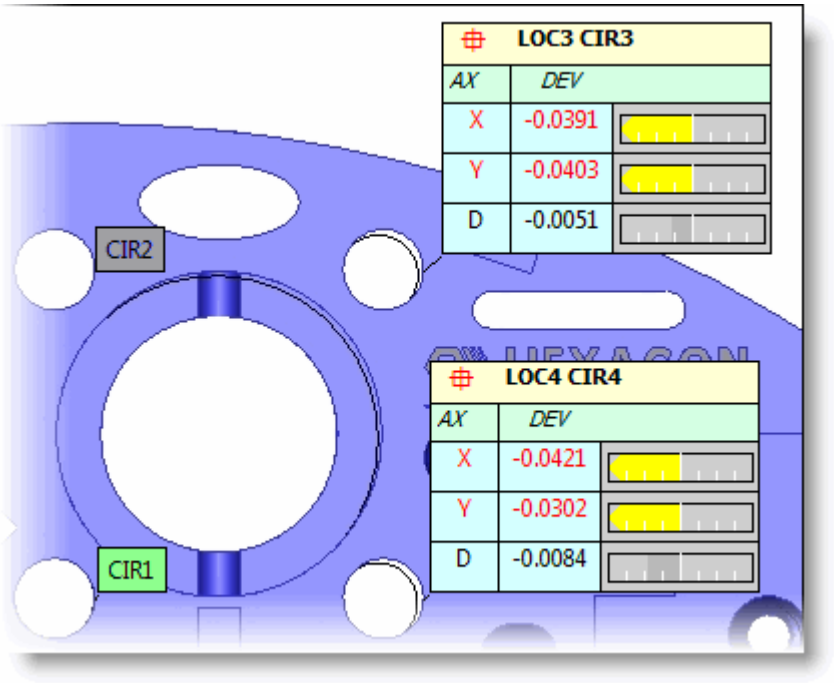
2. Execute your measurement routine.

3. Display the Report Window by selecting **View | Report Window**.

4. From the **Reporting** toolbar, click on the **Template Selection Dialog** icon . The **Report Templates** dialog box appears.
5. Click the **Add** button.
6. From the **Open** dialog box, select CADONLYREF_ID.RTP, and click **Open**. The report template is added into the **Report Templates** dialog box.
7. From the **Report Templates** dialog box, select CADONLYREF_ID.RTP again, and click **Open**.
8. PC-DMIS loads the report template. The Report window will contain a report of your measurement routine results using the newly created CADONLYREF_ID.RTP report template.

Notice that in-tolerance dimensions only display the feature name and that the background color is the dimension color and matches a color on the dimension color key at the bottom of the page. Out-of-tolerance dimensions use the LEGACY_DIMENSION_CAD.LBL label.

The following screen capture demonstrates what such a report might look like:



A sample report showing in-tolerance features (CIR1 and CIR2) and out-of-tolerance features (CIR3 and CIR4).

Congratulations, you've completed the tutorial!

Working with PDF 3D Files

PC-DMIS can print your report or export your CAD model as a PDF 3D file.

- To print your report, see "Printing the Report Window" in the "Using Basic File Options" chapter.
- To export your CAD model, see "Exporting to a PDF 3D File".

Supported Items and Known Limitations

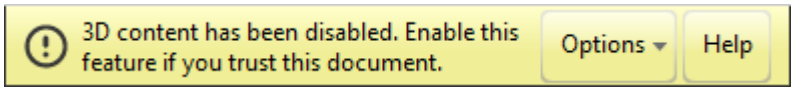
The PDF 3D file supports the Analysis command, Snapshot (live) command, CADReportObject, and the AnalysisWindowObject.

This file format does not support Legacy HyperReport objects or the ability to append to the file.

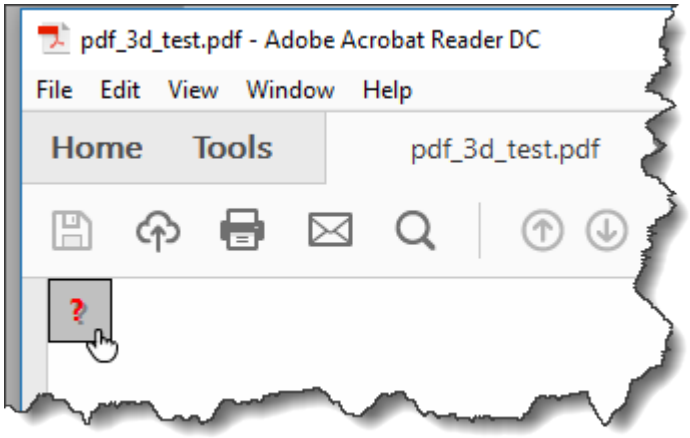
Viewing the CAD Model in the File

Once the PDF 3D file is generated, you can use any PDF viewer that is capable of supporting CAD data to view and interact with the CAD model. You can perform pan, zoom, rotate, and part-selection operations.

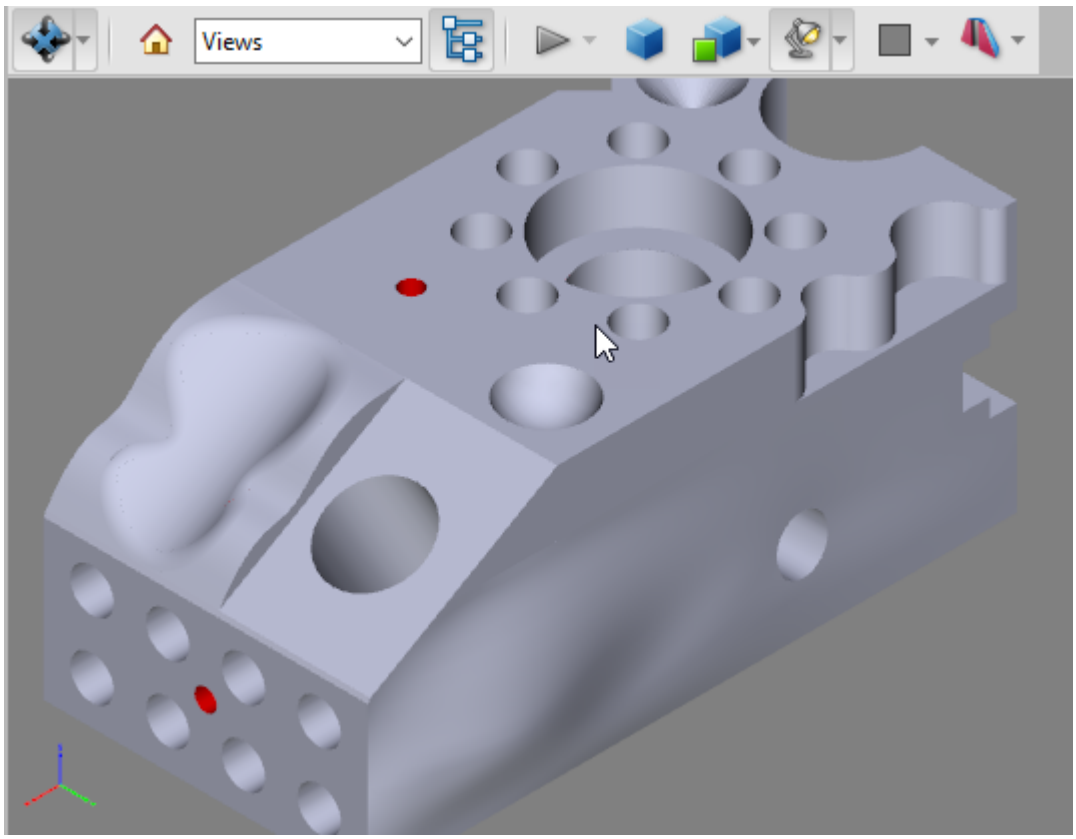
1. Open the exported PDF file inside of an Adobe viewer that supports 3D content. If you have not enabled 3D content, you must first trust the file.



2. Use the **Options** button to trust the file.
3. Once you trust the file, click the red question mark icon to open the CAD model.



4. With the CAD model visible, hover your pointer over the CAD model. Use the buttons on the toolbar to interact with the model.



Additional Information

For information on the different operations you can perform with a PDF 3D file, consult this Adobe documentation:

https://helpx.adobe.com/acrobat/using/displaying-3d-models-pdfs.html

QIF Report

The topics in this section include:

About QIF Report

Creating a QIF Report

Creating a QIF Report from a STEP File

About QIF Report

Quality Information Framework (QIF) is an ANSI standard. PC-DMIS now supports measurement data output in a QIF format report if the routine was created by importing a QIF MBD (Model-Based Definition) file.

For more information on QIF, refer to the QIF website.

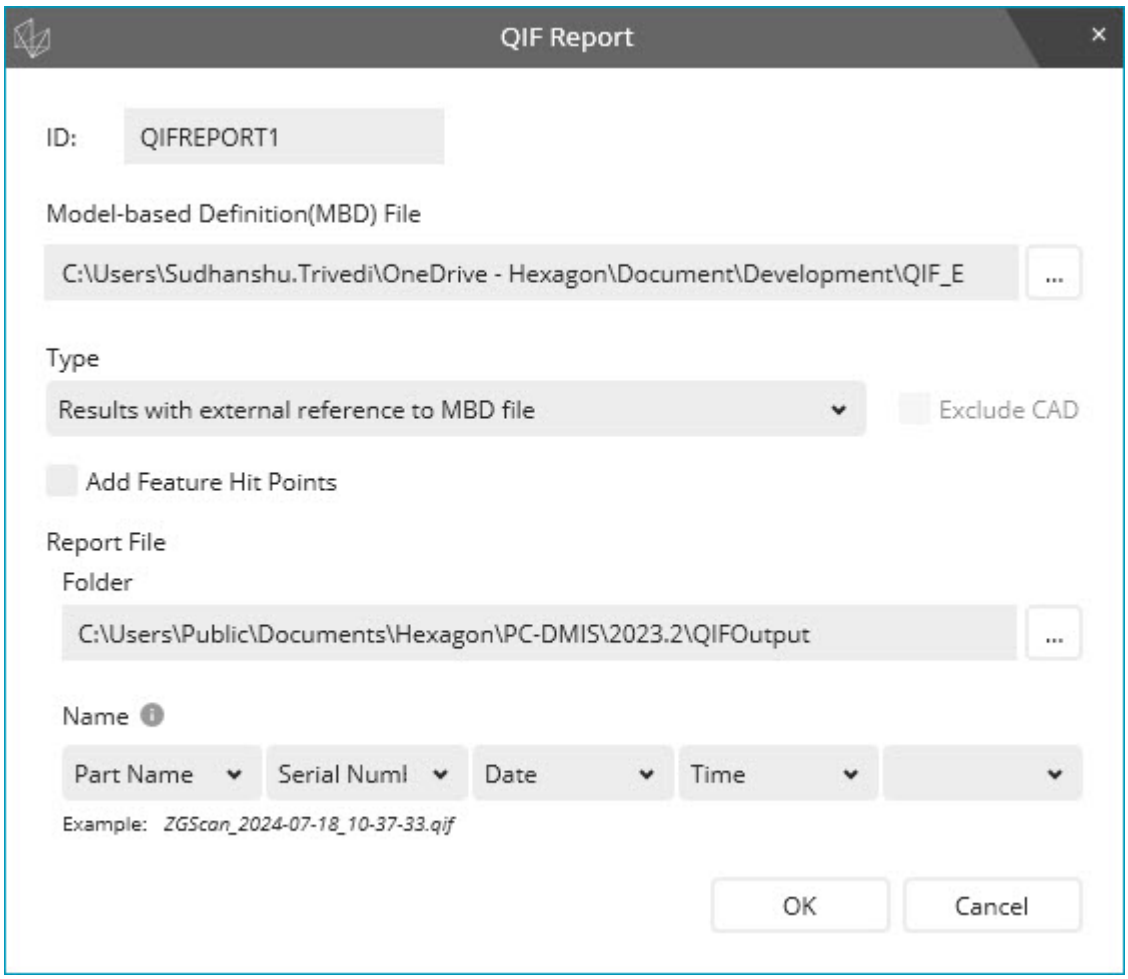
To output the results in QIF format, you must create a measurement routine by importing a CAD model using a QIF MBD file.

Creating a QIF Report

To create a QIF report, follow these steps:

1. Create a new measurement routine.
2. Import the CAD model using QIF MBD file. The CAD has the required information, such as feature and characteristic IDs. The QIF MBD file supports PMI data.
3. Define the measurement features using GD&T Selection Mode (from CAD). For information on how to do this, see the “Using GD&T Selection Mode (from CAD)” topic.

   When you create features and characteristics this way, PC-DMIS stores Feature ID, Characteristic ID, and other information required to output QIF results.
4. After you create the measurement routine, insert the QIF Report command. To do this, select the **Insert | Report Commands | QIF Report** menu option to open the **QIF Report** dialog box.

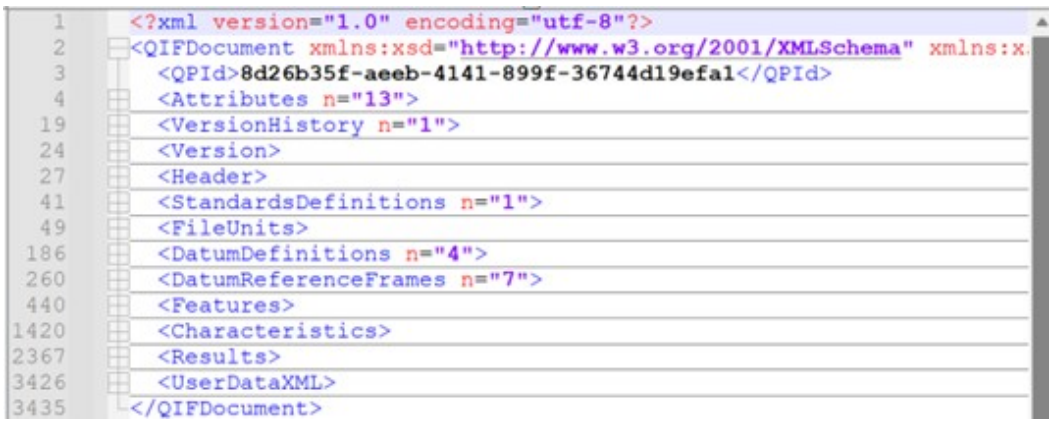


Complete these options:

- **ID** - ID of the QIF Report command.
- **Model-based Definition (MBD) File** – This is the location of the .qif file that PC-DMIS uses to obtain information for the output file.

  Ensure that the .qif file is available at this location during execution. QIF Report needs this file.

- **Type** - You can output the QIF Report file in these formats:
  - **Results with MBD data** - In this format, the result file includes the MBD data. This file has the advantage of containing all information in one file. However, adding information to the result file that is available in the MBD file increases the size of the result file.



- **Exclude CAD** - Use this check box to include or exclude the CAD data when you select the **Results with MBD data** option. PC-DMIS stores the CAD data in the `Product` node of the QIF MBD file. This option is enabled only if you select the **Results with MBD data** option.

  - **Results with external references to MBD file** - In this format, the result file does not contain the MBD data. It has a node to define the information on external QIF references. This file type is of minimum size as it includes only the results data.

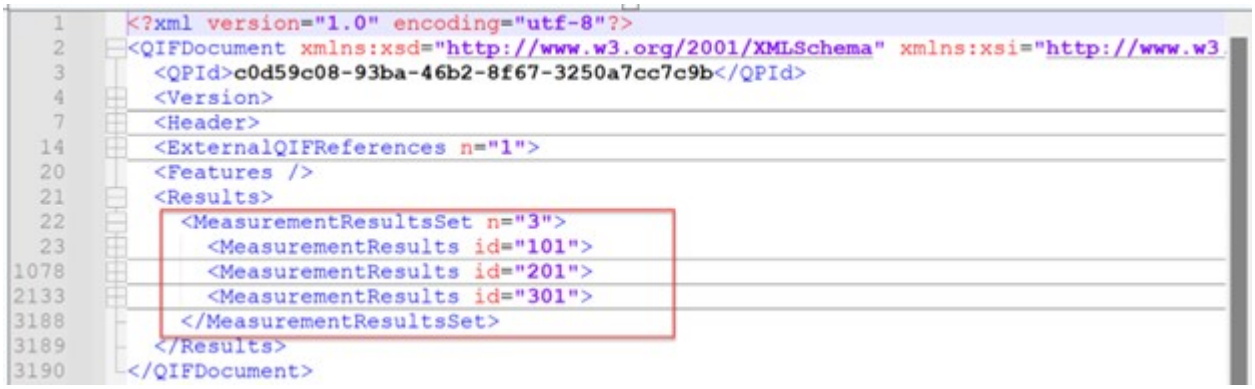
- **Add Feature Hit Points** - If you select this check box, PC-DMIS adds the Hit point data to the result file. This option is available for all output file types.

- **Report File**
  - **Folder** - Use this box to type the path to store the QIF result file, or click the Browser (...) button and navigate to the location where you want to store it.
  - **Name** - Use the drop-down list box to define a name rule for the result file. The options in the drop-down list are **Part Name**, **Serial Number**, **Revision Number**, **Date**, and **Time**.

5. To create a QIF Report, click **OK**.

Results of Multiple Executions in One QIF Report File

You can store multiple results in a single QIF Report file. To get a report of multiple executions in one file, create a name rule to generate report files with the same name. If PC-DMIS finds an existing report file with the same name, it only adds the result, and the previous data remains the same.



Creating a QIF Report from a STEP File

To create a QIF report, follow these steps:

Prerequisites: A STEP file that contains UUIDs for the features and characteristics.

1. Create a new measurement routine.

2. Import the STEP file that contains UUIDs for the features and characteristics. For information on how to import a STEP file, see the "Importing a STEP File" topic in the PC-DMIS Core documentation.

   When you import a STEP file that contains UUIDs into PC-DMIS, PC-DMIS automatically generates and imports a QIF Plan containing the QIF Bill of Characteristics in the background. This associates the digital thread IDs with the corresponding STEP features and characteristics.

3. Define the measurement features using GD&T Selection Mode (from CAD). For information on how to do this, see the "Using GD&T Selection Mode (from CAD)" topic.

4. After you create the measurement routine, insert the QIF Report command. To do this, select the **Insert | Report Commands | QIF Report** menu option to open the **QIF Report** dialog box.

   Complete these options:

   - **ID** - ID of the QIF Report command.
   - **Model-based Definition (MBD) File** – This is the location of the .qif file that PC-DMIS uses to obtain information for the output file.

Ensure that the .qif file is available at this location during execution. QIF Report needs this file.

- **Type** - You can output the QIF Report file in these formats:
  - **Results with MBD data** - In this format, the result file includes the MBD data. This file has the advantage of containing all information in one file. However, adding information to the result file that is available in the MBD file increases the size of the result file.

    - **Exclude CAD** - Use this check box to include or exclude the CAD data when you select the **Results with MBD data** option. PC-DMIS stores the CAD data in the `Product` node of the QIF MBD file. This option is enabled only if you select the **Results with MBD data** option.

  - **Results with external references to MBD file** - In this format, the result file does not contain the MBD data. It has a node to define the information on external QIF references. This file type is of minimum size as it includes only the results data.

- **Add Feature Hit Points** - If you select this check box, PC-DMIS adds the Hit point data to the result file. This option is available for all output file types.

- **Report File**
  - **Folder** - Use this box to type the path to store the QIF result file, or click the Browser (...) button and navigate to the location where you want to store it.
  - **Name** - Use the drop-down list box to define a name rule for the result file. The options in the drop-down list are **Part Name**, **Serial Number**, **Revision Number**, **Date**, and **Time**.

5. To create a QIF Report, click **OK**.

Results of Multiple Executions in One QIF Report File

You can store multiple results in a single QIF Report file. To get a report of multiple executions in one file, create a name rule to generate report files with the same name. If PC-DMIS finds an existing report file with the same name, it only adds the result, and the previous data remains the same.

Inserting Report Commands

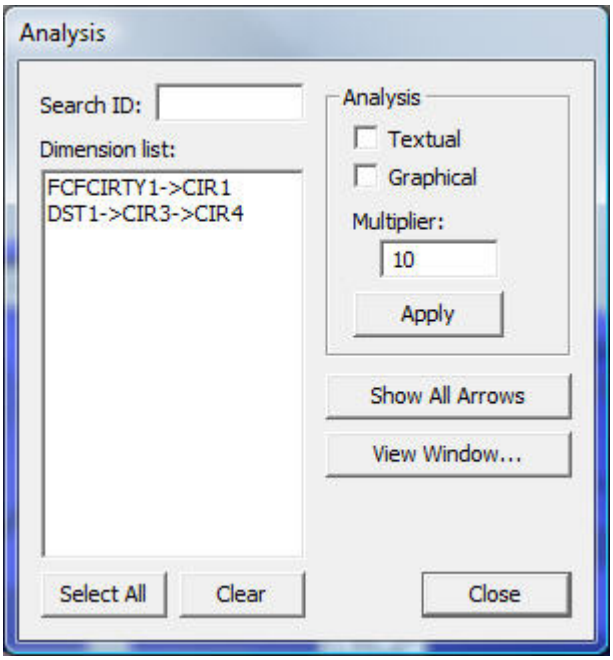
Inserting Report Commands: Introduction

PC-DMIS allows you to insert a variety of commands into the Edit window that affect how and what information gets displayed in reports. These commands, inserted by selecting menu options from the **Insert | Report Command** sub menu, allow the programmer to configure, view, print, and otherwise customize the appearance of the Edit window.

The following topics are covered in this chapter.

- Inserting Commands Related to the Analysis Window
- Inserting Dimension Info Boxes
- Inserting Point Info Boxes
- Inserting Programmer Comments
- Embedding Reports or Report Templates in a Measurement Routine
- Inserting External Objects
- Inserting a Print Command
- Inserting a Form Feed Command
- Working with Viewsets
- Inserting a FORM Command
- Inserting Screen Captures
- Inserting Snapshots

Inserting Commands Related to the Analysis Window

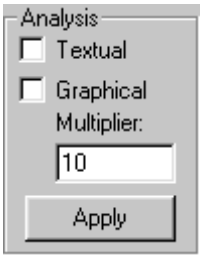


Analysis Dialog Box

The **Insert | Report Command | Analysis** menu option brings up the **Analysis** dialog box. This dialog box sends the dimensional printout to an **Analysis** window in a format suitable for close examination. From the Analysis window, you can insert an `ANALYSISVIEW` command into the Edit window to include the analysis on the report. For information on the Analysis window, see the "View Window" topic.

If this dialog box is open, you can click on a feature in the Graphic Display window to automatically highlight dimensions using that feature in the **Dimension List** box.

Analysis area



The **Analysis** area of this dialog box allows you to choose to view the dimension(s) selected from the **Dimension List** box in either a graphical or a textual readout.

By default, the check boxes in the **Analysis** area are not selected. When you select either the **Textual** or **Graphical** check box and click **Apply**, PC-DMIS will show the selected dimensions in a textual format or a graphical image. It will not display any CAD data.

It is helpful to have either the Graphical or Textual Analysis option on when having a problem with a feature whose cause needs to be determined.

Suppose you are inspecting a plane for flatness, and you find it is out of tolerance. Using the Graphical Analysis option allows you to examine the plane and determine if a specific area is bad or if the entire surface is irregular.

Graphical - If you select the Graphical check box, PC-DMIS stores the dimension information in a format that you can view graphically.

Textual - If you select the Textual check box, PC-DMIS stores the dimension information in a format that you can view textually.

Multiplier - The value in the Multiplier box is a scaling factor that magnifies the arrow and tolerance zone for the graphical analysis mode. For example, if you enter a value of 2.0, PC-DMIS scales the arrow two times the graphical image. You can use this option for viewing purposes only. It is not reflected in the text printout.

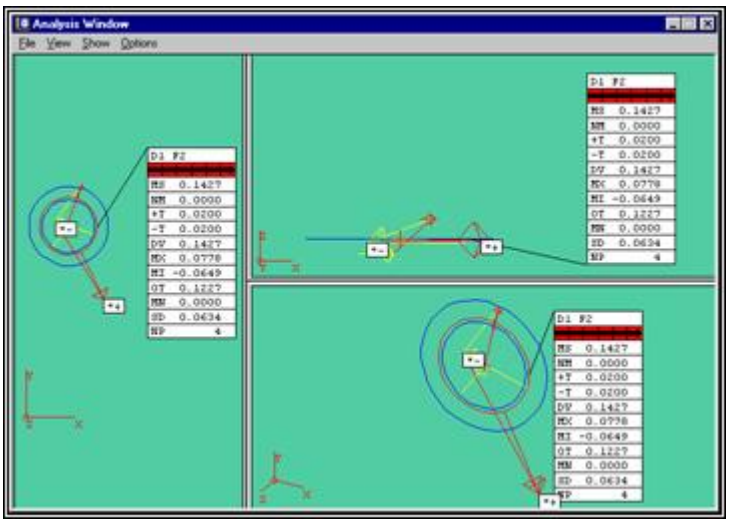
Show All Arrows

The **Show All Arrows** button shows the graphical analysis arrows used to mark deviation. These graphical analysis arrows can be hidden arrow by arrow. To do this, press CTRL + SHIFT, and click the arrows to hide. Clicking the **Show All Arrows** button re-displays the arrows. The graphical analysis arrows will then be reset for display purposes.

View Window (Analysis Window)

From the **Analysis** dialog box, the **View Window** button displays the Analysis window.

You can use the Analysis window's menu bar to alter the graphical image, capture the current graphics screen, or edit the selected dimension colors.



Analysis Window

To access this window:

1. Select **Insert | Report Command | Analysis** menu option to show the **Analysis** dialog box.
2. From the **Analysis** dialog box:
    - Select the dimension that needs to be examined in the Analysis window.
    - In the **Multiplier** box, type a value to magnify the arrow and tolerance zone.
3. Click **View window** button to open the Analysis window.

The menu bar on the Analysis Window provides these menus:

- **File**
- **View**
- **Show**
- **Options**

In order to determine the initial view of the graphical analysis in the Analysis Window, PC-DMIS uses either the scan cut vector for profile dimensions of scans or the current workplane for other dimensions. This view can be altered later.

File Menu

The *Analysis window's* **File** menu allows you to send the contents of the Graphics Analysis window directly to the printer for printing purposes.

View Menu

The *Analysis window's* **View** menu allows you to temporarily alter the graphics displayed for the selected dimension. By rotating, scaling, or changing the view, you can easily access the necessary dimensions.

This option is especially useful when viewing the profile error of a set of points.

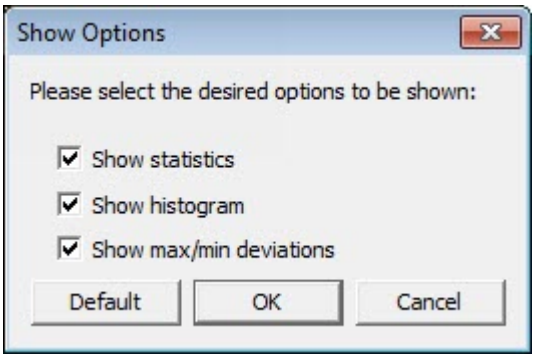
The **View | Change** menu option lets you create new views from a CAD file. This function is useful when a 2D IGES file is used that contains several views of a part in one plane and the views need to be associated with their correct orientation in the Graphic Display window. See "Setting Up the Screen View" in the "Editing the CAD Display chapter for more information on manipulating views.

The **View | Scale To Fit** menu option re-draws the part image to fit entirely within the Graphic Display window. This function is useful whenever the image becomes too large or small.

The **View | Rotate** menu option displays the **Rotate** dialog box, allowing you to rotate the part image in three dimensions.

The topic "Rotating the Drawing" in the "Editing the CAD Display" chapter describes rotating in further detail.

Show Menu



Show Options Dialog Box

The *Analysis window's* **Show | Show Options** menu command displays the **Show Options** dialog box. This dialog box allows you to choose what to display in the Analysis window.

The *Analysis window's* **Show | Show Dimensions Stats** brings up the **Edit Dimension Info** dialog box. This dialog box allows you to edit in depth the highlighted dimension. See

"Common Dimension Dialog Box Options" in the "Using Legacy Dimensions" chapter and "Inserting Dimension Info Boxes" in this chapter for more information.

Show Statistics - Displays various statistics in the Analysis window. If the **Show Statistics** check box is not selected, dimensional information text will not be displayed (for any dimensions). See the **Edit Dimension Info** menu option to change the format of the statistics displayed in the Analysis window.

Show Histogram - Displays a histogram of the deviations for each point. Histograms can be moved to new locations within the Analysis window.

To move to a new location within the Analysis window:

1. Click on the desired histogram.
2. Drag the cursor to the desired location.
3. Release the mouse button.

Show Max/Min Deviations - Displays the maximum and minimum deviations indicated with a '*+' or '*-' symbol.

Options Menu

The *Analysis window's* **Options** menu allows you to capture the current graphics screen for later use. It also provides access to the **Edit Color** dialog box and sizing of the Analysis window.

Create/Save Analysis View Command

The *Analysis window's* **Options | Create Analysis View Command** menu option uses the dimensions, views, and rotations used in the Analysis window and inserts that information into an `ANALYSISVIEW` command into the Edit window. When PC-DMIS executes the `ANALYSISVIEW` command, the following occurs:

- PC-DMIS opens the Analysis window momentarily and then takes a screen capture of its contents.
- PC-DMIS then displays this screen capture in the Report window. It automatically sizes the screen capture to fit the Report window. It is inserted into the Report window's underlying TextReportObject. For information on the TextReport object, see the "TextReportObject" topic in the "Reporting Measurement Results: Overview" chapter. It does not affect the AnalysisWindow object.

The Edit window command line for this option reads:

```
ANALYSISVIEW/D1,D2,D3,,
```

D1,D2,D3 = list of dimensions to be displayed.

There is no limit to the number of dimension parameters that can be used.

You can also type " `ANALYSISVIEW` " in the Edit window to creates an `ANALYSISVIEW` command. Any dimensions that you select for analysis become parameters for this command.

Save Graphics to Report

The image will remain on the clipboard until another screen is captured, or the measurement routine is closed.

The *Analysis window's* **Options | Save Graphics To Report** menu option captures the view in the Analysis window and stores it in a `DISPLAY/METAFILE` command. When executed this in turn sends the capture into the inspection report.

PC-DMIS does not have the ability to edit or format the captured image. The graphics will be displayed at the cursor's location.

This `DISPLAY/METAFILE` command differs from the `DISPLAY/METAFILE` command generated from the main menu in these ways:

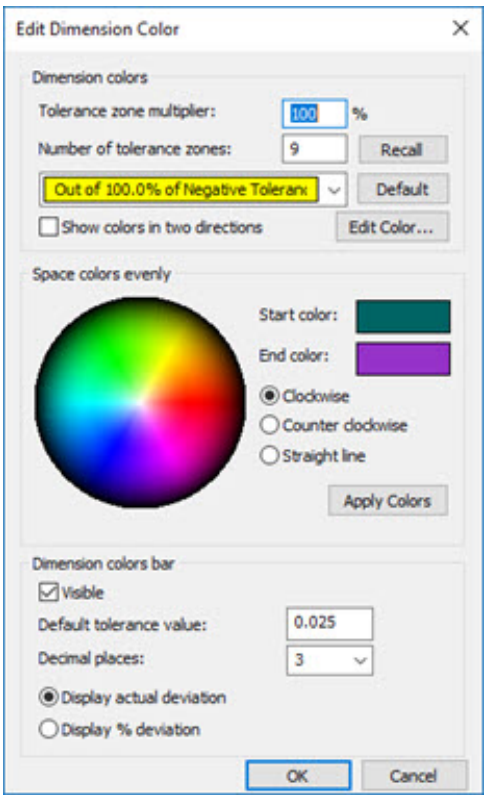
- It takes the screen capture of the view in the Analysis window when you select the menu item, not the Graphic Display window.
- The screen capture does not get retaken during execution, it is a static image.

See "Create Analysis View Command" for creating a screen capture that automatically updates itself upon execution.

See "Screen Captures" in the "Using the Edit Window" chapter for additional information on the `DISPLAY/METAFILE` command.

Edit Dimension Colors

The *Analysis window's* **Options | Edit Dimension Colors** menu option allows you to set the color for a specified tolerance range. Select this option to display the **Edit Dimension Colors** dialog box.

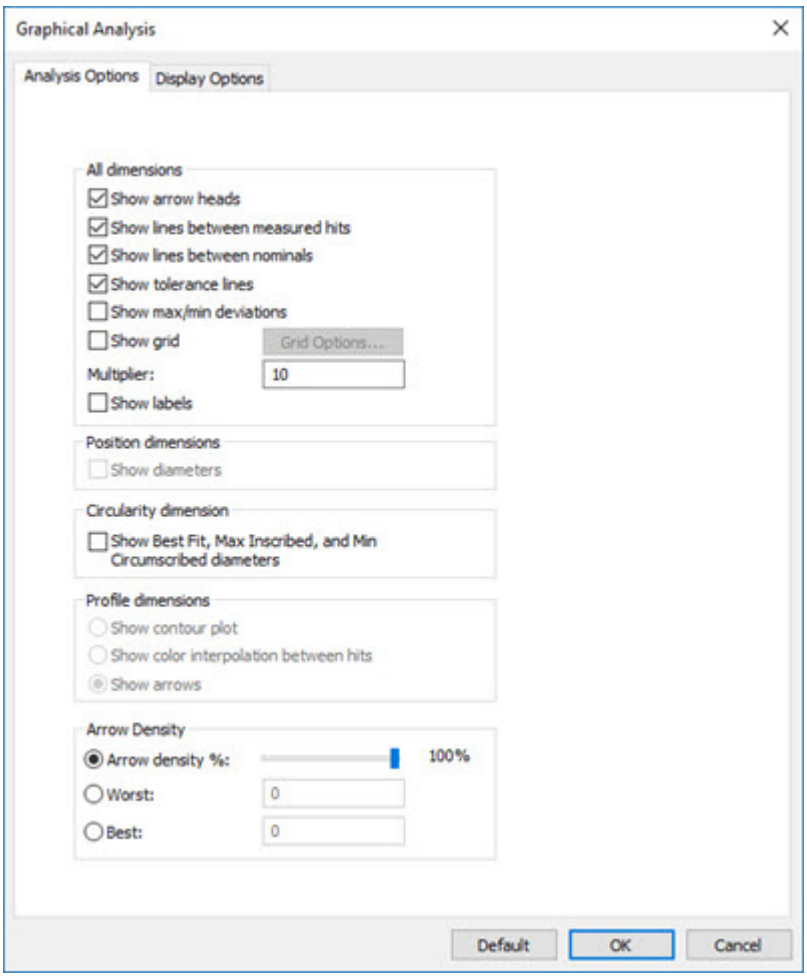


Edit Dimension Colors Dialog Box

For instructions on how to use this dialog box to change dimension colors for a tolerance, see the "Editing Dimension Colors" topic in the "Editing the CAD Display Options" chapter.

Analysis Options

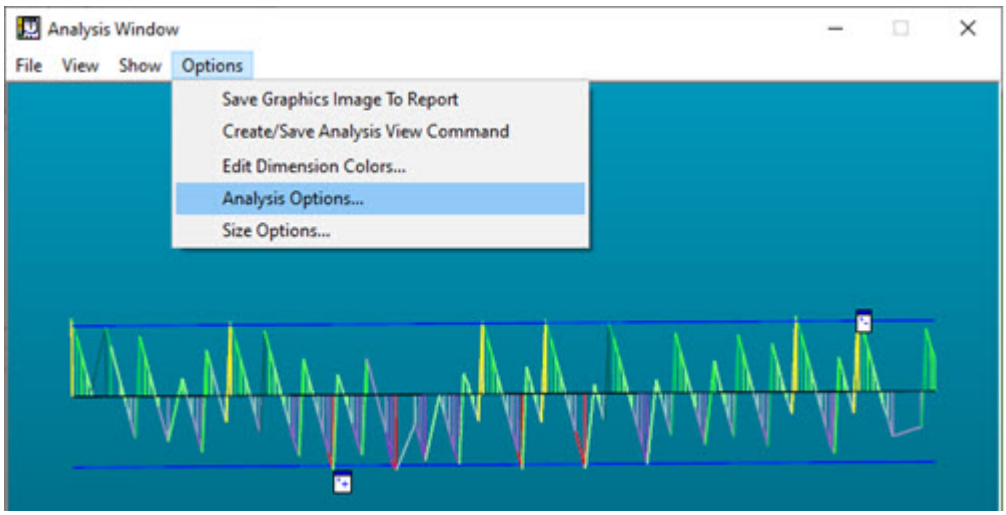
This **Graphical Analysis** dialog box determines the information that gets displayed in the Analysis window.



Graphical Analysis Dialog Box

To access this dialog box:

1. Select **Insert | Report Command | Analysis** from the menu to show the **Analysis** dialog box.
2. From the **Analysis** dialog box, from the **Dimension list** box, select the dimension.
3. Click **View Window** to show the Analysis window.
4. To open the **Graphical Analysis** dialog box, from the Analysis window's menu, select **Options | Analysis Options**.



Analysis Options Menu Option

You can quickly access the analysis settings from the main PC-DMIS menu (**Edit | Graphic Display | Analysis Options**) when:

- You change the dimension option from `GRAPH=OFF` to `GRAPH=ON` (or, for Geometric Tolerances, from `CADGRAPH=OFF` to `CADGRAPH=ON`), and...
- You want to change the analysis settings shown in the Graphic Display window

Prior to this, PC-DMIS required that you create an `ANALYSIS` command to get to these options.

The **Graphical Analysis** dialog box contains two tabs:

- **Analysis Options** - For a description of the items on this tab, see "Analysis Options tab" below.
- **Display Options** - For a description of the items on this tab, see the "AnalysisWindow Object" topic in the "Reporting Measurement Results" chapter where it covers the **Reporting Options** tab.

Note that when you open the **Graphical Analysis** dialog box from an analysis view, it shows the tab names as **Analysis Options** and **Display Options**. When you open the dialog box from within a report, it shows the tab names as **Analysis Options** and **Reporting Options**.

Analysis Options tab

The **Analysis Options** tab of the **Graphical Analysis** dialog box has these areas:

All dimensions area

Show arrow heads - This shows the arrow heads on the deviation lines.

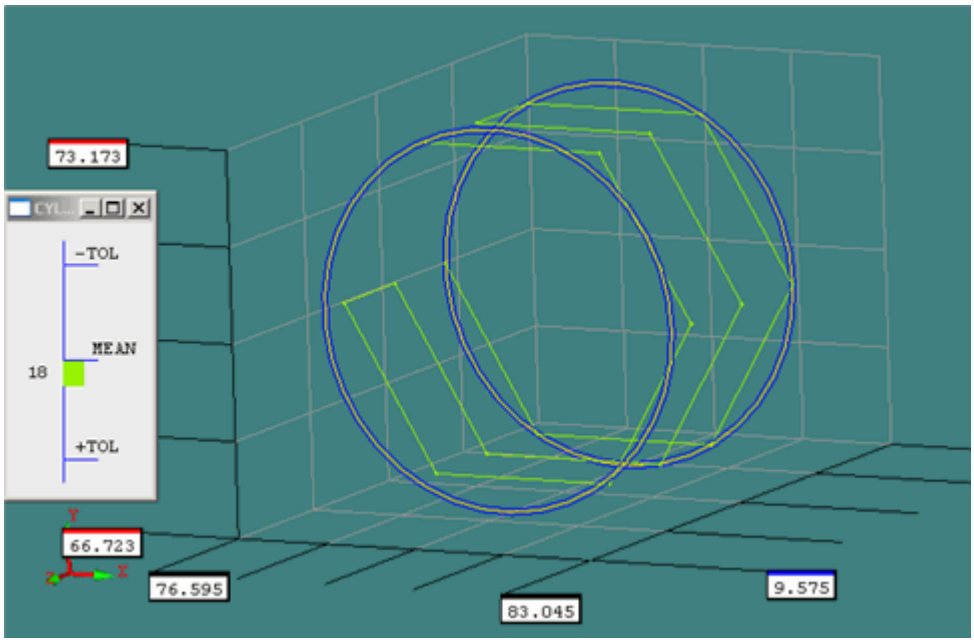
Show lines between measured hits - This shows the lines between the measured hits.

Show lines between nominals - This draws the lines that PC-DMIS draws between the nominal values.

Show tolerance lines - This displays the acceptable tolerances for the dimension.

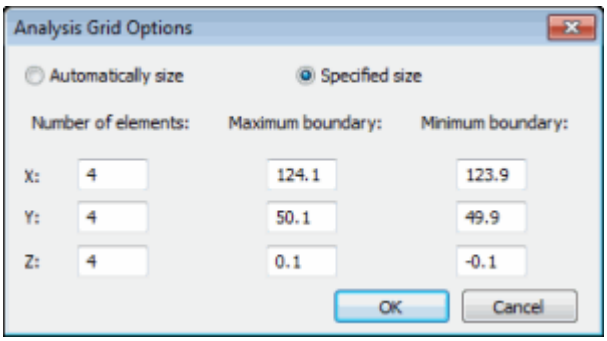
Show max/min deviations - This allows the maximum and minimum deviations to be indicated with a *+ or *- symbol.

Show grid - This displays a 3D grid-like backdrop for the graphical analysis. Enabling the grid may help you better visualize rotated items. It also enables the **Grid Options** button.



A sample Graphical Analysis window with the Grid option enabled.

Grid Options - This displays the **Analysis Grid Options** dialog box. You can use this dialog box to define your grid.



Analysis Grid Options Dialog Box

The dialog box contains these options:

Automatically size - This automatically sizes the grid based on the number of objects specified in the X, Y, and Z fields.

Specified size - This enables the **Maximum Boundary** and **Minimum Boundary** boxes, which let you type specific sizes for the maximum and minimum boundaries.

Number of elements - This defines the number of divisions that PC-DMIS draws on the analysis grid.

Maximum boundary - This defines upper limits of the analysis grid coordinates.

Minimum boundary - This defines the lower limits of the analysis grid coordinates.

Multiplier - This lets you type a scaling factor that magnifies the deviation arrows and the tolerance zone for the graphical analysis mode. If you enter a value of 2.0, PC-DMIS scales the arrows two times the calculated deviation for each feature hit.

This option is used for viewing purposes only and is not reflected in the text-only printout.

Position dimensions area

Show Diameters - This shows the diameters of the available Position dimensions.

Circularity dimension area

Show Best Fit Diameter, **Max Inscribed Diameter**, **Min Circumscribed Diameter** - These check boxes show the diameters for the Circularity dimension. These diameters represent the average, maximum, and minimum deviations for a round feature.

Profile dimensions area

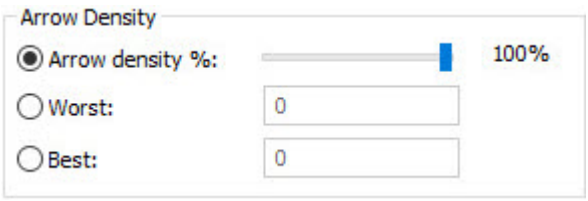
Show Contour Plot - This option only works for Profile dimensions applied to patch scans. The contour plot uses the patch scan's points to create a mesh. It then shades the mesh with the colors related to the profile deviations from each hit.

PC-DMIS can also display the contour plot on the CAD model in the Graphic Display window itself. For information, see "Displaying Surface Profile Contour Plots" in the "Using Legacy Dimensions" chapter.

Show Color Interpolation Between Hits - This inserts colors between hits. This option is available for Profile dimensions.

Show Arrows - This shows arrows for each point's deviation. This option is available for Profile dimensions.

Arrow Density area

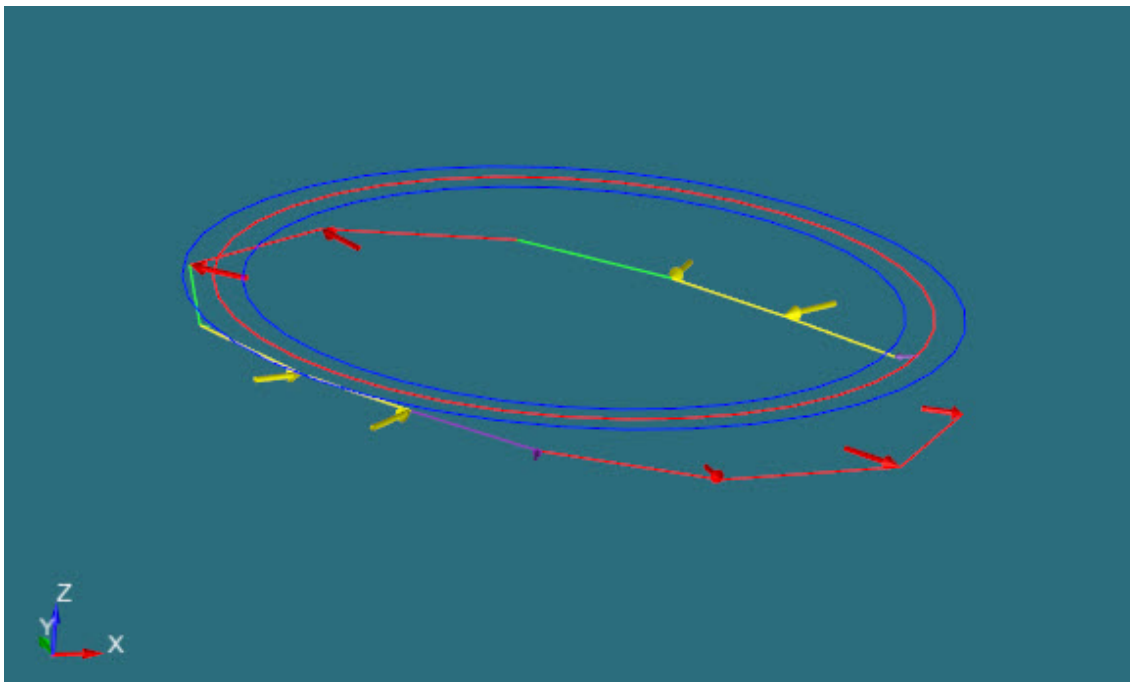


Arrow Density - This slider changes the density of arrows for the points displayed in any dimension in the entire measurement routine that uses Graphical Analysis.

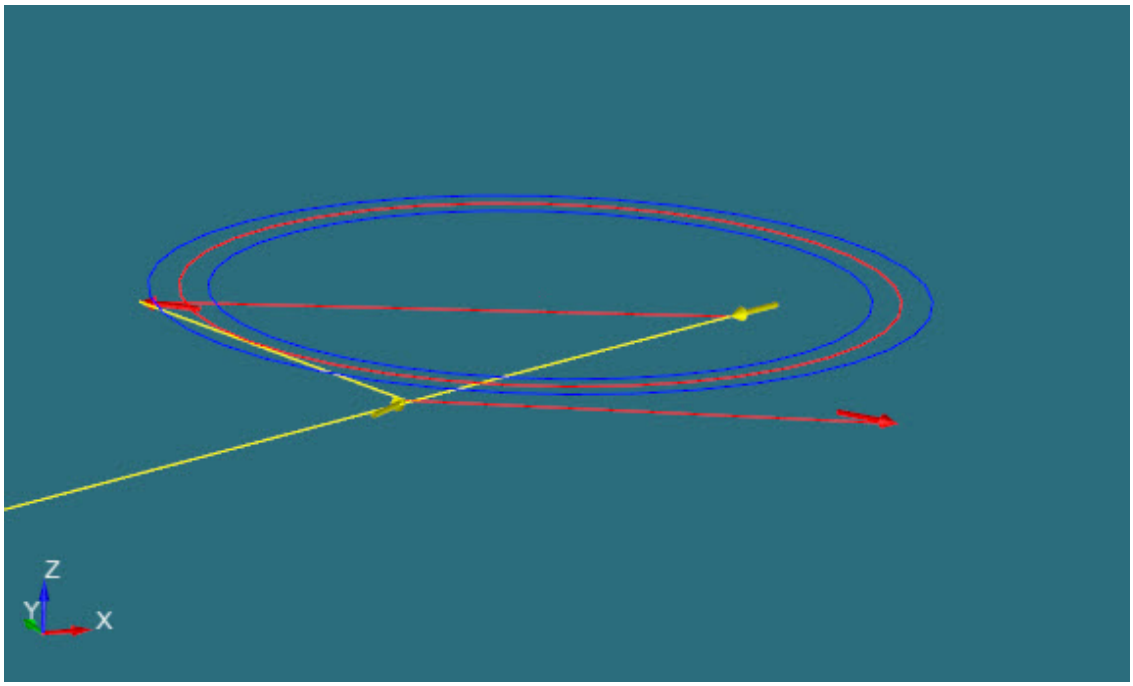
This differs from the **Arrow Density** functionality in the **Reporting** tab of the **Geometric Tolerance** dialog box. The setting in the **Reporting** tab only affects that specific dimension. See "Reporting Tab" in the "Using Geometric Tolerances" chapter.

Worst - This box defines the number of worst deviations for which to display arrows. The examples below show all arrows on the left and the three worst arrows on the right.

Best - This box defines the number of best deviations for which to display arrows.

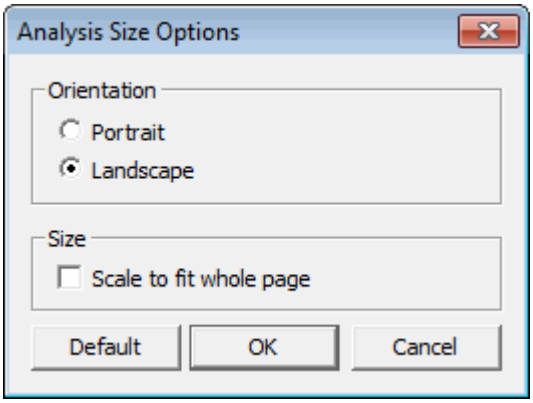


Example showing all the deviations (100% arrow density).



Example showing the three worst deviations.

Size Options



Analysis Size Options Dialog Box

The **Analysis Size Options** dialog box allows you to determine how PC-DMIS displays the Analysis window. These options also allow you to set your `ANALYSISVIEW` command so that PC-DMIS takes the screen capture in one of these selected modes during execution. (See "Create Analysis View Command".)

You can select the following options:

Portrait
This option sizes the Analysis window so that it matches the standard Portrait page size.

Landscape
This option sizes the Analysis window so that it matches the standard Landscape page size.

Scale to fit whole page
This check box scales the window so it would fit an entire printed page.

Inserting a 2D Plot Command

The topics in this section include:

About 2D Plot
Scan Plot

About 2D Plot

The 2D Plot function enables you to creates 2D curve plots. Use this function to generate plots for all types of 2D scans.

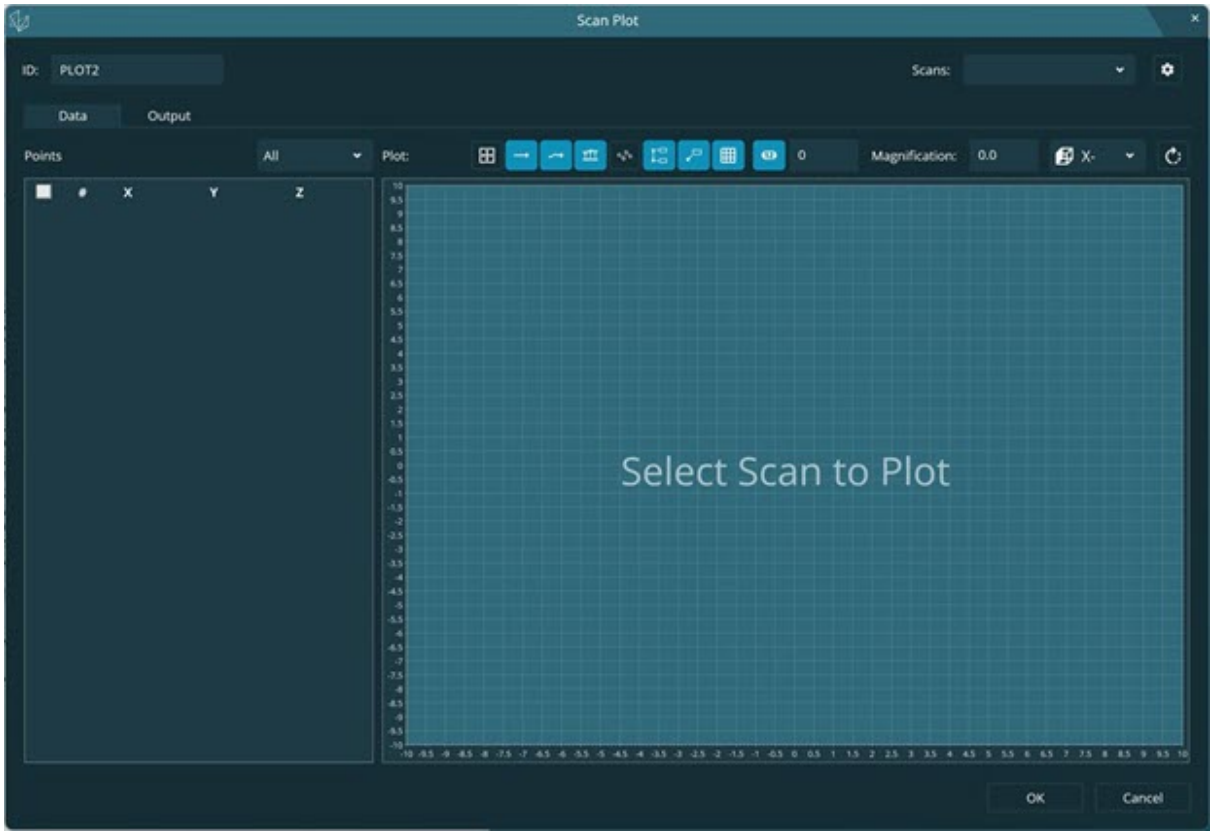
Scan Plot

PC-DMIS allows you to create a 2D plot of your scan.

Creating a Scan Plot

To create a Scan Plot, follow these steps:

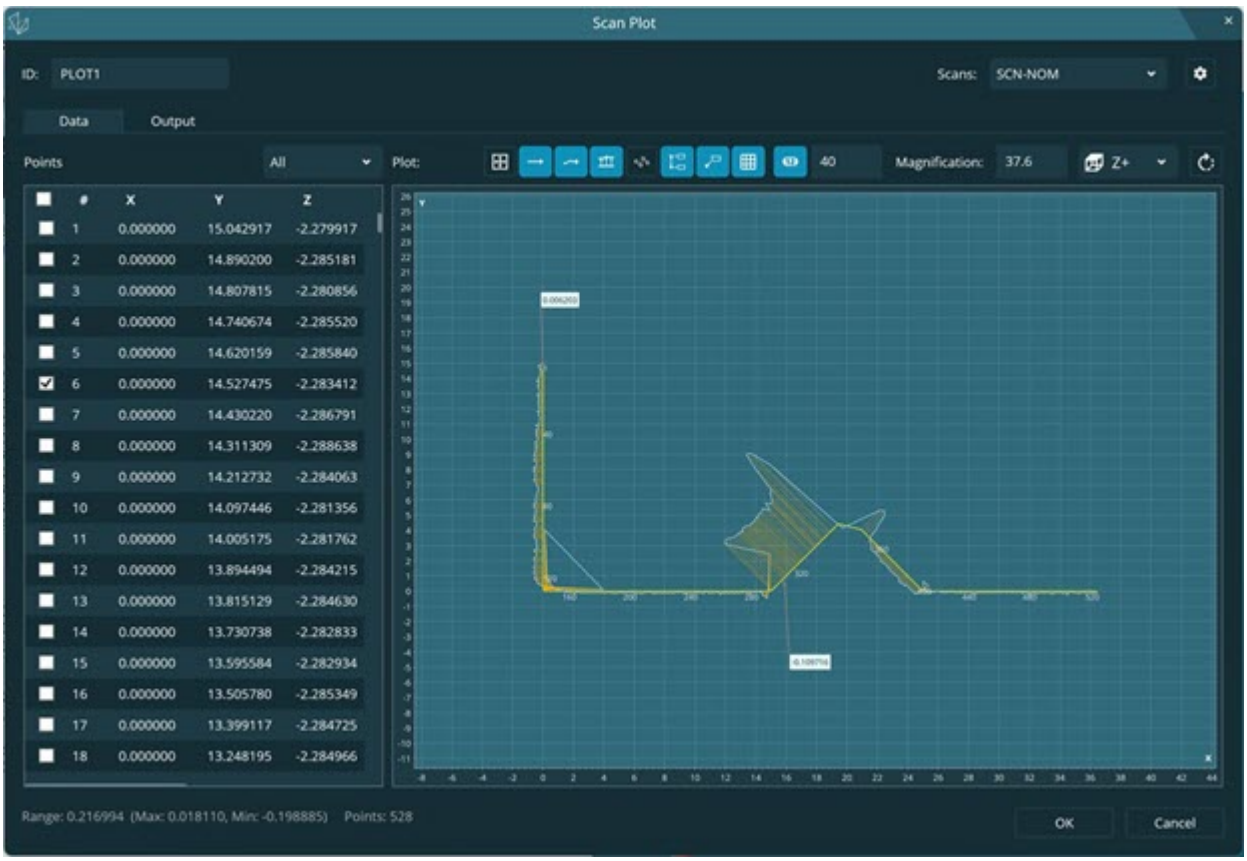
1. Select the **Insert | Report Command | 2D Plot | Scan Plot** menu option to open the **Scan Plot** dialog box.



2. Complete the options:
    - **ID** – Use this box to type in the name of the plot for your scan.
    - **Scans** – From the list, select the scan ID for which you want to create the plot.
3. Click the **OK** button to create the plot.

Understanding the Scan Plot Dialog Box

Select the **Insert | Report Command | 2D Plot | Scan Plot** menu option to open the **Scan Plot** dialog box.

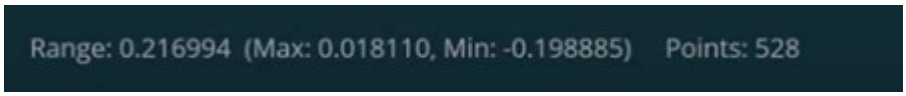


- **ID** - Use this box to enter the name of the plot for your scan.
- **Scans** - From the list, select the scan ID for which you want to generate the plot.
- **Settings** - Select this icon to open the **Settings** dialog box, where you can edit the default settings.

  - **Set transparent background for callout plotting** – Select this check box if you want the callout background to be transparent. This helps save ink when you do not want to print colored callouts.
  - **Hide coordinate axes and grid when plotting** – Select this check box to hide the coordinate axes and grid.

- **Set limit of callouts** – Use this option to define the maximum number of callouts to include in the plot. The default value is **50**. This ensures that the plot area remains uncluttered and provides meaningful information.

- **Status Bar**



The status bar, located at the bottom of the plot area, displays information about the Range, Max and Min deviations, and the total number of points in the scan.

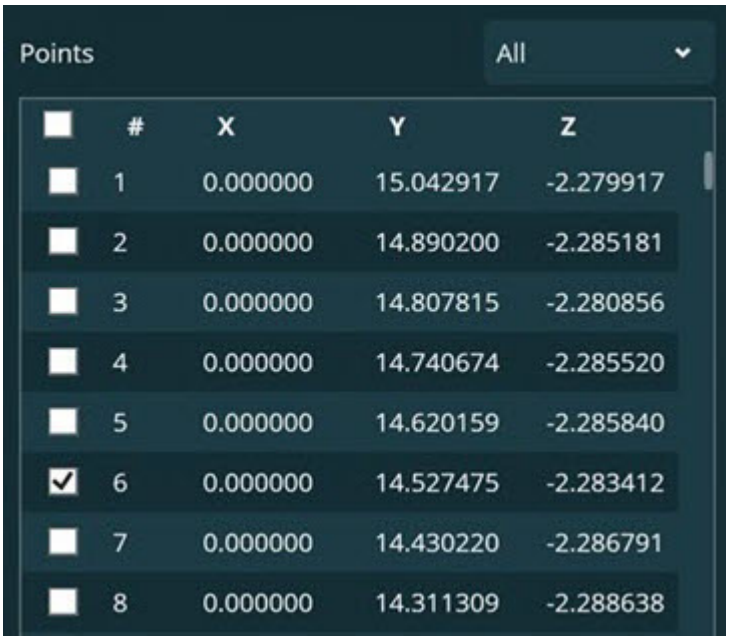
Data Tab

The Data tab has these two areas:

- Points Area
- Plot Area

Points Area

The **Points** area contains a list of all the points in a scan, ordered sequentially. You can drag the parting line to view each point's X, Y, Z, I, J, K, T, and tolerance values. The T value represents the deviation of the scan points from their normal.



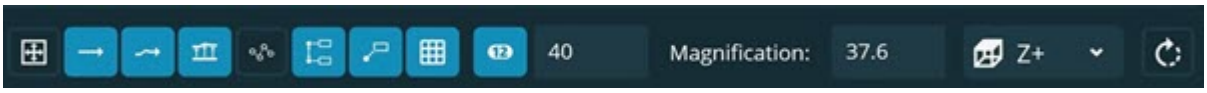
- **Check Boxes** – When you select the check box for a point, PC-DMIS shows the deviation for that point in the Plot area. PC-DMIS also adds the point to the textual analysis in the report.

  To select all points, select the check box in the header area. To deselect all points, deselect the check box in the header area.

- **Display** – This list allows you to control which points PC-DMIS displays in the Points area.

  - **All** – Select this option to show all the points in the Points area.
  - **Selected** - Select this option to show only the selected points in the Points area.
  - **Unselected** - Select this option to show only the unselected points in the Points area.

Plot Area



Click the icon to show or hide the plot object.

Scale to Fit – Click this button to adjust the plot to fit entirely within the plot area.

Show Nominal Curve – Click this icon to show or hide the nominal curve.

Show Measured Curve – Click this icon to show or hide the measured curve.

Show Deviations – Click this icon to show or hide the deviation from nominal values.

Show Points on Curve – Click this icon to show or hide the points on the curve.

Show Max/Min Deviations Callouts – Click this icon to show or hide the callouts for the point with the Max deviation and Min deviation. The Max deviation is a positive deviation that indicates more material than normal, while the Min deviation is a negative deviation that indicates less material than normal. Both Max deviation and Min deviation are dynamic and are selected and displayed with each execution.

Show Callouts – Click this icon to show or hide the deviation at nominal points.

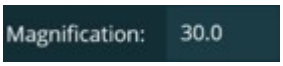
Use Ctrl + left-click on a nominal point in the plot area to display its callouts. PC-DMIS selects this point in the Points area. You can also select points from the point list area to display their callouts.

By default, the number of callouts is limited to 50. You can modify the number of callouts in the **Settings** dialog box. For information on how to modify the number of callouts, see the "Understanding the Scan Plot Dialog Box" section of the PC-DMIS Core documentation.

You can move the callouts to your desired location. To do this, left-click and hold on the callout, then drag it to your desired position. The plot remembers the callout position and prints it with each execution.

Show Grid – Click this icon to show or hide the grid.

Show Point Numbers – When you create a plot, PC-DMIS smartly assigns the point markings. It positions the point number evenly and ensures that the point number markings are spread apart to indicate the scan direction, making it easier to find the zone of interest. Click this icon to enable this feature.



Smart Magnification – When you create a plot, PC-DMIS smartly assigns the appropriate deviation magnification. It calculates the magnification to display the deviation curve clearly, without distortion, providing a clear picture of the deviations. This helps you make decisions quickly. You can also enter a magnification value of your choice.

View Axis list – From the list, select the required view axis. The plot plane can be XY, YZ, or ZX. By default, the corresponding view axes are X+, X-, Y+, Y-, Z+, and Z-, respectively.

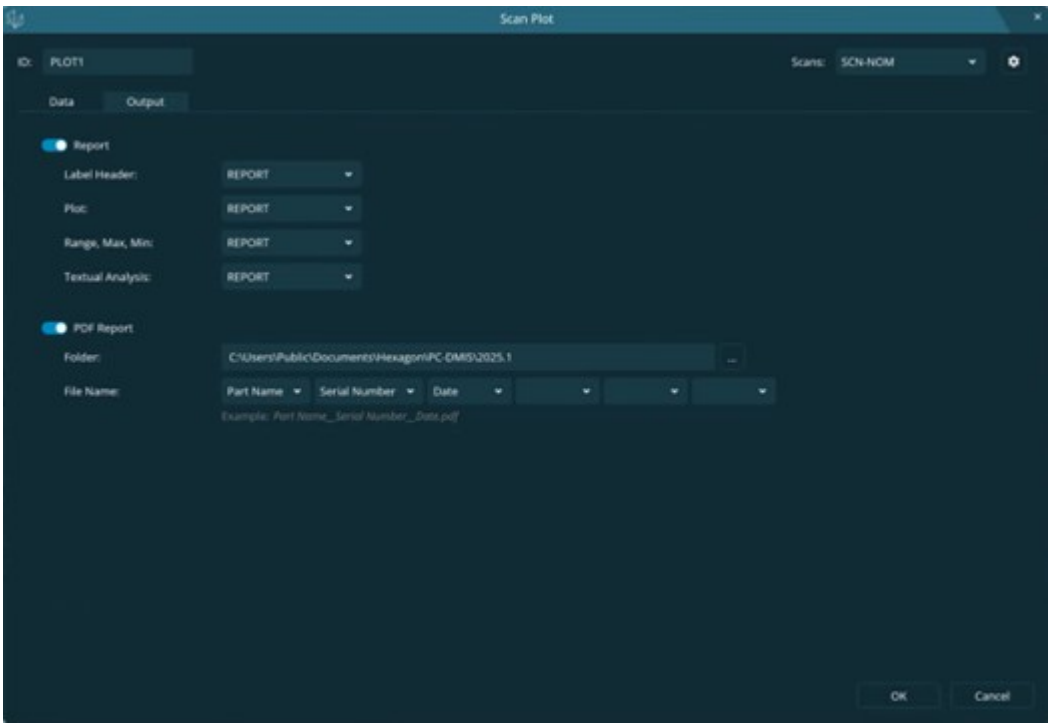
Rotate View – Click this icon to rotate the view by 90 degrees.

Panning and Zooming – Hold the left mouse button and move the plot to the desired position. Use the mouse scroll to zoom in and out.

Copy to Clipboard – You can copy a plot and paste it into any other document for reporting purposes. To copy a plot, right-click in the plot area and select **Copy to Clipboard**.

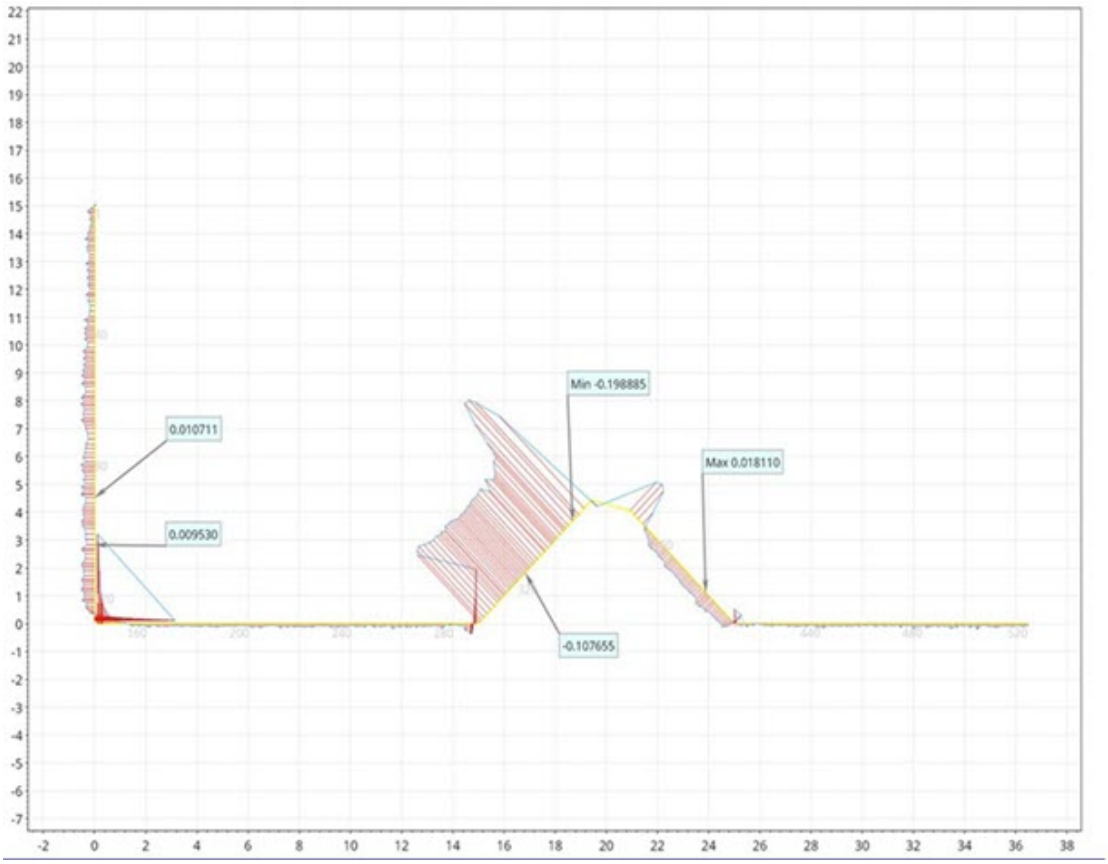
Output Tab

The **Output** tab allows you to set up the report.



- **Report** - Turn on this toggle button to generate a plot report.
  - **Label Header** - This is a **REPORT**/**NONE** option. If this is set to **REPORT**, PC-DMIS inserts the label header in the report. Otherwise, the label header is not inserted into the report.

  - **Plot** - This is a **REPORT**/**NONE** option. If this is set to **REPORT**, PC-DMIS inserts the plot in the report, as displayed in the plot tab. Otherwise, the plot is not inserted into the report.



- **Range**, **Max**, **Min** - This is a **REPORT/NONE** option. If this is set to **REPORT**, PC-DMIS inserts the Range, Max, and Min values in the report. Otherwise, the plot is not inserted into the report.

AX	NOMINAL	MEAS
RANGE	0.000000	0.216994
MAX_T (389)	0.000000	0.018110
MIN_T (345)	0.000000	-0.198885

- **Textual Analysis** - This is a **REPORT/NONE** option. If this is set to **REPORT**, PC-DMIS inserts the Range, Max, and Min values in the report. Otherwise, the plot is not inserted into the report.

HITS	THEO X	Y	Z	VECTOR I	J	K	T Value	+TOL	-TOL	OUTTOL
93	0.000000	4.518857	-2.284768	-1.000000	0.000000	0.000000	0.010711	0.050000	0.050000	0.000000
106	0.000000	2.827435	-2.288707	-1.000000	0.000000	0.000000	0.009530	0.050000	0.050000	0.000000
324	16.830554	1.830554	-2.280705	0.707107	-0.707107	0.000000	-0.107655	0.050000	0.050000	0.057655

- **PDF Report** - Turn on this toggle button to save the report as a PDF file.
  - **Folder** - Use this box to type the path to save the PDF file or click the Browse (…) button and navigate to the location where you want to save it.
  - **File Name** - Use the list box to define a name rule for the PDF file. The options in the list are **Part Name**, **ID**, **Serial Number**, **Revision Number**, **Date**, and **Time**.

Multiple Plots in a Single File

PC-DMIS allows you to save all the plots of a single run or a single part in one PDF file. If the plot file name is found in the selected folder, the Plot command appends the current plot to the same file. If the file is not found, PC-DMIS creates a new PDF file.

Multiple Plots in a Single File

- You can include multiple plots in the report for the same scan. To do this, follow these steps:

    1. Create Plot Command 1:

        a. From the **Label Header** and **Plot** list in the **Output** tab, select **REPORT**.

        b. From the **Range**, **Max**, **Min** and **Textual Analysis** list in the **Output** tab, select **NONE**.

    2. Duplicate the Command:

        a. Copy the first plot command and give it a new name.

        b. Adjust the plot to focus on the area of interest.

        c. From the **Range**, **Max**, **Min** and **Textual Analysis** list in the **Output** tab, select **REPORT**.

    This approach generates a report with three views of the scan.

- You can save multiple plots of the same part or multiple parts of the same type in a single file.

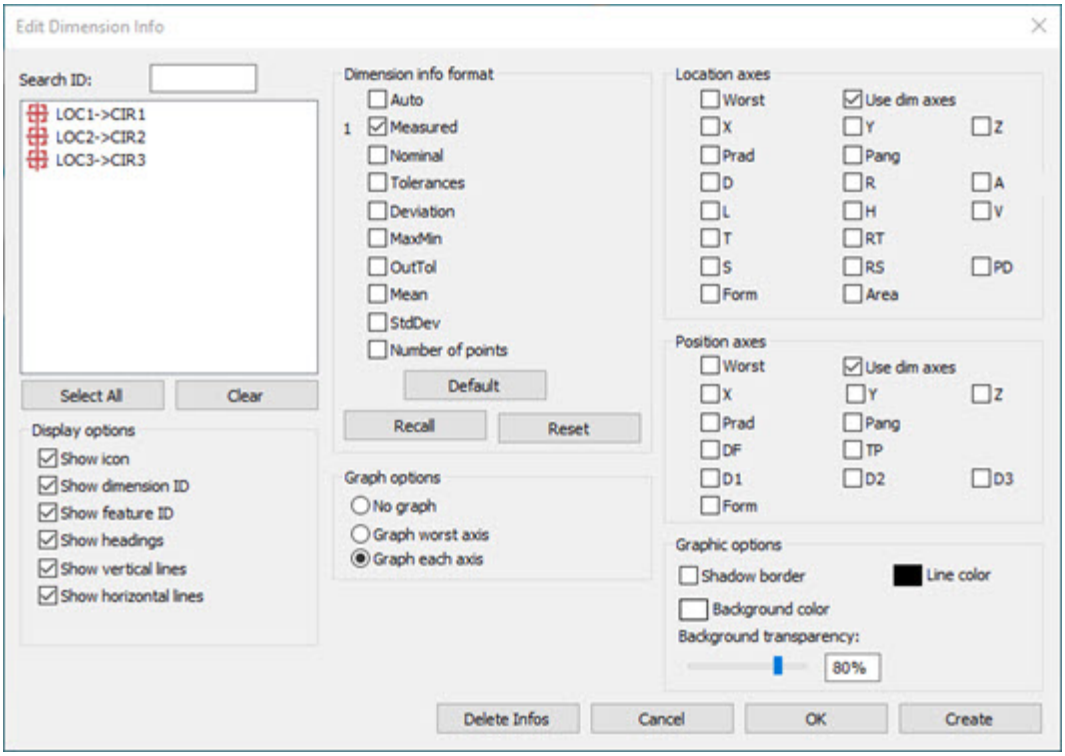
    - **Appending to the same file** - If the file name to save the plot is the same, PC-DMIS appends the new plots to the existing file.

    - **Separate File for Each Plot** - If you include the date and time in the file name, PC-DMIS saves each plot to a separate file.

    - **Single File for a Specific Part** - If you include the part number and serial number in the file name, PC-DMIS saves all the plots for a part with the same serial number to a single file.

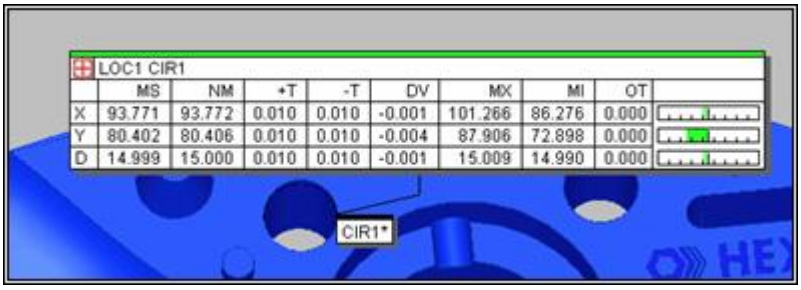
    - **Single File for Multiple Parts** - If you use only the part name in the file name, PC-DMIS saves plots from multiple parts to a single file.

Inserting Dimension Info Boxes



Edit Dimension Info Dialog Box

The **Insert | Report Command | Dimension Info** menu option brings up the **Edit Dimension Info** dialog box. This dialog box allows you to create a `DIMINFO` command that displays selected dimensional information in the Graphic Display window. See "DIMINFO Command" for information on editing a `DIMINFO` command in the Edit Window.



Example of a Dimension Info dialog box.

The dimension list inside the dialog box shows an asterisk (*) if the dimension already contains a DIMINFO text box. The dimension list shows a number sign (#) if the DIMINFO text box is hidden from view in the Graphic Display window.

```
LOC1->CIR1->*
LOC2->CIR2->*#
LOC3->CIR3
```

Example of a Dimension list with existing and hidden DIMINFO boxes.

The **Auto** check box (under the **Dimension Info Format** area of this dialog box) automatically determines the appropriate dimension output format to display, based on the type of dimension that was selected. To override this option, select the desired **Dimension Info format** check box(es). PC-DMIS indicates the order of the output selections by displaying a number to the left of the check box. In this way, you can define the order of the format to meet your needs. You can clear a check box by selecting it a second time.

If this dialog box is open, you can click on a feature in the Graphic Display window to automatically highlight dimensions that use that feature in the **Dimension List** box.

This **Edit Dimension Info** dialog box allows you to edit the dimension information that PC-DMIS displays. The following paragraphs describe the commands and options available to this dialog box.

Dimension Info Creation Rules

When you create a DIMINFO box in the **Edit Dimension Info** dialog box, the **Dimension List** box only displays those dimensions that exist above the cursor's current position.

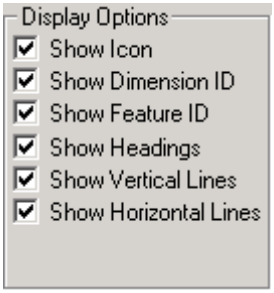
When you create DIMINFO boxes in Text Box Mode and box-select inside the Graphic Display window, PC-DMIS does not create a DIMINFO box for every selected feature. It only creates them for features that exist above the cursor's current position.

If the measurement routine has multiple viewsets, the DIMINFO box only appears in the viewset that contains the corresponding dimension and lower. For example, suppose that your measurement routine has these commands:

```
VIEWSET1
F1 = FEAT
VIEWSET2
VIEWSET3
D1 = DIMENSION
VIEWSET4
```

You could only add a DIMINFO box for feature F1 if the insertion point existed below D1. Once the DIMINFO box is created, PC-DMIS shows it in VIEWSET3 and 4, but not in VIEWSET1 and 2.

Display Options



The **Display Options** area allows different display possibilities for each dimension within the Graphic Display window.

The following options available are:

Show Icon check box
This check box toggles the displays the appropriate dimension icon in the header portion of the **Dimension Info** box.

Show Dimension ID check box
This check box toggles the ability to display the ID for the dimension within the Graphic Display window.

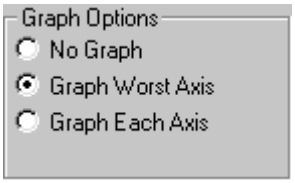
Show Feature ID check box
This check box toggles the ability to display the ID for the feature whose dimensions are being measured.

Show Headings check box
This check box toggles the display of row and column headings in the Dimension Info box.

Show Vertical Lines check box
This check box toggles the display of the vertical lines between columns inside the Dimension Info box.

Show Horizontal Lines check box
This check box toggles the display of the horizontal lines between rows inside the Dimension Info box.

Graph Options



The **Graph Options** area allows for graphical display of the dimension percentage in the **Dimension Info** box.

No Graph - Select this option if you do not want to display a graph in the **Dimension Info** box.

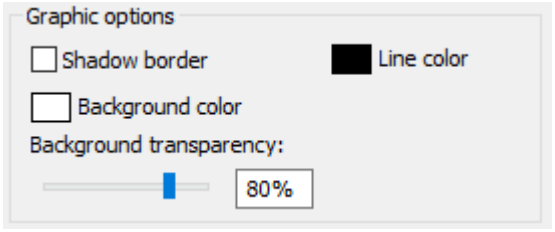
Graph Worst Axis - Select this option to display a graph at the top of the **Dimension Info** box. Only the worst dimension percentage will be used for the graph.

Graph Each Axis - Select this option to display a dimension percentage graph for every axis in the Dimension Info box.

	MS	NM	+T	-T	DV	MX	MI	OT	
X	93.771	93.772	0.010	0.010	-0.001	101.266	86.276	0.000	
Y	80.402	80.406	0.010	0.010	-0.004	87.906	72.898	0.000	
D	14.999	15.000	0.010	0.010	-0.001	15.009	14.990	0.000	

Dimension Info Box

Graphic Options



Graphic Options Area

The **Graphic Options** area allows you to set the graphic options for the current Dimension Info box in the Graphic Display window.

Shadow border
This check box displays a small shadow under the label.

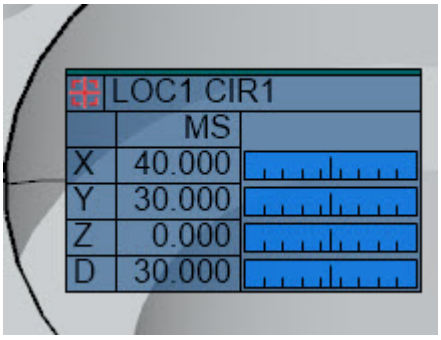
Background Color
This box opens a **Color** dialog box so that you can change the label's background color.

Background Transparency
This slider or the box to its right adjusts the transparency level of the label's

background color. The value can be from 0 (opaque) to 100 (completely transparent).

Line Color
This box opens a **Color** dialog box so that you can change the label's border color.

To change the graphic options for the Dimension Info box, select the desired options from this area and click **Create** or **OK** on the **Edit Dimension Info** dialog box.

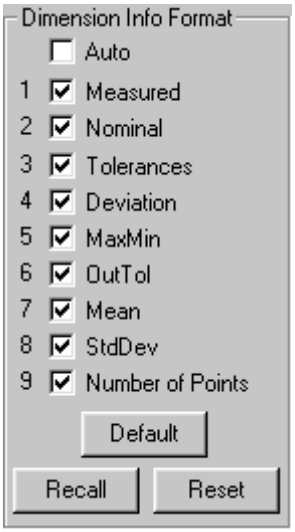


Example of a Dimension Info box set to a blue background color with 50% transparency.

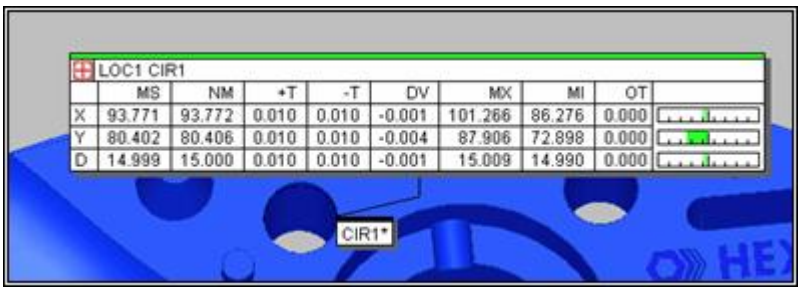
You can also set the default graphic options for future Dimension Info boxes. To do this, select the desired graphic options and then click the **Default** button in the **Dimension Info Format** area.

This topic only applies to legacy feature labels. You can enable legacy feature labels from the **Use legacy graphic labels** check box on the **Feature Appearance** dialog box. If you clear that check box and use the newer feature labels, this area doesn't affect those. For more information, see "Editing Feature Appearance" topic of the "Editing the CAD Display" chapter.

Dimension Info Format



The check boxes in the **Dimension Info Format** area allow you to select the type of information displayed in the Graphic Display window for each dimension. When the **Display** check box is selected from within a dimension's dialog box, PC-DMIS displays the information in the Graphic Display window.



Graphic Display window showing the dimensional data of the CIR1 feature.

The available check boxes in the **Dimension Info** area of the dialog box are:

Auto
The **Auto** check box automatically displays the following information: Measured, Nominal, Tolerances, Deviation, MaxMin, OutTol.

Measured
This check box displays the actual measured dimensions.

Nominal
This check box displays the theoretical values for the dimension.

Tolerances
This check box displays the acceptable tolerance levels either greater than or less than the nominal.

Deviation
This check box displays the deviation of the measured value from the nominal.

MaxMin
This check box displays the maximum and minimum deviation values from the points that make up the dimension. While you can mark this for any dimension, it only makes sense for Line Profile and Surface Profile dimensions. For an example of this, see the "Parameter Settings: Dimension tab" topic of the "Setting Your Preferences" chapter.

OutTol
This check box displays how far out of tolerance the measured value is from the nominal and tolerance values.

Mean
This check box displays the average of all the deviations for the dimension.

StdDev
This check box displays the standard deviation of all the deviations for the dimension.

Number of Points
This check box displays the number of points used to measure the feature of the dimension.

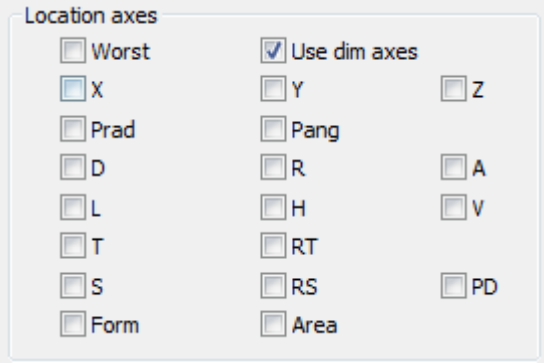
The command buttons are:

Recall - Recalls the set default.

Default - Sets the current selection of check boxes as the default.

Reset - Clears out any check marked boxes in this section and selects the **Auto** check box.

Location Axes



This table describes the available **Location Axes** and their functions that you can choose from when you edit dimension information.

The following options are available:

Worst check box
This option uses the axis that gives the worst out of tolerance condition. PC-DMIS searches through the available axes and selects the one that gives the worst case scenario for the dimension.

Use Dim Axes check box
This option simply uses the axes that were previously defined in the dimension's dialog box.

X check box
This option displays the X axis value.

Y check box
This option displays the Y axis value.

Z check box
This option displays the Z axis value.

Prad check box
Prad stands for Polar Radius. This option selects Polar coordinates.

Pang check box
Pang stands for Polar Angle. This option selects Polar coordinates.

Area check box
This option displays the area of a selected Blob feature. It appears as AR in the DIMINFO box and in the report. (PC-DMIS Vision uses Blob features.) Legacy reports only show this information if you also mark the **Use dim axes** check box from the **Position** area. For information on **Use dim axes**, see "Position Axes".

D check box
This option displays the Diameter value.

R check box
This option displays the Radius (half of Diameter) value.

A check box
This option displays the Angle (for cones) value.

L check box
This option displays the Length (used for cylinders, slots, cones, and ellipses).

H check box
This option displays the Height.

V check box
This option displays the Vector location.

T check box
For points on curved surfaces, this option displays the deviation from the nominal along the feature's vector.

RT check box
This option displays the deviation along the report vector.

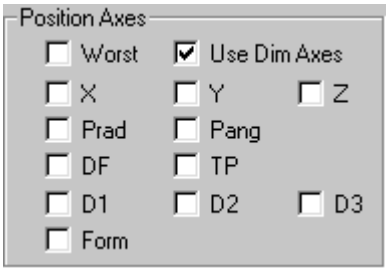
S check box
This option displays the deviation along the surface vector.

RS check box
This option displays the deviation along the surface report vector.

PD check box
This option displays the diameter of a circle (perpendicular to the pin vector).

Form check box
This option displays the integrated form dimension for the feature. See "Default Axes for Location Dimensions" in the "Using Legacy Dimensions" chapter.

Position Axes



This table describes the available **Position Axes** and their functions that you can choose from while editing dimension information.

The following options are available:

Worst check box
This check box uses the axis that gives the worst out of tolerance condition. PC-DMIS searches through the available axes and selects the one that gives the worst case scenario for the dimension.

Use Dim Axes check box
This check box simply uses the axes that were previously defined in the dimension's dialog box.

X check box
This check box displays the X axis value.

Y check box
This check box displays the Y axis value.

Z check box
This check box displays the Z axis value.

Prad check box
Prad stands for Polar Radius. This option selects Polar coordinates.

Pang check box
Pang stands for Polar Angle. This check box selects Polar coordinates.

DF check box
This check box displays diameter of the feature.

TP check box
This check box displays the position tolerance and its associated deviation.

D1 check box
This check box displays the diameter/width value of the first datum.

D2 check box
This check box displays the diameter/width value of the second datum.

D3 check box
This check box displays the diameter/width value of the third datum.

Form check box
This check box displays the integrated form dimension for the feature. See "Default Axes for Position Dimensions" in the "Using Legacy Dimensions" chapter.

Delete Infos

The **Delete Infos** button removes all `DIMINFO` commands from the measurement routine.

DIMINFO Command

You can create the `DIMINFO` command from the **Edit Dimension Info** dialog box (**Insert | Report Command | Dimension Info**).

When you insert a `DIMINFO` command in the measurement routine, PC-DMIS displays the dimension data in the Graphic Display window. You can modify the `DIMINFO` command in the Edit window. The command line for the `DIMINFO` command reads:

```
DIMINFO/Dim ID ;ICON,DIMID,FEATID,VERT,HORIZ; HEADINGS,
"GRAPH OPTION";"DIMENSION OUTPUT", ,$
"AXES OUTPUT"
```

Dim ID - This is the ID of the selected dimension.

ICON - A toggle string that shows a blank when it is OFF, and "ICON" when it is ON. When it is ON, the `DIMINFO` displays the dimension or feature ID with the appropriate icon.

DIMID - A toggle string that shows a blank when it is OFF, and "DIMID" when it is ON. When it is ON, the DIMINFO displays the dimension ID with the dimensional information.

FEATID - A toggle string that shows a blank when it is OFF, and "FEATID" when it is ON. When it is ON, the DIMINFO displays the ID of the dimension's first feature with the dimensional information.

VERT - A toggle string that shows a blank when it is OFF, and "VERT" when it is ON. When it is ON, the `DIMINFO` displays with the vertical lines between the columns.

HORIZ - A toggle string that shows a blank when it is OFF, and "HORIZ" when it is ON. When it is ON, the `DIMINFO` displays with the horizontal lines between the rows.

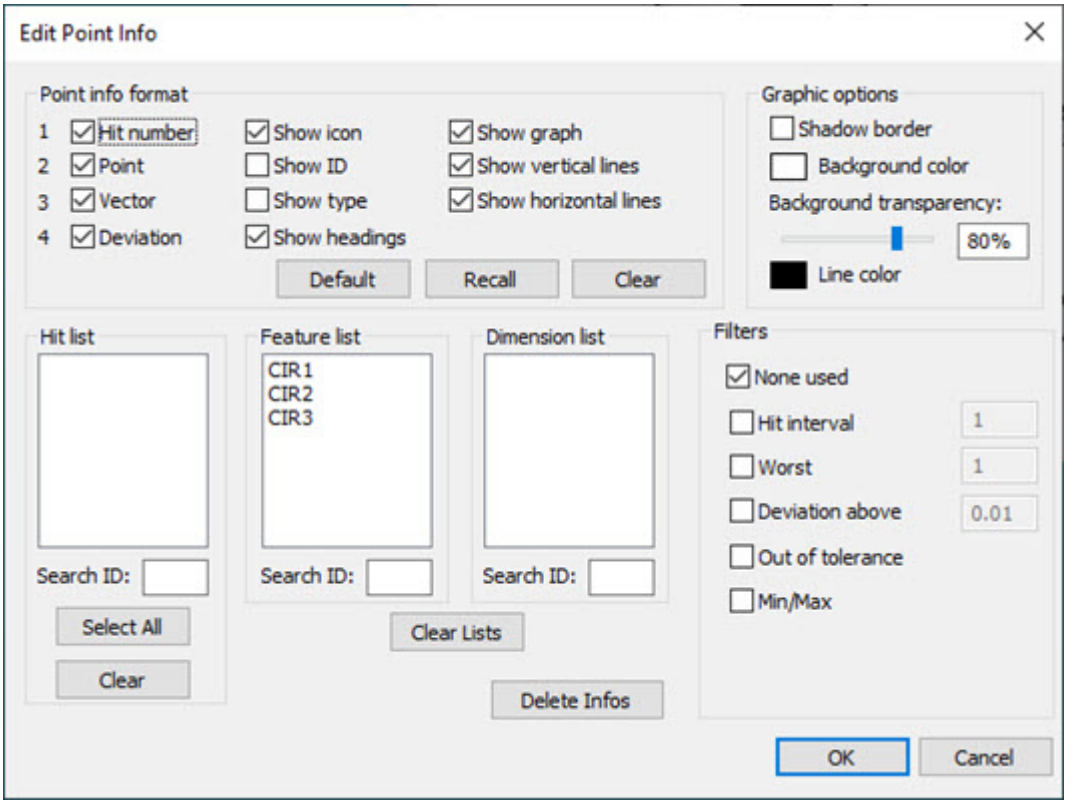
HEADINGS - A toggle string that shows a blank when it is OFF and "HEADINGS" when it is ON. When it is ON, PC-DMIS displays the column and row headers in the **Dimension Info** box.

GRAPH OPTION - The graph option for graphical display of the dimension percentage in the **Dimension Info** box. Possible toggle values are GRAPH WORST and GRAPH AXIS. When the toggle string shows a blank, PC-DMIS does not show the graph in the box.

DIMENSION OUTPUT - This defines the format of the displayed dimension information based on the order of selection. Available output options are MEAS, NOM, TOL, DEV, MAXMIN, OUTTOL, MEAN, STDDEV, and NUMPTS. You cannot duplicate options.

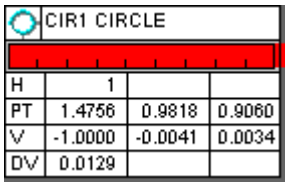
AXES OUTPUT - This defines the format of the displayed dimension axes based on the order of selection. Available axes depend upon the dimension type and include all location and position axes. If you toggle USEDIM in the first axis position, the DIMINFO displays the axes specified in the dimension. If you toggle WORST in any axis position, PC-DMIS displays the axis that produced the largest out-of-tolerance value. This output is only available for Location and Position dimensions . You cannot duplicate axes.

Inserting Point Info Boxes



Edit Point Info Dialog Box

The **Insert | Report Command | Point Info** menu option brings up the **Edit Point Info** dialog box. This dialog box creates a `POINTINFO` command that displays information boxes in the Graphic Display for individual points. Each information box may display the hit number, the XYZ position, the IJK vector, and the deviation related to a particular hit. For information on the `POINTINFO` command in the Edit Window, see the "POINTINFO Command" topic.



Point Info box showing the first hit in a circle feature

To insert point information in the Graphic Display window, follow these steps:

1. Choose **Insert | Report Command | Point Info** to open the **Edit Point Info** dialog box.

2. From the **Feature list** or the **Dimension list**, select at least one feature or dimension. The individual points associated with the item you choose appear in the **Hits List** box. If you choose more than one dimension or feature, the **Hit list** does

not appear, and all the points from the dimensions or features appear in the information box.

3. From the **Hit List** box, select one or more points that you want to show.
4. From the **Point info format** area, mark the items that you want to show. Any numbers that appear next to check boxes indicate the row order.
5. Click the **OK** button to create the information boxes in the Graphic Display window.

You can save, change, and move the formats similar manner to the **Dimension Info** box formats. For information on Dimension Info boxes, see "Inserting Dimension Info Boxes".

Point Info Format

This portion of the dialog box allows you to determine the type of information displayed in the Graphic Display area next to a feature or dimension. The check boxes in this section must be used in conjunction with the **Create** (**Apply** when editing) or the **OK** button to either select or remove information to display. Any numbers that appear next to check boxes indicate the row order.

Hit Number - This check box displays the hit sequence of a point on a feature.

If a circle generally takes four hits, and one of the hits used to measure that circle was selected, this option displays a number (one through four) indicating when that hit was taken in the sequence: 1st, 2nd, 3rd, or 4th.

Point - This check box displays the X, Y, and Z point location of the hit selected.

Vector - This check box displays the IJK vector of the hit selected.

Deviation - This check box displays the deviation of the point from the nominal.

- *For features*, the point deviation is the distance between the measured hits and the actual hits.
- *For dimensions*, the point deviation is related to the dimension type and is the same as the deviation displayed for the individual points in the textual analysis of the dimension.

Show Icon - This check box displays the feature's icon in the header portion of the Point Info box.

Show ID - This check box allows you to display the ID of a particular feature or dimension.

Show Type - This check box allows you to display the type of feature or dimension displayed.

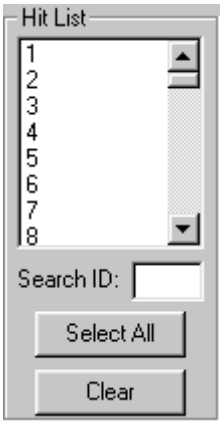
Show Headings - This check box allows you to display the row headers in the Point Info box.

Show Graph - This check box allows you to display the dimension percentage graph in the Point Info box.

Show Vertical Lines - This check box allows you to display or hide the vertical lines inside the Point Info box.

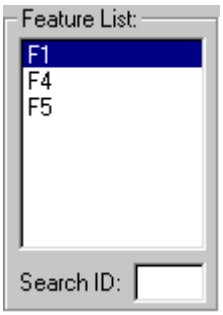
Show Horizontal Lines - This check box allows you to display or hide the horizontal lines inside the Point Info box.

Hit List



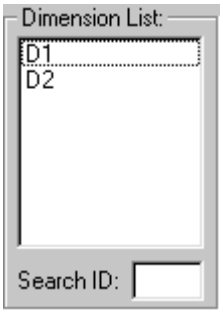
The **Hit List** box contains a list of all the hits associated with a particular feature or dimension. Simply select the hits whose information you would like to view.

Feature List Area



The **Feature List** box contains a list of all the features associated with a particular measurement routine. Select the feature whose hit information you would like to view. The hits associated with that feature will be displayed in the **Hit List** box.

Dimension List Area



The **Dimension List** box contains a list of all the dimensions that are associated with a particular measurement routine. Select the dimension whose hit information you would like to view.

PC-DMIS shows the hits that are associated with that dimension in the **Hit List** box.

Delete Infos

The **Delete Infos** button removes all `POINTINFO` commands from the measurement routine.

POINTINFO Command

The `POINTINFO` command is created by the **Edit Point Info** dialog box (**Insert | Report Command | Edit Point info**).

When a `POINTINFO` command has been inserted in the measurement routine, a **Point Info** box is displayed in the Graphic Display window. The `POINTINFO` command can be modified in the Edit window. The command line for the `POINTINFO` command reads:

```
POINTINFO/Dim ID or Feat ID; FILTER FILTER_TYPE
FILTER_NUM;ICON,ID,TYPE,VERT,HORIZ; HEADINGS,
GRAPH; ”OUTPUT FORMAT” ,$
"HIT NUMBERS"
```

Dim ID or Feat ID - The ID of the dimension or feature to be displayed.

FILTER_TYPE - A toggle string that shows the filter option of NONE, INTERVAL, WORST, DEVIATION, or OUTTOL.

FILTER_NUM - A number field available when the filter option is INTERVAL, WORST, or DEVIATION.

ICON - A toggle string that shows a blank when it is OFF, and "ICON" when it is ON. When it is ON, the `POINTINFO` will display the dimension or feature ID with the appropriate icon.

ID - A toggle string that shows a blank when it is OFF, and "ID" when it is ON. When it is ON, the `POINTINFO` will display the dimension or feature ID with the point information.

TYPE - A toggle string that shows a blank when it is OFF, and "TYPE" when it is ON. When it is ON, the `POINTINFO` will display feature or dimension type (i.e. CIRCLE, POINT, ROUNDNESS, LOCATION) with the point information.

VERT - A toggle string that shows a blank when it is OFF, and "VERT" when it is ON. When it is ON, the `POINTINFO` will display with the vertical lines between the columns.

HORIZ - A toggle string that shows a blank when it is OFF, and "HORIZ" when it is ON. When it is ON, the `POINTINFO` will display with the horizontal lines between the rows.

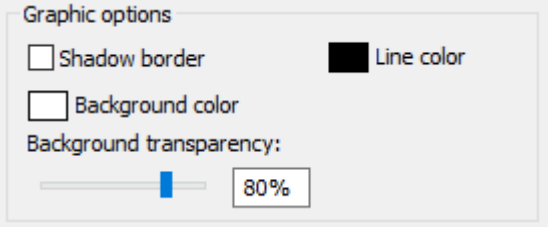
HEADINGS - A toggle string that shows a blank when it is OFF and "HEADINGS" when it is ON. When it is ON, the row headers will be displayed in the **Point Info** box.

GRAPH - A toggle string that shows a blank when it is OFF and "GRAPH" when it is ON. When it is ON, the dimension percentage will be graphically displayed in the **Point Info** box.

OUTPUT FORMAT - The format of the point information that will be displayed based on the order of selection. Available output options are HIT, PT, V, and DEV. Options cannot be duplicated.

HIT NUMBERS - The hit numbers are the specific numbered hits that are controlled by this particular `POINTINFO` command. Multiple hits can be displayed using the same `POINTINFO` command. Each field in the hit numbers is a toggle string. When a hit is ON, the string in the number position is the hit number (1,2,3, etc.). When a hit is OFF, the toggle string displays a blank.

Graphic Options



Graphic Options Area

The **Graphic Options** area allows you to set the graphic options for the current Point Info box in the Graphic Display window.

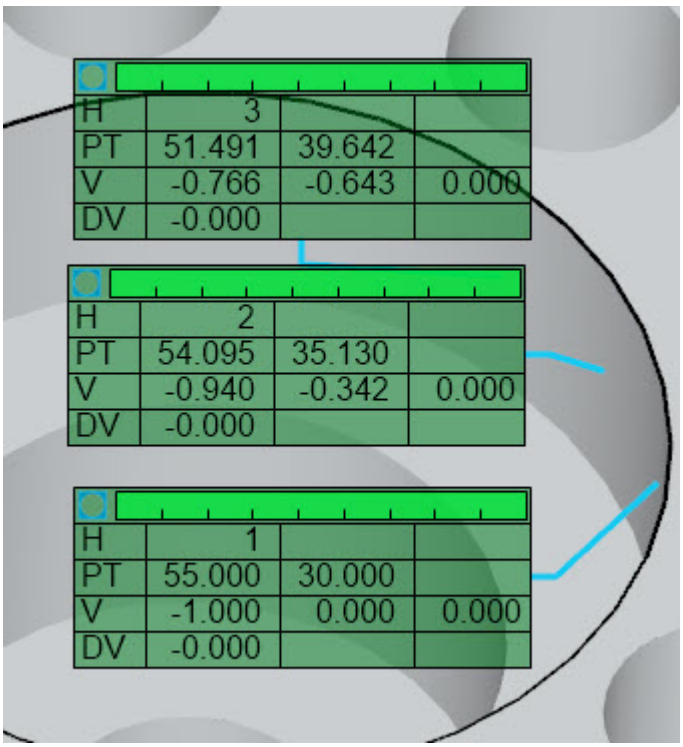
Shadow border
This check box displays a small shadow under the label.

Background Color
This box opens a **Color** dialog box so that you can change the label's background color.

Background Transparency
This slider or the box to its right adjusts the transparency level of the label's background color. The value can be from 0 (opaque) to 100 (completely transparent).

Line Color
This box opens a **Color** dialog box so that you can change the label's border color.

To change the graphic options for the Point Info box, select the desired options from this area and click **Create** or **OK** on the **Edit Point Info** dialog box.

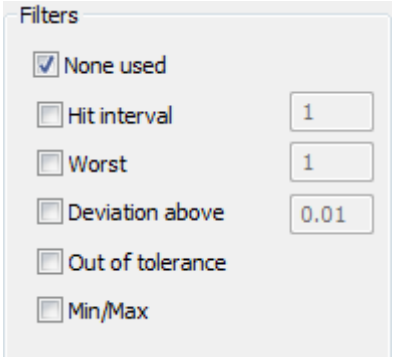


Example of Point Info boxes set to a green background color with 50% transparency.

You can set the default graphic options for future Point Info boxes. To do this, select the desired graphic options and then click the **Default** button in the **Point Info Format** area.

> This topic only applies to legacy feature labels. You can enable legacy feature labels from the **Use legacy graphic labels** check box on the **Feature Appearance** dialog box. If you clear that check box and use the newer feature labels, this area doesn't affect those. For more information, see "Editing Feature Appearance" topic of the "Editing the CAD Display" chapter.

Filters



Filters Area

The **Filters** area allows you to set filter options that PC-DMIS uses when it displays individual point information.

None Used - This filter option tells PC-DMIS not to use any filtering for the `POINTINFO` command. All hits selected will be displayed with the `POINTINFO` command.

Hit Interval - This filter option checks the integer value in the box to its right, and only displays the particular hit interval chosen with the `POINTINFO` command. For example, if 2 were chosen, then every 2nd hit would be displayed, if 3, then every 3rd hit, if 4 then every 4th hit, etc.

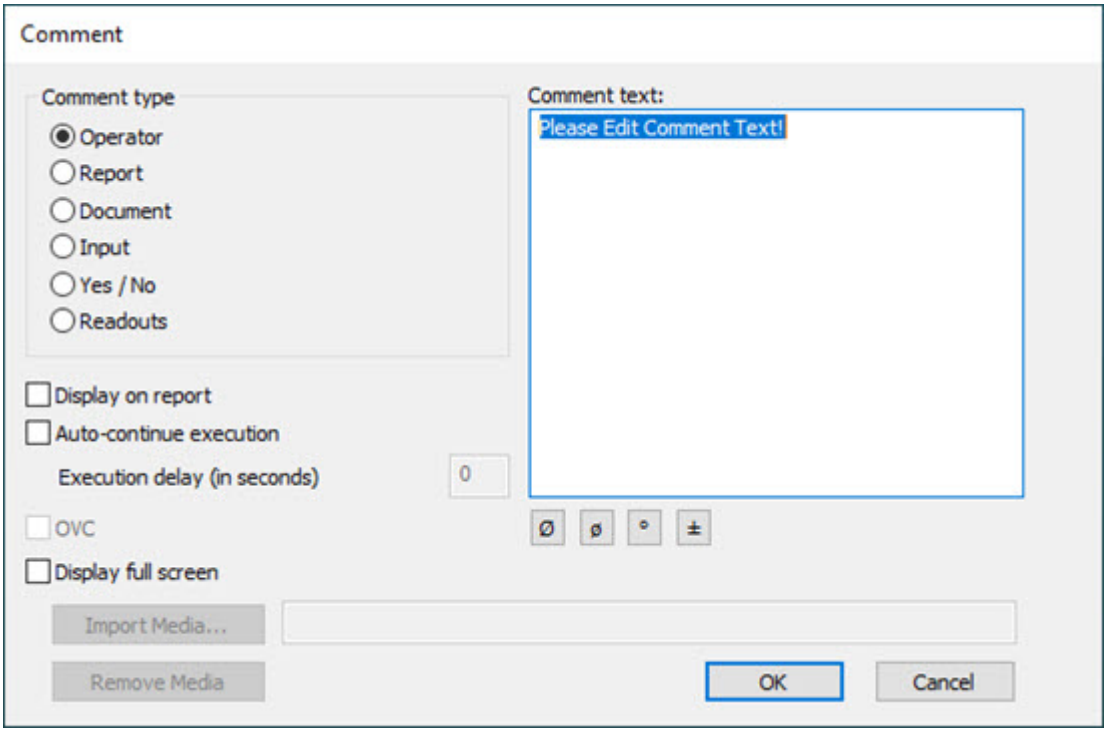
Worst - This filter option checks the integer value in the box to its right, and only displays the hits that give the worst deviations for the dimension. For example, if you type 3 in the box, the `POINTINFO` command only displays the three worst deviations.

Deviation Above - This filter option checks the value in the box to its right, and only displays the hits that have deviations above the value in the box for the dimension. For example, if you type 0.1 in the box, the `POINTINFO` command only displays hits that have deviations above the value in the box.

Out of Tolerance - This filter option only displays the hits that have deviations that are out of tolerance. For hits related to features (not related to dimensions), only those hits with deviations larger than the **Show Deviations Tolerance** on the **Setup Options** dialog box's **General** tab are displayed. (See "Show Deviations Tolerance" in the "Setting Your Preferences" chapter.)

Min/Max - This filter option only shows those hits that are the maximum and minimum deviation values for the dimension. For an example of MaxMin values, see the "Parameter Settings: Dimension tab" topic of the "Setting Your Preferences" chapter.

Inserting Programmer Comments



Comment Dialog Box

The **Insert | Report Command | Comment** menu option allows you to add operator notes, instructions, or supported media files into the Edit window that will be displayed in a message box when the measurement routine is executed or when the inspection report is printed. There is no limit to the length of the comment text; however, in Command Mode only 255 characters will fit per line. When the text reaches the right side of the Edit window, press the Enter key. (This allows the entire text to be viewed in the **Comment Text** box.) To create a new line, place the cursor in the desired location of the **Comment Text** box and press the Enter key.

Typing Comments

You can also type a comment into the Edit window in Command Mode. To do this, type `COMMENT` , press the Tab key on your keyboard, and then type the comment type you want: such as `OPERATOR` or `REPORT` and so forth. Press Tab to accept the command or to move to the field containing the comment text.

After you insert a PC-DMIS comment, to type additional PC-DMIS commands in Command Mode, you must first press Enter *twice* after the `COMMENT` command. This tells PC-DMIS that you no longer want to add text to the comment but are ready to add a new command.

Using Variables in Comment Strings

Suppose you want to concatenate, or add, a variable to an existing comment string. You can do this in two ways. First, you can press Enter, and type the variable on a new comment line, like this:

```
C1          =COMMENT/INPUT,NO,Full Auto-Continue=NO,
             Type your variable
             ASSIGN/V1=C1.INPUT
             COMMENT/OPER,NO,Full Auto-Continue=NO,
             Your V1 variable is
             V1
```

Second, you can place variables and your comment string on the same line by placing quotation marks around the non-variable string and using the plus sign operator to add the variable to the string, like this:

```
COMMENT/OPER,NO,Full Screen=YES,Auto-Continue=NO,

"Your V1 variable is "+V1
```

Changing Comment Color

You may want your comments to stand out more. You can do this by changing your comment color.

- To change them in the Edit window, see "Defining Edit Window Colors".
- To change comment colors for comments that appear in the Report window, change the **Colors** property of the TextReportObject in the in the Report Template Editor.

Another way to change a comment's color in the report is to insert this special prefix directly in front of the comment text:

```
~~#
```

The # represents 01, 02, 03, or 04. These stand for the Marked, Unmarked, Step Mode, or Error colors respectively. For information on these colors, see the **Edit Window Colors** dialog box.

So, to display some comment text in the text color assigned to Error, your command needs to look like this:

```
COMMENT/rept, ~~04 Some Comment Text
```

Operator

The **Operator** option displays the comment text to the operator when the software executes the comment command.

To use **Operator** option:

1. Place the cursor in the Edit window where you want to insert the comment command.
2. Select the **Insert | Report Command | Comment** menu option to open the **Comment** dialog box.
3. From the **Comment** dialog box, select the **Operator** option.
4. In the **Comment Text** box, type the comment text.
5. Click the **OK** button to close the dialog box and insert the comment.

   The Edit window command line for this option reads:
   ```
   COMMENT/OPER,TOG1,FULL SCREEN=TOG2,AUTO-CONTINUE=TOG3,
   comment text
   ```

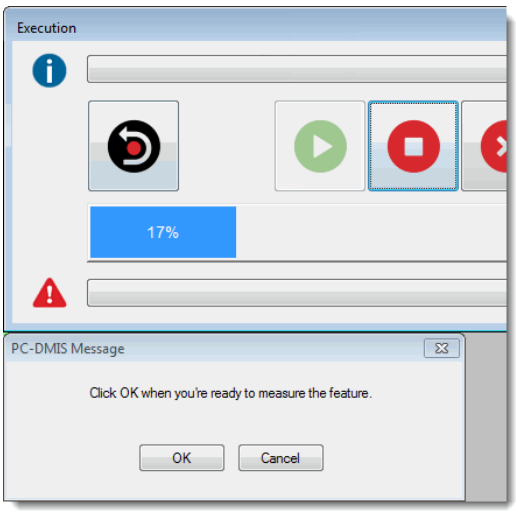
   TOG1 - This YES/NO field allows you to specify whether or not the comment shows up in the inspection report.

   TOG2 - This YES/NO field determines whether or not the comment will be displayed to fill the entire screen.

   TOG3 - This YES/NO field determines whether or not the comment will use a countdown timer and automatically continue execution once the timer reaches zero. When the countdown timer reaches zero, PC-DMIS will continue as if you had clicked the **OK** button.

How it Works

When PC-DMIS executes the measurement routine, a message box displays the appropriate comments just under the **Execution** dialog box.



PC-DMIS Message Dialog Box

PC-DMIS doesn't allow you to edit this message. Click the **OK** button to continue execution. Click **Cancel** to cancel measurement routine execution.

Report

Report

The **Report** option sends text to the inspection report.

To use the **Report** option:

1. Place the cursor in the Edit window where you want to insert the comment command.
2. Select the **Insert | Report Command | Comment** menu option to open the **Comment** dialog box.
3. From the **Comment** dialog box, select the **Report** option.
4. In the **Comment Text** box, type the comment text.
5. Click the **OK** button to close the dialog box and insert the comment.

When PC-DMIS executes the measurement routine, these messages are not viewed. PC-DMIS does, however, send these comments to the inspection report when it is printed.

The Edit window command line for this option reads:

```
COMMENT/REPT,

comment text
```

To visually separate content, you can include dashes (or other characters) as a second comment line, like this:

```
COMMENT/REPT,

Inspection Report Comment

COMMENT/REPT,

-----------------------------------
```

The above would look like this in the report:

```
Inspection Report Comment

-----------------------------------
```

Document

The **Document** option adds text to the internal measurement routine. Its only use is to store programmer notes. It does not appear in the inspection report (unless you mark **Display On Report**), nor does it display anything when executed.

To use the **Document** option:

1. Place the cursor in the Edit window where you want to insert the comment command.
2. Select the **Insert | Report Command | Comment** menu option to open the **Comment** dialog box.
3. From the **Comment type** area of the **Comment** dialog box, select the **Document** option.
4. In the **Comment Text** box, type the comment text.
5. Click the **OK** button to close the dialog box and insert the comment.

The Edit window command line for this option reads:

```
$$ TOG1,
    Please Edit Comment Text!
```

TOG1 = This YES/NO field allows you to specify whether the comment shows up in the inspection report or not.

If your measurement routine contains unsupported commands, (perhaps from a newer version of PC-DMIS) when you open the measurement routine, PC-DMIS converts them to this comment type. For more information, see "Save As" in the "Using Basic File Options" chapter.

Input

The Input option is similar to the **Operator** option in that it allows you to display text when executing a measurement routine. In addition to displaying a message box with the previously entered text, a comment box will appear. This allows you to enter *numerical* information that will be written to the inspection report.

This option is extremely helpful to users wishing to enter a part number or serial number while executing the measurement routine.

To use the **Input** option, follow these steps:

1. Place the cursor in the Edit window where you want to insert the comment command.
2. Select the **Insert | Report Command | Comment** menu option to open the **Comment** dialog box.
3. From the **Comment** dialog box, select the **Input** option.
4. In the **Comment Text** box, type the comment text.
5. Click the **OK** button to close the dialog box and insert the comment.

   The Edit window command line for this option reads:

   ```
   comment ID=COMMENT/INPUT,TOG1,Full Screen=TOG2,
   comment text
   ```

   TOG1 = This YES/NO field allows you to specify whether or the comment shows up in the inspection report.

   TOG2 = This YES/NO field allows you to specify whether or not the comment fills the entire screen when displayed.

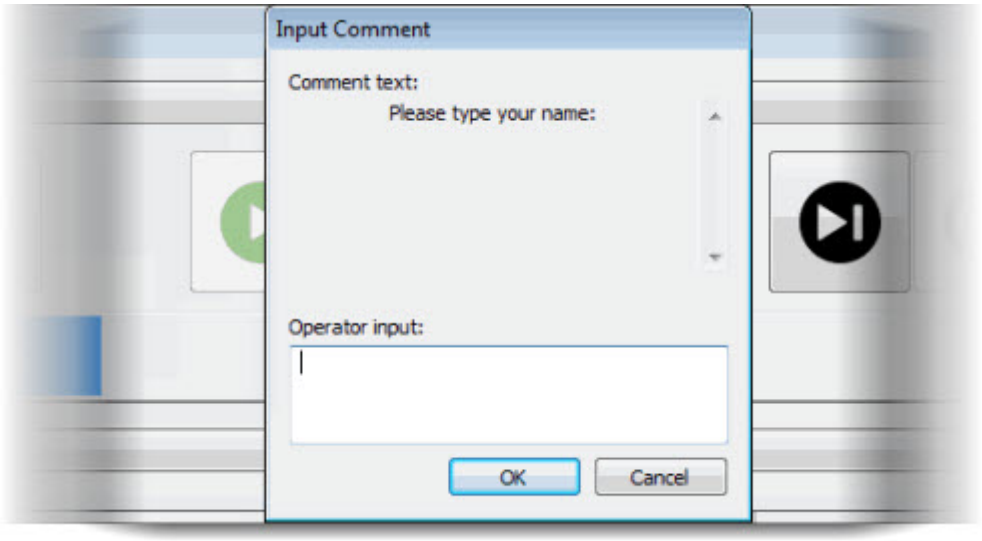
The input is assigned to the variable specified on the left hand side of the command. The variable is coerced to be of type string. This variable can then be used anywhere an expression is allowed by using this syntax <COMMENT ID>.INPUT. For example if your comment ID is C1, you can pass that variable into another variable like this:

```
C1 = COMMENT/INPUT,NO,Full Screen=NO,
```

```
"Please type your name:"
ASSIGN/V1=C1.INPUT
```

How it Works

During execution, the message box displays the prompt to enter the necessary number (such as a serial number) and then it displays this value in the inspection report. This prompt appears on top of the **Execution** dialog box:



Input Comment Dialog Box

Once the operator types his text and clicks **OK**, PC-DMIS stores it in the comment's variable. The variable is ID.INPUT (by default the ID for the variable is C1 for the first Input comment, C2 for the second, and so on). If the operator clicks **Cancel**, it stops execution.

Yes / No

The **Yes / No** option functions similarly to the Operator option in that it allows you to display text when you execute a measurement routine. In addition, **Yes**, **No** and **Cancel** buttons appear at the bottom of the dialog box of the **PC-DMIS Message** dialog box; this enables the operator to answer yes or no to simple questions.

To use the **Yes / No** option, follow these steps:

1. Place the cursor in the Edit window where you want to insert the comment command.
2. Select the **Insert | Report Command | Comment** menu option to open the **Comment** dialog box.
3. From the **Comment** dialog box, select the **Yes / No** option.

4. In the **Comment Text** box, enter the comment text.

5. If you do not click Yes or No on the **PC-DMIS Message** dialog box and you want the measurement routine to auto-execute after a set time, select the **Auto-continue execution** check box. You can then enter the number of seconds for the delay in the **Execution delay (in seconds)** box. For details, see "Auto-Continue Execution".

6. Click the **OK** button to close the dialog box and insert the comment.

   The Edit window command line for this option reads:

   ```
   comment ID = COMMENT/YESNO,TOG1,FULL SCREEN=TOG2,AUTO-CONTINUE=TOG3,

   comment text
   ```

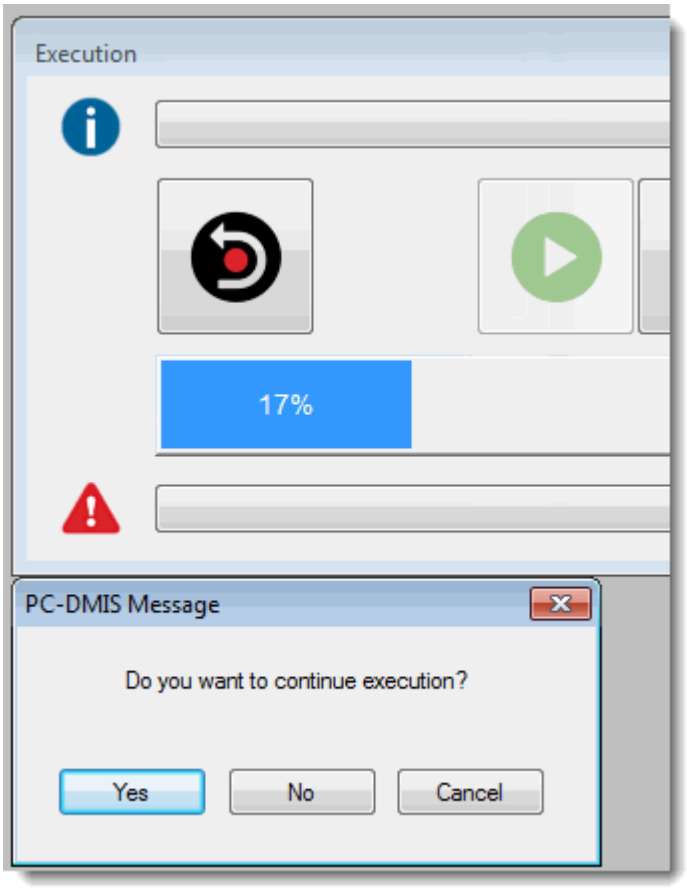
   TOG1 - This YES/NO field allows you to specify whether or not the comment shows up in the inspection report.

   TOG2 - This YES/NO field allows you to specify whether or not the comment fills the entire screen when displayed.

   TOG3 - This YES/NO field determines whether or not the comment will use a count-down timer and automatically continue execution once the timer reaches zero. If the operator does not click a button by the time 0 is reached, the measurement routine execution continues with the assumption that the operator clicked the **Yes** button.

How it Works

During execution, the **PC-DMIS Message** dialog box appears below the **Execution** dialog box. This enables the operator to click **Yes**, **No**, or **Cancel**:



PC-DMIS Message dialog box with buttons.

Execution pauses until the operator clicks a button. A variable stores the answer. The variable is C1.INPUT.

The answer the operator selects is accessible using expressions with the ID of the comment.

Example 1: If the comment has an ID of C1 and the operator clicks the **Yes** button, the expression "C1.INPUT" contains the value "YES". If the operator clicks the **No** button, the expression "C1.INPUT" contains the value " NO ". This option is useful to users who want to branch or loop on a "YES" or "NO" string response.

Example 2: If the comment has an ID of C1 and the operator clicks the **Yes** button, the expression "C1.INPUTVALUE" contains the value 1. If the operator clicks the **No** button, the expression "C1.INPUTVALUE" contains the value 2. This option is useful to users who want to branch or loop on a 1 or 2 integer response.

In either case, if the operator clicks **Cancel**, the measurement routine execution is canceled.

When you use a conditional branching statement to test for the value of a YES / NO comment using the .INPUT expression, be aware that your test must look for an uppercase "YES" or "NO" value. A lowercase "Yes" or "No" does not work. For information on measurement routine branching, see the "Branching by Using Flow Control" chapter.

Readouts

The **Readouts** option displays the comment text at the bottom of the Probe Readouts window. You must select the **Display prompt history** check box on the **Probe Readouts Setup** dialog box for this to work.

To use the **Readouts** option:

1. Place the cursor in the Edit window where you want to insert the comment command.
2. Select the **Insert | Report Command | Comment** menu option to open the **Comment** dialog box.
3. From the **Comment** dialog box, select the **Readouts** option.
4. In the **Comment Text** box, type the comment text.
5. Click the **OK** button to close the dialog box and insert the comment.

   The Edit window command line for this option reads:
   ```
   COMMENT/READOUTS,TOG1,
   comment text
   ```

   TOG1 = This YES / NO field allows you to specify whether or not the comment shows up in the inspection report.

For more information on setting up Probe Readouts, see "Setting Up the Probe Readouts Window" in the "Setting Your Preferences" chapter.

For more information on the Probe Readouts window, see "Using the Probe Readouts Window" in the "Using Other Windows, Editors, and Tools" chapter.

Display On Report

This check box allows you to determine whether or not your comment and any submitted text (if using an Operator comment, for example) appear in the final report generated in the

Report window. If selected, the comment's YES/NO toggle field, which specifies whether or not a comment shows up in the report, is set to YES.

This check box is hidden if you select the **Report** comment type.

The Edit window command line for this option reads:

```
COMMENT/TOG1,TOG2,
comment text
```

TOG1 = Any comment type except Report.

TOG2 = This YES/NO field allows you to specify whether or the comment shows up in the inspection report.

Auto-Continue Execution

Auto-continue execution: This check box determines whether a comment that PC-DMIS displays during execution closes itself after a specified number of seconds. By default, this check box is not selected.

Operators may find this useful when they use a measuring device that is not near the computer, and they want the execution to continue after a certain amount of time. If you select this check box, the **Execution delay (in seconds)** box becomes available.

Execution delay (in seconds): This box defines the number of seconds to delay execution while PC-DMIS displays the comment. You can specify any number of seconds from 1 to 600, inclusive.

- If you use an execution delay with a movie file and the movie's play time exceeds the delay value, PC-DMIS waits until the movie finishes playing before continuing.
- If your movie value is shorter than the specified execution delay, the comment displays until the execution delay counts down to zero.

During execution, the software displays a count-down timer on the Operator comment type's **OK** button inside parentheses:

For the Yes / No comment type, it appears on the **Yes** button.

Once the timer reaches zero:

- For an Operator comment, execution continues as if the operator clicked the **OK** button.

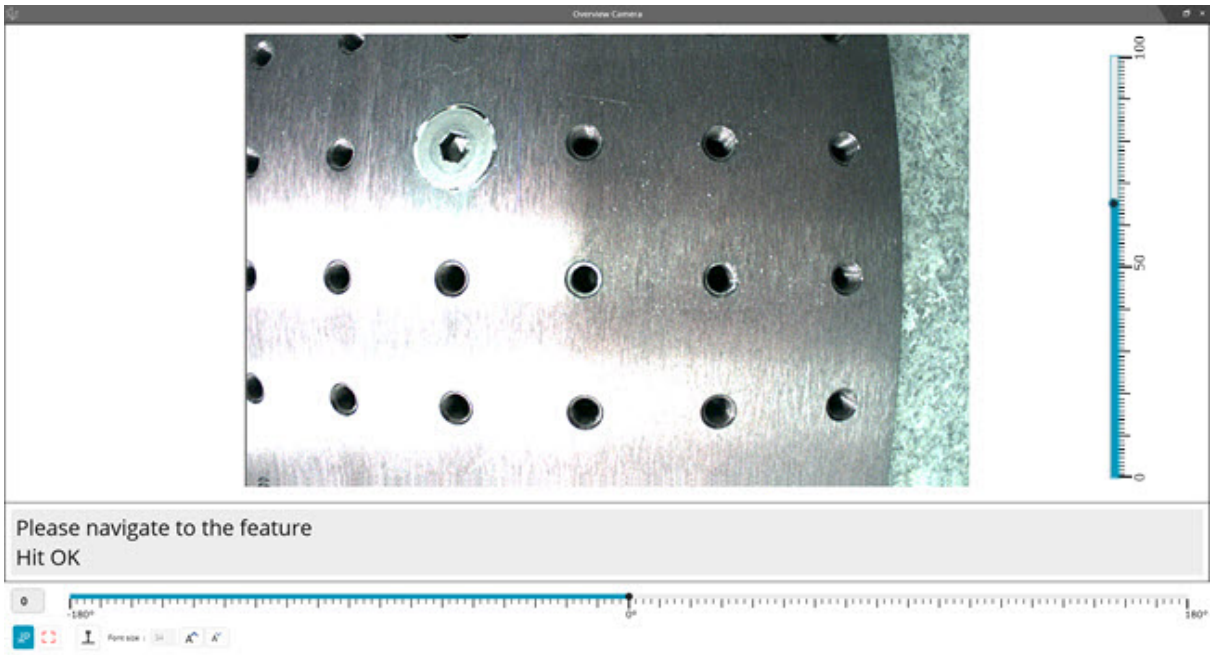
- For a Yes / No comment, execution continues as if the operator clicked the **Yes** button.

OVC

The **OVC** option displays the **Overview Camera** dialog box, which you can use to enter comments.

To use the **OVC** option, follow these steps:

1. Place the cursor in the Edit window where you want to insert the comment command.
2. Select the **Insert | Report Command | Comment** menu option to open the **Comment** dialog box.
3. From the **Comment** dialog box, select the **OVC** check box to open the **Overview Camera** dialog box.



Overview Camera Dialog Box

4. In the box, type the comment for the operator. You can use the and icons to increase and decrease the font size respectively.
5. Click "X" to close the **Overview Camera** dialog box.
6. From the **Comment** dialog box, click the **OK** button to close the dialog box and insert the comment.

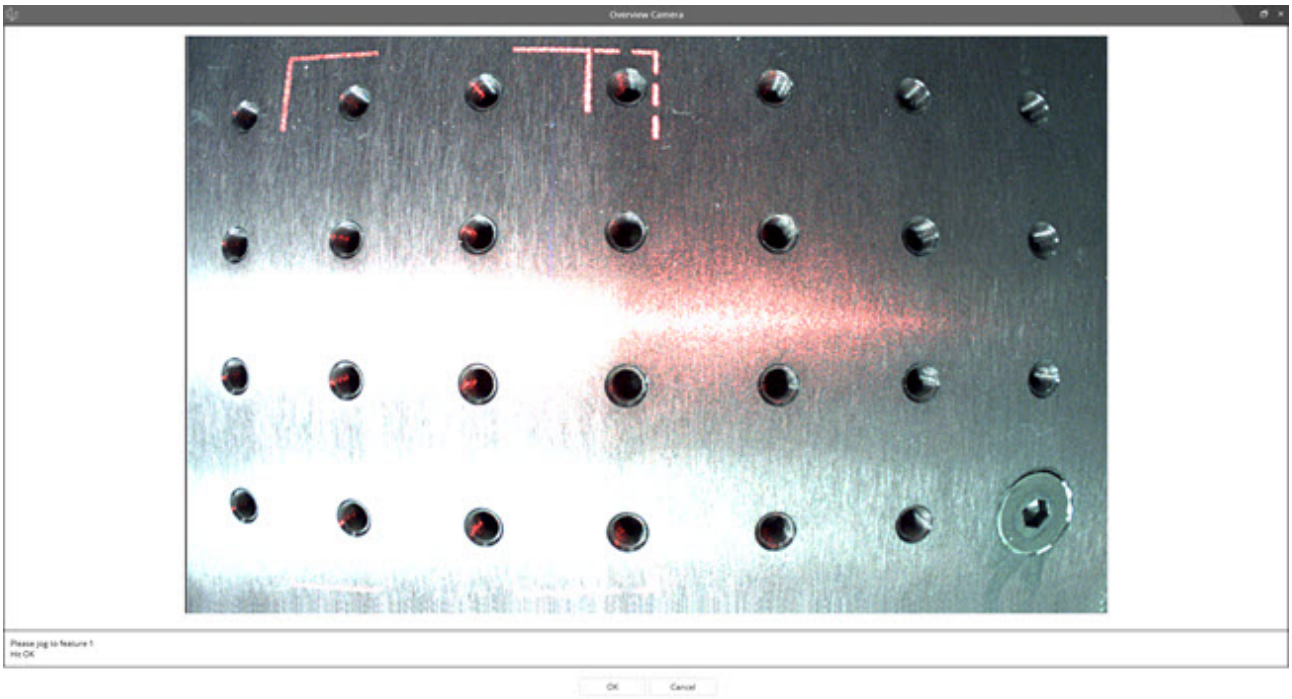
   The Edit window command line for this option reads:

```
 COMMENT/OPER,TOG1,FULL SCREEN=TOG2,AUTO-
CONTINUE=TOG3,OVC=TOG4,
comment text
```

- **TOG1** - This is a YES/NO field. If this is set to YES, PC-DMIS inserts the comment into the inspection report. Otherwise, the comment is not inserted into the report.
- **TOG2** - This is a YES/NO field. If this is set to YES, PC-DMIS displays the comment in a full screen. Otherwise, the comment is not displayed in a full screen.
- **TOG3** - This is a YES/NO field. If this is set to YES, the comment uses a countdown timer, and PC-DMIS automatically continues execution when the timer reaches zero. At zero, PC-DMIS behaves as if you clicked the **OK** button and continues the execution of the measurement routine. Otherwise, the countdown timer is not used.
- **TOG4** - This is a YES/NO field. If this is set to YES, PC-DMIS displays the OVC comment during the execution of the measurement routine. Otherwise, the OVC comment is not displayed during the execution of the measurement routine.

How it Works

When PC-DMIS executes the measurement routine, a message box displays the relevant comments just below the **Execution** dialog box.



PC-DMIS Message Dialog Box

PC-DMIS doesn't allow you to edit this message. Click **OK** to continue execution of the measurement routine. Click **Cancel** to cancel the execution of the measurement routine.

Display Full Screen

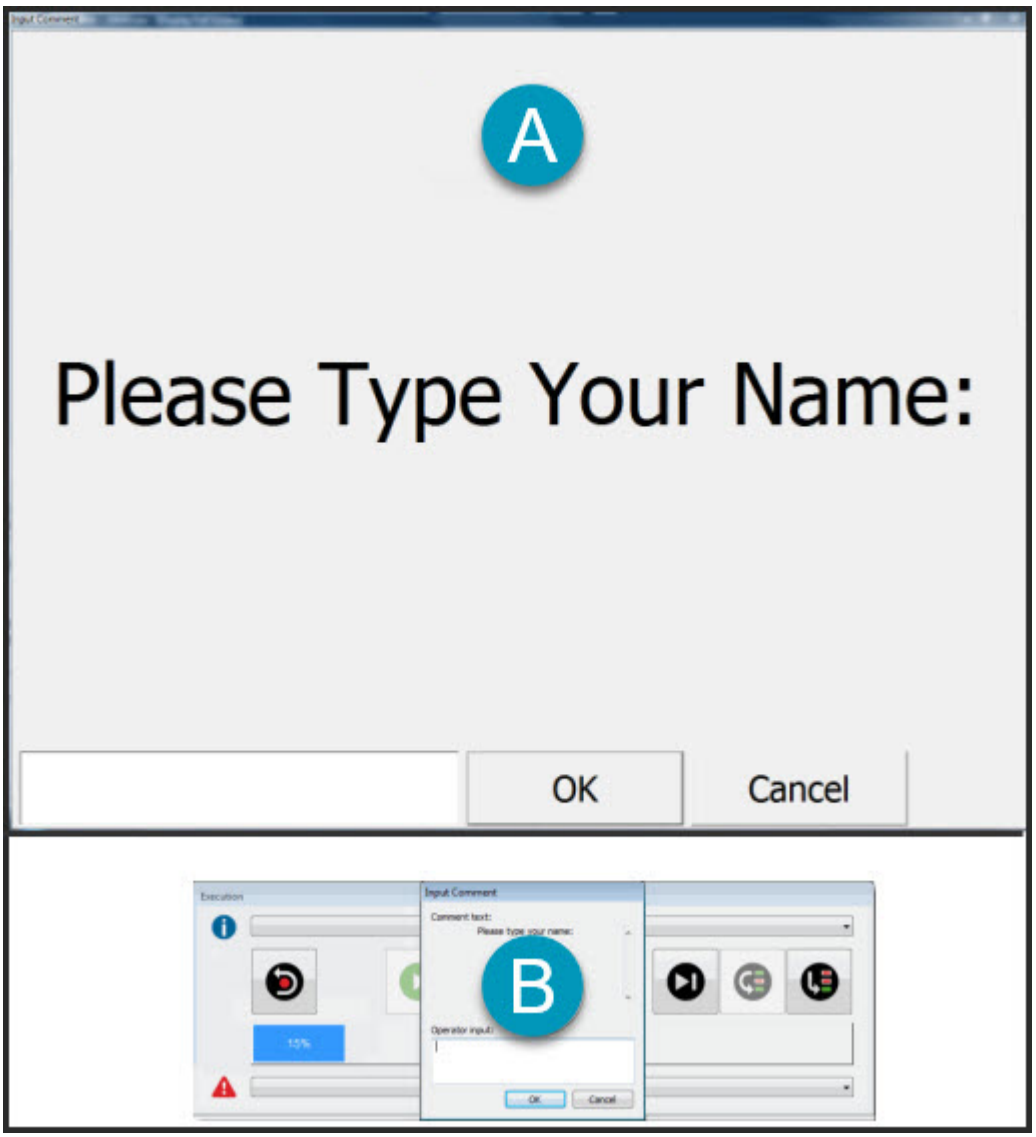
This check box determines whether or not your comment's text is displayed in an enlarged size that fills the entire screen once the command is executed. This functions with **Input**, **Yes / No**, and **Operator** comments. If you select other comment types, PC-DMIS disables this check box. Also, with this check box marked, you have the option to display certain media (images or movies) within the displayed comment. In that case, the **Import Media** and **Remove Media** buttons become enabled. For information on those buttons, see "Import Media" or "Remove Media".

> The Edit window command line for this option reads:
> `COMMENT/TOG1,TOG2,Full Screen=TOG3,`
> `comment text`

TOG1 = An INPUT, YESNO or OPERATOR comment.

TOG2 = This YES/NO field allows you to specify whether or not the comment shows up in the inspection report.

TOG3 = This YES/NO field allows you to specify whether or not the comment fills the entire screen when displayed.



Example of a full screen input comment (A) and a normal sized comment (B).

Import Media

To import this button, you must first mark the **Display Full Screen** check box.

The **Import Media** button lets you browse to a valid media file and *import* that file into your measurement routine. PC-DMIS then displays it within a full-screen comment when the measurement routine executes that comment. When you click **OK**, the file is *imported into* the measurement routine and *becomes a component* of the measurement routine. This makes it so you don't need to remember to move image and video files when you move the measurement routine to another computer system or directory. However, it can also make your measurement routine size quite large, depending on the type and number of media files you choose to include.

The chosen file appears in the box to the right of the **Import Media** button.

Valid image file types include the following:

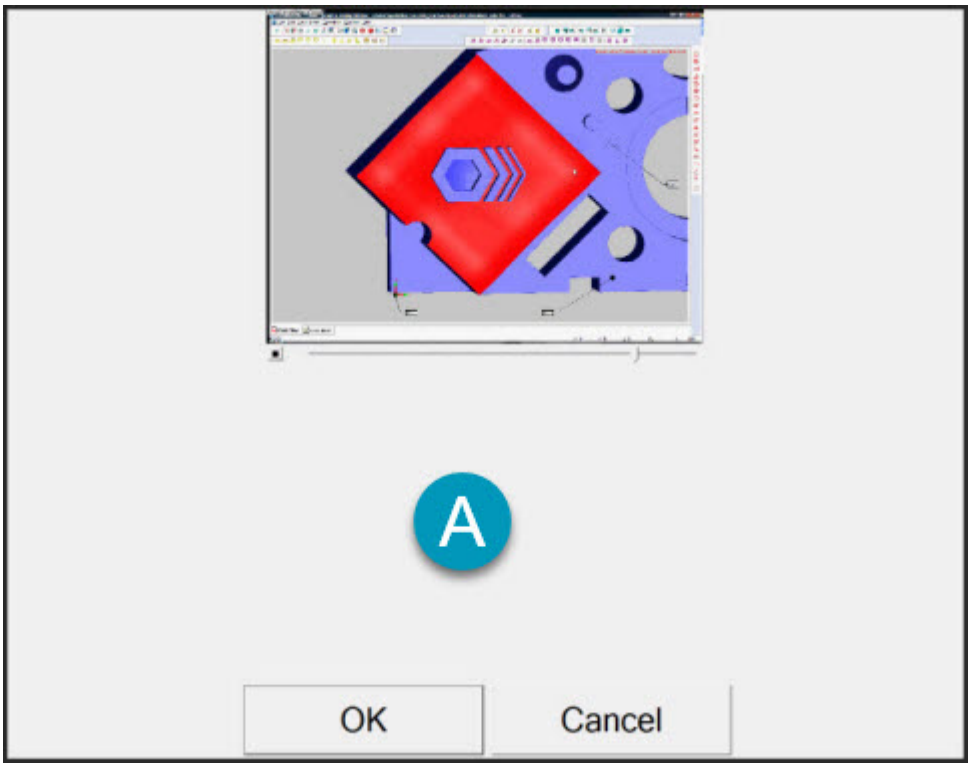
- .bmp
- .png
- .jpg

Valid movie file types include the following:

- .avi

About the Media Container

When PC-DMIS executes a comment containing a media file, it sizes the displayed media to fit within a portion of the full-screen comment called a "container". This means PC-DMIS sizes the image or movie to fit within the container.



This sized image shows a full-screen Operator comment. Notice that the media container in the top portion of the comment contains a movie sized to fit within that container.
(A) - Take four hits on the top of the part, as shown in the video above.

The horizontal slider below the container displays the current progression of a loaded movie file. You can drag the slider to jump to different spots along the movie's timeline.

This icon stops a movie file from playing.

This icon resumes playing a stopped movie file.

Supported AVI Codecs

A video codec is the algorithm that compresses and decompresses a video file. If you try to use an .avi video file with an unsupported codec in an Operator comment, during execution, you may receive an "MCI Error" that says, "No Driver installed" or "The specified file cannot be played on the specified MCI device."

If you get any of these errors, check your video format and your codec.

You must use an .avi file that was created or compressed with the Microsoft Video 1 (MS-CRAM) codec.

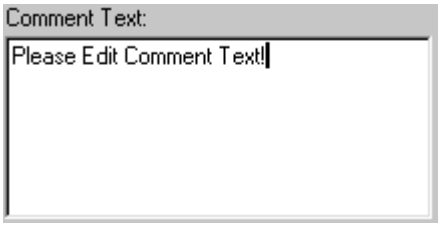
- To check your video's codec, you can use the free and open source VLC media player from https://www.videolan.org/vlc/.
- To create a video with the Microsoft Video 1 codec, here are some possible options to consider:
  - Use the older free and unregistered HyperCam 2 software and record with the Microsoft Video 1 codec.
  - Use a newer recording application that supports recording or exporting in the Microsoft Video 1 codec. For example, with TechSmith Camtasia 2021, you can import a modern video format, such as .mp4 file, and then export that file as an .avi with the Microsoft Video 1 codec.

Remove Media

This becomes enabled if you first mark the **Display Full Screen** check box.

The **Remove Media** button removes the media from the comment. While this removes the media from the measurement routine, be aware that due to limitations with the Windows file system, you may still see a file size higher than it was originally before you imported the media. In these cases, you can always do a **File | Save As** and save the measurement routine to a different file name to get a measurement routine with its original file size.

Comment Text



The **Comment Text** box contains the text you wish to display in conjunction with the Comment Type options as shown here:

- Operator
- Report
- Input
- Document
- Yes / No
- Readouts

Inserting ASCII Characters

ASCII Character Buttons

These buttons on the **Comment** dialog box insert some commonly used ASCII characters into the **Comment Text** box.

Embedding Reports or Templates into a Measurement Routine

You can embed these reports into your measurement routine:

- Legacy report (HyperView report)
- Report template
- Custom report
- Label template

When PC-DMIS executes the embedded code, it launches the report or template. You can then print it, view it, and pass values to and from the embedded item.

Legacy reports are older reports that use the HyperView report editor. PC-DMIS versions 3.0, 3.2, 3.25, 3.5, or 3.7 used this editor. For information on these reports, see "Working with Legacy (HyperView) Reports".

To embed a report or template:

1. Make sure the Edit window is in Command Mode.
2. Select **Insert | Report Command**, and then choose one of these menu items.
   - Custom Report
   - Template Report
   - Legacy Report
   - Report Label

   A dialog box appears allowing you to select your report or template.
3. Select the report or template you want to embed in the Measurement Routine.
4. Click the **Open** button to insert the command.

PC-DMIS inserts one of the following commands into the Edit window at the cursor position:

- `REPORT/CUSTOM`
- `REPORT/TEMPLATE`
- `REPORT/LEGACY`
- `REPORT/LABEL`

The REPORT Command

The Report command object is identified with the `REPORT` command in the Edit window.

The REPORT Command Syntax

A `REPORT` command has the following syntax in the Edit window in Command Mode:

```
<ID>        =REPORT/<TOG1>, FILENAME= <PATHWAY>,
AUTOPRINT=<TOG2>, INLINE REPORT=<TOG3>,
Section=<NUM1>,REPORTMODE=<MODE>
            PARAM/=
            ENDREPORT/
```

<ID>

This is the ID for the REPORT command.

REPORT/<TOG1>

This changes the type of `REPORT` command. It can be CUSTOM, LEGACY, TEMPLATE, or LABEL.

FILNAME=<PATHWAY>

This determines the report or template to load. <PATHWAY> is the full file name path that points to the desired file. If you only use the name of the report or template, PC-DMIS looks in the default Reporting directory.

AUTOPRINT =<TOG2>

<TOG2> can switch between PRINT and PDF and NO. It only applies to `REPORT/LEGACY` commands.

Setting AUTOPRINT=PRINT prints the HyperView report to the default printer after it loads and executes. The report closes immediately after the print job has spooled and execution of the measurement routine resumes.

Setting AUTOPRINT=PDF prints the HyperView Report to a Portable Document Format (PDF) file. The following rules apply:

- The name of the generated PDF file has the same base name as the report or template file name appended by a numerical index and extension.
- The generated file is located in the same directory as the Report file.
- If a file exists with the same name as the generated file name, the index automatically increments itself until a unique file name is found.

Setting AUTOPRINT=NO does not print anything during execution of this command.

INLINE REPORT=<TOG3>

This is only used with Legacy (HyperView) Reports that have AUTOPRINT set to PDF. It determines if HyperView report information appears in line with the other generated data from the Report window in a PDF output.

<TOG3> switches between ON and OFF.

ON - When this command executes, and the **Output Configuration** dialog box generates a PDF automatically by the **Overwrite**, **Auto**, or **Append** options, the data from the specified legacy (HyperView) report appears in line with the other normal report output in the PDF file.

If the **Prompt** option is used, and this is set to ON, then multiple PDFs are generated, one for the HyperView report and additional PDFs as needed to cover the rest of the Report window's content.

OFF - Data from the HyperView report appears in its own PDF file based off the name of the HyperView report. It is not included in the PDF generated from the **Output Configuration** dialog box.

Be aware that this option overrides the AUTOPRINT option for HyperView commands.

For more information on legacy HyperView reports, see "Working with Legacy (HyperView) Reports".

Section=<NUM>
<NUM> determines the section into which the report or template is inserted. This item does NOT apply to label templates.

If you type -1 or a value greater than the number of sections in the default template, the report gets inserted at the end.

REPORTMODE=<MODE>
When a measurement routine executes and a default report template is specified, it starts to generate the report using the default report template. Once it reaches the REPORT command, the generation changes based on the specified report mode:

<MODE> - This can either be SWITCH or INSERT. This mode only applies to the REPORT/TEMPLATE commands.

SWITCH - This switches the report template to use the one in this command until another REPORT command is encountered or until the end of the measurement routine.

INSERT - This generates report data for previously-executed commands. It uses the template in this command. When this REPORT command finishes, PC-DMIS returns to using the default report template to generate the rest of the report data.

PARAM/
The PARAM/ option allows you to map PC-DMIS expressions to a report or a report template's variables or properties. This option does not apply to REPORT/LABEL commands.

The syntax of the PARAM/ option is:

```
PARAM/{object or variable name}={PC-DMIS expression}
```

If you have a Global Variable in a report named NumBoltHoles, the following PARAM/ option would map the PC-DMIS expression to NumBoltHoles:

```
PARAM/NumBoltHoles=360.0/angle
```

Changes to the variable in the editor can also change the PC-DMIS variable.

Using the following PARAM/ option, the variable NumBoltHoles is set equal to the variable numBolts. Any changes within the HyperView report to the HyperView variable NumBoltHoles are reflected in the PC-DMIS variable numBolts:

```
PARAM/NumBoltHoles=numBolts
```

After execution, any objects you changed by passing parameters into a Report template or a HyperView report revert to what they had been before execution if you redraw or modify the report in any way. This means if you want to retain the results of passing a parameter to your template or report, you need to first print the report before you make modifications. You can do this using the AUTOPRINT parameter or by printing directly from the Report window.

See "Using the PARAM command to Map PC-DMIS Expressions to Object Properties" for additional information on using parameters.

You can press F9 on a `REPORT/CUSTOM` command to open the custom report in the Custom Report Editor.

REPORT/TEMPLATE Report Generation

PC-DMIS generates the default report as usual until it reaches this command. When it executes this command, PC-DMIS utilizes the specified template and generates a separate report for all the measurement routine commands in a new section within the current report. After PC-DMIS generates this new report section, it switches back to the previous report and continues to generate commands in the original report from that point forward.

Using the PARAM command to Map PC-DMIS Expressions to Object Properties

PC-DMIS expressions can be mapped to property objects using the `PARAM/` command in the Edit window. The syntax for mapping a PC-DMIS expression to an object property is:

PARAM/{object code}.{property name}={PC-DMIS expression}

The following PARAM/ option changes the BorderStyle property of the object, Text1: `PARAM/Text1. BorderStyle =1`

Inserting External Objects

To add external objects to your report, select the **Insert | Report Command | External Object** menu item. For more information, see the "Adding External Elements" chapter.

Inserting a Print Command

When PC-DMIS executes a `PRINT/REPORT` command, it sends the measurement results up to that point in the measurement routine to the defined output destination (printer or file). After PC-DMIS executes the command, it clears the contents of the Report window, and only the remaining measurement results appear in the Report window.

However, you can always click the **View Report Mode** icon on the **Reporting** toolbar to view the full report.

To insert a `PRINT/REPORT` command into the Edit window, do the following:

1. If the Edit window isn't already visible, choose **View | Edit Window** to open the Edit window.
2. Choose **View | Command Mode** to place the Edit window into Command Mode.
3. Select the **Insert | Report Command | Print Command** menu option (or type **PRINT** at the desired location and press Tab). PC-DMIS inserts a `PRINT/REPORT` command with various options you can configure.
4. To configure the command, press F9 on the command and use the **Output Configuration** dialog box. For more information, see "Editing the PRINT/REPORT Command".

The `PRINT/REPORT` command controls the printing of reports from within the measurement routine. When PC-DMIS executes this command, a report is generated and sent to the specified output destination.

To control how PC-DMIS handles a report header *after* a `PRINT/REPORT` command, see "Header after Print Command" area in the "Edit Text Reporting" topic of the "Reporting Measurement Results" chapter.

Related Topics:

Using the Print Command in a Loop

Understanding the Syntax for the PRINT/REPORT Command

The syntax of the command is as follows:

```
PRINT/REPORT,EXEC MODE=END,$
   TO_FILE=OFF,TOG1,AUTO,OUTPUT_FORMAT/TOG2,$
   RESET_REPORT=YES,AUTO OPEN=OFF,$
   TO_PRINTER=OFF,COPIES=,$
   TO_DMIS_REPORT=OFF,FILE_OPTION=TOG3,FILENAME=,$
REPORT_THEORETICALS=ALL,REPORT_FEATURE_WITH_DIMENSIONS=YES,$
   TO_EXCEL=OFF,TOG4, AUTO OPEN=OFF,$
   PREVIOUS_RUNS=DELETE_INSTANCES
```

EXEC MODE = Because DMIS and PC-DMIS manage report data differently, this option controls how and when the software sends report data to DMIS and PC-DMIS output files. DMIS requires that the output filenames and other printing parameters be defined first *before* the routine is executed. PC-DMIS, on the other hand, waits until *after* the measurement routine is executed before deciding where to dump the report data. With this option, you can support both formats. It takes one of two values, either **START** or **END**.

START

This tells PC-DMIS to begin printing when it either encounters the end of the measurement routine or another `PRINT/REPORT` command. If you import a DMIS file, and it has a print report command, it uses **START** as its initial value.

END

This tells PC-DMIS to print everything already executed up to this `PRINT/REPORT` command. If you don't import a DMIS file with a print report command, but instead insert your own `PRINT/REPORT` command from within PC-DMIS, it has **END** as its initial value.

If your measurement routine contains more than one `PRINT/REPORT` command, be aware that PC-DMIS may not print some commands. For example, if your first `PRINT/REPORT` command uses **END** and your second print report command uses **START**, then PC-DMIS does not print everything in between.

Also if a `PRINT/REPORT` command uses **START** and then your very next print report command uses **END**, the second printing is empty, because the first print report command has cleared the report buffer.

TO_FILE= Use this option to indicate whether the printed report should be sent to a file (**ON**) or not (**OFF**).

TOG1 This value controls the action taken when sending the print output to an .rtf, .pdf, or .txt file. The options available are **APPEND / OVERWRITE / AUTO / PROMPT**. Depending on the option selected, different information may appear.

APPEND

Use this option to append report information to the specified filename. When you select the **APPEND** option, this keyword is followed by a filename field, for example, `APPEND=D:\REPORTS\FILE001.RTF` . Note that you must specify the complete path; otherwise, PC-DMIS assumes the same directory as the measurement routine. Also, if the file does not exist, PC-DMIS creates it when the `PRINT/REPORT` command is executed.

OVERWRITE

Use this option to overwrite report information to the specified filename. When you select the **OVERWRITE** option, this keyword is followed by a filename field, for example, `OVERWRITE=D:\REPORTS\FILE001.RTF` . If the file does not exist, PC-DMIS creates it when the `PRINT/REPORT` command is executed. If you don't provide a pathway, it defaults to the measurement routine's folder. If there is no path in this field, you can set this to a variable name (see the example below).

AUTO

Use this option to have PC-DMIS generate the report filename automatically. When you select the **AUTO** option, this keyword is followed by a numeric field, for example, `AUTO=10` . PC-DMIS uses the name of the measurement routine to name the generated file, and appends the numerical index value to the end of it with the .rtf extension. Also, PC-DMIS sends the generated file to the same directory as the measurement routine. If a file exists with the same name as the

generated filename, **AUTO** increments the index until a unique filename is found.

PROMPT

Use this option to cause a **Save As** dialog box to appear that you can use to type a filename and select a location to save the report information.

OUTPUT_FORMAT - Use this option to determine whether PC-DMIS sends output to a text file (.txt), Rich Text Format (.rtf) or Portable Document Format (.pdf) file.

TOG2= You can set TOG2 to **RTF**, **PDF**, **TXT**, or **PDF3D**. For information on the toggle options, refer to the Output Configuration topic.

RESET_REPORT - Use this option to determine if PC-DMIS resets the report after each `PRINT/REPORT` command.

YES

This option clears the report buffer and prints only the items executed after the current `PRINT/REPORT` command until it encounters the end of the measurement routine or another `PRINT/REPORT` command.

NO

If the measurement routine hits a `PRINT/REPORT` command, PC-DMIS prints everything in the buffer from:

- The beginning of the measurement routine up to the current `PRINT/REPORT` command if there were no other `PRINT/REPORT` commands before the current `PRINT/REPORT` command, or
- From the last `PRINT/REPORT` command that was set to **YES** up to the current `PRINT/REPORT` command, or
- The beginning of the measurement routine through all `PRINT/REPORT` commands as long as they were all set to **NO** up to the current `PRINT/REPORT` command.

AUTO OPEN= Use this option to determine whether PC-DMIS opens the generated .rtf, .pdf, or .txt file after the `PRINT/REPORT` command executes. This can be **ON** or **OFF**.

TO_PRINTER= Use this option to indicate whether to send the report to the printer (**ON**) or not (**OFF**).

COPIES= This value determines the number of report copies to send to the printer.

TO_DMIS_REPORT= Use this option to determine whether or not PC-DMIS sends the report to a DMIS Output file (.dmo) specified in **FILENAME**. This can be **ON** or **OFF**.

FILENAME= Use this option to specify a DMIS output directory location and filename. If **TO_DMIS_REPORT** is set to **ON** then PC-DMIS stores the report data in the file specified. For example, if `FILENAME=D:\PCDMISREPORTS\MYDMIS.DMO`, PC-DMIS causes the report data to be saved in the MYDMIS.dmo file in a PCDMISREPORTS folder on drive D. If you don't provide a pathway, it defaults to the measurement routine's folder. If there is no path, you can set this to a variable name.

FILE_OPTION=TOG3 You can set TOG3 to the following file options for your DMIS file output:

APPEND

This appends the report data to the end of the DMIS file specified in **FILENAME**.

OVERWRITE

This overwrites the DMIS file specified in **FILENAME** with the latest report data.

INDEX

This appends to the DMIS filename specified in **FILENAME** a numerical value that increments on subsequent measurement routine executions. For example, if `FILENAME=MYDMIS.DMO`, on the next execution the filename increments by one, becoming mydmis001.dmo, mydmis002.dmo, mydmis003.dmo, and so on, similar to the **AUTO=** option.

REPORT_THEORETICALS= This tells how PC-DMIS reports theoretical values in the DMIS output file.

ALL

PC-DMIS outputs all theoretical values along with the measured values to the output DMIS file.

NONE

No theoretical values are included in the report.

IMPORT_SETTINGS

Only those theoretical values explicitly output by the original DMIS file are output in the report.

REPORT_FEATURE_WITH_DIMENSIONS= This determines whether or not PC-DMIS keeps the measured features and associated tolerances together in the output file. It takes either **YES** or **NO**.

YES

In the DMIS report file, PC-DMIS writes the measurement results immediately before their associated tolerance results for each dimension associated to the feature itself. If a feature is not associated with any tolerance, PC-DMIS does not generate any output.

NO

In the DMIS report file, PC-DMIS writes the measurement results exactly when the feature is measured, but not later when PC-DMIS executes the associated dimensions.

TO_EXCEL= This determines whether or not PC-DMIS sends the output to a Microsoft Excel file. It takes either **ON** or **OFF**.

ON

An Excel file is generated for all the items in the measurement routine to this point.

OFF

No Excel file is generated by this print command.

To modify Excel output options, press F9 on this command and modify the options in the **Excel** tab.

Additional Notes:

- If this is set to **ON**, but the measurement routine's **Output Configuration** dialog box has the **Excel output** check box cleared, PC-DMIS generates the Excel for this specific command only.
- If this is set to **OFF**, but the measurement routine's **Output Configuration** dialog box has the **Excel output** check box marked, an Excel file is generated at the very end of the execution.
- If this is set to **ON**, and the measurement routine's **Output Configuration** dialog box has the **Excel output** check box also marked, you may end up with two generated output files, one for each. In this case, dimensions that follow a `PRINT/REPORT` command are generated in a different file.
- Looping is supported with the Excel output. If you run the `PRINT/REPORT` command through a loop and the Excel output is set to append, it generates the content as additional worksheets inside the Excel file.

- To change the number of decimal places for the Excel output file output, you can insert a `DISPLAYPRECISION` command just before the `PRINT/REPORT` command.

TOG4= This value controls the action taken when sending the print output to an Excel file (.xls, .xlsx, csv). For information on the toggle options, refer to the similar TOG1 item above.

FILENAME= Use this option to specify the output directory location and filename for the Excel file. If **TO_EXCEL_OUTPUT** is set to **ON**, then PC-DMIS stores the report data in the file specified. For example, if `FILENAME=D:\PCDMISREPORTS\MYEXCEL.XLS` , PC-DMIS causes the report data to be saved in the MYEXCEL.xls file in a PCDMISREPORTS folder on drive D. If you don't provide a pathway, it defaults to the measurement routine's folder. If there is no path in this field, you can set this to a variable name (see the example below).

AUTO OPEN= Use this option to determine whether PC-DMIS opens the generated Excel file (.xls, .xlsx, .csv) after the `PRINT/REPORT` command executes. This can be **ON** or **OFF**.

PREVIOUS_RUNS= Use this with a `PRINT/REPORT` command from within a loop. When a feature is measured more than once in a single execution, previous instances of that feature's measured data are saved. You can choose to delete (**DELETE_INSTANCES**) or keep (**KEEP_INSTANCES**) these instances.

Variable for FILENAME

In this example, the variable V1 takes the value of the Input comment stored in C1.INPUT. Then the FILENAME statement for the Excel output uses the value of variable V1 for the Excel file's folder and filename:

```
C1=COMMENT/INPUT,YES,FULL SCREEN=NO,

Type your Excel report pathway and file name:

ASSIGN/V1=C1.INPUT

PRINT/REPORT,EXEC MODE=END,$

TO_FILE=OFF,AUTO=1,AUTO OPEN=OFF,$

TO_PRINTER=OFF,COPIES=1,$

TO_DMIS_REPORT=OFF,FILE_OPTION=INDEX,FILENAME=,$

REPORT_THEORETICALS=NONE,REPORT_FEATURE_WITH_DIMENSIONS=NO,
$

TO_EXCEL=ON,OVERWRITE,FILENAME=V1,AUTO OPEN=ON,$

PREVIOUS_RUNS=DELETE_INSTANCES
```

For example, if the operator typed D:\Temp\MyReport.xls in the Input comment, PC-DMIS would save the Excel data to that directory and report name.

Editing the PRINT/REPORT Command

You can edit the `PRINT/REPORT` command's options in its **Output Configuration** dialog box.

1. Place the cursor over the `PRINT/REPORT` command line.
2. Press F9.
3. Make any changes.
4. Click **OK**.

PC-DMIS updates the command to match your change. You may not always see a visual indication in the command text itself of the change.

Understanding the Different Output Configuration Dialog Boxes

Note that PC-DMIS uses the **Output Configuration** dialog box in these locations:

From File | Printing | Report Window Print Setup

The main **Output Configuration** dialog box from that menu does *not* insert or modify the `PRINT/REPORT` command. Instead, it controls the overall printing defaults for the report. Unlike the `PRINT/REPORT` command, the main dialog box only affects printing when the measurement routine has completed execution. For information on the options in this dialog box, see "Printing the Report Window" in the "Using Basic File Options" chapter.

For Each `PRINT/REPORT` Command

When you press F9 on one of these commands, its specific **Output Configuration** dialog box opens.

- You can use the `PRINT/REPORT` command more than once in the measurement routine.
- Each `PRINT/REPORT` commands can have different outputs.
- Each `PRINT/REPORT` command is a unique instance of the information contained in the main **Output Configuration** dialog box. Therefore, options that are selected from the main dialog box are independent of any `PRINT/REPORT` command.

Inserting a Form Feed Command

PC-DMIS lets you insert a `FORMFEED` command into the Edit window. This command causes the printed page of a report to be ejected from the printer when the `FORMFEED` command has been marked and executed. The `FORMFEED` command has no effect when printing to a file.

To insert a `FORMFEED` command in to the Edit window, follow these steps:

1. Open the Edit window (**View | Edit Window**).
2. Click the **Command Mode** icon from the **Edit window** toolbar, placing PC-DMIS into Command Mode.
3. Select the **Insert | Report Command | Form Feed** menu option (or type `FORMFEED` at the desired location and press Tab). PC-DMIS displays the `FORMFEED` command.

Working with Viewsets

You can use `VIEWSET` commands to create and save different Graphic Display window views (termed "viewsets"). You can later recall and display saved viewsets in your Graphic Display window and CAD reports with `RECALL/VIEWSET` commands.

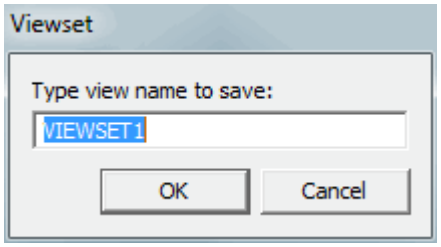
Viewsets store the following:

- The CAD model's orientation
- The CAD model's shading
- ID label visibility
- ID label position

The **Create Viewset** menu option allows you to create an unlimited number of viewsets in your measurement routine. You can recall multiple viewsets as often as desired.

To Create a Viewset:

1. Set up the view as desired. To do this, select **Edit | Graphic Display Window | View Setup** and use the **View Setup** dialog box to modify the zoom and rotation of the part in the Graphic Display window. For information on how to do this, see "Setting Up the Screen View" in "Editing the CAD Display".
2. Select **Insert | Report Command | Create Viewset** or from the **Graphic Modes** toolbar, choose **Create Views** ( ). A small **Viewset** dialog box opens with the prompt "Type view name to save." This dialog box contains a default name starting with VIEWSET1, and then it increments the number for subsequent viewsets (VIEWSET2, VIEWSET3, and so on):



Viewset dialog box with a default name.

3. In the box, type the desired name (19-character limit) for the view.
4. Click the **OK** button or press Enter. PC-DMIS sets the current viewset equal to the name you chose by inserting a `<NAME>=VIEWSET` command, where <NAME> is the defined viewset name.

To Recall a Viewset:

To recall the created viewset, do one of the following:

- From the **Settings** toolbar, select the **Views** list.
- From the PC-DMIS portable **QuickMeasure** toolbar, select **Recall Views** ( ).
- From the menu bar, choose **Insert | Report Command | Recall Viewset**.

Select the viewset that you want to recall. PC-DMIS inserts a `RECALL/VIEWSET,<NAME>` command into the Edit window.

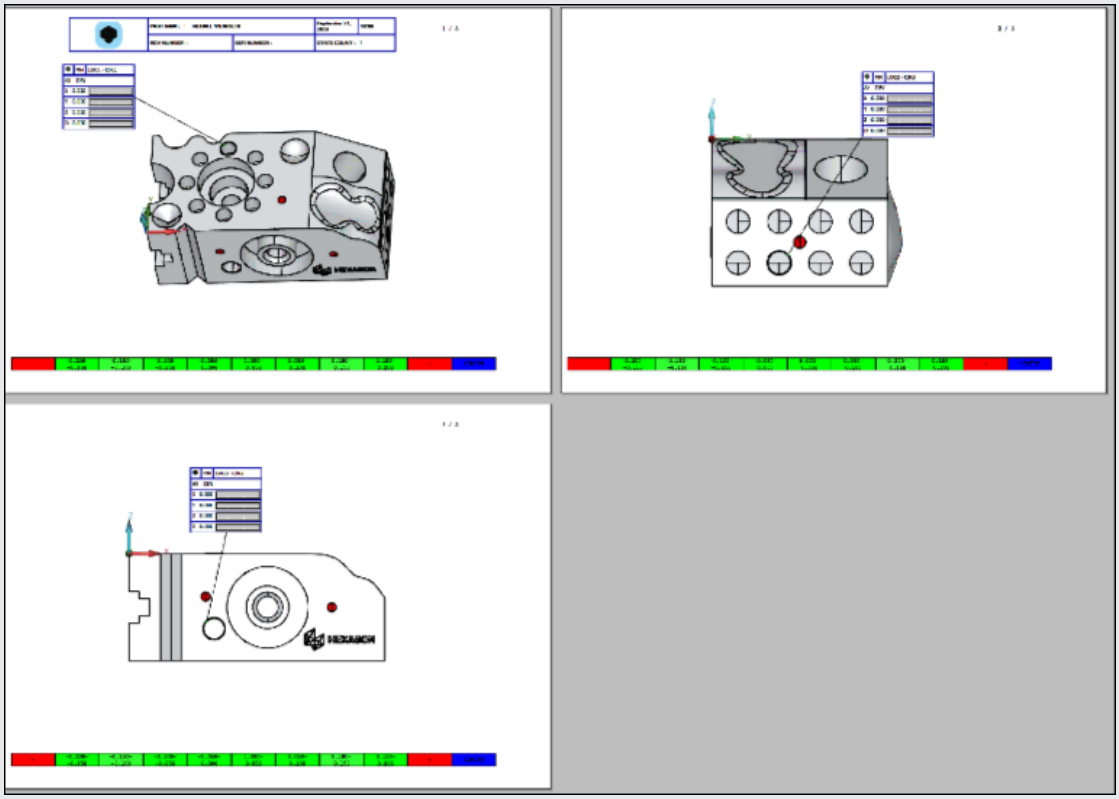
When your cursor is on or under the `RECALL/VIEWSET,<NAME>` command in the Edit window, PC-DMIS displays the created viewset in the Graphic Display window, where <NAME> is the defined viewset name. If you mark and execute this command, PC-DMIS displays the saved view in the Graphic Display window during measurement routine execution as well.

Additionally, recalled viewsets appear in your final report if the Report Window uses a template or custom report that displays a CADReportObject.

You can make viewsets in reports appear on a new page for each `RECALL/VIEWSET` command if your measurement routine has a dimension or colormap command after the `RECALL/VIEWSET` command. This approach orients the view in the report and forces a new page for the dimensions to show.

This example in the Edit window shows three `RECALL/VIEWSET` commands, each with a dimension command after it. These dimension commands force each viewset to appear on its own page inside the report:

```
             RECALL/VIEWSET,VIEWSET1
DIM LOC1= LOCATION OF CIRCLE CIR1  UNITS=MM ,$
GRAPH=OFF  TEXT=OFF  MULT=10.00  OUTPUT=BOTH  HALF ANGLE=NO
AX     NOMINAL       +TOL       -TOL       MEAS        DEV      OUTTOL
X       40.000       0.050      0.050     40.000      0.000      0.000 ---#----
Y       50.500       0.050      0.050     50.500      0.000      0.000 ---#----
Z        0.000       0.050      0.050      0.000      0.000      0.000 ---#----
D        8.200       0.050      0.050      8.200      0.000      0.000 ---#----
END OF DIMENSION LOC1
             RECALL/VIEWSET,VIEWSET2
DIM LOC2= LOCATION OF CIRCLE CIR3  UNITS=MM ,$
GRAPH=OFF  TEXT=OFF  MULT=10.00  OUTPUT=BOTH  HALF ANGLE=NO
AX     NOMINAL       +TOL       -TOL       MEAS        DEV      OUTTOL
X      120.000       0.050      0.050    120.000      0.000      0.000 ---#----
Y       23.000       0.050      0.050     23.000      0.000      0.000 ---#----
Z      -42.000       0.050      0.050    -42.000      0.000      0.000 ---#----
D        8.000       0.050      0.050      8.000      0.000      0.000 ---#----
END OF DIMENSION LOC2
             RECALL/VIEWSET,VIEWSET3
DIM LOC3= LOCATION OF CIRCLE CIR2  UNITS=MM ,$
GRAPH=OFF  TEXT=OFF  MULT=10.00  OUTPUT=BOTH  HALF ANGLE=NO
AX     NOMINAL       +TOL       -TOL       MEAS        DEV      OUTTOL
X       40.000       0.050      0.050     40.000      0.000      0.000 ---#----
Y        0.000       0.050      0.050      0.000      0.000      0.000 ---#----
Z      -35.000       0.050      0.050    -35.000      0.000      0.000 ---#----
D       10.000       0.050      0.050     10.000      0.000      0.000 ---#----
END OF DIMENSION LOC3
```



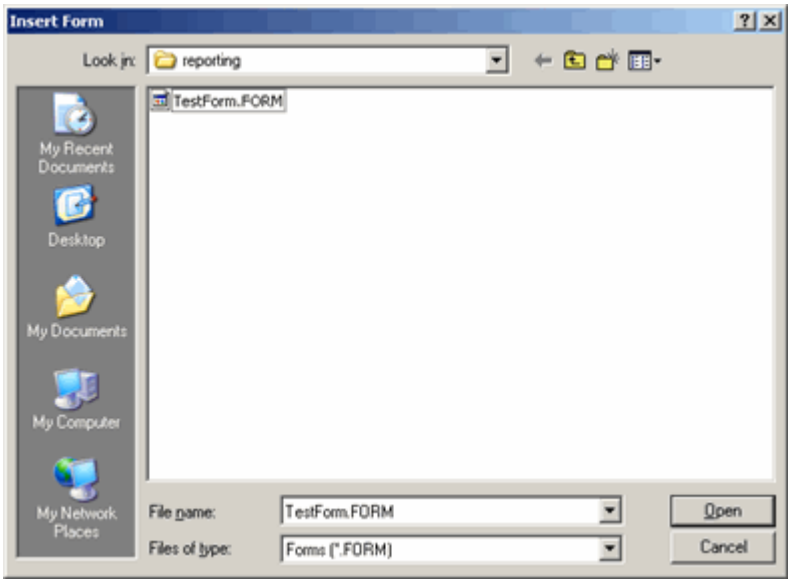
To Update a Viewset:

You can also modify an existing viewset. From the Edit window, select the `RECALL/VIEWSET,<NAME>` , modify the Graphic Display window as desired for that view, and then select the **Insert | Report Command | Save Viewset** menu option. Or from the **Graphic Modes** toolbar, select the **Save Viewset** icon ( ).

If you just want to change and then save the current viewset without creating a new viewset, select the **Save Viewset** menu option instead.

Inserting a FORM Command

The **Insert | Report Command | Form** menu item lets you insert a predefined .FORM file into your measurement routine. When you select this menu item, an **Insert Form** dialog box appears.



Insert Form Dialog Box

Navigate to the .FORM file, select it, and click **Open**. PC-DMIS inserts a FORM/FILENAME command similar to the following into the Edit window:

```
CS1=FORM/FILENAME=C:\PCDMIS40RELEASE\REPORTING\TESTFORM.FORM
    PARAM/=
    ENDFORM/
```

FILENAME = This defines the location of the .FORM file to load.

PARAM/ - This lets you send information to the form. For example, using a PARAM statement of `PARAM/Text1. Text =C1. INPUT` sends the value of the comment `C1. INPUT` to the control.

Alternately, you can type FORM and press TAB to insert the FORM/FILENAME command into the measurement routine, and then manually type the path to load the desired form.

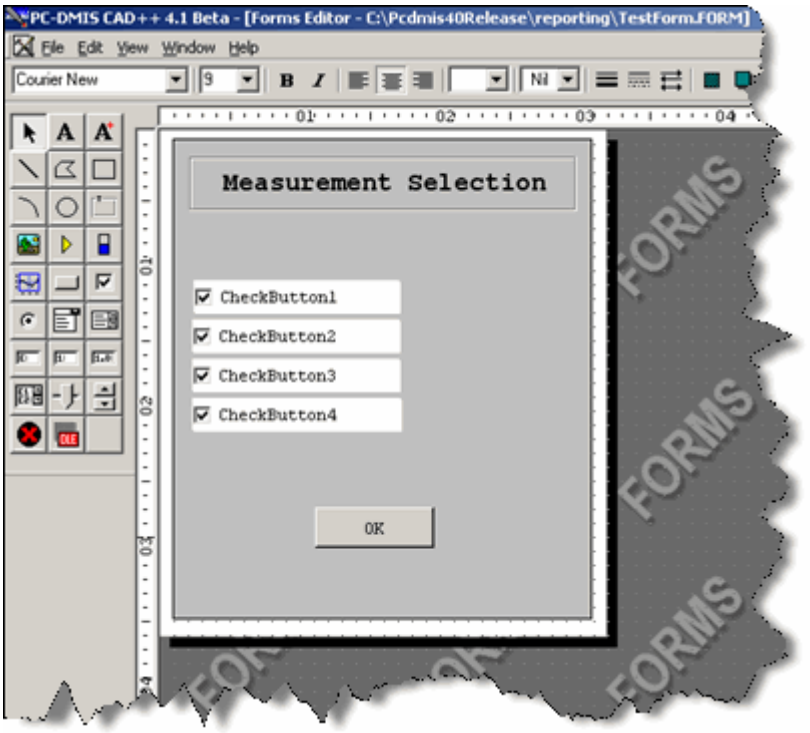
When PC-DMIS executes this command, it launches the defined form, and then passes any defined parameters to the controls in the form.

Communicating between the FORM and the Measurement Routine

You can pass values to and from a form by using a combination of ASSIGN and PARAM statements. This lets you establish useful two-way communications between the form and the measurement routine.

ASSIGN Statements - You can initialize values for a form's controls through ASSIGN statements. These statements also create variables that can later receive updated values from the form when the form closes.

For example, suppose you have a form that has four unnamed check boxes, like this:



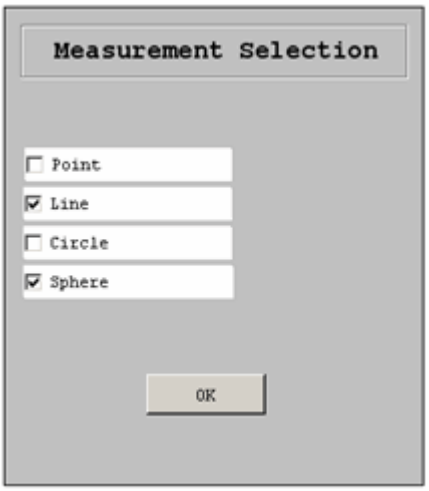
However, you want the measurement routine to give them names and values dynamically. In the Edit window, you can use the ASSIGN statements to name and initialize the check boxes as follows:

```
ASSIGN/CHECK1VALUE=0
ASSIGN/CHECK1TEXT="Point"
ASSIGN/CHECK2VALUE=1
ASSIGN/CHECK2TEXT="Line"
ASSIGN/CHECK3VALUE=0
ASSIGN/CHECK3TEXT="Circle"
ASSIGN/CHECK4VALUE=1
ASSIGN/CHECK4TEXT="Sphere"
```

PARAM Statements - Now that you have several variables, you can use the PARAM statements to establish the connection between the variables and the form itself, like this:

```
CS1=FORM/FILENAME= C:
\PCDMIS40RELEASE\REPORTING\TESTFORM.FORM
   PARAM/CHECKBUTTON1.VALUE=CHECK1VALUE
   PARAM/CHECKBUTTON1.TEXT=CHECK1TEXT
   PARAM/CHECKBUTTON2.VALUE=CHECK2VALUE
   PARAM/CHECKBUTTON2.TEXT=CHECK2TEXT
   PARAM/CHECKBUTTON3.VALUE=CHECK3VALUE
   PARAM/CHECKBUTTON3.TEXT=CHECK3TEXT
   PARAM/CHECKBUTTON4.VALUE=CHECK4VALUE
   PARAM/CHECKBUTTON4.TEXT=CHECK4TEXT
   PARAM/=
   ENDFORM/
```

When the form loads, CHECKBUTTON1 is unchecked, and its text label displays "Point"; CHECKBUTTON2 is checked, and its text label is "Line"; CHECKBUTTON3 is unchecked, and its text label is "Circle"; and CHECKBUTTON4 is checked, and its text label is "Sphere", like this:



With the form loaded, you can select or clear the check boxes to something different. When you close the form, the variables that initially set the state of the checked state (CHECK1VALUE, CHECK2VALUE, CHECK3VALUE, and CHECK4VALUE) now hold the current values of the check boxes.

Inserting Screen Captures

This topic details the old way to add screen captures. It remains for backwards compatibility. Try out the new **Snapshot** menu option instead; it has more functionality. For information, see "Inserting Snapshots" in this chapter.

You can use the **Insert | Report Command | Screen Capture** menu item to display screen captures of the part in your report. This menu option places a `DISPLAY/METAFILE` command in the Edit window. When this command is marked and executed, PC-DMIS automatically refreshes the screen capture and displays it in the report.

Command line in the Edit window:

```
DISPLAY/METAFILE,"___",TOG1,TOG2
```

___ = This field will allow you to enter a description of the captured screen. The maximum text is 255 characters.

TOG1 = This field determines the size of the screen capture. You can toggle between the following: 25%, 50%, 75%, 100%, TO FIT.

TOG2 = This field determines the quality of the screen capture. You can toggle between the following: **HIGH**, **GOOD**, **LOW**

For this to appear in the Report window, right-click on some text within the Report window, select **Edit**, and when the **Report** dialog box appears, select the **Show Screen Capture** check box.

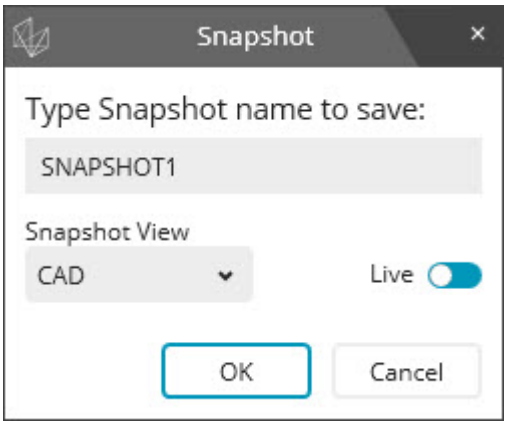
This command is similar to the `ANALYSISVIEW` command and the `DISPLAY/METAFILE` command that are created in the Analysis Window. For more information on the Analysis Window, see "Analysis area" in this chapter.

A **True Type Font** for text in the Graphic Display window gives the best results when capturing the image.

Inserting Snapshots

The `SNAPSHOT` command displays screen captures of the part in your report.

To access the **Snapshot** dialog box, select **Insert | Report Command | Snapshot** or from the **Graphic Modes** toolbar, click the **Insert Snapshot** button ( ).



Snapshot Dialog Box

Type Snapshot name to save - This box lets you type the snapshot name.

Snapshot View - This list lets you select **CAD** or **OVC** for the snapshot view.

Live - This button toggles Live Mode On and Off.

- When Live Mode is On, the software captures snapshots of the measurements from a continuous data stream. This means that PC-DMIS displays the probe data “live” (real-time) in the Graphic Display and Probe Readouts window.
- When Live Mode is Off, PC-DMIS takes a measurement as a single snapshot. PC-DMIS does not update the Graphic Display and the Probe Readout windows.

OK - This button inserts a `SNAPSHOT` command with that name in the Edit window. When this command is marked and executed, PC-DMIS automatically refreshes the screen capture and displays it in the report.

In the Edit window in Command Mode, you can also manually type `SNAPSHOT` and press Tab. When you press Tab, PC-DMIS stores the properties for the state of the Graphic Display window in the command. During execution, PC-DMIS inserts the capture into the report the moment the software executes the command.

Command line in the Edit window:
```
TOG1 =SNAPSHOT/
```

TOG1 = This field holds the name of the snapshot.

Differences from the DISPLAY/METAFILE Command

The `SNAPSHOT` command provides better screen captures than the `DISPLAY/METAFILE` command. While the snapshot functionality is similar to `DISPLAY/METAFILE`, it has these differences:

- A `SNAPSHOT` command updates the various analysis-related items you see on the Graphic Display window in the screen capture. These analysis items include graphical analysis, pointcloud color maps, dimension info labels, scan arrows with deviation colors, and so on. `DISPLAY/METAFILE` results in a much more static image.
- A `SNAPSHOT` command saves your screen orientation and zoom level.
- A `SNAPSHOT` command works with multiple views.

Default Snapshot Names

If you don't type a snapshot name, the default names follow this pattern SNAPSHOT1, SNAPSHOT2, SNAPSHOT3... and so on.

If you first select a CAD model view from the list on the **CAD Setup** toolbar and then access the **Snapshot** dialog box, the default pattern follows the name of the current model view.

Suppose you have a CAD model view with the name of **Right** to show the right side of your part. If you select **Right** from the list and then access the **Snapshot** dialog box, PC-DMIS shows the name of the snapshot as "Right1". If you do it again, PC-DMIS names the next snapshot as "Right2", and so on.

Inserting a Snapshot Command

1. In the Graphic Display window, pan, zoom, and rotate your part to the way you want it.

2. From the **Graphic Modes** toolbar, click **Insert Snapshot** ( ) to show a **Snapshot** dialog box.

3. In the **Snapshot** dialog box, type a name for the screen capture, select a view, and set the Live Mode.

4. Click **OK** to insert the `SNAPSHOT` command at the selected spot in the Edit window.

5. If PC-DMIS cannot insert at the current position, it shows a message box that asks how you want to handle the insertion. You can choose one of these three items on the message box:

    - **Next Position** - This inserts the command at the next valid position.
    - **End of Program** - This inserts the command at the end of the measurement routine.
    - **Don't Insert** - This does not insert the command.

Viewing the Snapshot in the Graphic Display Window

1. Select the `SNAPSHOT` command in the Edit window.

2. Press Ctrl + E to execute only that command. This shows the snapshot in the Graphic Display window.

Updating a Snapshot Command from the Graphic Display Window

1. From the Edit window, select the `SNAPSHOT` command you want to update.

2. Press F9 to open its **Snapshot** dialog box. The Graphic Display window loads the view stored in the snapshot.

3. In the Graphic Display window, pan, zoom, and rotate your part to the way you want it for the updated snapshot.

4. If you like, modify the name.

5. Click **OK** to update that snapshot with the new Graphic Display window properties.

Updating a Snapshot Command from Your Report

1. Execute the routine and then select **View | Report Window** to access the report in the Report window.

2. From the Report window, double-click on the snapshot image to convert it into a CADReportObject (CRO).

3. Pan, zoom, and rotate on the part model in the CRO to modify it. For information on working with the CRO, see "CadReportObject" in the "Reporting Measurement Results" chapter.

4. Double-click outside of the CRO to accept your CRO changes to the report. PC-DMIS applies these same CRO changes to your `SNAPSHOT` command in the Edit window. Subsequent executions of that command use the updated `SNAPSHOT` command.

Adding Snapshots into Custom Reports

1. In the Report window, edit a custom report, or create a new custom Report. For information on custom reports, see "Creating Custom Reports" in the "Reporting Measurement Results" chapter of the PC-DMIS Core documentation.

2. From the Edit window in Summary Mode, select the snapshot command you want in your report.

3. Drag and drop it into the custom report to see the screen capture.

Deleting Referenced Commands

Any command in the Edit window that creates a visible element in the Graphic Display window (such as a Dimension Info box) is considered a referenced command by the snapshot command. The snapshot command requires the referenced command to create its screen capture. Snapshot commands cannot reference commands that don't exist. Therefore, if you delete any of these referenced commands, PC-DMIS asks if you want to also delete the associated snapshot commands.

Using File Input / Output

Using File Input / Output: Introduction

This chapter explains how to input and output information to and from your measurement routines. The available menu options allow for opening files in read or write mode. Data can then be read from or written to these files. The file I/O commands allow data to be read in from external files that are to be used in a measurement routine . Also, measurement and tolerancing information can be written back out to files using these commands. You can also perform other file operations by using these commands.

This chapter details these file I/O operations and includes functional examples for each of the various operations. These examples use items discussed in the "Branching by Using Flow Control" chapter and the "Using Expressions and Variables" chapter.

The main topics described in this topic include:

- Understanding Basic File I/O Concepts
- Using the File I/O Dialog Box
- Opening a File for Reading or Writing
- Closing an Opened File after Reading or Writing
- Reading a Character from a File
- Reading a Line from a File
- Reading a Block of Text from a File
- Reading Text up to a Delimiter
- Writing a Character to a File
- Writing a Line to a File
- Writing a Block of Text to a File
- Positioning a File Pointer at the Beginning of a File
- Saving a File Pointer's Current Position
- Recalling a Saved File Pointer's Position
- Copying a File

- Moving a File
- Deleting a File
- Checking for a File's Existence
- Displaying a File Dialog Box
- Checking for the End of a File or the End of a Line

Command Mode Commands after Comments

Because many of the code samples in this chapter use typed `COMMENT` commands, consider the following:

After you insert a PC-DMIS comment, to type additional PC-DMIS commands in Command Mode, you must first press Enter *twice* after the `COMMENT` command. This tells PC-DMIS that you no longer want to add text to the comment but are ready to add a new command.

Understanding Basic File I/O Concepts

Checking for File Existence:
For all the file I/O operations, you probably want to first check for the file's existence. This should probably be put in an IF / THEN loop so that if the check fails, you can notify the user. When you write to a file, you must first create the file inside the windows environment.

See "Checking for a File's Existence".

Opening and Closing Files:
For operations that read from or write to files, you need to first open them to your system's processes. You do this by assigning the file to a variable called a file pointer. When you open a file, you can specify whether the file is opened for reading, writing (overwriting), or appending. Once opened, you can then read from or write to the file. When you're finished working with a file, you should close the file pointer; this closes the file and allows it to be accessed by other system processes. You cannot open files that are already opened by another process.

See "Opening a File for Reading or Writing" and "Closing an Opened File after Reading or Writing".

File Pointers and Positions:
File pointers are variables that point to a file. They store an opened file's name and location and are then used to read from or write to that file. Once a file is opened and set

to a file pointer, the pointer behaves like a cursor acts in a word processor. They indicate where you are currently reading from or writing to within the file.

- If you're appending to a file, the file pointer is usually at the end of the file.
- If you're reading a file or overwriting a file, the file pointer should usually start at the beginning of a file.

Using Delimiters When Writing or Reading

When writing data, consider using delimiters to separate pieces of data. This makes it easier to read the data back into a measurement routine. A delimiter can be any character or string of characters. For example, suppose you have a point, named PNT1 with the X,Y, and Z measured values of 2.5,4.3,6.1. You can easily write these values separated by a comma delimiter into a data file with code similar to the following:

```
FILE/WRITELINE,FPTR,PNT1.X + "," + PNT1.Y + "," + PNT1.Z
```

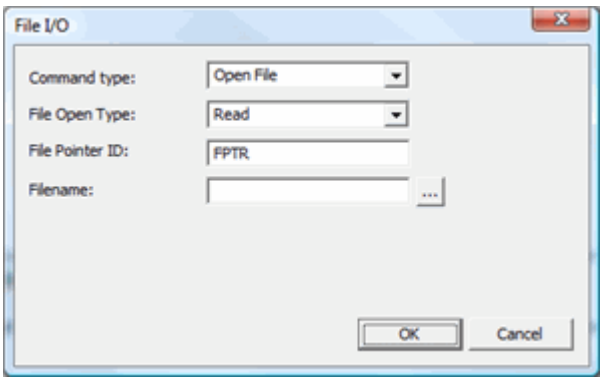
When reading data, you can separate the incoming data based on a specified delimiter and place the data into variables for later manipulation. For example, suppose you want to read in the same X, Y, and Z values listed above. The values should be in a single line of text like this: 2.5,4.3,6.1. You can separate the text at the comma and place those values into corresponding variables using a line of code similar to the following:

```
V1=FILE/READLINE,FPTR,{ValX}+","+{ValY}+","+{ValZ}
```

You can then use `ValX` , `ValY` , and `ValZ` as normal variables in your measurement routine. Resulting in: ValX = 2.5, ValY = 4.3, and ValZ = 6.1.

Using the File I/O Dialog Box

All file I/O commands are initially inserted into the measurement routine by selecting the appropriate file I/O menu option (select **Insert | File I/O Command** from the menu). Once a command exists in the Edit window, you can then press F9 on the command to access its associated **File I/O** dialog box.



File I/O Dialog Box

This dialog box provides a visual way to edit the *current* file I/O command. Alternately, you can modify a command inside the Edit window by using the techniques discussed in the "Using the Edit Window" chapter.

You should not use this dialog box to insert *new* file I/O commands. That must be done by selecting the appropriate menu option or by typing the commands directly into the Edit window.

Opening a File for Reading or Writing

The **Insert | File I/O Command | File Open** menu option allows you to put a command in the Edit window that opens a file from your computer during execution of the measurement routine.

Files can be opened simply to view information or to add and save information.

The syntax of this command in the Edit window is:

```
<filepointername> =File/Open,<filename>,<openmode>
```

Descriptions for some of the components of this command are:

<filepointername> - This is the user chosen ID of the filepointer that is used to access the opened file. This ID is used to refer to the open file in other file I / O commands.

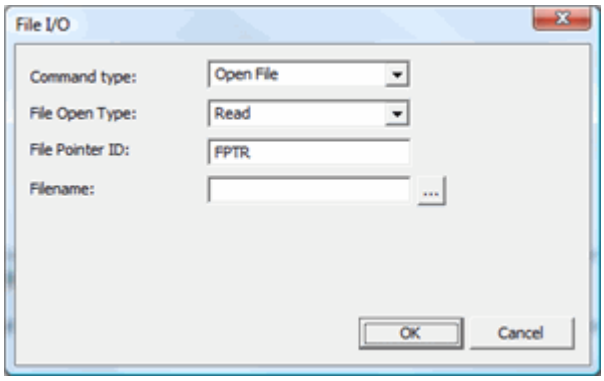
<filename> - This is the filename of the file to open.

<openmode> - This is the mode the file should be opened in. Files can be opened in the following modes: Read, Write, or Append.

To access the dialog box associated with this File I / O command:

1. Open the Edit window.

2. Place your cursor on the File Open command.
3. Press F9.



Sample Code for File Open

The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

This code opens a file named TEST.TXT for reading, writing, and appending. It stores the file name to a file pointer named `FPTR` .

```
FPTR=FILE/OPEN,C:\PCDMISW\TEST.TXT,READ
FPTR=FILE/OPEN,C:\PCDMISW\TEST.TXT,WRITE
FPTR=FILE/OPEN,C:\PCDMISW\TEST.TXT,APPEND
```

Be aware that you can use an input comment to take the full pathway as an input and use it in a `FILE/OPEN` command. You can also do the same thing by using the `FILE/DIALOG` command. Consider these examples:

```
C1=COMMENT/INPUT,Type the full pathway and name of the
file.
V1=FILE/DIALOG, CHOOSE A FILE TO OPEN
FPTR=FILE/OPEN,C1.INPUT,READ
FPTR=FILE/OPEN,V1,READ
```

See "Displaying a File Dialog Box".

Closing an Opened File after Reading or Writing

The **Insert | File I/O Command | File Close** menu option allows you to insert a command in the Edit window that closes an opened file when the measurement routine is executed. Closing files frees up resources used when files are open and commits any changes that have been made to the file to disk.

The syntax of this command in the Edit window is:

```
File/Close, <filepointername>,<closemode>
```

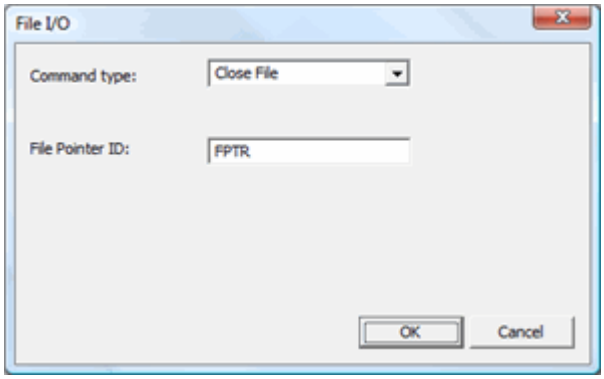
Descriptions for some of the components of this command are:

<filepointername>
This is the ID used to identify the file and is created when the file is opened.

<closemode>
This parameter has two options, KEEP or DELETE. Using KEEP, PC-DMIS simply closes the file defined in the file pointer. Using DELETE, PC-DMIS closes the file and then deletes it.

To access the dialog box associated with this File I / O command:

1. Open the Edit window.
2. Place your cursor on the File Close command.
3. Press F9.



Sample Code for File Close

The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

This code simply closes the file assigned to the file pointer, `FPTR` :

```
FILE/CLOSE,FPTR,KEEP
```

This code, which uses the `DELETE` parameter, closes and deletes the file assigned to `FPTR` :

```
FILE/CLOSE,FPTR,DELETE
```

Reading a Character from a File

The **Insert | File I/O Command | Reading Commands | Read Character** menu option places a command in the Edit window that reads a single character from the file specified by the filepointername field (see syntax below). It assigns that character to the variable specified in the variable name field.

The syntax of this command in the Edit window is:

```
<varname> = File/ReadCharacter,<filepointername>
```

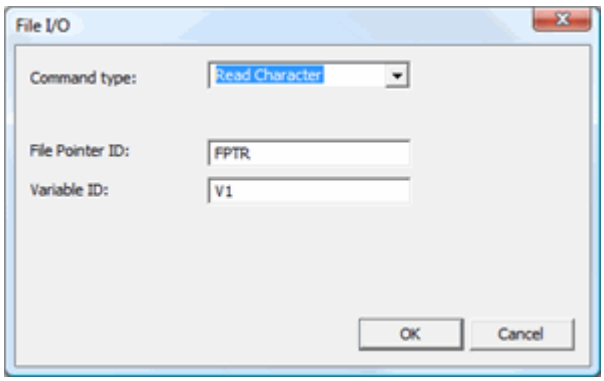
Descriptions for some of the components of this command are:

<filepointername> - This is the ID used to open the file.

<varname> - This is the name of the variable that holds that character.

To access the dialog box associated with this File I / O command:

1. Open the Edit window.
2. Place your cursor on the Read Character command.
3. Press F9.



Sample Code for Read Character

The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

Consider this example that reads in a line from a data file one character at a time until it encounters a space.

```
   V1=FILE/EXISTS,test.txt
   IF/V1<>0
      COMMENT/OPER,Able to read from data file. Click OK to
continue.
      ASSIGN/V3=""
      FPTR=FILE/OPEN,D:\Program Files\pcdmis35\test.txt,READ
      DO/
         V2=FILE/READ_CHARACTER,FPTR
         ASSIGN/V3=V3+V2
      UNTIL/V2==" "
      FILE/CLOSE,FPTR
      COMMENT/OPER,"The first word from a line of text from
the file is: "+V3
   END_IF/
   ELSE/
      COMMENT/OPER,Wasn't able to read from data file.
Routine will now quit.
      GOTO/END
   END_ELSE/
   END=LABEL/
   ROUTINE/END
```

Code Explanation

V1=FILE/EXISTS

This line checks to see if the specified file exists. The file must be placed in the directory where PC-DMIS resides for this code to work, otherwise the line containing the file must

also contain the full pathway for the file. `V1` receives the result of the file check. It's a non-zero value if it exists; 0 otherwise.

```
IF/V1<>0
```

This line takes the value of `V1` and checks to see if it evaluates to a non-zero value. If so, then a comment appears signifying that it's ready to begin the read process. If equal to zero then the measurement routine ends.

```
ASSIGN/V3=""
```

This line creates an empty string and assigns it to `V3` . The code uses this variable to build a string from the individual read in characters. If you don't create the empty string, then `V3` has its default value of 0.

```
FPTR=FILE/OPEN
```

This line opens the specified file for reading and assigns it to the default file pointer `FPTR` .

```
DO
```

This line begins a `DO / UNTIL` loop. It bounds the `FILE/READ_CHARACTER` code so that characters are continually read in one at a time. The loop exits whenever it reads in a character space.

```
V2=FILE/READ_CHARACTER,FPTR
```

This line reads in a character from the open file tied to the file pointer, `FPTR` . The character is stored in the variable, `V2` .

```
ASSIGN/V3=V3+V2
```

This line uses the empty `V3` variable, concatenates the string `V3` with `V2` , and then reassigns the value to `V3` . So, with subsequent runs of the DO/UNTIL loop, `V3` will get one more character added to it.

```
UNTIL/V2==" "
```

This line ends the DO / UNTIL loop once the `FILE/READ_CHARACTER` code encounters a space character from the opened file.

```
FILE/CLOSE,FPTR
```

This line closes the opened data file, thereby allowing it to be accessed by other system processes. The rest of the code finishes running and displays the first word from the data file in an operator comment.

Reading a Line from a File

The **Insert | File I/O Command | Reading Commands | Read Line** menu option places a command in the Edit window that reads a line from the specified file during execution. This command sets the variable specified by the variable ID to 1 (true) or 0 (false) to indicate success (true) or failure (false) of the call. The expression required by this command can be used to delimit the line read in and to automatically fill up variables and references with data read in from the file. Information is read in from the input file up to the next carriage return character.

The syntax of this command in the Edit window is:

```
<varname> = File/ReadLine,<filepointername>,<expr>
```

Descriptions for some of the components of this command are:

<varname> - This is the name of the variable that holds the result indicating success or failure of the ReadLine command. It returns "OK" or "EOF".

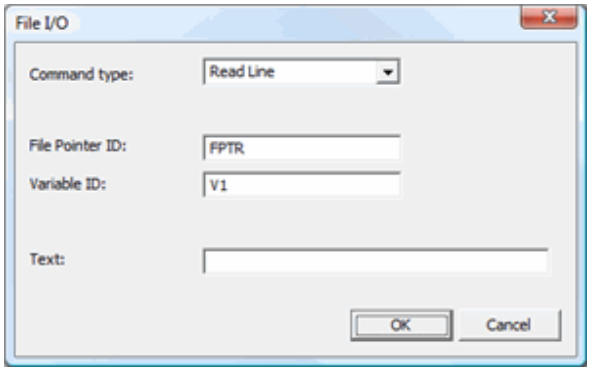
<filepointername> - This is the name specified for the file pointer when the file was opened.

<expr> - This is the destination variable(s) for the input data. Input data can be delimited by text to allow for ease in parsing incoming lines of data. Variables and feature references should be surrounded by curly brackets.

To access the dialog box associated with this File I / O command:

1. Open the Edit window.
2. Place your cursor on the Read Line command.

3. Press F9.



Sample Code for Read Line

> The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

Consider this example that reads in a line from a data file one line at a time until the `FILE/READ_LINE` command encounters an empty line. The measurement routine then displays the resulting block of text and quits.

```
.
.
.
V1    =FILE/EXISTS,D:\HEXAGON\PCDMIS
FILES\BASIC_SCRIPTS\TEST.TXT
      IF/V1<>0
         COMMENT/OPER,NO,FULL SCREEN=NO,AUTO-
CONTINUE=NO,OVC=NO,
         Able to read from data file. Click OK to continue.
         ASSIGN/V3=""
FPTR  =FILE/OPEN,D:\HEXAGON\PCDMIS
FILES\BASIC_SCRIPTS\TEST.TXT,READ
         DO/
V2          =FILE/READLINE,FPTR,{LINE}
            ASSIGN/V3=V3+LINE
            COMMENT/OPER,NO,FULL SCREEN=NO,AUTO-
CONTINUE=NO,OVC=NO,
            "The current value of variable V3 is: "+V3
         UNTIL/V2=="EOF"
         FILE/CLOSE,FPTR,DELETE
         COMMENT/OPER,NO,FULL SCREEN=NO,AUTO-
CONTINUE=NO,OVC=NO,
         "The block of text reads as follows: "+V3
      END_IF/
      ELSE/
         COMMENT/OPER,NO,FULL SCREEN=NO,AUTO-
CONTINUE=NO,OVC=NO,
         Wasn't able to read from data file. Routine will
now quit.
         GOTO/END
      END_ELSE/
END   =LABEL/
.
.
.
```

Code Explanation

Much of this code is similar to that explained in "Sample Code for Read Character". Only code unique to this example is listed here.

DO

This line begins a DO / UNTIL loop. It bounds the `FILE/READ_LINE` code so that the lines are continually read in one at a time. The loop exits when it reaches the end of the file.

V2=FILE/READLINE,FPTR,{LINE}

This line reads in all the text until it encounters a carriage return. Instead of storing the text in `V2`, like FILE/READ_CHARACTER would, however, this code acts differently.

- `V2` in this case returns two values: either "OK" or "EOF". "OK" if there's still a line to read in. "EOF" if the end of the file is reached.
- The `{LINE}` code is a user-entered variable that stores the actual text. It is enclosed in curly brackets to tell PC-DMIS it's a variable and not a part of any delimiting text. Without the curly brackets, PC-DMIS would look for a string of characters in the file called "LINE" and would return only the text after "LINE" and before the carriage return.

`ASSIGN/V3=V3+LINE`

This line uses the empty `V3` variable and concatenates the string `V3` with `LINE`, and then reassigns the concatenated value to `V3`. So, with subsequent runs of the DO/UNTIL loop, `V3` will get one more line added to it.

`UNTIL/V2=="EOF"`

This line tests for the condition of the DO / UNTIL loop. Once the `FILE/READLINE` code encounters the end of file, the loop exits. Once the routine flow exits the loop, the rest of the code finishes running and displays the entire block of code inside an operator comment.

`Result=File/ReadLine,F1,"Part ID :"+{V1}` - This causes any text appearing in the read in line after the text "Part ID:" to be assigned to V1. The line is read in from the file opened using F1 as the file pointer name. The result of the read (success or failure) would be stored in the variable Result.

```
File/ReadLine,F1,"Location:"+{VARX}+","+{VARY}+","+
{VARZ}+","+{VARI}+","+{VARJ}+","+{VARK}

ASSIGN/CIR1.XYZ=MPOINT(VARX,VARY,VARZ)

ASSIGN/CIR1.IJK=MPOINT(VARI,VARJ,VARK)
```

The above three command lines read in comma delimited text after the string "Location:" and store the values in the X, Y, Z, and I, J, K values of CIR1.

`File/ReadLine,F1,"Value # "+loopvar+" : "+{var2}` - This causes var2 to be filled with the text appearing after the colon. The loopvar variable in this example is not surrounded by curly brackets and as a result contributes to the delimiting text.

Sample Code Dealing with Numbers Containing Preceding Zeros

If the file you are reading contains lines of numbers, you will notice that PC-DMIS ignores preceding zero characters. For example, if your line contained a value of 005450, it would

read this value strictly as a number and return the value of 5450, ignoring the two preceding zeros. You may or may not want this.

Suppose you have a text file created by an external barcode reader software and it contains these two lines of data:

290291143;582750;0010

291143;5827;0010

You could use some simple code like this to get the number values in-between the semi-colons:

```
   ASSIGN/FIRST_VALUE=0
   ASSIGN/SECOND_VALUE=0
   ASSIGN/THIRD_VALUE=0
   ASSIGN/LINENUM=1
FPTR=FILE/OPEN,D:\TEMP\CODES.TXT,READ
   DO/
   INLINE=FILE/READLINE,FPTR,{FIRST_VALUE}+";"+
{SECOND_VALUE}+";"+{THIRD_VALUE}
   COMMENT/OPER,NO,"LINE NUMBER: "+LINENUM
      ,"First Value: "+FIRST_VALUE
      ,"Second Value: "+SECOND_VALUE
      ,"Third Value: "+THIRD_VALUE
   UNTIL/INLINE=="EOF"
   FILE/CLOSE,FPTR,KEEP
```

While this will successfully parse the lines of text and return the number values, it will also remove any preceding zeros for any values it returns. So, the THIRD_VALUE variable would contain a value of 10, instead of 0010.

To keep the preceding zero values, you would need to treat the whole line as a string and instead use the INDEX, LEFT, and MID string functions to locate the positions of semi-colons in a line of text and obtain the number values:

```
        FPTR=FILE/OPEN,D:\TEMP\CODES.TXT,READ
           ASSIGN/LINENUM=1
           DO/
        LINESTATUS=FILE/READLINE,FPTR,{LINESTR}
           ASSIGN/LINESTR=STR(LINESTR)
           ASSIGN/FIRST_INDEX=INDEX(LINESTR,";")
           ASSIGN/FIRST_VALUE=STR(LEFT(LINESTR,FIRST_INDEX-1))
           ASSIGN/REMAINSTR=STR(MID(LINESTR,(FIRST_INDEX)))
           ASSIGN/SECOND_INDEX=INDEX(REMAINSTR,";")
           ASSIGN/SECOND_VALUE=STR(LEFT(REMAINSTR,SECOND_INDEX-1)
    )
           ASSIGN/THIRD_VALUE=STR(MID(REMAINSTR,SECOND_INDEX))
           COMMENT/OPER,NO,"LINE NUMBER: "+LINENUM
              ,"First Value: "+FIRST_VALUE
              ,"Second Value: "+SECOND_VALUE
              ,"Third Value: "+THIRD_VALUE
           ASSIGN/LINENUM=LINENUM+1
           UNTIL/LINESTATUS=="EOF"
           FILE/CLOSE,FPTR,KEEP
```

Explanation of Code

Much of this code is similar to what is explained above. Only code explanations unique to the mentioned string functions are listed here.

`ASSIGN/FIRST_INDEX=INDEX(LINESTR,";")`

This line locates the position of the first semi-colon in the line and assigns that to the `FIRST_INDEX` variable.

`ASSIGN/FIRST_VALUE=STR(LEFT(LINESTR,FIRST_INDEX-1))`

This line assigns the `FIRST_VALUE` variable the string of characters up to, but not including, the first semi-colon in the `LINESTR` variable. `LINESTR` contains the entire line of text.

`ASSIGN/REMAINSTR=STR(MID(LINESTR,(FIRST_INDEX)))`

This line assigns the `REMAINSTR` variable (standing for "remaining string") the string of left over characters starting from the `FIRST_INDEX` position (the position of the first semi-colon) until the end of the line.

`ASSIGN/SECOND_INDEX=INDEX(REMAINSTR,";")`

This searches inside the REMAINSTR variable for another semi-colon (the second semi colon in the line) and assigns the position to the `SECOND_INDEX` variable.

`ASSIGN/SECOND_VALUE=STR(LEFT(REMAINSTR,SECOND_INDEX-1))`

This line assigns the `SECOND_VALUE variable` the string of characters up to, but not including, the first semi colon in the `REMAINSTR` variable (the second semi-colon in the entire line).

```
ASSIGN/THIRD_VALUE=STR(MID(REMAINSTR,SECOND_INDEX))
```

This line assigns the `THIRD_VALUE` variable the string of characters starting from the `SECOND_INDEX` position, until the end of the line.

Reading a Block of Text from a File

The **Insert | File I/O Command | Reading Commands | Read Block** menu option places a command in the Edit window that reads in a block of characters from an open file at execution time. The amount of characters read in is indicated by the size parameter.

The syntax of this command in the Edit window is:

```
<varname>=File/Read_Block,<fptrname>,<size>
```

Descriptions for some of the components of this command are:

<varname> - This is a variable id for the variable that receives the value indicating success or failure of the read block operation.

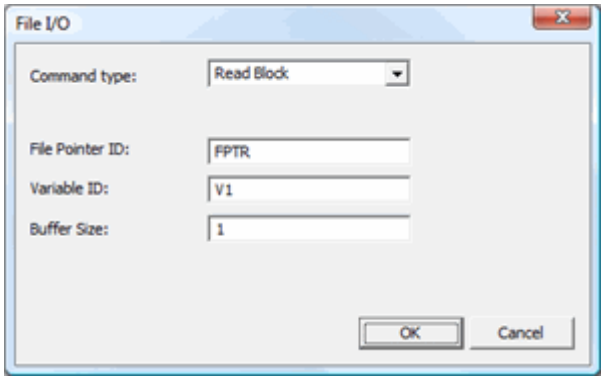
<fptrname> - This is the name specified for the file pointer when the file was opened.

<size> - This is the number of characters to read.

To access the dialog box associated with this File I / O command:

1. Open the Edit window.
2. Place your cursor on the Read Block command.

3. Press F9.



Sample Code for Read Block

> The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

Suppose you have various external data files that contain miscellaneous part data and the first few characters of each file designate what the file is for. You can use the `File/Read_Block` command to read only those first few characters before deciding to read in and process every line. Consider this code:

```
   C3=COMMENT/INPUT,Please type the name of the
   ,file code to search for.
   ASSIGN/BLOCKSIZE=LEN(C3.INPUT)
   ASSIGN/FILECODE=C3.INPUT
   DO/
      C1=COMMENT/INPUT,Please type the full pathway,
      ,filename, and extension to the
      ,file you want to process.
      ,Type [Q] to quit.
      IF/C1.INPUT=="Q" OR C1.INPUT=="q"
         COMMENT/OPER,You've chosen to quit. Routine now
ending.
         GOTO/END
      END_IF/
      V1=FILE/EXISTS,C1.INPUT
      IF/V1<>0
         COMMENT/OPER,"Data file ["+C1.INPUT+"] exists.
Click OK to continue."
         FPTR=FILE/OPEN,C1.INPUT,READ
         V2=FILE/READ_BLOCK,FPTR,BLOCKSIZE
         FILE/CLOSE,FPTR
         IF/V2<>FILECODE
            COMMENT/OPER,"The file's code of ["+V2+"]
doesn't match"
            ,"the FILECODE of ["+FILECODE+"]."
         END_IF/
         COMMENT/OPER,"File ["+C1.INPUT+"] is a match."
         ,"The file's code of ["+V2+"] matches"
         ,"the FILECODE of ["+FILECODE+"]."
         COMMENT/OPER,Routine then processes the file.
      END_IF/
      ELSE/
         COMMENT/OPER,"Data file ["+C1.INPUT+"] doesn't
exist. Please retry using an existing data file."
         GOTO/END
      END_ELSE/
   UNTIL/V2==FILECODE
   END=LABEL/
   ROUTINE/END
```

Code Explanation

Some of this code is similar to that explained in "Sample Code for Read Character" or in "Sample Code for Read Line".

Only explanations unique to this example are given here.

`ASSIGN/BLOCKSIZE=LEN(C3.INPUT)`

This line creates a user-defined variable named `BLOCKSIZE` that contains an integer equal to the number of characters found in `C3.INPUT` . This will be used as the size of the block of characters to read in.

ASSIGN/FILECODE=C3.INPUT

This line creates the FILECODE variable and gives it the value of C3.INPUT.

C1=COMMENT/INPUT

This comment stores the full pathway entered by the user into the C1.INPUT variable.

V1=FILE/EXISTS,C1.INPUT

This line checks for the existence of the file name defined in the C1 comment.

DO/

This line begins a DO / UNTIL loop. It bounds the block of code that allows the user to specify a file to read from. It will continue looping until the text assigned to FILECODE variable matches the text read from the file.

V2=FILE/READ_BLOCK,FPTR,BLOCKSIZE

This line reads the amount of characters equal to the integer contained in the BLOCKSIZE variable. The text is then stored in V2 variable.

IF/V2FILECODE

This line begins an IF / END IF code block that tests to see if the text in the V2 variable matches the text stored in the FILECODE variable. If it does match, then the routine continues running. Otherwise it displays a message saying the two codes don't match.

UNTIL/V2==FILECODE

This line checks the condition of the DO / UNTIL loop to see if the text in the V2 variable matches the text in the FILECODE variable. If the statement evaluates to false, the DO loop runs again, allowing the user to choose a different file name. If the statement evaluates to true, then the loop exits and the routine displays a message saying it matches. PC-DMIS could then continue to read each line of data from the specified data file.

Reading Text up to a Delimiter

The **Insert | File I/O Command | Reading Commands | Read Up To** menu option places a command in the Edit window that reads all text "up to" one of the given delimiters from the specified file during execution. Any text read by this command is placed in the specified destination variable. The command stops reading text when PC-DMIS encounters the following:

- Defined delimiters

- Carriage returns
- Line feed characters

If the end of the file is reached, the destination variable is set to "EOF" (End of File).

The syntax of this command in the Edit window is:

```
<varname> = FILE/READ_UPTO,<fptrname>,<delimiters>
```

Descriptions for some of the components of this command are:

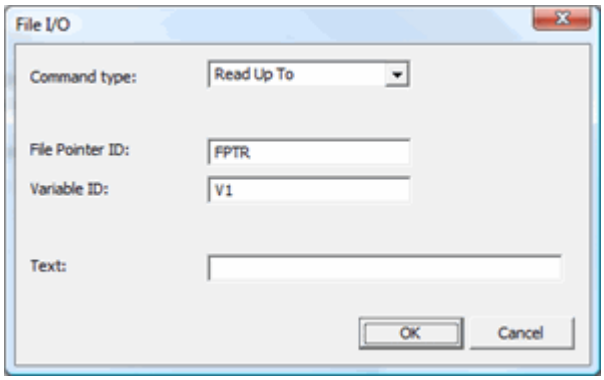
<varname> - This is the name of the destination variable.

<fptrname> - This is the name specified for the file pointer when the file was opened.

<delimiters> - This is a string which contains zero or more delimiter characters.

To access the dialog box associated with this File I / O command:

1. Select the **Edit Window** to open the Edit window.
2. Place your cursor on the `FILE/READ` command.
3. Press F9. The **File I/O** dialog box opens.



Once the dialog box appears:

1. Type the variable name that receives the read in information into the **Variable ID** box.
2. Type the file pointer name into the **File Pointer ID** box.
3. Type the delimiter into the **Text** box (be sure and use quotation marks around your chosen delimiter).
4. Click **OK**.

Sample Code for Read Up To

The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

Consider this example where you have a text file named "sample.txt" in your D:\Temp directory which contains this information on the first line.

```
CIR1:2.54:CIRCLE
```

To use the Read Up To command on this file:

1. Insert a `FILE/OPEN` command in the Edit window.
2. Use a File Pointer Name of your choice to name your File Open command. This example uses "sample" as the file pointer name.

The File Open command should look something like this:

```
SAMPLE      =FILE/OPEN,D:\TEMP\SAMPLE.TXT,READ
```

Now, use PC-DMIS Read Up To commands to define some variables that call different segments of data. This example uses the following variables looking for a colon character ":" (without the quotation marks) as the delimiter.

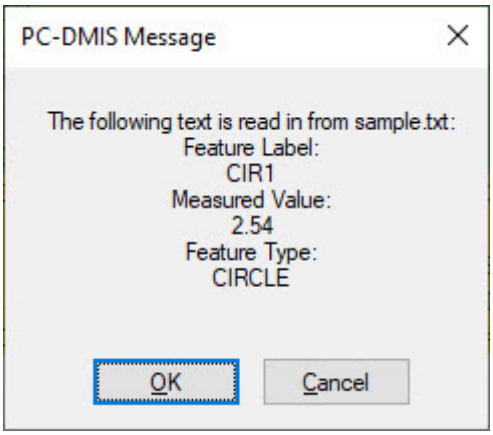
```
V_LABEL    =FILE/READ_UPTO,SAMPLE,:
V_VALUE    =FILE/READ_UPTO,SAMPLE,:
V_TYPE     =FILE/READ_UPTO,SAMPLE,:
```

Thus, when PC-DMIS executes these lines, it sets these variables to hold these values:

- V_LABEL = CIR1
- V_VALUE = 2.54
- V_TYPE = CIRCLE

To display this on screen during execution, you can use an operator comment such as the one shown here:

```
COMMENT/OPER,NO,FULL SCREEN=NO,AUTO-CONTINUE=NO,OVC=NO,
The following text is read in from sample.txt:
Feature Label:
V_LABEL
Measured Value:
V_VALUE
Feature Type:
V_TYPE
```



Writing a Character to a File

The **Insert | File I/O Command | Writing Commands | Write Character** menu option inserts a command into the Edit window that causes a single character to be output to a file on your computer upon execution.

The syntax of this command in the Edit window is:

```
File/Write_Character,<fptrname>,<expr>
```

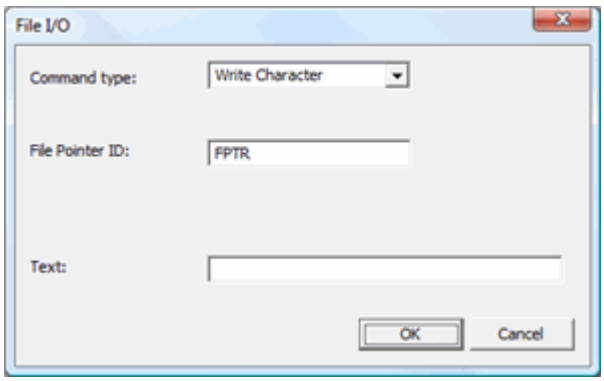
Descriptions for some of the components of this command are:

<fptrname> - This is the name of the file pointer specified when the file was opened.

<expr> - This is the character to be written to file. If the expression evaluates to more than one character, only the first character is written.

To access the dialog box associated with this File I / O command, follow these steps:

1. Open the Edit window.
2. Place your cursor on the Write Character command.
3. Press F9.



Sample Code for Write Character

The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

Consider this code that writes a string provided by the user to a data file one character at a time.

```
C1=COMMENT/INPUT,Type the name of the file to write
,to (include the complete path).
FPTR=FILE/OPEN,C1.INPUT,WRITE
C2=COMMENT/INPUT,Type something to send to the file.
,This will send the string one character
,at a time.
ASSIGN/COUNT=0
ASSIGN/LENGTH=LEN(C2.INPUT)
DO/
   ASSIGN/WRITETHIS=MID(C2.INPUT,COUNT,1)
   FILE/WRITE_CHARACTER,FPTR,WRITETHIS
   ASSIGN/COUNT=COUNT + 1
UNTIL/COUNT==LENGTH
```

Code Explanation

Some of this code is similar to that explained in "Sample Code for Read Character" or in "Sample Code for Read Line".

Only explanations unique to this example are given here.

`FPTR=FILE/OPEN,C1.INPUT,WRITE`

This line opens the file specified in the C1 comment for writing, and assigns it to the file pointer, `FPTR` . All data in this file will get overwritten as long as the file pointer begins at the start of the data file.

`ASSIGN/COUNT=0`

This line assigns a user defined variable COUNT a value of zero. This is used for looping purposes to print the string one character at a time.

ASSIGN/LENGTH=LEN(C2.INPUT)

This line uses the LEN( ) function to return the length of a string. This function takes one parameter, the string. It counts the number of characters in the string (including spaces) and returns an integer value of that amount. In this case, the user defined variable, LENGTH holds this value.

DO/

This line begins a DO / UNTIL loop. Code between the DO and the UNTIL statements will be executed until the loop's condition evaluates to true.

ASSIGN/WRITETHIS=MID(C2.INPUT,COUNT,1)

This line creates a user defined variable called WRITETHIS and uses the MID( ) function to return a substring character from the C2.INPUT string and give it to WRITETHIS .

MID( ) takes three parameters.

- Parameter 1: is the string from which to get values. In this case C2.INPUT is used.
- Parameter 2: is the position in the string to take the character from. The first character in a string would be position 0, the second position 1, the third position 2 and so forth. In this case, the variable COUNT is used.
- Parameter 3: is how many characters starting from the position of the second parameter to grab. In this case, the value of 1 is used (the sample only writes one character at a time, so there's no reason to get more).

FILE/WRITE_CHARACTER,FPTR,WRITETHIS

This line writes the character stored in the WRITETHIS variable to the file specified by the file pointer, FPTR .

ASSIGN/COUNT=COUNT+1

This line takes the current **COUNT** value, increments it by one, and then places the new value back into COUNT .

UNTIL/COUNT==LENGTH

This line tests the condition of the DO / UNTIL loop. In this case, the loop will keep incrementing the COUNT variable until it has the same value as the LENGTH variable. Then the loop will exit, ending the routine.

Writing a Line to a File

The **Insert | File I/O Command | Writing Commands | Write Line** menu option inserts a command into the Edit window that causes a line of text to be output to a file on your computer upon execution. Use expression syntax to output variables and measurement routine information to file. A carriage return is automatically appended to the text written out.

The syntax of this command in the Edit window is:

```
File/WriteLine,<fptrname>,<expr>
```

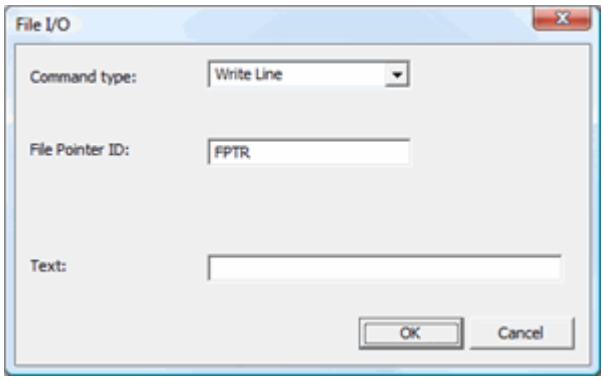
Descriptions for some of the components of this command are:

<fptrname> - This is the name of the file reference specified when the file was opened.

<expr> - This is the text to be written to file. Expressions can be used in this field.

To access the dialog box associated with this File I / O command, follow these steps:

1. Open the Edit window.
2. Place your cursor on the Write Line command.
3. Press F9.



Sample Code for Write Line

The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

Suppose you want to export some measured XYZ values to a data file. The following code allows you to input a feature label and a data file and send the X,Y, and Z data for that feature to a data file.

```
C1=COMMENT/INPUT,Type the label of the feature.
,to use.
C2=COMMENT/INPUT,Type the name of the file to write
,to (include the complete path).
FPTR=FILE/OPEN,C2.INPUT,APPEND
ASSIGN/FEATNAME=C1.INPUT
ASSIGN/ALLVALS=FEATNAME.X+","+FEATNAME.Y+","+FEATNAME.Z
COMMENT/OPER,"Text to write is: "+ALLVALS
FILE/WRITELINE,FPTR,ALLVALS
FILE/CLOSE,FPTR
```

Code Explanation

Some of this code is similar to that explained in "Sample Code for Read Character" or in "Sample Code for Read Line".

Only explanations unique to this example are given here.

`FPTR=FILE/OPEN,C2.INPUT,APPEND`

This line opens the file specified in the C2 comment for appending, and assigns it to the file pointer, `FPTR`. If instead, you change `APPEND` to `WRITE`, then existing content in the data file will get overwritten.

`ASSIGN/FEATNAME=C1.INPUT`

This line assigns the string of the feature label from `C1.INPUT` to the user defined variable, `FEATNAME`.

`ASSIGN/ALLVALS=FEATNAME.X+","+FEATNAME.Y+","+ FEATNAME.Z`

This line gives the user defined variable `ALLVALS` the value of `FEATNAME.X,FEATNAME.Y,FEATNAME.Z`, in other words it now holds the X, Y, and Z values of the feature label typed into the C1 input comment.

`FILE/WRITELINE,FPTR,ALLVALS`

This line writes the values contained in `ALLVALS` to the file specified by the file pointer, `FPTR`.

Writing a Block of Text to a File

The **Insert | File I/O Command | Writing Commands | Write Block** menu option inserts a command into the Edit window that causes a block of text to be output to a file on your computer upon execution. Use expression syntax to output the variables and measurement routine information to file. Unlike the write line command, write block does *not* append a carriage return at the end.

The syntax of this command in the Edit window is:

```
File/WriteBlock,<fptrname>,<expr>
```

Descriptions for some of the components of this command are:

<fptrname> - This is the name of the file reference specified when the file was opened.

<expr> - This is the text to be written to file. Expressions can be used in this field.

Unlike the write line command, write block does *not* append a carriage return at the end. However, if you need to place text on a new line inside your text block, you can insert a carriage return and line feed manually by using the CHR(10) code outside of your quoted string, as shown here in this example:

```
FILE/WRITEBLOCK,FPTR, "CHR (10) inserts text... " + CHR(10)
+ " ...on a new line."
```

This would yield this result inside your output file:

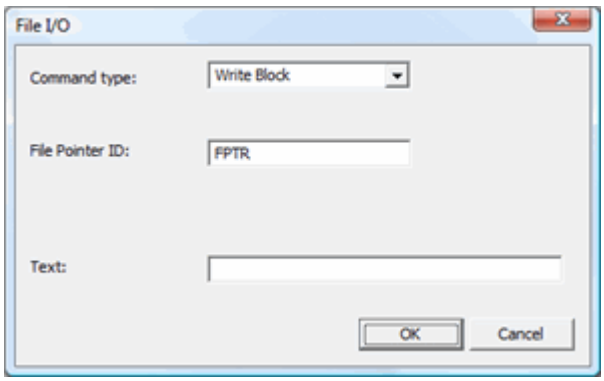
```
CHR(10) inserts text...

 ...on a new line.
```

Notice that if CHR(10) is inside the quotation marks the actual text of CHR(10) gets sent to the file.

To access the dialog box associated with this File I / O command:

1. Open the Edit window.
2. Place your cursor on the Write Block command.
3. Press F9.



Sample Code for Write Block

The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

The following code writes whatever the user inputs into an input comment, and appends a colon to be used as a delimiter.

```
   C1=COMMENT/INPUT,Type any string. PC-DMIS will append a
colon (for delimiter purposes) and write the string to a
file of your choice
   C2=COMMENT/INPUT,Type the name of the file to write
   ,to (include the complete path).
   FPTR=FILE/OPEN,C2.INPUT,APPEND
   ASSIGN/WRITETHIS=C1.INPUT+":"
   COMMENT/OPER,"Text to write is: "+WRITETHIS
   FILE/WRITELINE,FPTR,WRITETHIS
   FILE/CLOSE,FPTR
```

Code Explanation

Some of this code is similar to that explained in "Sample Code for Read Character" or in "Sample Code for Read Line".

Only explanations unique to this example are given here.

`FPTR=FILE/OPEN,C2.INPUT,APPEND`

This line opens the file specified in the C2 comment for appending, and assigns it to the file pointer, `FPTR`.

`ASSIGN/WRITETHIS=C1.INPUT+":"`

This line appends a colon to the text contained in `C1.INPUT` and assigns the new string to the user defined variable, `WRITETHIS`.

`FILE/WRITELINE,FPTR,WRITETHIS`

This line writes the values contained in `WRITETHIS` to the file specified by the file pointer, `FPTR` . You can later read-in text from the file by using the colon as a delimiter.

Positioning a File Pointer at the Beginning of a File

The **Insert | File I/O Command | Position Commands | Rewind To Start** menu option inserts a command into the Edit window that will position the file pointer to the beginning of the file stream.

The syntax of this command in the Edit window is:

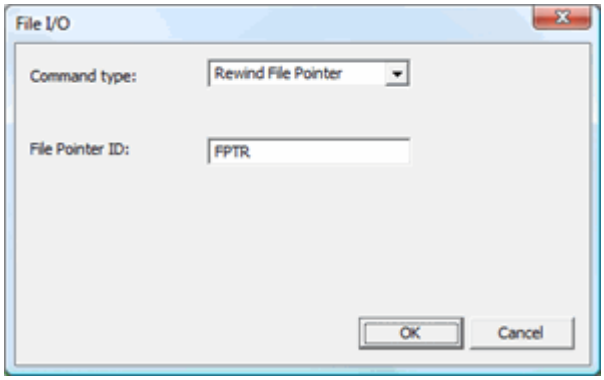
```
File/Rewind,<fptrname>
```

Descriptions for some of the components of this command are:

<fptrname> - This is the name of the file pointer to reposition at the beginning of the file.

To access the dialog box associated with this File I / O command:

1. Open the Edit window.
2. Place your cursor on the Rewind to Start command.
3. Press F9.



Sample Code for Rewind to Start

The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

Consider this example that reads in data from an external file one line at a time. After each line, you have the option of starting over and reading from the beginning of the file. This illustrates the use of the `FILE/REWIND` command.

```
C1=COMMENT/INPUT,Please type a file to read from.
,(include the full path)
V1=FILE/EXISTS,C1.INPUT
IF/V1<>0
   DO/
      FPTR=FILE/OPEN,C1.INPUT,READ
      C2=COMMENT/YESNO,Do you want to read from the
beginning?
      IF/C2.INPUT == "YES"
         FILE/REWIND,FPTR
      END_IF/
      V2=FILE/READLINE,FPTR,{LINE}
      COMMENT/OPER,"The current line is: " + LINE
   UNTIL/V2=="EOF"
END_IF/
FILE/CLOSE,FPTR
COMMENT/OPER,Routine quitting.
```

Code Explanation

Some of this code is similar to that explained in "Sample Code for Read Character" or in "Sample Code for Read Line".

Only explanations unique to this example are given here.

`C2=COMMENT/YESNO`

This line asks if you want to start reading the file from the beginning. It stores the YES/NO response into the variable, `C2.INPUT` .

`IF/C2.INPUT == "YES"`

This line begins an IF / END IF block. It tests the condition of `C2.INPUT` having the value of YES. If the condition is true, then PC-DMIS executes the lines following the `IF` statement. If the condition is false, then PC-DMIS executes the code following the `END_IF` statement.

`FILE/REWIND,FPTR`

This line rewinds the file pointer to the beginning of the data file.

`END_IF/`

This line quits the IF / END IF code block.

Saving a File Pointer's Current Position

The **Insert | File I/O Command | Position Commands | Save File Position** menu option inserts a command into the Edit window that saves the current position of a file pointer within the file stream. The saved position can later be recalled using the recall file position command.

The syntax of this command in the Edit window is:

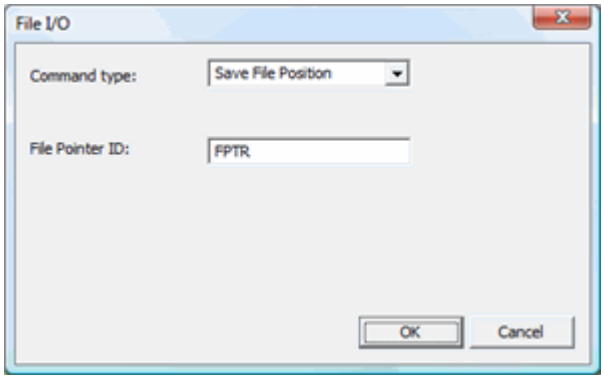
```
File/SavePosition,<fptrname>
```

Descriptions for some of the components of this command are:

<fptrname> - This is the name of the file pointer whose file position is saved.

To access the dialog box associated with this File I / O command:

1. Open the Edit window.
2. Place your cursor on the Save File Position command.
3. Press F9.



Sample Code for Save File Position

The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

Consider this example that reads in data from an external file one line at a time. After each line, you have the option of saving the file position for later recall. This illustrates the use of the `FILE/SAVE_POSITION` command.

```
C1=COMMENT/INPUT,Please type a file to read from.
,(include the full path)
V1=FILE/EXISTS,C1.INPUT
IF/V1<>0
   DO/
      FPTR=FILE/OPEN,C1.INPUT,READ
      C2=COMMENT/YESNO,Do you want to save the file
position and recall it later? The loop will quit.
      IF/C2.INPUT == "YES"
         FILE/SAVE_POSITION,FPTR
         GOTO/QUITLOOP
      END_IF/
      V2=FILE/READLINE,FPTR,{LINE}
      COMMENT/OPER,"The current line is: " + LINE
   UNTIL/V2=="EOF"
END_IF/
FILE/CLOSE,FPTR
QUITLOOP=LABEL/
COMMENT/OPER,You've stopped reading.
ROUTINE/END
```

Code Explanation

This code is similar to that explained in "Sample Code for Rewind to Start".

Only explanations unique to this example are given here.

`C2=COMMENT/YESNO`

This line asks if you want to store the current file position and exit the loop. It stores the YES/NO response into the variable, `C2.INPUT` .

`FILE/SAVE_POSITION,FPTR`

This line stores the file pointer's position in the file stream.

As long as you open the same file with same file pointer name in the same measurement routine, you can recall a stored file position and continue reading where you left off. To continue this example, see the "Sample Code for Recall File Position" topic.

Recalling a Saved File Pointer's Position

The **Insert | File I/O Command | Position Commands | Recall File Position** inserts a command into the Edit window that recalls a previously-saved file position. Use the save file position command to save a position within an open file.

The syntax of this command in the Edit window is:

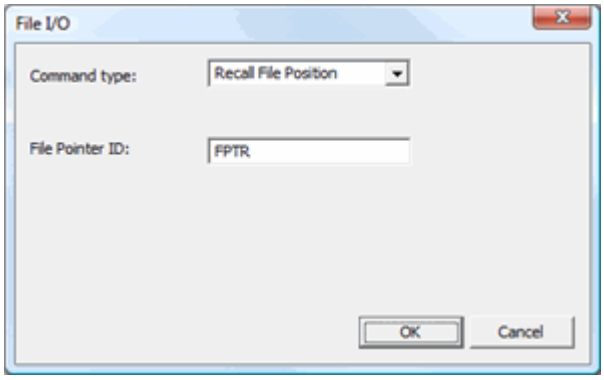
```
File/RecallPosition, <fptrname>
```

Descriptions for some of the components of this command are:

<fptrname> - This is the name of the file pointer whose position is being recalled.

To access the dialog box associated with this File I / O command:

1. Open the Edit window.
2. Place your cursor on the Recall File Position command.
3. Press F9.



Sample Code for Recall File Position

The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

This example opens a previously-closed file, uses a previous file pointer, and recalls the stored file pointer's saved position. It then reads in data from that position. This code illustrates the use of the `FILE/RECALL_POSITION` command. It continues the code sample given in the "Sample Code for Save File Position" topic.

```
   COMMENT/OPER,The routine will now recall the stored file
position.
   FPTR=FILE/OPEN,C1.INPUT,READ
   FILE/REWIND,FPTR
   COMMENT/OPER,To test, file has been rewound.
   ,The first line will be read in to test the rewind.
   V3=FILE/READLINE,FPTR,{LINE}
   COMMENT/OPER,The first line is:
   ,LINE
   FILE/REWIND,FPTR
   FILE/RECALL_POSITION,FPTR
   COMMENT/OPER,Previously stored file position has been
recalled.
   ,Data on the line at the stored position will now print.
   V4=FILE/READLINE,FPTR,{STORED}
   COMMENT/OPER,The text at the stored position is:
   ,STORED
```

Code Explanation

This code is similar to that explained in "Sample Code for Rewind to Start".

Only explanations unique to this example are given here.

`FILE/RECALL_POSITION,FPTR`p

This line recalls the stored file pointer position in the file stream for the file pointer designated as `FPTR` .

`V4=FILE/READLINE,FPTR,{STORED}`

This line reads in the next line after the stored file pointer position and assigns it to the user-defined variable of `STORED` . This variable is then printed out in the next operator comment.

Copying a File

The **Insert | File I/O Command | File Copy** menu option inserts a command into the Edit window that causes a file copy operation to occur upon execution.

The syntax of this command in the Edit window is:

```
File/Copy,<srcfilename>,<destfilename>,<replacemode>
```

Descriptions for some of the components of this command are:

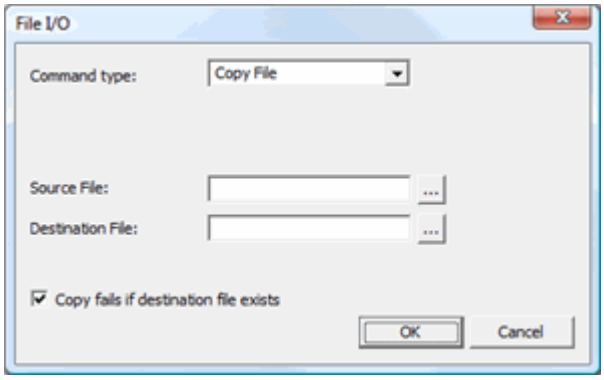
<srcfilename> - This is the name of the source file (the file copied from).

<destfilename> - This is the name of the destination file (the file copied to).

<replacemode> - This is the action to take if the destination file already exists. The two modes are overwritten and fail if the destination exists.

To access the dialog box associated with this File I / O command:

1. Open the Edit window.
2. Place your cursor on the File Copy command.
3. Press F9.



Sample Code for File Copy

The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

The following code asks for a file name to copy and for a destination directory and file to copy to.

```
C1=COMMENT/INPUT,Please type a file you want to copy.
,(Include full file path)
C2=COMMENT/INPUT,Please type a destination file name.
,(Include full file path)
V1=FILE/EXISTS,C1.INPUT
IF/V1<>0
   COMMENT/OPER,File exists to copy. Copying commencing.
   FILE/COPY,C1.INPUT,C2.INPUT,FAIL_IF_DEST_EXISTS
   V2=FILE/EXISTS,C2.INPUT
   IF/V2==0
      COMMENT/OPER,"File doesn't exist at: " + C2.INPUT
      ,Copy ending.
      ROUTINE/END
   END_IF/
ELSE/
   COMMENT/OPER,File copy successful.
   ROUTINE/END
END_ELSE/
END_IF/
COMMENT/OPER,File to copy doesn't exist.
```

Code Explanation

Much of this code is similar to that explained in "Sample Code for Read Character" or in "Sample Code for Read Line".

Only explanations unique to this example are given here.

`C1=COMMENT/INPUT`

This line takes the full pathway of the file to copy and places it into the `C1.INPUT` variable.

`C2=COMMENT/INPUT`

This line takes the full pathway of the destination file and places it into the `C2. INPUT` variable.

`FILE/COPY,C1.INPUT,C2.INPUT,FAIL_IF_DEST_EXISTS`

This line copies the original file to a destination file. This command takes three parameters.

- Parameter 1 is `C1. INPUT` . This is the full path to the file to copy.
- Parameter 2 is `C2. INPUT` , or the full path to the destination file.
- Parameter 3, in this case, aborts the FILE/COPY procedure if it encounters an existing file with the same destination filename. You can set this so that it overwrites existing files of the same name.

Moving a File

The **Insert | File I/O Command | File Move** menu option inserts a command into the Edit window that causes a file move operation to occur upon execution.

The syntax of this command in the Edit window is:

```
File/Move,<oldfilename>,<newfilename>
```

Descriptions for some of the components of this command are:

<oldfilename> - This is the location and name of the file.

<newfilename> - This is the new location and name of the file.

To access the dialog box associated with this File I / O command:

1. Open the Edit window.
2. Place your cursor on the File Move command.
3. Press F9.

Sample Code for File Move

The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

The following code asks for a file name to move and a location directory and file name to move to. It then performs the file move operation.

```
C1=COMMENT/INPUT,Please type a file you want to move.
,(Include full file path)
C2=COMMENT/INPUT,Please type a destination file name.
,(Include full file path)
V1=FILE/EXISTS,C1.INPUT
IF/V1<>0
   COMMENT/OPER,File exists to move. File move
commencing.
   FILE/MOVE,C1.INPUT,C2.INPUT
   V2=FILE/EXISTS,C2.INPUT
   IF/V2==0
      COMMENT/OPER,"File doesn't exist at: " + C2.INPUT
      ,The MOVE didn't function properly.
      ROUTINE/END
   END_IF/
ELSE/
   COMMENT/OPER,File MOVE successful.
   ROUTINE/END
END_ELSE/
END_IF/
COMMENT/OPER,Original file doesn't exist. Try again.
```

Code Explanation

Much of this code is similar to that explained in "Sample Code for File ".

Only explanations unique to this example are given here.

`FILE/MOVE,C1.INPUT,C2.INPUT`

This line copies the original file to a destination file. This command takes two parameters.

- Parameter 1 is `C1.INPUT` . This is the full path to the file to move.
- Parameter 2 is `C2.` INPUT, or the full path to the destination file.

Deleting a File

The **Insert | File I/O Command | File Delete** menu option inserts a command into the Edit window that deletes a file when the command executes.

The syntax of this command in the Edit window is:

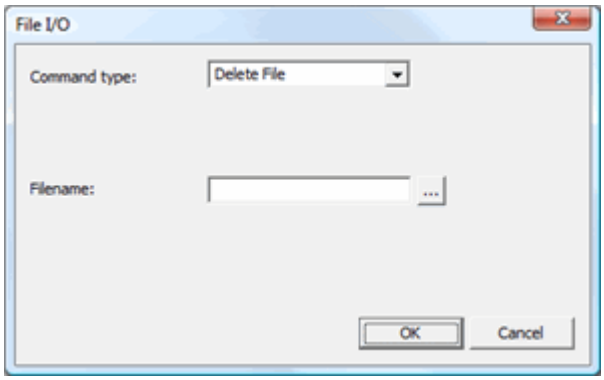
```
File/Delete,<filename>
```

Descriptions for some of the components of this command are:

<filename> - This is the name of the file to delete.

To access the dialog box associated with this File I / O command:

1. Open the Edit window.
2. Place your cursor on the File Delete command.
3. Press F9.



Sample Code for File Delete

> The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

The following code asks for a file name and then deletes the file.

```
C1=COMMENT/INPUT,Please type a file you want to delete.
,(Include full file path)
V1=FILE/EXISTS,C1.INPUT
IF/V1<>0
   COMMENT/OPER,File exists. Ready to delete.
   FILE/DELETE,C1.INPUT
   V2=FILE/EXISTS,
   IF/V2==0
      COMMENT/OPER,File deleted successfully
      ROUTINE/END
   END_IF/
ELSE/
   COMMENT/OPER,File still exists
   ROUTINE/END
END_ELSE/
END_IF/
COMMENT/OPER,File doesn't exist to delete. Choose a file
that exists.
```

Code Explanation

Much of this code is similar to that explained in "Sample Code for File Move ".

Only explanations unique to this example are given here.

`FILE/DELETE,C1.INPUT` - This line deletes the file specified. This command takes one parameter, the name of the file to delete. In this case, `C1.INPUT` .

Checking for a File's Existence

The **Insert | File I/O Command | File Exists** menu option inserts a command into the Edit window that checks for the existence of a file when executed and sets the supplied variable with the result.

The syntax of this command in the Edit window is:

```
<varname> = File/Exists,<filename>
```

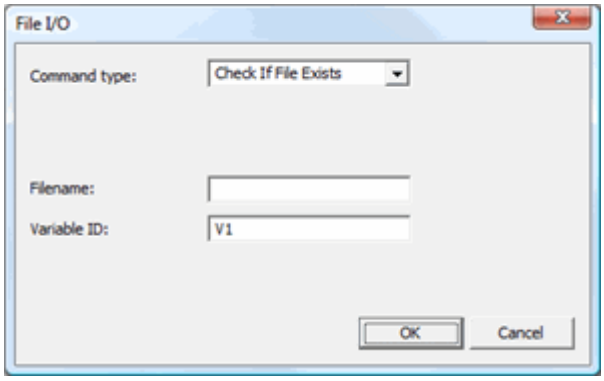
Descriptions for some of the components of this command are:

<varname> - This is the name of the variable that is set to the result of the check that is performed. The variable is set to 1 if the file exists and 0 if the file does not exist.

<filename> - This is the name of the file being checked to see if it exists on the disk.

To access the dialog box associated with this File I / O command:

1. Open the Edit window.
2. Place your cursor on the File Exists command.
3. Press F9.



Sample Code for File Exists

The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

The following code asks for a file name and then checks for the file's existence.

```
C1=COMMENT/INPUT,Please type a file you want to check.
V1=FILE/EXISTS,C1.INPUT
IF/V1<>0
   COMMENT/OPER,File exists.
END_IF/
ELSE/
   COMMENT/OPER,File doesn't exist
END_ELSE/
```

Code Explanation

Much of this code is similar to that explained in "Sample Code for Read Character" or in "Sample Code for Read Line".

Only explanations unique to this example are given here.

`V1=FILE/EXISTS,C1.INPUT`

This line checks to see if the specified file exists. The file must be placed in the directory where PC-DMIS resides for this code to work; otherwise, the line containing the file must

also contain the full pathway for the file. `V1` receives the result of the file check. It's a non-zero value if it exists; 0 otherwise.

Displaying a File Dialog Box

The **Insert | File I/O Command | File Dialog** menu option inserts a command into the Edit window that brings up an **Open** dialog box during execution. This allows the operator to choose a file name at run time. It stores the name of the file chosen in the specified variable.

The syntax of this command in the Edit window is:

```
<varname> = File/Dialog,<expr>
```

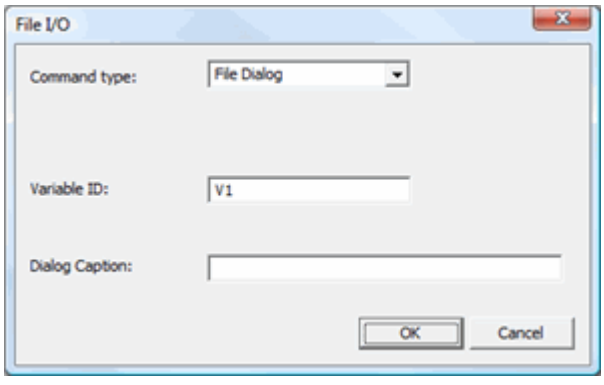
Descriptions for some of the components of this command are:

<varname> - This is the name of the variable that is set to the name of the file chosen by the user in the file dialog box.

<expr> - This is the text that appears on the title bar of the file dialog box.

To access the dialog box associated with this File I / O command:

1. Open the Edit window.
2. Place your cursor on the File Dialog command.
3. Press F9.



Sample Code for File Dialog

The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

The following code submits a dialog box that allows you to choose a file to delete.

```
V1=FILE/DIALOG,Choose a file to delete.
V2=FILE/EXISTS,V1
IF/V2<>0
   COMMENT/OPER,File exists. Ready to delete.
   FILE/DELETE,V1
   V3=FILE/EXISTS,
   IF/V3==0
      COMMENT/OPER,File deleted successfully
      ROUTINE/END
   END_IF/
ELSE/
   COMMENT/OPER,File still exists
   ROUTINE/END
END_ELSE/
END_IF/
COMMENT/OPER,File doesn't exist to delete. Choose a file
that exists.
```

Much of this code is similar to that explained in "Sample Code for Read Character" or in "Sample Code for Read Line".

Only explanations unique to this example are given here.

`V1=FILE/Dialog,Choose a file to delete`

This line displays a dialog box with the title "Choose a file to delete". You can browse to a file and when you click **Open**, PC-DMIS gives V1 the full path to the selected file. The rest of the routine deletes the selected file.

Checking for the End of a File or the End of a Line

PC-DMIS allows you to check for the End of a File by using the functions `EOF` or `EOL` in a conditional test.

`EOF` stands for END OF FILE. This function takes a file pointer of type string. When properly placed within a conditional statement, it tests to see if the file pointer has reached the end of the specified file. If it has, then the function returns true.

`EOL` stands for END OF LINE. This function takes a file pointer of type string. When properly placed within a conditional statement, it tests to see if the file pointer has reached the end of a line in the specified file. If it has, then the function returns true. This works best inside of a loop.

The syntax of this command in the Edit window is:

`EOF(<filepointer>)` or `EOL(<filepointer>)`

Descriptions for some of the components of this command are:

<filepointer> - This is the name of the file pointer that you're checking.

Sample code for EOF and EOL

The sample code below should be entered inside the Edit window's Command Mode and not inside the **File I/O** dialog box.

The following code opens test.txt and reads through the file. As long as the end of file hasn't been reached (designated with the code, `WHILE/! EOF )` , PC-DMIS reads through the file character by character, and assigns a character to V1.

If PC-DMIS reaches the end of a line in the file, PC-DMIS shows the last character on that line.

This repeats until PC-DMIS reaches the end of the file. PC-DMIS then shows the text "End of File Reached…".

```
   FPTR=FILE/OPEN,D:\temp\test.txt,READ
   WHILE/!EOF("FPTR")
   V1=FILE/READ_CHARACTER,FPTR
   IF/EOL("FPTR")
   COMMENT/OPER,NO,"End of Line Reached. The last character
is:"
   ,V1
   END_IF/
   END_WHILE/
   COMMENT/OPER,NO,"End of File Reached..."
```

Using Expressions and Variables

Using Expressions and Variables: Introduction

An expression is a user-defined condition used with PC-DMIS's flow control commands. Using flow control statements, you can test these conditions in your measurement routine. If the condition is met or not, you can determine what action PC-DMIS takes.

Expressions are important to making PC-DMIS accomplish your specific tasks. When you use expressions in conjunction with flow control commands, you can unleash even more of PC-DMIS's powerful functionality.

This chapter explains how to create and use expressions inside the PC-DMIS Edit window. When you work with expressions, you should place the Edit window into Command Mode. This allows you to view the Edit window code directly.

The following major topics are covered in this chapter:

- Using Expressions in a Measurement Routine
- Creating Expressions with the Expression Builder
- Using Variables with Expressions
- Understanding Expression Components
- Accessing a Report's Object Properties
- Accessing Information from a Constructed Scan Minimum Circle

If you're looking for information on Reporting Expressions, see the "About Report Expressions" in the "Reporting Measurement Results" chapter.

Using Expressions in a Measurement Routine

The PC-DMIS Edit window allows expressions in most of its editable fields. Editable fields are usually those fields that highlight in yellow when you press the Tab key inside the Edit

window while in Command Mode. Fields that change the type of the feature do not allow expressions.

The box of an Auto feature that specifies the type of the Auto feature, such as a Surface point, Auto Circle, Auto Round Slot, and so on, does not allow expressions.

The subtopics under this topic offer a complete reference to available expressions.

Viewing Expression Values

To see the value of an expression, position the mouse cursor over the expression and leave it in position for at least one second. The expression is evaluated and a small yellow pop-up window that displays the expression and its current value appears just below the mouse cursor.

Keeping Expression Values Only

To immediately solve an expression in the Edit window and keep only the value, follow these steps:

1. Select the expression text in the Edit window.
2. Precede the expression text with a ` (accent grave) character.

Suppose you type the expression`**1/7** in a numeric field. The expression is immediately solved and only the value (**0.143**) is placed in the field.

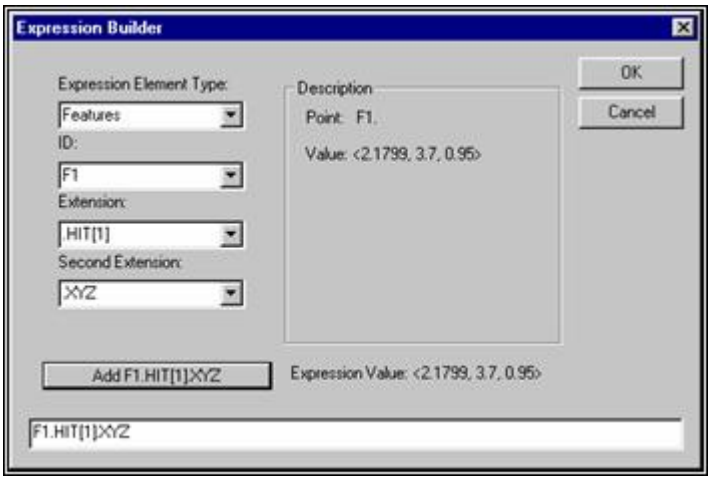
Using Expressions with Branching

The flow control commands use expressions to determine flow of routine execution. Refer to the "Branching by Using Flow Control" chapter for information on when branching may or may not occur.

Using Expressions with File Input / Output

Writing data to an external data file or reading data from an external data file often uses variables and other expressions to effectively manage and store or display that data. Refer to the "Using File Input / Output" chapter for more information.

Creating Expressions with the Expression Builder



Expression Builder Dialog Box

PC-DMIS allows you to create and add expressions into the Edit window by typing them or using the interface of the **Expression Builder** dialog box. The **Edit | Expression** menu option displays the **Expression Builder** dialog box.

This dialog box allows you to create an expression and insert it into an editable field. Pressing the F2 key while the cursor is on a field that allows expressions also displays the **Expression Builder** dialog box.

The **Expressions Builder** dialog lists all of the types of operators and functions that are available for expressions.

Creating an Expression by Typing

To create an expression by typing it directly into the Edit window:

1. Open the Edit window (**View | Edit Window**).
2. Place the Edit window into Command Mode.
3. Press Tab to move your cursor to an editable field where you want to insert the expression. Fields with a yellow highlight are considered "editable".
4. Type the expression.

Creating an Expression with the Expression Builder

You must be in Command Mode for the Expression option to be enabled.

To enter an expression by using the Expression Builder dialog box (**Edit | Expression**):

1. Open the Edit window (**View | Edit Window**).
2. Place the Edit window into Command Mode (**View | Command Mode**).
3. Move the cursor to an editable field where you want to insert the expression.
4. Press the F2 key while the cursor is on a field that allows expressions. The **Expression Builder** dialog box appears. The **Expression Builder** dialog box lists all of the operators, operands, and functions. The following can be referenced through this dialog box:
    - Available expression types
    - Variables
    - Features
    - Dimensions
    - Alignments
    - Comments
5. Select the expression element type from the first drop-down list. Depending on your selection, other combination boxes appear.
6. Select the desired ID from the **ID** drop-down list.
7. Select an extension from the **Extension** drop-down list.
8. Select another extension from the **Second Extension** drop-down list. If the expression is usable, the **Add** button becomes available.
9. Click the **Add** button. The expression appears in an edit box.
10. Click the **OK** button. The expression now appears where your cursor is in the Edit window.

You can also open the **Expression Builder** dialog box from these other dialog boxes:

- The **If Expression** dialog box - Select **Insert | Flow Control Command | If Goto**. Click on the **Expression** button.
- The **Assignment** dialog box - Select **Insert | Assignment**. Click the **Assign To** or **Assign From** button.

Once the expression is created, PC-DMIS automatically inserts the expression at the next legal position in the Edit window.

Checking the Expression for Correctness

When your cursor leaves the field where you added the expression, PC-DMIS attempts to check the expression for correctness. If there is a problem with the expression, an error message that indicates an invalid number may appear, or the expression text may turn red. Also, expressions that refer to non-existent objects appear in red text.

Since the test of expression correctness occurs at the time you leave a field, a field that turned red due to a reference of a nonexistent object, (ex. CIRCLE1.X) will remain red even if the new object (for example, CIRCLE1) is added. The field remains red until the expression is retested for correctness.

To retest the expression for correctness:

1. Move your cursor to the field of the expression.
2. Press the F2 key. The **Expression Builder** dialog box opens again. Any changes to your expression appear in the edit box.
3. Press the ENTER key to close the dialog box.

Expression Element Type

The Expression Element Type drop-down list in the **Expression Builder** dialog box (**Edit | Expression**) lists the various expression element types available to be placed into expressions. These include:

- Functions
- Operators
- Alignments
- Comments

- Dimensions
- Features
- Variables

ID

The **ID** drop-down list in the **Expression Builder** dialog box (**Edit | Expression**) lists the set of items available based on the expression element type selected in the **Expression Element Type** drop-down list.

The list of available items depends on the selected expression element:

- When you select **Functions & Operators** from the **Expression Element Type** drop-down list, the **ID** drop-down list contains a list of the available functions and operators.
- When you select **Features** from the **Expression Element Type** drop-down list, the **ID** drop-down list displays the IDs of the features in the measurement routine.

Extension

The **Extension** drop-down list in the **Expression Builder** dialog box (**Edit | Expression**) becomes available when the item chosen in the **ID** drop-down list requires the addition of an extension in order to form a usable expression element. The **Extension** drop-down list displays available extensions based on the item selected in the **ID** drop-down list.

Suppose you select a feature from the **ID** drop-down list. PC-DMIS shows the possible extensions that you can use to reference data of that feature (such as "X", "Y", "Z", "Diam", "Length", etc.) in the **Extension** drop-down list.

Possible extensions include these measured or theoretical data types:

Measured

- All – All the values of the feature are assigned to the variable. See the example below.
- X – Measured X values of the hits
- Y – Measured Y values of the hits
- Z – Measured Z values of the hits

- XYZ – Measured XYZ values of the hits
- I – Measured I values of the hits
- J – Measured J values of the hits
- K – Measured K values of the hits
- IJK – Measured IJK values of the hits

Theoretical

- TX – Theoretical X values of the hits
- TY – Theoretical Y values of the hits
- TZ – Theoretical Z values of the hits
- TXYZ – Theoretical XYZ values of the hits
- TI – Theoretical I values of the hits
- TJ – Theoretical J values of the hits
- TK – Theoretical K values of the hits
- TIJK – Theoretical IJK values of the hits

Suppose this code snippet is part of a measurement routine:

```
F1=GENERIC/POINT,DEPENDENT,CARTESIAN,$
     NOM/XYZ,<8,9,10>,$
     MEAS/XYZ,<7.98,8.98,9.98>,$
     NOM/IJK,<1,0,0>,$
     MEAS/IJK,<1,0,0>
     ASSIGN/MYFEATURE=F1.ALL
     ASSIGN/V1=MYFEATURE.X
     ASSIGN/V2=MYFEATURE.TX
```

When the measurement routine completes the above code snippet, PC-DMIS assigns the variables with these values:

```
V1 = 7.98
V2 = 8
```

Second Extension

The **Second Extension** drop-down list becomes available only if the item chosen in the **Extension** drop-down list requires the addition of a second extension in order to form a usable expression element.

Suppose you are referencing the nominal value of the X location axis of a dimension named "D1". You would:

1. Choose **D1** from the **ID** drop-down list.
2. Select **X** from the **Extension** drop-down list.
3. Select **Nom** from the **Second Extension** drop-down list.

Add Button

Whenever you select a usable or complete expression element from a list, the **Add** button becomes available. This button displays the text to be added to the expression.

For example, if you chose the following items for your expression:

- Dimensions from the **Expression Element Type** list
- D1 from the **ID** list
- X from the **Extension** list
- Nom from the **Second Extension** list

Then the **Add** button becomes enabled and has the following text: **Add D1.X.NOM**.

When you click the **Add** button, the text then appears in the edit box at the bottom of the dialog box.

When you click the **OK** button, PC-DMIS adds the text from the edit box to the expression field in the Edit window where your cursor is. If you select an item from the Edit window's expression field, and the text to be added contains parenthesis, then the selected item would be placed inside of the parenthesis of the added text.

Edit Box

At the bottom of the **Expression Builder** dialog box (**Edit | Expression**) is an edit box that shows the current expression. You can type the expression directly into this box, or you can use the **Add** button.

Description Area

The **Expression Builder** dialog box (**Edit | Expression**) also contains a **Description** area that gives information about items selected from the drop-down lists. A field next to the **Add** button also shows the current value of the expression.

Invalid expressions have a value of 0.

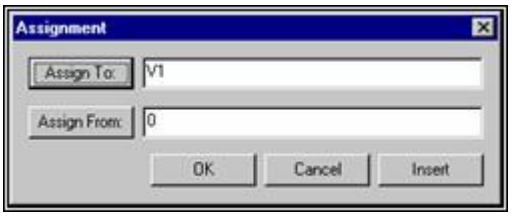
Using Variables with Expressions

Variables are objects that hold values. Variables refer to integer, real, string, or point operands. Variables are essential to using expressions. A variable has a name and a value. The name is used to access the value of the variable. The name is constant; the value can be changed. You can use the `ASSIGN/` command to assign a value to a variable.

For example, the statement `ASSIGN/V1=2` creates a variable with a name of V1 and a value of 2. `ASSIGN/V2=V1+2` accesses the value of V1. If V1 still had a value of 2 when this assign statement was executed, V2 would then have a value of 4.

For more information on variables, see "Variables".

Assigning Values to Variables by Using the Assignment Dialog Box



Assignment Dialog Box

The **Insert | Assignment** menu option displays the **Assignment** dialog box. Use this dialog box to assign a value to a variable or data element of a measurement routine feature, dimension, or alignment. Use of the assignment command requires a basic understanding of PC-DMIS expressions.

Assign To button - This button designates the variable that is receiving the value calculated in the **Assign From** box. Information chosen using the **Assign To** button is placed in the **Assign To** box. This value can be the name of a variable or a reference to a data element of a feature, dimension, or alignment.

The result of solving the mathematical expression for a value is what is meant by the term "evaluated".

Assign From button - This button places the value being assigned into the **Assign From** box. If this box contains an expression, the expression is evaluated at execution time and the result or value of the calculation is assigned to the object specified in the **Assign To** box.

Insert button - This button inserts an assignment command into the measurement routine while keeping the **Assignment** dialog box open. A series of assignment commands can be inserted without closing the dialog box.

Understanding Expression Components

Expressions have these types of operands:

- Integers
- Real Numbers
- Strings

- Points
- Feature Pointers
- Arrays
- Functions

These are discussed in detail below.

Operand Types

The operands may exist in the form of:

- Literals
- References
- Variables
- Structures
- Pointers
- Arrays

Literals

***Integers:** 1, -6, 209

Reals: 1, -6, 2.4, -0.1, 345.6789

Strings: "Hello World", "47", "CIRCLE 1"

Points: A literal representation is not available for points. However, points can be made from other literals using the MPOINT function: For example, `MPOINT (0,0,1`), `MPOINT (2.2,3.1,4.0)` .

Pointer: The name of a feature enclosed in French brackets: `{CIR1},{LIN2},{F3}`

Arrays: A literal representation is not available for arrays. However, arrays can be created from other literals using the ARRAY function: For example, `ARRAY (3,5,6)` , `ARRAY ("Hello",2.3,9)` . These functions create 3 element arrays with the integer elements 3, 5, and 6 in the first example and the string element "Hello", double element 2.3, and integer element 9 in the second example.

Functions: A literal representation is not available for functions. Functions are defined using the `FUNCTION` keyword and accessed via variable ids. For example, `ASSIGN/ Add2= FUNCTION((X),X+2)` defines a function that takes one argument and adds 2 to

it. The variable Add2 is assigned the function. The function can be called using the variable Add2 as follows. `ASSIGN/Result=Add2(5)` . Result is assigned the value 7.

Numeric Literals are interpreted as real numbers unless the operator or function implies the use of integers. For example, the expression 10 / 8 evaluates to 1.25 instead of 1. Note also that discrete division is also possible via the operand coercion operators. The expression INT(10) / INT(8) does evaluate to 1.

References

References refer to data members of other objects in a measurement routine. References use the ID of an object in the measurement routine followed by a dot and an extension that refers to the data member of the object.

If CIRCLE1 were the name of a measured circle in the measurement routine, `CIRCLE1 .X` would refer to the measured value of the X component of CIRCLE1. All references are evaluated in part coordinates relative to the current alignment.

References of Type Double

The following reference expressions are available:

Valid Extensions for Feature References of Type Double by Example

Format: <Feature Id>.<Extension> -> `CIRCLE1 .X`

CIRCLE1.X Measured X value of CIRCLE1
CIRCLE1.Y Measured Y value of CIRCLE1
CIRCLE1.Z Measured Z value of CIRCLE1

CIRCLE1.TX Theoretical (Nominal) X value of CIRCLE1
CIRCLE1.TY Theoretical (Nominal) Y value of CIRCLE1
CIRCLE1.TZ Theoretical (Nominal) Z value of CIRCLE1

LINE1.SX Measured X value of the Startpoint of LINE1
LINE1.SY Measured Y value of the Startpoint of LINE1
LINE1.SZ Measured Z value of the Startpoint of LINE1

LINE1.TSX Theoretical X value of the Startpoint of LINE1
LINE1.TSY Theoretical Y value of the Startpoint of LINE1
LINE1.TSZ Theoretical Z value of the Startpoint of LINE1

LINE1.EX Measured X value of the Endpoint of LINE1
LINE1.EY Measured Y value of the Endpoint of LINE1
LINE1.EZ Measured Z value of the Endpoint of LINE1

LINE1.TEX Theoretical X value of the Endpoint of LINE1
LINE1.TEY Theoretical Y value of the Endpoint of LINE1
LINE1.TEZ Theoretical Z value of the Endpoint of LINE1

POINT.I Measured I Component of Vector for POINT
POINT.J Measured J Component of Vector for POINT
POINT.K Measured K Component of Vector for POINT

POINT.TI Theoretical I Component of Vector for POINT
POINT.TJ Theoretical J Component of Vector for POINT
POINT.TK Theoretical K Component of Vector for POINT

FEAT1.TYP The type of the feature (i.e. circle, slot, cone). You can use this to change the type of a generic feature (`ASSIGN/Gen1.TYP=Feat1.TYP`).

FEAT1.ALL Refers to all elements of the feature. This is valuable for copying information to a generic feature. (`ASSIGN/Gen1.ALL=Feat1.ALL`)

Surface Vector

EDGE.SURFI

EDGE.SURFJ

EDGE.SURFK

EDGE.TSURFI

EDGE.TSURFJ

EDGE.TSURFK

Angle Vector

CIR.ANGJ

CIR.ANGK

CIR.TANGI

CIR.TANGJ

CIR.TANGK

Radius

CIRCLE1.R

CIRCLE1.TR

CIRCLE1.RAD

CIRCLE1.TRAD

CIRCLE1.RADIUS

CIRCLE1.PR – Polar Radius

CIRCLE1.TPR – Theoretical Polar Radius

CIRCLE1.TRADIUS (Only the First Characters are significant)

Diameter

CIRCLE1.D

CIRCLE1.TD

CIRCLE1.DIAM

CIRCLE1.TDIAM

CIRCLE1.DIAMETER

CIRCLE1.TDIAMETER (Only the first characters are significant)

Angle

CONE.A

CONE.TA

CONE.ANG

CONE.TANG

CONE.ANGLE

CONE.TANGLE

CONE.PA – Polar Angle

CONE.TPA – Theoretical Polar Angle (Only the first characters are significant)

Length

LINE.L

LINE.TL

LINE.LEN

LINE.TLEN

LINE.LENGTH

LINE.TLENGTH (Only the first characters are significant)

Height

CYLINDER.PH – Polar Height

CYLINDER.TPH – Theoretical Polar Height

Radius, Angle, Height

POINT.RAH – Point with Measured Radius, Angle, and Height

POINT.TRAH – Point with Theoretical Radius, Angle, and Height

Area

BLOB1.AREA - Returns the measured Area value for a Blob feature.

BLOB1.TAREA - Returns the Theoretical Area value for a Blob feature.

For example, `ASSIGN/V1=BLOB1 .AREA` returns the measured area value of the BLOB1 feature and assigns it to the V1 variable.

Currently, only the Blob feature works with these area extensions. For information on the Blob feature, see the "Vision Blob" topic in the "PC-DMIS Vision" documentation.

Valid Extensions for Dimension Reference of Type Double by Example

Format: <Dimension ID>.<AXIS>.<Dimension Element> -> `DIM1 .X.NOM`

DIM1.X.NOM	The Nominal Value for X Axis Location of DIM1
DIM1.X.MEAS	The Measured Value for the X Axis Location of DIM1
DIM1.X.MAX	The Max Deviation for X Axis Location of DIM1
DIM1.X.MIN	The Min Deviation for X Axis Location of DIM1
DIM1.X.PTOL	The Plus Tolerance Value for the X Axis Location of DIM1
DIM1.X.MTOL	The Minus Tolerance Value for the X Axis Location of DIM1
DIM1.X.DEV	The Deviation on the X Axis Location of DIM1
DIM1.X.OUTTOL	The Out of Tolerance value on the X Axis Location of DIM1
DIM1.Y.NOM	The Nominal Value for the Y Axis Location of DIM1
DIM1.Z.DEV	The Deviation on the Z Axis Location of DIM1
DIM3.PA.MEAS	The Measured Value for the Polar Angle Location of DIM3
DIM4.M.PTOL	The Plus Tolerance Value for the M Axis of DIM4
DIM4.PTOL	The Plus Tolerance Value for the M Axis of DIM4 (See *Note under "Valid Axes " below).
DIM5.BTOL	The Bonus Tolerance Value where DIM5 is a Position.

Valid Axes:

X, Y, Z, D, R, A, T, V, L, PR, PA, M, PD, RS, RT, S, H, DD, DF, TP

* Dimensions that have only one axis by definition (such as roundness, concentricity, and so on) can omit the axis qualifier. If you use the axis qualifier, note that all of these types of dimensions (that have only one axis) use the M Axis qualifier with the exception of 2D and 3D angle dimensions, which use the A Axis qualifier.

Valid Extensions for Alignment References of Type Double by Example:

Format: <Alignment ID>.<Alignment Axis or Origin>.<Alignment Axis or Origin Component> -> `A1 .ORIGIN.X`

A1.ORIGIN.X	X Component of alignment A1's measured origin
A2.ORIGIN.Y	Y Component of alignment A2's measured origin
A1.ORIGIN.Z	Z Component of alignment A1's measured origin
A1.XAXIS.I	I Component of alignment A1's measured X axis
A1.YAXIS.J	J Component of alignment A1's measured Y axis
A1.ZAXIS.K	K Component of alignment A1's measured Z axis
A1.CORIGIN.X	X Component of alignment A1's origin based on theoretical (C is for CAD) data
A1.CXAXIS.J	J Component of alignment A1's X axis based on theoretical (C is for CAD) data

References of Type Point

The following reference expressions are available:

Valid Extensions for Feature References of Type Point by Example

Format: <Feature ID>.<Extension> -> CIRCLE1.XYZ

`CIRCLE1.XYZ`	Measured centroid of CIRCLE1
`CIRCLE1.TXYZ`	Theoretical centroid of CIRCLE1
`LINE1.SXYZ`	Measured start point of LINE1
`LINE1.TSXYZ`	Theoretical start point of LINE1
`LINE1.EXYZ`	Measured end point of LINE1
`LINE1.TEXYZ`	Theoretical end point of LINE1
`CIRCLE1.IJK`	Measured Vector of CIRCLE1
`CIRCLE1.TIJK`	Theoretical Vector of CIRCLE1
`EDGE.SURFIJK`	Measured Surface Vector of EDGE
`EDGE.TSURFIJK`	Theoretical Surface Vector of EDGE
`AUTOCIR1.ANGIJK`	Measured Angle Vector of AUTOCIR1
`AUTOCIR1.TANGIJK`	Theoretical Angle Vector of AUTOCIR1

Valid Extensions for Alignment Reference of Type Point by Example

Format: <Alignment ID>.<Alignment Axis or Origin> -> A1.XAXIS

A1.ORIGIN	Measured origin of alignment A1
A1.XAXIS	Measured X axis of alignment A1
A1.YAXIS	Measured Y axis of alignment A1
A1.ZAXIS	Measured Z axis of alignment A1
A1.CORIGIN	Theoretical origin of alignment A1
A1.CXAXIS	Theoretical X axis of alignment A1
A1.CYAXIS	Theoretical Y axis of alignment A1
A1.CZAXIS	Theoretical Z axis of alignment A1

References of Type String

References to comments are the only object types that are of type string. Only INPUT comments or YES/NO comments can be referred to via references. These comment types have an ID that you can use to identify the comment.

Format: <Comment ID>.INPUT -> `C1 .INPUT`

C1.INPUT - The input value (from the operator) for comment C1

YES/NO comment types set the input to the appropriate yes or no string based on the current language of PC-DMIS. In the English version of PC-DMIS, if the operator presses the yes button, the string is set to "YES". If the operator presses the no button, the string is set to "NO". When comparing strings to test for "YES" or "NO", the comparison is case sensitive. Thus, comparing against "yes" or "no" always fails even if the YES/NO comment input is set to "YES" or "NO".

Variables

Variables can be of any of the seven operand types: integer, real, string, point, feature pointer, array, and function. Variables come into existence and receive their values and types via the `ASSIGN` statement.

The variable ID can be any alphanumeric string that does not begin with a numeric character. You can use underscores in the variable id as long as the underscore is not the first character.

As long as the measurement routine remains open, PC-DMIS saves variable values between execution runs. This means when execution finishes, PC-DMIS uses the values as the end of the routine when you restart the routine. You may or may not want this behavior. If you want fresh variable values, it's good practice to clear out your values with assign statements at the beginning of your routine. For example, if you use a V1 variable value in some number calculations, you can use `ASSIGN/V1=0` to clear out that variable.

If the Edit window is active, PC-DMIS indicates the current value of the variable whenever the cursor is placed in the field. During execution, variable values change based on execution flow. Position the mouse pointer over the desired variable to find out its current value.

```
ASSIGN/V1=2.2+2
```
Variable V1 is a real number with the value of 4.2

```
ASSIGN/VAR1=CIRCLE1. X
```
Variable VAR1 is a real number with a value equal to the measured value of CIRCLE1.X at the time of assignment.

```
ASSIGN/MYVAR=LINE1. XYZ
```
Variable MYVAR is a point with the same value of the measured centroid of LINE1 at the time of assignment.

```
ASSIGN/SVAR="Hello World"
```
Variable SVAR is a string with the value "Hello World"

In these examples, variables are assigned values. Once a variable is assigned a value, you can use the variable as an operand in any expression field.

Here, V1 is used in a numeric field. It is used as the prehit value of the prehit command:

```
ASSIGN/V1=1/3PREHIT/V1
```

Because expressions can be used in most fields that you can modify, the following expression is also legal and has the same effect: PREHIT / 1/3.

The components of variables of type point can be referred to individually using the dot extension notation used for references.

```
ASSIGN/V1= MPOINT (3,4,5)
```
V1 is of type point with value of 3, 4, 5

```
ASSIGN/XVAR=V1. X
```
XVAR is of type double with the value of 3

```
ASSIGN/YVAR=V1. Y
```
YVAR is of type double with the value of 4

```
ASSIGN/IVAR=V1. I
```
IVAR is of type double with the value of 3

```
ASSIGN/REDUNVAR=V1. XYZ
```
REDUNVAR is of type point with the value of 3, 4, 5

The following extensions are equivalent to each other. Both are provided to clarify the meaning of an expression in a measurement routine.

Given that V1 is of type point.

V1.X is the same as V1.I
V1.Y is the same as V1.J
V1.Z is the same as V1.K

V1.XYZ is the same as V1.IJK and V1 without any extension.

If a variable of type string has a string value equal to the name of the id of a feature, dimension, or alignment, you can use the variable as a reference object:

```
ASSIGN/V1="CIRCLE1"
```

The following operands are possible and valid provided a feature with the name CIRCLE1 exists.

V1.X - The measured X value of CIRCLE1
V1.TX - The theoretical X value of CIRCLE1
V1.Diameter - The measured diameter of CIRCLE1
V1.Radius - The measured radius of CIRCLE1

This type of indirection available on string variables is only available to one level of indirection. The following will not work.

```
ASSIGN/V1="CIRCLE1"
 ASSIGN/V2="V1"
```

V2.X - This evaluates to 0 instead of the current measured value of CIRCLE1.X.

The reference V2.X is *not* flagged as an error with red text even though an expression above it sets its type to a string. The reason it cannot be flagged as an error is because the flow of execution of the measurement routine is not known until execute time.

However, if you use curly brackets the following does work:

```
ASSIGN/V1={CIRCLE1} ASSIGN/V2={V1}
```

V2.X - This gives you the value of CIRCLE1.X.

Consider the following example:

```
ASSIGN/V1="CIRCLE1"
 ASSIGN/V2="V1" IF/CIRCLE1.X>CIRCLE1.TX,GOTO,L2
 L1=LABEL/ ASSIGN/V3=V2.X
 GOTO/LABEL,L3 L2=LABEL / ASSIGN/V2=MPOINT(2,5,7)
 GOTO/LABEL,L1 L3=LABEL/
```

During routine execution, if the value of CIRCLE1.X is greater than the value of CIRCLE1.TX, then the expression V2.X valid and evaluates to 2. Otherwise, the expression V2.X evaluates to 0 since the value of V2 at the time of the ASSIGN for V3 is the string "V1". It is the responsibility of the part programmer to ensure that expressions do as expected in these cases.

You can use almost all of the feature references on the left-hand side of the `ASSIGN` statement to put a value into a measured or theoretical data member of a feature. The only exception is the single I, J, K components of vectors. To assign to vectors, you must assign the complete vector at once with an expression that evaluates to a point. Vector data is normalized as it is input into the feature's vector data members.

```
ASSIGN/CIRCLE1.I=2-illegal
 ASSIGN/CIRCLE1.IJK=MPOINT(2,0,0)-legal(vector
 is normalized to 1,0,0)
```

For information on using variables within dimensions, see the "Dimensioning Variables" topic in the "Using Legacy Dimensions" chapter.

Structures

You can use a variable type called *structures* to place extensions on a variable to identify a sub-element of that variable. You can see that in this code snippet:

```
ASSIGN/V1.HEIGHT=6
 ASSIGN/V1.WIDTH=4.3
 ASSIGN/V1.MODE="CIRCULAR"
 ASSIGN/V1.POINT
 = MPOINT(100.3,37.5,63.1)
```

Where:

- `V1` is the structure
- `HEIGHT`, `WIDTH`, `MODE`, and `POINT` are sub-elements of the structure

Rules for Structures

- Like Variables, structures do not need to be declared.
- Sub-elements of a structure can be any of these variable types:
  - Integer
  - Double
  - Point
  - Feature Pointer
  - Function
  - Array
  - Structure

For example, it is possible to have structure elements that are arrays and array elements that are structures. You can see the valid expressions in the following code snippet:

```
 ASSIGN/
CAR.LEFTSIDE.DOOR[2].QUADRANT[3].JOINT[5].HIT[4]=MPOINT(558.89,910.12,

 COMMENT/OPER,"Current Z Position:
"+CAR.LEFTSIDE.DOOR[2].QUADRANT[3].JOINT[5].HIT[4].Z

 ASSIGN/CURRENTJOINT=LEFTSIDE.DOOR[2].QUADRANT[3].JOINT[5]

 COMMENT/OPER,"Next Hit: "+CURRENTJOINT.HIT[4]
```

Structures with Variables of Type Point

If a variable is of type point, you can still use the .X, .Y, .Z, .I, .J, and .K extensions to get at individual items of the point. You can also use any of the extensions from this example in their structures without being forced to use them as point elements as shown here:

```
ASSIGN/V1.X="Some
 string" ASSIGN/V1.Y=ARRAY(1,3,5,9,7)
 ASSIGN/V1.Z=MPOINT(3,5,7)
```

`COMMENT/REPT,V1.X`	Output is "Some string"
`COMMENT/REPT,V1.Y[2]`	Output is 3, the second element of the array.
`COMMENT/REPT,V1.Z.Y`	Output is 5, the Y value of the MPOINT.

By combining structures with the function capability of the PC-DMIS expression language, it is possible to have dynamic structure references as shown here:

```
ASSIGN/DYNAMICSTRUCT=FUNCTION((X,Y),X.Y)
 C1=COMMENT/INPUT,Please enter in item ASSIGN/
TESTSTR=C1.INPUT
 ASSIGN/FRONT=LEFT(TESTSTR,INDEX(TESTSTR,".")-1)
 ASSIGN/BACK=MID(TESTSTR,INDEX(TESTSTR,"."))
 ASSIGN/RESULT=DYNAMICSTRUCT(FRONT,BACK)
```

This portion of the example asks you to input a variable reference, splits the reference at the first '.', and then assigns `RESULT` to be equal to that reference by using the function `DYNAMICSTRUCT` .

So, if you had typed `V1.Y[4]` for the C1.INPUT variable, `RESULT` would end up with the value of 9 (the fourth element of the array assigned to `V1.Y)`.

The learn time evaluation of expressions has been enhanced to accurately show all elements of a structure or an array.

Pointers

Pointers are also known as "Feature Pointers". See the Glossary term "Feature Pointers" for more information.

Pointers provide a way to reference a feature via a variable or to pass objects using the call sub command. Pointers are similar to indirection via string names. However, the advantage of using pointers is with subroutines. Pointers, unlike strings, when passed in as arguments of a subroutine, allow for direct modification of the object pointed to by the subroutine. Pointers are not used in complex expressions. If it is used in a complex expression, the pointer evaluates to zero.

Consider the following examples.

Pointer Use Example:

In this example, `V1` is defined as a pointer that points to CIR1:

```
ASSIGN/V1={CIR1}
```

In this example, `DIST` is assigned the value of the distance of CIR1 from the origin:

```
ASSIGN/DIST=DOUBLE(V1.XYZ)
```

You can also put an expression between curly brackets in order to obtain a feature pointer. Now the following examples are all legal ways to get the pointer to feature CIR1:

```
ASSIGN/FEATCOUNT=1

ASSIGN/V1={"CIR"+FEATCOUNT}
```

Assigns expression "CIR1" to V1.

```
ASSIGN/V2="CIR1"

ASSIGN/V3={V2}
```

Assigns expression "CIR1" from variable V2 to variable V3.

```
C1=COMMENT/INPUT,Please type a feature name.

ASSIGN/V4={C1.INPUT}
```

This takes the feature name of C1.INPUT and places it into variable, V4.

Subroutine Example:

In the calling routine:

```
CS1=CALLSUB/SUB.PRG,CHANGEX,{CIR1}
```

In the subroutine:

```
GEN1=GENERIC/FEATURE

SUBROUTINE/CHANGEX,ARG1={GEN1}
```

(During execution, when the code passes CIR1 to the routine, CIR1 takes the place of GEN1)

```
ARG1.X=5
```

(Sets the measured X value of CIR1 to 5)

```
END/SUBROUTINE
```

Complex Expression Example:

```
ASSIGN/V1={CIR1}+2
```

{CIR1} evaluates to zero and so entire expression evaluates to 2.

Arrays

Three types of arrays are available: Feature, hit, and variable.

Even though multi-dimensional arrays are displayed as multi-dimensional in the software, you can really only use them as single dimensional arrays until you precede the arrays with an ARRAY INDICES command (see the "Array Indices Object:" topic).

Feature Arrays

When a feature is measured more than once during routine execution because of some kind of loop, the software creates a feature array automatically. The number of elements in the feature array is equal to the number of times that the feature has been executed.

If a measured circle feature is inside a while loop that executes five times, then an array of five measured circles exists. If the id of the measured circle is CIR1, then you can use an array expression to access individual instances of the measured circle object. You use square brackets to indicate the instance you want, like this:

```
ASSIGN/V1=CIR1[3].X
```

V1 is assigned the measured X value of the third instance of the CIR1 circle.

When a feature array exists for a given feature, but array notation is not used in a reference to that feature, the most recent instance is used. From the above example, the reference `CIR1.X` would be the same as `CIR1[5].X`, since the fifth instance would be the most recent instance of the object.

You can use expressions within the square brackets of an array expression:

`CIR1[3].` X and `CIR1[2+1].` X would therefore be equivalent.

This next example uses two While / End While loop command blocks. The first block executes the CIR1 circle five times. The second block uses the V1 variable inside of square brackets, like this, `CIR1[V1].XYZ`, to send the measured centroid of each of the five executions to the Report window:

```
            ASSIGN/V1=1
            WHILE/V1<6
CIR1         =FEAT/CIRCLE,CARTESIAN,IN,LEAST_SQR
              THEO/<40,30,-4.824>,<0,0,1>,30
              ACTL/
<40.002,29.991,-4.836>,<0,0,1>,29.982
              MEAS/CIRCLE,4,ZPLUS
                HIT/
BASIC,NORMAL,<41.984,44.868,-2.885>,<-0.132272,-0.9912
135,0>,<41.972,44.85,-2.891>,USE THEO=YES
                HIT/
BASIC,NORMAL,<51.721,39.36,-5.094>,<-0.781412,-0.62401
55,0>,<51.706,39.375,-5.107>,USE THEO=YES
                HIT/
BASIC,NORMAL,<54.792,32.491,-5.44>,<-0.9861119,-0.1660
821,0>,<54.775,32.474,-5.453>,USE THEO=YES
                HIT/
BASIC,NORMAL,<52.526,21.748,-5.879>,<-0.8350841,0.5501
223,0>,<52.537,21.764,-5.893>,USE THEO=YES
              ENDMEAS/
              ASSIGN/V1=V1+1
            END_WHILE/
            ASSIGN/V1=1
            WHILE/V1<6
              COMMENT/REPT,
              "Centroid of CIR1, instance #" + V1
              CIR1[V1].XYZ
              COMMENT/REPT,
              --------------------
              ASSIGN/V1=V1+1
            END_WHILE/
```

Here is the generated output to the Report window:

Pc	PART NAME : Top Holes - Concentric		May 23, 2022 15:25
	REV NUMBER : Rev1	SER NUMBER : 12345	STATS COUNT : 1

```
Centroid of CIR1, instance #1
<39.994, 30.016, -4.833>
--------------------
Centroid of CIR1, instance #2
<40.039, 30.011, -4.821>
--------------------
Centroid of CIR1, instance #3
<40.032, 30.013, -4.819>
--------------------
Centroid of CIR1, instance #4
<39.991, 30.013, -4.819>
--------------------
Centroid of CIR1, instance #5
<40.016, 30.003, -4.83>
--------------------
```

Arrays also exist on dimensions and alignments that have been executed multiple times in a given execution run. Thus, `Dim1[2].` Nom and `Align1[4].` Origin would be available given that the Dimension "Dim1" has executed at least twice and the alignment "Align1" has executed at least four times.

If a feature array reference is out of bounds (for example, the user asks for `CIR1[2.5]` or `CIR1["Hello, World"]`) the upper or lower bound item is returned. If `CIR1` had 3 instances, then `CIR1[4]` and above would return the value for `CIR1[3],` and `CIR1[0]` and below would return the value for `CIR1[1]` . All expressions between square brackets are coerced to integer, thus 2.5 would become 2 and "Hello World" would become 0.

Array Indices Object

By default, feature arrays are always one-dimensional arrays. If it is more convenient to treat a feature array as a multi-dimensional array, you can do this with an array indices object.

The array indices object allows you to specify upper and lower bounds for multiple array dimensions.

- When you set the upper and lower bounds of the first dimension, PC-DMIS creates a two dimensional array where the first dimension is bound and the second dimension is unbound.
- When you set the upper and lower bounds of the first two dimensions of an array, PC-DMIS creates a three dimensional array. The last dimension is always unbound.

Suppose feature F1 is located inside a nested WHILE loop. The inner WHILE loop executes five times and the outer WHILE loop executes three times. At completion of execution, F1 has been executed 15 times and so 15 instances of F1 exist.

Consider the following example measurement routine segment:

```
ARRAY_INDICES/1..5,..

ASSIGN/V1=1

WHILE/V1<=3

     ASSIGN/V2=1

     WHILE/V2<=5

          F1=FEAT/POINT,RECT

          THEO/V2,V1,0,0,0,1

          ACTL/1,1,0,0,0,1

          MEAS/POINT,1

          HIT/BASIC,V2,V1,0,0,0,1,1,1,0

          ENDMEAS/

          ASSIGN/V2=V2+1

          COMMENT/REPT,"Location of
         F1["+V2+","+V1+"] :"+F1[V2,V1].XYZ

     END_WHILE/

     ASSIGN/V1=V1+1

END_WHILE/
```

This code segment creates a 3 X 5 grid of 15 measured points.

The array indices command has limited the first dimension of the feature array to be between 1 and 5 inclusively. Thus on the inspection report, instead of appearing as F1[1] – F1[15], the objects appear as F1[1, 1] – F1[5, 3], more consistent with the layout of the features. Notice that the comment also refers to the feature array using a two dimensional array syntax.

To insert an array indices object in a measurement routine:

1. Using the keyboard, type "**Array**" on an empty line in the Edit window.
2. Press the Tab key on your keyboard.

If you clear the **Display Brackets for Feature Arrays** check box, the feature will not appear with the bracketed name. See the "Display Brackets for Feature Arrays" description in the "Setup Options ID Setup Tab" topic of the "Setting Your Preferences" chapter.

Hit Arrays

The hits of a given feature are available as an array and can be accessed via expressions using array syntax of the form <FeatID>.Hit[<Array Expression>].<Extension> or the form <FeatID>.RawHit[<Array Expression>].<Extension>. Hit returns probe compensated data when probe compensation is on. RawHit always returns uncompensated data. Valid extensions are X, Y, Z, I, J, K, TX, TY, TZ, TI, TJ, TK, XYZ, TXYZ, IJK, and TIJK

```
Circle1. Hit [1]. XYZ
```
The measured centroid (probe compensated) of hit 1 of "Circle1".

```
Circle1. Hit [2]. IJK
```
The measured vector of hit 2 of "Circle1"

Hit data is available for all objects that have hits, whether the actual hits are displayed in the Edit window or not. Thus, hits can be obtained for scans and Auto features.

Using Hit Arrays to Define Constructed Feature Inputs

You can use Hit arrays to define the inputs for constructed features.

For constructed features, when you use the feature.HIT[start..end] or feature.HITS[start..end] methods, the start and end properties are optional:

- If the start value is not defined, PC-DMIS assumes it to be the value of "1".
- If the end value is not defined, PC-DMIS assumes it to be the total number of hits for the feature.

This is the same if you entered "feature.NUMHITS".

These examples show three different ways to use the same hits from CIR1:

Example 1

In this example, the start and end values are explicitly defined:

```
CIR3    =FEAT/CIRCLE,CARTESIAN,IN,NO
         THEO/
<20.97629,22.90352,0>,<0,0,-1>,20.97629
         ACTL/
<20.96578,22.89023,-0.01243>,<0,0,-1>,20.96578
         CONSTR/
CIRCLE,REV,CIR1.HIT[1..CIR1.NUMHITS]
```

Example 2

In this example, only the start value of "1" is defined. Since the end value is not defined, PC-DMIS defines the end value as "CIR1.NUMHITS":

```
CIR3    =FEAT/CIRCLE,CARTESIAN,IN,NO
         THEO/
<20.97629,22.90352,0>,<0,0,-1>,20.97629
         ACTL/
<20.96578,22.89023,-0.01243>,<0,0,-1>,20.96578
         CONSTR/CIRCLE,REV,CIR1.HIT[1..]
```

Example 3

In this example, neither the start nor end values are defined. Because of this, PC-DMIS defines the start value as "1" and the end value as "CIR1.NUMHITS":

```
CIR3    =FEAT/CIRCLE,CARTESIAN,IN,NO
         THEO/
<20.97629,22.90352,0>,<0,0,-1>,20.97629
         ACTL/
<20.96578,22.89023,-0.01243>,<0,0,-1>,20.96578
         CONSTR/CIRCLE,REV,CIR1.HIT[..]
```

The following sections describe some additional array functions that are useful for finding the minimum or maximum points in a scan:

Assigning a Range of Hits to an Array

You can also assign a range of hits to an array by using this syntax:

<Feature Id>.<Hittype>[<Startnum>..<Endnum>].<Extension>

where

<Feature Id> is the name of the feature.

<Hittype> can be either the word "HIT" for compensated data or "RAWHIT" for uncompensated data. If probe compensation is turned off, the returned values are always uncompensated.

<Startnum> is an expression that identifies the first index value of the range of hits.

<Endnum> is an expression that identifies the second index value of the range of hits.

<Extension> identifies the type of data. Possible extensions include the measured or theoretical data types listed in the next section.

Example of how to use implied Start and End values in an expression.

Suppose you want to find all the hit points that define a plane (PLN1). You can write it out this way:

```
PLN1.HIT[1..PLN1.NUMHITS]
```

A shorter way to do this is to use inferred Start and End hit values. You can write the same code this way:

```
PLN1.HIT[..]
```

In this case, since we did not define the Start and End hit values, PC-DMIS assumes the Start hit value to be 1 and the End hit value to be NUMHITS.

Measured

- X – Measured X values of the hits
- Y – Measured Y values of the hits
- Z – Measured Z values of the hits
- XYZ – Measured XYZ values of the hits
- I – Measured I values of the hits
- J – Measured J values of the hits
- K – Measured K values of the hits

- IJK – Measured IJK values of the hits

Theoretical

- TX – Theoretical X values of the hits
- TY – Theoretical Y values of the hits
- TZ – Theoretical Z values of the hits
- TXYZ – Theoretical XYZ values of the hits
- TI – Theoretical I values of the hits
- TJ – Theoretical J values of the hits
- TK – Theoretical K values of the hits
- TIJK – Theoretical IJK values of the hits

For example:

```
ASSIGN/V1=SCAN1. HIT [1..10]. X
```
V1 is assigned to an array of 10 values, which are the measured X values from the first 10 hits of SCAN1.

```
ASSIGN/V2=SCAN1. HIT [1..SCAN1.NUMHITS]. XYZ
```
V2 is assigned to an array of points from each of the centroids of the hits in the scan.

Sorting Arrays

PC-DMIS allows you to sort arrays in either ascending or descending order. The following two expressions take an array and return a sorted array:

To sort in *ascending* order use:
```
SORTUP (<array>)
```

To sort in *descending* order use:
```
SORTDOWN (<array>)
```

For example:

```
ASSIGN/V1= ARRAY (5,8,3,9,2,6,1,7)
```
V1 is assigned the array of "5,8,3,9,2,6,1,7".

```
ASSIGN/V2= SORTUP (V1)
```
V2 will hold the array values sorted in ascending order: "1,2,3,5,6,7,8,9".

```
ASSIGN/V3= SORTDOWN (V1)
```
V3 will hold the array values sorted in descending order: "9,8,7,6,5,3,2,1".

Returning the Greatest or Least Index Values from an Array

You can input an array into a function and return the index number of the element that has the greatest or the least value by using these functions:

To return the index value of the element with the *greatest* value, use:

```
MAXINDEX (<array>)
```

To return the index value of the element with the *least* value, use:

```
MININDEX (<array>)
```

For example,

```
ASSIGN/V1= ARRAY (5,8,3,9,2,6,1,7)
```
V1 is assigned the array of "5,8,3,9,2,6,1,7".

```
ASSIGN/V2= MAXINDEX (V1)
```
V2 will hold the array's index value of 4. The actual value of that array element is 9.

```
ASSIGN/V3= MININDEX (V1)
```
V3 will hold the array's index value of 7. The actual value of that array element is 1.

You can then use returned index values to get the actual array element value.

Returning Sorted Index Values from an Array

You can input an array into a function, sort the array's values in ascending or descending order, and then return the index values by using these functions:

To return the array's index positions in order of their values sorted from greatest to least use:

```
MAXINDICES (<array>)
```

To return the array's index positions in order of their values sorted from least to greatest use:

```
MININDICES (<array>)
```

For example:

```
ASSIGN/V1= ARRAY (4,8,2,9,5,7)
```
V1 is assigned the array of "4,8,2,9,5,7".

```
ASSIGN/V2= MAXINDICES (V1)
```
V2 will hold an array with these values: "4,2,6,5,1,3".

```
ASSIGN/V3= MININDICES (V1)
```
V3 will hold an array with these values: "3,1,5,6,2,4".

Example of Using Array Functions to Find the Minimum and Maximum Points in a Scan

The main purpose of the hit array functions discussed above is to give you an easy way to find the minimum and maximum points in a scan.

To dimension the point from SCAN1 that has the greatest measured X value, you could use this expression:

```
ASSIGN/MAXPTINDEX=MAXINDEX(SCAN1.HIT[1..SCAN1.NUMHITS].X)

D1=LOCATION OF FEATURE SCAN1.HIT[MAXPTINDEX]
```

To find the three highest points in the Z axis of SCAN2, you could use this expression:

```
ASSIGN/MI=MAXINDICES(SCAN2.HIT[1..SCAN2.NUMHITS].Z)

ASSIGN/
THREEPOINTS=ARRAY(SCAN2.HIT[MI[1]].XYZ,SCAN2.HIT[MI[2]].XYZ
,SCAN2.HIT[MI[3]].XYZ)
```

Variable Arrays

Variable arrays do not need to be declared. Variable arrays come into existence via the assign statement when the expression on the right hand side of the assign statement evaluates to an array or when the left hand side of the assign statement refers to an element in a variable array.

`ASSIGN/V1=Array(3,4,5,6,7)`
Creates 5 element array and assigns it to V1.

`ASSIGN/V2=V1[3]`
Assigns V2 the value of the third element in array V1: 5.

`ASSIGN/V1[4]=23`
Assigns 4th element of array V1 to 23.

Arrays are created and allocated dynamically. Thus an array can be created by using an array reference on the left hand side of an assign statement.

`ASSIGN/V3[5]=8`
Dynamically creates array with 5th element set equal to 8.

When referencing an array element that has never received a value, the array expression will evaluate to 0.

```
ASSIGN/V3[5]=8
```

```
ASSIGN/V4=V3[5]
```
V4 is set equal to the value 8.

```
ASSIGN/V5=V3[6]
```
If the sixth element of V3 has never been set, V5 is set equal to 0.

Like other array types, expressions can be used within the square brackets.

```
ASSIGN/V3[5]=8
```

```
ASSIGN/V4=V3[2+3]
```
V4 is set equal to the value 8.

Variable arrays can have multiple dimensions.

```
ASSIGN/V6= Array ( Array (4,7,2), Array (9,2,6))
```
V6 is set to a 2 by 3 dimensional array where V6[1, 1] equals 4, V6[1, 2] equals 7, V6[1, 3] equals 2, V6[2, 1] equals 9, V6[2,2] equals 2, and V6[2,3] equals 6.

```
ASSIGN/V7=V6[2,1]
```
V7 is set to the value 9.

Variable arrays can have negative indexes:

```
ASSIGN/V8[-3]=5
```
The –3rd index of array V8 is set to 5.

Array assignment will overwrite previous values:

```
ASSIGN/V8="Hello"
```
The variable V8 is equal to the string "Hello"

```
ASSIGN/V8[2]=5
```
V8 is no longer of type string, but of type array, the second element of which has a value of 5.

```
ASSIGN/V8=9
```
V8 is no longer an array, but an integer of value 9.

Arrays can be made up of multiple types:

```
ASSIGN/V9= Array ("Hello",3,2.9,{FEAT1})
```
Creates array V9 with four elements. The first element is a string, the second

element is an integer, the third element is a real number, and the fourth element is a pointer to FEAT1.

Arrays can be increased in size to include more elements:

```
ASSIGN/V10=ARRAY(3,1,5)
```

```
ASSIGN/V10[ LEN (V10)+1]=7
```

The first statement creates an initial array V10 with three elements (3,1, and 5). The second statement then grows the array in V10 by one element and gives the final element a value of 7.

Operators for Expressions

The following basic operators are available inside PC-DMIS:

+ Addition: <*Expression*> + <*Expression*>

Adds the two expressions together. In the case of strings, strings are concatenated.

- Subtraction: <*Expression*> - <*Expression*>

Subtracts the second expression from the first expression.

***** Multiplication: <*Expression*> * <*Expression*>

Multiplies the two expressions.

/ Division: <*Expression*> / <*Expression*>

Divides first expression by the second expression.

^ Exponentiation: <*Expression*> ^ <*Expression*>

Raises the first expression to the power of the second expression.

% Modulo: <*Expression*> % <Expression>

Returns the remainder of one expression divided by the other.

- Additive Inverse -<*Expression*>

Returns the additive inverse of the expression.

! Logical Not: *!*<*Expression*>

Returns the logical not of the expression.

== Equal To: <*Expression*> == <*Expression*>

Evaluates to 1 if expressions are equal. Otherwise, it evaluates to 0. (Two equal signs are used to distinguish from the assignment operator = in the assignment statement).

<> Not Equal To*:* <*Expression*> <> <*Expression*>

Evaluates to 1 if expression are not equal. Otherwise, it evaluates to 0.

> Greater Than*:* <*Expression*> > <*Expression*>

Evaluates to 1 if first expression is greater than second expression. Otherwise, it evaluates to 0.

>= Greater Than or Equal To:<*Expression*> >= <*Expression*>

Evaluates to 1 if the first expression is greater than or equal to the second expression. Otherwise, it evaluates to 0.

< Less Than: <*Expression*> < <*Expression*>

Evaluates to 1 if first expression is less than the second expression. Otherwise, it evaluates to 0.

<= Less Than or Equal To: <*Expression*> <= <*Expression*>

Evaluates to 1 if the first expression is less than or equal to the second expression. Otherwise, it evaluates to 0.

AND Logical And: <*Expression*> *AND* <*Expression*>

Evaluates to 1 if both expressions does not evaluate to 0. Otherwise, it evaluates to 0.

OR Logical Or: <*Expression*> *OR* <*Expression*>

Evaluates to 1 if either expressions does not evaluate to 0. Otherwise, it evaluates to 0.

() Parenthesis: *(* <*Expression*> *)*

Gives evaluation to precedence to expression inside of parenthesis.

Precedence

Expressions are evaluated with the precedence shown below (listed from highest precedence to lowest precedence).

Highest Precedence

- Operands
- (unary minus), !, (), functions (such as ABS, COS, STR, LEN, CROSS, and so on.)

- ^
- *, /, %
- +, -
- ==, <>, <, <=, >, >=
- AND
- OR

Lowest Precedence

Functions

Functions are PC-DMIS specific expressions or user-defined expressions that usually take parameters and then return results. The parameters are substituted into the expression before the expression is evaluated.

Functions List

The following alphabetical list contains all the functions available to PC-DMIS's expression language.

- ABS (mathematical)
- ACOS (mathematical)
- ANGLEBETWEEN (point)
- ARCSEGMENTENDINDEX (miscellaneous)
- ARCSEGMENTSTARTINDEX (miscellaneous)
- ARRAY (array)
- ASIN (mathematical)
- ATAN (mathematical)
- CHR (string)
- CONCAT (string)
- COS (mathematical)
- CROSS (point)

- DEG2RAD (mathematical)
- DELTA (point)
- DIST2D (pointer)
- DIST3D (pointer)
- DOT (point)
- ELEMENT (string)
- EOF (miscellaneous)
- EOL (miscellaneous)
- EQUAL (array)
- EQUAL (string)
- EXP (mathematical)
- FORMAT (string)
- FUNCTION (function)
- GETCOMMAND (pointer)
- GETPROGRAMINFO (string)
- GETROTABDATA (miscellaneous)
- GETSETTING (string)
- GETTEXT (string)
- GETTRACEVALUE (string)
- IF (miscellaneous)
- INDEX (string)
- ISIOCHANNELSET (miscellaneous)
- LEFT (string)
- LEN (array)
- LEN (pointer)
- LEN (string)
- LINESEGMENTENDINDEX (miscellaneous)

- LINESEGMENTSTARTINDEX (miscellaneous)
- LN (mathematical)
- LOG (mathematical)
- LOWERCASE (string)
- MAX (array)
- MID (string)
- MIN (array)
- MPOINT (point)
- ORD (string)
- PCDMISAPPLICATIONPATH (string)
- PCDMISUSERHIDDENDATAPATH (string)
- PCDMISUSERVISIBLEDATAPATH (string)
- PCDMISSYSTEMHIDDENDATAPATH (string)
- PCDMISSYSTEMVISIBLEDATAPATH (string)
- PCDMISSYSTEMREPORTINGPATH (string)
- PROBEDATA (miscellaneous)
- QUALTOOLDATA (miscellaneous)
- RAD2DEG (mathematical)
- RIGHT (string)
- ROUND (mathematical)
- SETROTABDATA (miscellaneous)
- SIN (mathematical)
- SQRT (mathematical)
- SYSTEMDATE (string)
- SYSTEMTIME (string)
- SYSTIME (string)
- TAN (mathematical)

- TUTORELEMENT (miscellaneous)
- UNIT (point)
- UPPERCASE (string)

String Functions

The following functions are used with text strings.

CHR

Character Conversion: *CHR(<Integer>)*

This function returns a string, which consists of the character corresponding to the ASCII decimal value.

CONCAT

This function concatenates all of the strings specified in expressions 1 through N together into one string: `CONCAT (<expression1>, <expression2>, & <expressionN>)`

ELAPSEDEXECUTIONTIME

Formatted Elapsed Execution Time: *ELAPSEDEXECUTIONTIME()*

This function returns the time that has elapsed since the measurement routine or mini routine started to execute. The elapsed execution time is the time spent during the DCC portion of the execution; it does not track time for pauses due to the attention required by the user. Such pauses include execution pauses during comment execution or PC-DMIS messages, and error messages that may stop the execution altogether.

You can record the elapsed execution time at any point in the measurement routine or mini routine by assigning the function to a variable, such as:

```
ASSIGN/V1=ELAPSEDEXECUTIONTIME()
```

The default format of the returned time is "hh:mm:ss". You can measure the elapsed execution time in other formats as well:

- Use `ASSIGN/V1=FORMAT(ELAPSEDEXECUTIONTIME(),"hh:mm:ss")` or `ASSIGN/V1=ELAPSEDEXECUTIONTIME()` to get the time in hours, minutes, and seconds.
- Use `ASSIGN/V1=FORMAT(ELAPSEDEXECUTIONTIME(),"mm:ss")` to get the time in minutes and seconds.
- Use `ASSIGN/V1=FORMAT(ELAPSEDEXECUTIONTIME(),"ss")` to get the time in seconds.

ELEMENT

Delimited substring location: *ELEMENT(<Integer>, <String1>, <String2>)*

This function returns the nth substring (element) from string2 using string1 as the delimiting text that divides the elements in string2.

Suppose string2 is "6, 12, 8, 4, 5" and string1 is a comma character ",". The five elements that can be individually retrieved with the element command are "6", "12", "8", "4", and "5".

EQUAL

Case-insensitive string comparison: *EQUAL(<String1>, <String2>)*

This function compares two strings (ignoring the case) to determine if they are identical. It returns an integer set to 1 if the strings are the same, and 0 if they are not.

FORMAT

Format: FORMAT(<String>,<Integer,double, or point>)

This function takes two expressions and returns a formatted string similar to using the *sprintf* function inside C++.

- Expression 1 should be a *string* type that contains one or three format specifiers. If it is a different type, the expression evaluator attempts to coerce it to a string. The string should contain *one* format specifier if Expression 2 is an integer or double types and *three* format specifiers (see paragraphs below) if Expression 2 is a point type.
- Expression 2 is expected to be of type *integer*, *double*, or *point*. If a different type is used, the value of the expression is 0.

Format Specifier for FORMAT Function:

The format specifier should have the same syntax as a format specifier used in the *sprintf* function used in the C++ programming language.

A format specifier consists of optional and required fields and has the following syntax:

%[flags] [width] [.precision] type

Each field of the format specifier is either a single character or a number that signifies a particular format option. The simplest format specifier uses only the percent sign and a type character (for example, %d). If a percent sign is followed by a character that has no meaning as a format field, the character is copied to STDOUT. For example, to print a percent-sign character, use %%.

The optional flag, width, and precision fields, which appear before the type character, control other aspects of the formatting. These are described below:

flags

These *optional characters* control output justification and the printing of signs, blanks, decimal points, and octal or hexadecimal prefixes. More than one flag can appear in a format specifier.

Here are the possible flags:

–

Meaning: Left align the result within the given field width.

Default: Right align.

+

Meaning: Prefix the output value with a sign (+ or –) if the output value is of a signed type.

Default: Sign appears only for negative signed values (–).

0

Meaning: If the width is prefixed with 0, zeros are added until the minimum width is reached. If 0 and – appear, the 0 is ignored. If 0 is specified with an integer format (i, u, x, X, o, d) the 0 is ignored.

Default: No padding.

blank (' ')

Meaning: Prefix the output value with a blank if the output value is signed and positive; the blank is ignored if both the blank and + flags appear.

Default: No blank appears.

#

Meaning 1: When used with the o, x, or X type, the # flag prefixes any nonzero output value with 0, 0x, or 0X, respectively.

Default 1: No prefix appears.

Meaning 2: When used with the e, E, or f type, the # flag forces the output value to contain a decimal point in all cases.

Default 2: Decimal point appears only if digits follow it.

Meaning 3: When used with the g or G format, the # flag forces the output value to contain a decimal point in all cases and prevents the truncation of trailing zeros.

Default 3: Decimal point appears only if digits follow it. Trailing zeros are truncated. This is ignored when used with d, i, or u.

width

This second optional field, or argument, controls the minimum number of characters printed. It is a non-negative decimal integer.

- If the number of characters in the output value is less than the specified width, blanks are added to the left or the right of the values — depending on whether the – flag (for left alignment) is specified — until the minimum width is reached.
- If the width is prefixed with 0, zeros are added until the minimum width is reached (not useful for left-aligned numbers).
- The width specification never causes a value to be truncated. If the number of characters in the output value is greater than the specified width, or if the width is not given, all characters of the value are printed (subject to the precision specification listed below).

precision

This third optional field, or argument, specifies the number of characters to be printed, the number of decimal places, or the number of significant digits. Unlike the width specification, the precision specification can cause either truncation of the output value or rounding of a floating-point value. It is a non-negative decimal integer preceded by a period (.).

type

This required character determines whether the associated argument is an integer, a double, or a point. The list of available types includes:

d - signed decimal integer

i - signed decimal integer

o - unsigned octal integer

u - unsigned decimal integer

x - unsigned hexadecimal integer, using "abcdef"

X - unsigned hexadecimal integer, using "ABCDEF"

e - double in exponential form [-]d.dddd e [sign]ddd

E - same as e, except uses E to introduce the exponent

f - double with the form [-]dddd.dddd

g - formats to either the e or f format depending on which is more compact

G - same as g, except uses E to introduce the exponent

FORMAT Example

This example shows several statements using the FORMAT function inside a measurement routine:

`ASSIGN/ V1=PROBEDATA("OFFSET")`	V1 becomes type point representing the offsets of the current probe. Using the values from the measurement routine used for this example, V1 becomes: <-1.8898, 1.8898, 5.704>
`ASSIGN/V3=FORMAT("%.5f, %.5f,%.5f",V1)`	V3 becomes type string. The string is formatted using the point object of variable V1. V3 now has: -1.88976, 1.88976, 5.70403
`ASSIGN/V4=1.123456789`	V4 becomes type double.
`ASSIGN/V5=FORMAT("%.5f ",V4)+FORMAT("%.6f ",V4)+FORMAT("%.7f ",V4)+FORMAT("%.8f",V4)`	V5 becomes type string with this value: 1.12346 1.123457 1.1234568 1.12345679
`ASSIGN/V6A="The value of V4 is: "+FORMAT("%.8f",V4)`	V6A becomes type string with value of: The value of V4 is: 1.12345679
`ASSIGN/V6B=FORMAT("The value of V4 is: %.8f",V4)`	The expression result remains the same as V6A above.
`ASSIGN/V7=4444`	V7 becomes type double since all numbers are assumed double unless coerced to an integer.
`ASSIGN/ V8=FORMAT("%o",INT(V7))`	V8 becomes type string with this value: 10534
`ASSIGN/ V9=FORMAT("%u",INT(-1))`	V9 becomes type string with this value: 4294967295

`ASSIGN/ V10=FORMAT("%x",INT (2143))`	V10 becomes type string with this value: 85f
`ASSIGN/ V11=FORMAT("%X",INT (9567))`	V11 becomes type string with this value: 255F
`ASSIGN/ V12=FORMAT ("%e",0.0005432)`	V12 becomes type string with this value: 5.432000e-004
`ASSIGN/ V13=FORMAT ("%E",145.3421)`	V13 becomes type string with this value: 1.453421E+002
`ASSIGN/V14=FORMAT(", %6d,",INT(1))`	`V14 becomes type string with this value: ,     1,`
`ASSIGN/V15=FORMAT(", %-6d,",INT(1))`	`V15 becomes type string with this value: ,1     ,`

GETSETTING

This function allows you to return various settings of PC-DMIS based on the string parameter inserted.

GETSETTING(<*String*>)

You can use these string parameters:

- "DCC Mode" – Returns a 1 if PC-DMIS is in DCC Mode, 0 otherwise.
- "Manual Mode" – Returns a 1 if PC-DMIS is in Manual Mode, 0 otherwise.
- "Current Alignment" – Returns a string of the current alignment.
- "Current Workplane" – Returns a string of the current workplane.
- "Workplane Value" – Returns a numerical value of the current workplane.

- "PreHit" – Returns the current prehit value as a double precision number.
- "Retract" – Returns the current retract value as a double precision number.
- "Check" – Returns the current check value as a double precision number.
- "Touch Speed" – Returns the current Touch Speed value as a double precision number.
- "Move Speed" – Returns the current Move Speed value as a double precision number.
- "Fly Mode" – Returns a 1 if PC-DMIS uses the Fly Mode, 0 otherwise.
- "Ph9 present" – Returns a 1 if the Ph9/Ph10 is present, 0 otherwise.
- "Manual CMM" – Returns 1 if the CMM is a manual CMM, 0 otherwise.
- "LangStr(<Number or ID>)" – Returns a string from PC-DMIS's resources in the current language from a resource ID number or from one of these IDs:

  "Yes", "No", "Oper", "Rept", "Input", "Doc", "YesNo", "Readout", "Internal", "External", "Rect ", "Polr ", "Out", "In", "Least_Sqr", "Min_Sep", "Max_Insc", "Min_CircSc", "Fixed_Rad", "Workplane", "Xaxis", "YAxis", "ZAxis", "Xplus", "Xminus", "YPlus", "YMinus", "ZPlus", "ZMinus", "Point", "Plane", "Line", "Circle", "Sphere", "Cylinder", "Round_Slot", "Square_slot", "Cone", or "None".

  If the value you use is a positive number, PC-DMIS pulls the string from its resource.dll file. If you use a negative number, PC-DMIS pulls the string from its strings.dll file (the strings table).
- "Extended Sheet Metal" – Returns a 1 if the **Show Extended Sheet Metal Options** check box is selected inside the **Setup Options** dialog box, 0 otherwise.
- "LastHitMove(X)" – Returns the X value of the most recent HIT /BASIC or MOVE/POINT command. PC-DMIS must be in DCC Mode for this to work.
- "LastHitMove(Y)" – Returns the Y value of the most recent HIT/BASIC or MOVE/POINT command. PC-DMIS must be in DCC Mode for this parameter to work.
- "LastHitMove(Z)" – Returns the Z value of the most recent HIT/BASIC or MOVE/POINT command. PC-DMIS must be in DCC Mode for this parameter to work.

You can use the GETSETTING function to determine whether PC-DMIS is in Manual Mode or DCC Mode as shown below:

`ASSIGN/DCCMODEVAR=GETSETTING("DCC Mode")` - This gives the variable DCCMODEVAR the value of 1 if PC-DMIS is in DCC Mode, otherwise 0.

`ASSIGN/MANMODEVAR=GETSETTING("Manual Mode")` - This gives the variable MANMODEVAR the value of 1 if PC-DMIS is in Manual Mode, otherwise 0.

You can use the GETSETTING function to determine the current workplane as shown below:

`ASSIGN/WORKPLANE_ID=GETSETTING("Current Workplane")` - This gives the variable WORKPLANE_ID the string value of the current workplane (ZPLUS, ZMINUS etc.).

`ASSIGN/WORKPLANE_VALUE=GETSETTING("Workplane Value")` - This gives the variable WORKPLANE_VALUE a numerical value representing the workplane. The workplanes have these values associated with them: ZPLUS = 0, ZMINUS = 3, XPLUS = 1, XMINUS = 4, YPLUS = 2, or YMINUS = 5.

GETTEXT

This function returns the current text from the specified data field:

`GETTEXT (<String or Integer>,<Integer>,<Pointer>)`

This function has three fields.

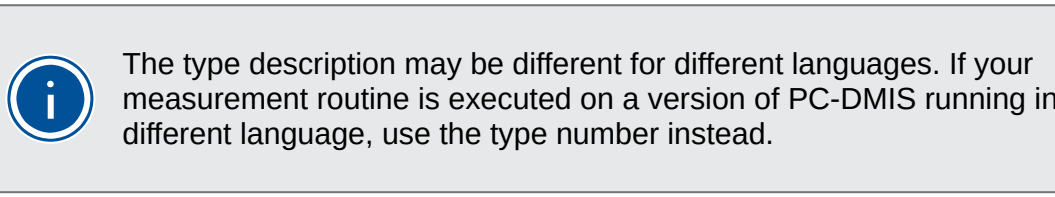
First Field—Data Field Number or Description

The first field can be either a string description of the data field, indicated by item (A) in the image below or the data field number, indicated in item (C) in the image below.

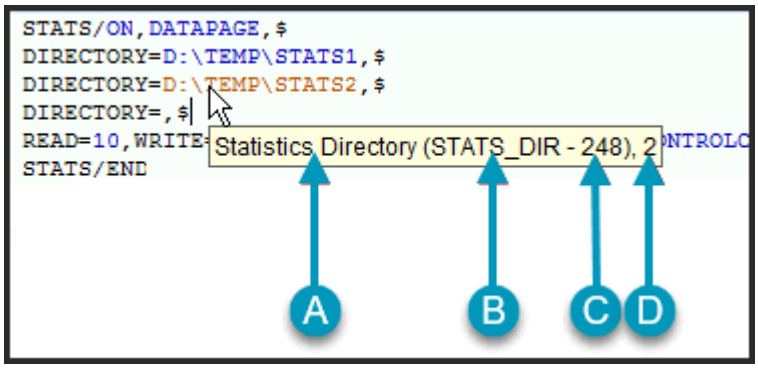
Item (B) in the image below is not used in this function but is sometimes used in automation or in report expressions.

To obtain these values:

1. Place PC-DMIS in Command Mode. Right-click anywhere in the Edit window. A shortcut menu appears.
2. From the shortcut menu, select **Change Pop-up Display** and then **Data Type Information**.
3. Position the mouse over a data field in the Edit window. The type description, type number, and type index for that data item display.



The type description may be different for different languages. If your measurement routine is executed on a version of PC-DMIS running in a different language, use the type number instead.



Sample Data Type Information Showing (A) Type Description, (B) Type String Identifier, (C) Type Number, and (D) Type Index

Second Field—Type Index

The second field is the type index, indicated as (D) in the above image. This field is usually zero unless you have more instances of the same type of field in the same command, such as multiple DIRECTORY fields shown in the above image. The correct value for this field can be obtained in the same manner as described for the first field.

Third Field—Command Pointer

The third field is a command pointer. It points to the command containing the field from which the text is being obtained. You can use the command pointer notation (i.e., {F15}) to specify this field, or you can use the GETCOMMAND expression as shown below:

`ASSIGN/V1=GETTEXT("Best Fit Math Type",0,{F15})` - This command assigns V1 the current value of the best fit math type toggle of feature F15.

`ASSIGN/V2=GETCOMMAND("Comment","TOP",1)` - V2 is assigned a pointer to the first comment from the top of the measurement routine.

`ASSIGN/V3=GETTEXT("Comment Type",1,V2)` - V3 is assigned the value of the Comment Type toggle field. If the first comment in the measurement routine is a comment to be displayed to the operator, the value of V3 will be the string "OPER".

See the "Pointer Functions" for information on the GETCOMMAND expression used for setting a pointer to a command.

GETTEXTEX

This function returns the current text from the specified data field:

`GETTEXTEX (<String or Integer>,<Integer>,<String>,<Pointer>)`

This function has four fields.

First Field—Data Field Number or Description

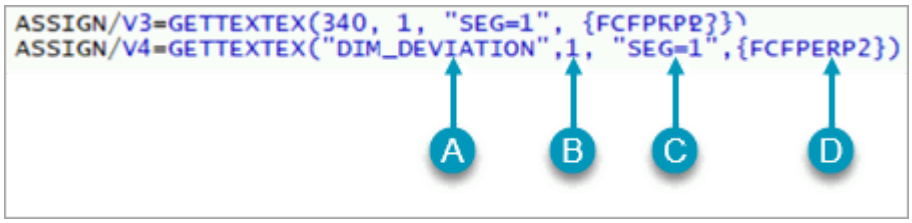
The first field can be either a string description of the data field or the data field number, indicated in item (A) in the image below.

> If you use the Type String Identifier instead of the Numeric Identifier (Item (A) in the image below), PC-DMIS will automatically convert it to the correct numeric value.
>
> For example, if you pass in the string identifier "DIM_DEVIATION", internally, PC-DMIS will convert it to the numeric value 340. When you then hover over the command in the Edit window, the pop-up command shows the text string as well as the actual numeric identifier value. In this example then, if you hover the cursor over the Edit window command, the command pop-up will show `(DIM_DEVIATION - 340), 1, SEG=1` .
>
> You can also just pass in the numeric value if known.

To obtain these values:

1. Place PC-DMIS in Command Mode and then right-click anywhere in the Edit window. A shortcut menu appears.
2. From the shortcut menu, select **Change Pop-up Display** and then **Data Type Information**.
3. Position the mouse over a data field in the Edit window. The type description, type number, and type index for that data item display. Hover over an Extended D_Type to show the content string after the colon.

The type description may be different for different languages. If your measurement routine is executed on a version of PC-DMIS running in a different language, use the type number instead.



*Sample Data Type Information Showing (**A**) Type String or Numeric Identifier, (**B**) Type Index, (**C**) Content String, and (**D**) Command Pointer*

Second Field - Type Index

The second field is the type index, indicated as B in the above image. This field is usually zero unless you have more instances of the same type of field in the same command, such as multiple DIRECTORY fields shown in the above image. You can

obtain the correct value for this field in the same manner as described for the first field.

Third Field—Content String

The third field is the content string of the extended D_TYPE, indicated as C in the image above.

Fourth Field—Command Pointer

The fourth field is a command pointer, indicated as D in the image above. It points to the command that the expression extracts data from. You can use either the command pointer notation (i.e., {FCFPERP2}) or the GETCOMMAND expression as shown below:

`ASSIGN/V1= GETTEXTEX ("DIM_DEVIATION",1,"SEG=1", {FCFPERP2})` - This command assigns V1 the current value of the deviation from feature 1, segment 1, dimension FCFPERP2.

See the "Pointer Functions" for information on the GETCOMMAND expression used for setting a pointer to a command.

The GETTEXTEX function adds support for the Extended DTypes which contain a CONTENT string. Currently, only the PC-DMIS Geometric Tolerance commands use Extended DTypes.

GETPROGRAMINFO

This function returns the measurement routine's information based on the parameters passed in: `GETPROGRAMINFO (<String>, <Optional String>)`

This function has at most two strings as parameters. For most items, you only need the first parameter. The string fields are not case sensitive.

First Field—String

The first field is a string input detailing what information to return.

CADMODELFILE - Returns the full path to the file name of the CAD model that you imported into the measurement routine.

CADMODELFILENAME - Returns the name of only the CAD model (not the path) that you imported into the measurement routine.

DATE - Returns the current date.

DRAWING - Like REVISION, this also returns the revision number as defined in the heading.

ELAPSEDTIME - Returns the time that has passed since the beginning of the execution.

FILENAME - Returns the measurement routine's file name (.prg).

NUMMEAS - Returns the number of dimensions executed.

NUMOOT - Returns the number of out of tolerance dimensions executed.

PARTNAME - Returns the part name as defined in the measurement routine header.

PARTPATH - Returns the full pathway to the measurement routine file.

PCDMISVERSION - Returns a string value of the actual installed version of the PC-DMIS software.

PRGSCHEMA - Returns an integer of the PC-DMIS schema number of the measurement routine file. This is an internal value used by PC-DMIS to indicate the commands and options that are serialized.

PRGVERSION - Returns a string value of the PC-DMIS version number of the measurement routine file. You can save a measurement routine file to be compatible with a specific version. For more information, see "Save As" in the "Using Basic File Options" chapter.

PROBEFILE - Returns the name of the current probe file in use.

REPORTNAME - Returns the current output file name.

REVISION - Returns the revision number as defined in the heading.

SERIALNUM - Returns the serial number as defined in the header.

SEQNUM - Like STATSCOUNT, this string also returns the current stats count number.

SHRINK - Returns the global scale factor.

STATSCOUNT - Returns the current stats count.

TEMP - Returns the temperature for the optional second input string. See "Second Field—Optional String" below.

TIME - Returns the current time.

TIPID - Returns the name of the current tip in use.

Second Field—Optional String

The second field is an optional string input. It's only needed if TEMP is used in the first input field. The possible strings below come from the Temperature Compensation command. For more information, see "Compensating For Temperature" in the "Setting Your Preferences" chapter.

HIGH_THRESHOLD - Returns the high threshold temperature

LOW_THRESHOLD - Returns the low threshold temperature

REF_TEMP - Returns the reference temperature

TEMPP - Returns the temperature for the part sensor

TEMPX - Returns the temperature for the X axis sensor

TEMPY - Returns the temperature for the Y axis sensor

TEMPZ - Returns the temperature for the Z axis sensor

Example

```
$$ NO, This code sample displays the number of total
dimensions and the number of out-of-tolerance dimensions.
      ASSIGN/V1=GETPROGRAMINFO("NUMMEAS")
      ASSIGN/V2=GETPROGRAMINFO("NUMOOT")
      COMMENT/REPT
      "Total Dimensions: "+V1
      "Total Out of Tolerance: "+V2
$$ NO,This code sample returns the temperature on the Z
sensor axis.
      ASSIGN/V3=GETPROGRAMINFO("TEMP", "TEMPZ")
      COMMENT/REPT
      "Temperature on the Z axis: "+V3
```

GETTRACEVALUE

Read Trace Value: *GETTRACEVALUE(<string>)*

This function takes a single string parameter. It returns a value from a `TRACEFIELD` command in the measurement routine.

<string> represents a case-sensitive string of the trace name whose value you want to return.

If you have multiple tracefields with the same trace name, this function returns the value of the most recent tracefield above this function. If a tracefield doesn't contain a value, this function returns a value of 0. In the example below, "Operator" is the tracefield name in the measurement routine:

```
ASSIGN/V2=GETTRACEVALUE("Operator")
```

INDEX

Substring Location*: INDEX(<String>, <String>)*

This function returns the location of the second string within the first string. The first letter of string is 1. A return value of zero indicates that the sub string is not found in the string.

For an example of this function, see the "Sample Code for Read Line" topic in the "Using File Input / Output" chapter.

LASTEXECUTIONTIME

Formatted Last Execution Time: *LASTEXECUTIONTIME()*

This function returns the last execution time that PC-DMIS recorded and stored in the <*name of measurement routine*>.MiniRoutines.xml file. The last execution time appears in the **Execution** dialog box. The time is returned in "hh:mm:ss" format.

LEFT

Left number of characters of a string: *LEFT(<String>, <n>)*

This function returns a string consisting of a number of left-most characters specified by the second expression (n) from the string specified in the first expression (String).

The first expression (String) is coerced to type string. The second expression (n) is coerced to type integer.

For an example of this function, see the "Sample Code for Read Line" topic in the "Using File Input / Output" chapter.

LEN

Length of string: *LEN(<String>)*

This function returns the number of characters of the string.

LOWERCASE

Create lowercase string: *LOWERCASE(<String>)*

This function returns a string that is the lowercase equivalent of the expression string.

MID

Middle n characters of a string: *MID(<String>, <Integer>, <Optional Integer>)*

This function returns a substring consisting of the characters of the string specified in the first parameter starting at the position specified by the second parameter for a length of n characters as specified by the third parameter. If the third parameter is not supplied, the rest of the string is returned.

For an example of this function, see the "Sample Code for Read Line" topic in the "Using File Input / Output" chapter.

ORD

Ordinal Conversion: *ORD(<String>)*

This function returns the integer ASCII value of first letter of the string (0-255).

PCDMISAPPLICATIONPATH

Full pathway display: PCDMISAPPLICATIONPATH*()*

This function returns the string value containing the full path to the application directory where PC-DMIS is installed. This directory contains the main executable and other necessary program files to run PC-DMIS.

PCDMISUSERHIDDENDATAPATH

Full pathway display: PCDMISUSERHIDDENDATAPATH*()*

This function returns the string value containing the full path of the hidden user data directory used by PC-DMIS. See "Understanding File Locations" for the files contained in this directory.

PCDMISUSERVISIBLEDATAPATH

Full pathway display: PCDMISUSERHIDDENDATAPATH*()*

This function returns the string value containing the full path of the visible user data directory used by PC-DMIS. See "Understanding File Locations" for the files contained in this directory.

PCDMISSYSTEMHIDDENDATAPATH

Full pathway display: PCDMISSYSTEMHIDDENDATAPATH*()*

This function returns the string value containing the full path of the hidden system data directory used by PC-DMIS. See "Understanding File Locations" for the files contained in this directory.

PCDMISSYSTEMVISIBLEDATAPATH

Full pathway display: PCDMISSYSTEMVISIBLEDATAPATH*()*

This function returns the string value containing the full path of the visible system data directory used by PC-DMIS. See "Understanding File Locations" for the files contained in this directory.

PCDMISSYSTEMREPORTINGPATH

Full pathway display: PCDMISSYSTEMREPORTINGPATH*()*

This function returns the string value containing the full path to the Reporting directory used by PC-DMIS. This directory contains the report and label templates used by the Report window.

RIGHT

Right n characters of string: *RIGHT(<String>, <Integer>)*

This function returns a string consisting of the n rightmost characters specified by integer from the string.

SYSTEMDATE

System Date: SYSTEMDATE(<Date Format String>)

This function returns the date-formatted string with the current date details filled in. For example, the command SYSTEMDATE("MM’/’dd’/’yy") returns the string "02/12/14" if the current date is February 12, 2014.

Use the following string elements to create the date string. Elements must be in the same case as shown below (MM instead of mm). Non-date characters (such as spaces) that appear between date format string elements appear in the output string in the same location as the input string. Characters in the input string delimited by single quotes appear in the same location in the output string without the single quotes.

d - Day of the month as digits. No leading zero for single-digit dates.

dd - Day of the month as digits. Leading zero used for single-digit dates.

ddd - Three-letter abbreviation for the day of the week.

dddd - Full name for the current day of the week.

M - Month as digits with no leading zeros for single-digit months.

MM - Month as digits with leading zero for single-digit months.

MMM - Month as three-letter abbreviation.

MMMM - Full name of month.

y - Year as digits with no leading zeros for single-digit years.

yy - Year as digits with leading zero for single-digit years.

yyyy - Year represented by four digits.

SYSTEMTIME

Formatted System Time: *SYSTEMTIME(<Time Format String>)*

This function returns the time-formatted string with the current time details filled in. For example, the command SYSTEMTIME("hh:mm:ss tt") returns the time in a formatted string, like this "11:29:40 PM".

Use the following string elements to create the time string. Elements must be in the same case as shown below (**tt** instead of **TT**). Non-time characters (such as spaces) appearing between time format string elements will appear in the output string in the

same location as the input string. Characters in the input string delimited by single quotes will appear in the same location in the output string without the single quotes.

h - Hours with no leading zero for single-digit hours; 12-hour clock

hh - Hours with leading zero for single-digit hours; 12-hour clock

H - Hours with no leading zero for single-digit hours; 24-hour clock

HH - Hours with leading zero for single-digit hours; 24-hour clock

m - Minutes with no leading zero for single-digit minutes

mm - Minutes with leading zero for single-digit minutes

s - Seconds with no leading zero for single-digit seconds

ss - Seconds with leading zero for single-digit seconds

t - One character time marker string, such as A or P

tt - Multi-character time marker string, such as AM or PM

SYSTIME

System Time: *SYSTIME()*

This function returns a string with the current system time. This function differs from the SYSTEMTIME function described above. It automatically returns the day, date, and time, followed by the year.

Example: "Wed February 12 13:50:21 2014"

The returned string, showing the current system time, is adjusted to local time zone settings.

UPPERCASE

Creates uppercase string: *UPPERCASE(<String>)*

This function returns a string that is the uppercase equivalent of string.

Mathematical Functions

ABS

Absolute Value: *ABS(<Double>)*

Returns the absolute value of the input.

EXP

Exponential: *EXP(<Double>)*

Returns the exponential of the expression.

LOG

Log Base 10: *LOG(<Double>)*

Returns the log base 10 of the expression.

LN

Natural Log: *LN(<Double>)*

Returns the natural logarithm of the expression.

ROUND

Rounding:*ROUND(<Double>)*

Returns the input rounded to the nearest integer.

SQRT

Square Root: *SQRT(<Double>)*

Returns the square root of the input.

Trigonometry Functions

By default, each of the trigonometry functions takes and returns radians. If you want values in degrees, use the RAD2DEG function described below.

ACOS

ArcCosine: *ACOS(<Double>)*

Returns the arc cosine of the expression. For example, ACOS(5.0) returns 0. In general, ACOS(<expression>) returns the arc cosine of the value of the expression.

ASIN

ArcSine: *ASIN(<Double>)*

Returns the arc sine of the input.

ATAN

ArcTangent: *ATAN(<Double>)*

Returns the arc tangent of the input.

COS

Cosine: *COS(<Double>)*

Returns the cosine of the input.

DEG2RAD

Degrees to Radians: *DEG2RAD(<Double>)*

Returns the input divided by 360 and multiplied by 2p. This converts from degrees to radians.

RAD2DEG

Radians to Degrees: *RAD2DEG(<Double>)*

Returns the input multiplied by 360 and divided by 2p. This converts from radians to degrees.

SIN

Sine: *SIN(<Double>)*

Returns the sine of the input.

TAN

Tangent: *TAN(<Double>)*

Returns the tangent of the input.

Functions where the input is out of range (like ACOS, ASIN, LOG, LN, SQRT and so on, that would cause the computer to crash) return 0.

Point Functions

ANGLEBETWEEN

Angle Between: *ANGLEBETWEEN(<vector>, <vector>)*

Returns the value of the angle in degrees between the two vectors. The two parameters must be expressions that evaluate to a vector type. To get the vector from a feature, for example, you need to use the feature ID followed by the .IJK extension. You can see this in the code snippet below:

```
F1          =GENERIC/POINT,DEPENDENT,CARTESIAN,$
             NOM/XYZ,<3,3,3>,$
             MEAS/XYZ,<3,3,3>,$
             NOM/IJK,<1,0,0>,$
             MEAS/IJK,<1,0,0>
F2          =GENERIC/POINT,DEPENDENT,CARTESIAN,$
             NOM/XYZ,<10,10,10>,$
             MEAS/XYZ,<10,10,10>,$
             NOM/IJK,<0,0,1>,$
             MEAS/IJK,<0,0,1>
             ASSIGN/V1=F1.IJK
             ASSIGN/V2=F2.IJK
             ASSIGN/V3=ANGLEBETWEEN(V1,V2)
             COMMENT/OPER,NO,FULL SCREEN=NO,AUTO-CONTINUE=NO,
             "The angle between "+V1+" and "+V2+" is: "+V3
```

CROSS

Cross Product: *CROSS(<Point>, <Point>)*

Return value is of type point and is the unit vector in the direction of the cross product of the first and second expressions.

DELTA

Vector Offset*: DELTA(<Point>, <Point>, <Double>)*

The function takes the first expression (Point) and calculates a new point in the direction of the second expression (vector) at an offset of the third expression. For example, `DELTA ( MPOINT (0,0,0), MPOINT (1,0,0),10)` returns the point 10,0,0.

DOT

Dot Product: *DOT(<Point>, <Point>)*

Returns the dot product of the two points (vectors).

UNIT

Unit Vector: *UNIT(<Point>)*

Returns the point divided by its length. For example, `UNIT ( MPOINT (0,0,0))` returns the point 0,0,1.

MPOINT

Point Coercion: *MPOINT(<Expression1>, <Expression2>, <Expression3>)*

Coerces the three expressions to a type Point as shown in this code snippet:

```
ASSIGN/V1= MPOINT (2.5,3.6,4)
```

Where:

V1.X = 2.5

V1.Y = 3.6

V1.Z = 4.0

See "Point Coercion".

Pointer Functions

DIST2D

2d Distance: DIST2D(<FEAT1>, <FEAT2>, <FEAT3>)

> The features must be inside curly braces.

This calculates the distance between the first two arguments in the command (Feat1 and Feat2), perpendicular to the third argument (Feat3).

- If the third argument is a plane, PC-DMIS calculates the distance between the first two arguments perpendicular to the plane.
- If the third argument is a line or cylinder, PC-DMIS calculates the distance between the first two arguments perpendicular to the third argument in the active workplane.

For example, if you have the XY plane as your third argument, it will have a Z+ vector (0,0,1) and the distance reported will only be in the Z axis.

Example

```
ASSIGN/V3=DIST2D({CIR1},{CIR2},{PLN1})
            COMMENT/OPER,NO,FULL SCREEN=NO,AUTO-CONTINUE=NO,
            V3
```

DIST3D

3D Distance: DIST3D(<FEAT1>, <FEAT2>)

Calculates the 3D distance between Feat1 and Feat2.

> The features must be inside curly braces.

Example

```
ASSIGN/V3=DIST3D({CIR1},{CIR2})
            COMMENT/OPER,NO,FULL SCREEN=NO,AUTO-CONTINUE=NO,
            V3
```

GETCOMMAND

Obtains a pointer to the command specified by the parameters:
`GETCOMMAND (<Integer or String>, <String>,<Integer>`

First Parameter-Command Info Field

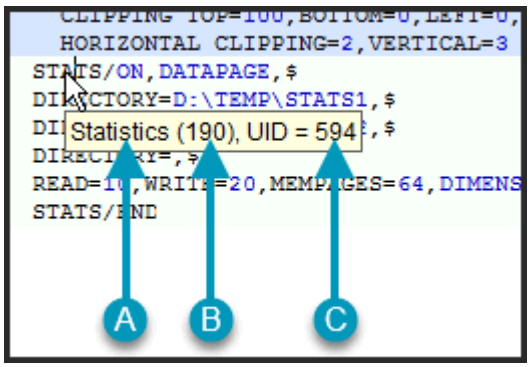
The first parameter is the command info field. It specifies the command type for which to search. The following can be passed in:

- A command description string. See (A) in the graphic below.
- A command type number. See (B) in the graphic below.
- The unique number identifier. See (C) in the graphic below.

If the unique id of the command is passed in, no other arguments are necessary.

To obtain the command description string, the command type number, and the command's unique number identifier:

1. Right-click in the Edit window
2. Choose **Change Pop-up Display | Command Information** (PC-DMIS must be in Command Mode).
3. Position the mouse over the desired command. PC-DMIS displays the command description, type number, and unique number identifier for that command in the pop-up.



A. *Command Description String*

B. *Command Type Number*

C. *Unique Number Identifier (UID)*

Second Parameter - Search Direction

The second parameter is the search direction. Legal values include:

Value	Description
UP	This value signifies that the search should start at the current command and proceed upwards
DOWN	This value signifies that the search should start at the current command and proceed downwards.
TOP	This value signifies that the search should begin at the start of the measurement routine in a downwards direction
BOTTOM	This value signifies that the search should begin with the last object in the measurement routine in an upwards direction

Third Parameter - Which Instance to Find

The third parameter indicates which instance of the command should be found if multiple instances of the same command are in the measurement routine.

If the measurement routine has two instances of a STATS/ON command and you would like to obtain a pointer to the second instance from the top, pass in " 2 " as the third parameter and pass in " TOP " as the second parameter as shown here.

```
ASSIGN/V1= GETCOMMAND ("Statistics", "TOP" ,2)
```

You can use the GETCOMMAND function to supply the third parameter to the GETTEXT string function. See "String Functions" for information on GETTEXT.

LEN

Pointer loop count: *LEN(<POINTER>)*

Returns the number of times a pointer has been in a loop. For example, if feature CIR1 is in a loop that iterates 10 times, you can store how many times CIR1 has been measured in a variable with an `ASSIGN` statement like this: `ASSIGN/V1= LEN ({CIR1})`

Array Functions

ARRAY

Create Array: *ARRAY(<EXPRESSION1>, <EXPRESSION2>, <EXPRESSION3>, …)*

Creates an array object with the array elements indicated by the expression parameters. The array elements are numbered with a base index of 1.

AVERAGE

Average array elements: *AVERAGE(<ARRAY>)*

Returns the average value of elements in the array.

EQUAL

Element by Element Array Comparison: *EQUAL(<ARRAY>, <ARRAY>)*

Compares the two arrays, element by element, to determine if the arrays hold the same elements. If the two arrays are not the same size, or if any of the elements in one array do not match the corresponding element in the other array, the function returns 0. Otherwise, the function returns 1.

LEN

Array element count: *LEN(<ARRAY>)*

Returns the number of elements in the array.

MAX

Largest array element: *MAX(<ARRAY>)*

Returns the largest element in the array. Items in the array are compared numerically or alphabetically.

MIN

Smallest array element: *MIN(<ARRAY>)*

Returns the smallest element in the array. Items in the array are compared numerically or alphabetically.

SUM

Sum array elements: *SUM(<ARRAY>)*

Returns the sum of elements in the array.

Miscellaneous Functions

ARCSEGMENTENDINDEX

This function returns the index number of the ending point of a specified arc segment from a scan: ARCSEGMENTENDINDEX*(<ID>, <index>,<tol1>,<tol2>)*

<ID> - The first parameter is a string value of the ID of the scan on which this function pulls out the index number of the ending point for the arc. This parameter can either be the ID in quotation marks or any expression that when coerced to type string ends up being the ID of a scan.

<index> - The second parameter is the index number for the arc from which you want to get the ending point number. This is a one-based value. For example, the arc index number would be 3 if you want the ending point number for the third arc in the scan.

<tol1> - The third parameter is the general feature tolerance. It is a maximum form error used to break up the scan into lines and arcs.

<tol2> - The fourth parameter is the refine tolerance. Generally, this tighter tolerance is used to drop points from either end of the feature until the form error of the segment is within this tolerance.

Once you have the Start and End indices for an arc, you can use these points inside a constructed feature to construct a separate arc feature. For a similar example, see "Example of a Line Feature Created from a Scan Segment".

ARCSEGMENTSTARTINDEX

This function returns the index number of the starting point of a specified arc segment from a scan: ARCSEGMENTSTARTINDEX*(<ID>, <index>,<tol1>,<tol2>).*

<ID> - The first parameter is a string value of the ID of the scan on which this function pulls out the index number of the start point for the arc. This parameter can either be the ID in quotation marks or any expression that when coerced to type string ends up being the ID of a scan.

<index> - The second parameter is the index number for the arc from which you want to get the start point number. This is a one-based value. For example, the arc index number would be 3 if you want the start point number for the third arc in the scan.

<tol1> - The third parameter is the general feature tolerance. It is a maximum form error used to break up the scan into lines and arcs.

<tol2> - The fourth parameter is the refine tolerance. Generally, this tighter tolerance is used to drop points from either end of the feature until the form error of the segment is within this tolerance.

There are two additional parameters, which control whether an identified arc segment in a scan is acceptable. These can only be changed with the PC-DMIS Settings Editor. Any arc segment with a radius less than the value for the `MinimumArcSegmentRadiusInMM` entry is rejected. The default value for this parameter is 2 mm. Similarly, any arc segment with a radius greater than the value for the `MaximumArcSegmentRadiusInMM` entry is rejected. The default value for this parameter is 2000 mm (it should not be necessary to change this value).

Once you have the Start and End indices for an arc, you can use these points inside a constructed feature to construct a separate arc feature. For a similar example, see "Example of a Line Feature Created from a Scan Segment".

EOF and EOL

For information on these functions, see "Checking for the End of a File or the End of a Line" in the "Using File Input / Output" chapter.

FUNCTION

Creates a function: FUNCTION*((<PARAM1>, <PARAM2>…), <EXPRESSION>)*

Creates a function that takes the number of parameters indicated by the parameter list and substitutes those parameters into the expression.

- The first item when using the `FUNCTION` keyword is the parameter list.
- This list consists of parameter names separated by commas.
- The parameter list is also surrounded by parenthesis.
- The second item is the expression.
- The expression contains the parameter names where the parameters should be substituted when the function is called.

For an example, see the "Generic Function Example" topic.

GETROTABDATA

This function returns the center, angular position, and vector values for the specified rotary table.

GETROTABDATA(<*PARAMETER*>[,<*TABLE*>])

The function returns the values for the following configurations:

- Single rotary table
- Dual (independent) rotary tables
- Stacked rotary tables

The data that the function returns matches the data in the **Rotary Table Setup** dialog box (**Edit | Preferences | Rotary Table Setup**). For more information about this dialog box, see "Defining the Rotary Table".

CENTER

- "CENTER" - Returns the rotary table's current XYZ center.
- "CENTER","V" - Returns the current XYZ center for rotary table V in a dual-table or stacked-table configuration.
- "CENTER","W" - Returns the current XYZ center for rotary table W in a dual-table or stacked-table configuration.

Examples:

`ASSIGN/ V1=GETROTABDATA("CENTER")`	V1 is set to the rotary table's current XYZ center.
`ASSIGN/ V1=GETROTABDATA("CENTER","V")`	V1 is set to the current XYZ center for rotary table V.
`ASSIGN/ V1=GETROTABDATA("CENTER","W")`	V1 is set to the current XYZ center for rotary table W.

ANGULAR POSITION

- "ANGLE" - Returns the rotary table's current angular position.
- "ANGLE","V" - Returns the current angular position for rotary table V in a dual-table or stacked-table configuration.
- "ANGLE","W" - Returns the current angular position for rotary table W in a dual-table or stacked-table configuration.

Examples:

`ASSIGN/ V2=GETROTABDATA("ANGLE")`	V2 is set to the rotary table's current angular position.
`ASSIGN/ V2=GETROTABDATA("ANGLE","V")`	V2 is set to the current angular position for rotary table V.
`ASSIGN/ V2=GETROTABDATA("ANGLE","W")`	V2 is set to the current angular position for rotary table W.

VECTOR

- "VECTOR" - Returns the rotary table's current IJK vector.
- "VECTOR","V" - Returns the current IJK vector for rotary table V in a dual-table or stacked-table configuration.
- "VECTOR","W" - Returns the current IJK vector for rotary table W in a dual-table or stacked-table configuration.

Examples:

`ASSIGN/ V3=GETROTABDATA("VECTOR")`	V3 is set to the rotary table's current IJK vector.
`ASSIGN/ V3=GETROTABDATA("VECTOR","V")`	V3 is set to the current IJK vector for rotary table V.
`ASSIGN/ V3=GETROTABDATA("VECTOR","W")`	V3 is set to the current IJK vector for rotary table W.

The [TABLE] argument is optional. If you do not specify table V or W, PC-DMIS does one of the following:

- If you are using a single-table or stacked-table configuration, it returns the values for rotary table W.
- If you are using a dual-table configuration, it returns the values for the rotary table that is activated on the **Active Rotary Table** toolbar. For more information about the toolbar, see "Active Rotary Table Toolbar".

PC-DMIS has two internal table definitions to accommodate dual-table and stacked-table configurations. For a single-table configuration, the second table definition is not actually used. Because it does exist internally, an error will not occur if you specify table V in a single-table configuration; however, this is not recommended. The values that the function returns are not generally useful because the table does not actually exist.

IF

Conditional expression evaluation: IF*(<EXPRESSION1>, <EXPRESSION2>, <EXPRESSION3>)*

If expression1 evaluates to true (non-zero), then this function returns the value of expression2; otherwise, this function returns the value of expression3.

ISIOCHANNELSET

This expression takes two parameters. The first parameter indicates which I/O channel will be checked (the range of numbers that is available is based on the machine being used). The second parameter determines whether the software will query the Arm1 or Arm2 machine. If the second parameter is set to 1 (one), it will query the Arm2 controller. If the second parameter is not present (or is set to zero), then the IO Channel will query the Arm1 controller. The Arm1 controller is your only option if you are not in multiple arm mode.

If an invalid probe data type, tip id, probe file name, or channel number is supplied, the expression evaluates to 0.

Example:

`ASSIGN/ V4= ISIOCHANNELSET (3,0)`	V4 will equal 1 (evaluate to true) when the channel is set, otherwise it will equal 0 (evaluate to false).

LINESEGMENTENDINDEX

This function returns the index number of the ending point of a specified line segment from a scan: LINESEGMENTENDINDEX*(<ID>, <index>,<tol1>,<tol2>).*

<ID> - The first parameter is a string value of the ID of the scan on which this function pulls out the index number of the ending point for the line segment. This parameter can either be the ID in quotation marks or any expression that when coerced to type string ends up being the ID of a scan.

<index> - The second parameter is the index number for the line segment from which you want to get the end point number. This is a one-based value. For example, the line segment index number would be 3 if you want the end point number for the third line in the scan.

<tol1> - The third parameter is the general feature tolerance. It is a maximum form error used to break up the scan into lines and arcs.

<tol2> - The fourth parameter is the refine tolerance. Generally, this tighter tolerance is used to drop points from either end of the feature until the form error of the segment is within this tolerance.

Once you have the Start and End indices for a line segment, you can use these points inside a constructed feature to construct a separate line feature. For an example, see "Example of a Line Feature Created from a Scan Segment".

LINESEGMENTSTARTINDEX

This returns the index number of the starting point of a specified line segment from a scan: LINESEGMENTSTARTINDEX*(<ID>, <index>,<tol1>,<tol2>).*

<ID> - The first parameter is a string value of the ID of the scan on which this function pulls out the index number of the start point for the line segment. This can either be the ID in quotation marks or any expression that when coerced to type string ends up being the ID of a scan.

<index> - The second parameter is the index number for the line segment from which you want to get the start point number. This is a one-based value. For example, the line segment index number would be 3 if you want the start point number for the third line in the scan.

<tol1> - The third parameter is the general feature tolerance. It is a maximum form error used to break up the scan into lines and arcs.

<tol2> - The fourth parameter is the refine tolerance. Generally, this tighter tolerance is used to drop points from either end of the feature until the form error of the segment is within this tolerance.

There is an additional parameter that controls whether an identified line segment in a scan is acceptable. This can only be changed with the PC-DMIS Settings Editor. Any line

segment of a length less than the value for the `MinimumLineSegmentLengthInMM` entry is rejected. The default value for this parameter is 2 mm.

Once you have the Start and End indices for a line segment, you can use these points inside a constructed feature to construct a separate line feature. See "Example of a Line Feature Created from a Scan Segment" for an example.

PROBEDATA

This function returns data about the current or specified probe : PROBEDATA*(<OPTPROBEDATATYPE>, <OPTTIPID>, <OPTPROBEFILENAME>)*

This function takes up to three optional parameters. You only need to provide commas between the parameters if you use more than one parameter. You do not need to use commas between empty parameters. For example, to obtain the current probe's diameter you would use `ASSIGN/V1= PROBEDATA("DIAM")` .

OPTPROBEDATATYPE - Optional parameter which specifies what probe data the expression should return. If this parameter is not supplied, the current tip ID is returned. This parameter is of type string. Any expression that evaluates to a valid string expression can be put in the first expression slot. Valid string expressions (not case sensitive) for the first parameter include the following. These are string expressions and should be inside double quotation marks:

"**A**" - Tip A Angle. Returns type double.

*"**B***" - Tip B Angle. Returns type double.

*"**C**"* **-** The C angle of a CW43 light probe head. Returns type integer.

*"**Date**"* - Date the tip was last qualified. Returns type string.

"**Diam"** *or* **"Diameter**" - Measured tip diameter. The first four letters are required "Diam", but could include more letters up to the full name of "Diameter". Returns type double.

*"**ID**"* - Tip ID. Default parameter. Returns type string.

"**Offset**" - Measured tip X,Y,Z offset. Returns type point.

"PrbRdv" - The probe's radial deviation. Returns type double.

"**Rotation**" - This is the rotation about the tip vector in radians. Returns type double.

*"***Standarddeviation***"* - The probe's standard deviation. Returns type double.

*"**Thick"** or **"Thickness**"* - Measured tip thickness. The first five letters are required "Thick", but could include more letters up to the full name of "Thickness". Returns type double.

"Time" - Time the tip was last qualified. Returns type string.

*"**Vector**"* - Tip Vector. Returns type point.

> Adding a "**T**" in front of "**Diameter**", "**Offset**", or "**Thickness**" returns the theoretical information (for example, **TDIAMETER**, **TOFFSET**, and **TTHICKNESS**).

OPTTIPID - This optional parameter specifies the tip to be used when obtaining the probe data specified in the first expression. If not supplied, the current tip is used. This parameter should be type string.

OPTPROBEFILENAME - This optional parameter specifies the probe filename to be used in obtaining the probe data. If this is not supplied, the current probe file is used.

Examples:

`ASSIGN/V1= PROBEDATA ()`	V1 is set to current tip id (i.e. "T1A0B0")
`ASSIGN/ V2= PROBEDATA ("TOFFSET","T1A45B0")`	V2 is set to the theoretical probe offset for the tip T1A45B0
`ASSIGN/ V3= PROBEDATA ("Date","T1A90B90","MYPROB")`	V3 is set to a string representing the date tip T1A90B90 of the probe file MYPROB was last qualified.

QUALTOOLDATA

This function returns data about the current or specified calibration tool. It has this syntax:

QUALTOOLDATA(<*TOOLINFO*>, <*TOOLID*>, <*FACENUMBER*>)

This function takes up to three parameters. It needs at least one parameter to return any data:

The first parameter, <*TOOLINFO*>, is a *string* that specifies the type of information to return about the calibration tool. If you don't pass this parameter, this function returns the name of the current or specified calibration tool.

- "***CTE***" or "***COEFFICIENTOFTHERMALEXPANSION***" - Either one of these strings returns the coefficient of thermal expansion as a double value.
- "***DIAM***" - This string returns the diameter of the tool as a double value.
- "**ID**" - This string returns the name of the tool as a string value.
- "**LENGTH**" - This string acts the same as "DIAM". It also returns the diameter of the tool as a double value.
- "**OVERRIDEIJK**" - This string returns the search override IJK vector as a point value.
- "**POLYDIAM**" - This string returns the diameter of the specified polyhedral face as a double value.

- "**POLYIJK**" - This string returns the IJK vector of the specified polyhedral face as a point value.
- "**POLYXYZ**" - This string returns the XYZ center of the specified polyhedral face as a point value.
- "**SHANKIJK**" - This string returns the IJK vector of the shank as a point value.
- "**TYPE**" - This string returns the type of tool as an integer value (0 for a sphere, 1 for an Arm2 sphere, 2 for a polyhedral, 3 for an Arm2 polyhedral).
- "***WIDTH***" - This parameter is no longer used.
- "**XYZ**" - This string returns the XYZ location of the tool as a point value.

  The second parameter, <*TOOLID*>, is a *string* that specifies the name for the calibration tool for which you would like to receive information. If you don't pass this parameter, PC-DMIS assumes you want information from the current calibration tool. The string is not case sensitive.

  The third parameter, <*FACENUMBER*>, is a parameter that you only need when you work with a polyhedral calibration tool and only when the first parameter is "POLYXYZ", "POLYIJK", or "POLYDIAM". This is an integer value that specifies the face of the polyhedral tool to use in order to obtain data.

The calibration tool does not have a global setting that automatically applies to all the probes in a measurement routine. When you calibrate a probe for the first time, you need to select the calibration tool to use. PC-DMIS saves this calibration tool information for each probe. When you recalibrate the same probe, PC-DMIS will use the same calibration tool.

Examples:

`ASSIGN/ VDIAM=QUALTOOLDATA("DIAM ","SPHERE_1_IN")`	Gives the variable VDIAM the diameter of the tool SPHERE_1_IN.
`ASSIGN/ VID=QUALTOOLDATA("ID")`	Gives the variable VID the current tool's name.
`ASSIGN/ VTYPE=QUALTOOLDATA("TYPE")`	Gives the variable VTYPE the current tool's type.
`ASSIGN/ VPOLYDIAM=QUALTOOLDATA(" POLYDIAM","POLYTEST",3)`	Gives the variable VPOLYDIAM the diameter of face 3 on the polyhedral tool, POLYTEST.

SETROTABDATA

This function sets the center or vector to the new input value:
SETROTABDATA(<*PARAMETER*>,<*NewValue*>[,<*TABLE*>])
This function works in the following configurations:

- Single rotary table
- Dual (independent) rotary tables
- Stacked rotary tables

CENTER

- "CENTER", - Sets the rotary table's XYZ center to the new value.
- "CENTER",,"V" - Sets the XYZ center for rotary table V in a dual-table or stacked-table configuration to the new value.
- "CENTER",,"W" - Sets the XYZ center for rotary table W in a dual-table or stacked-table configuration to the new value.

Examples:

`ASSIGN/ V1= SETROTABDATA("CENTER",NewValue)`	V1 is a return code (1=success, 0=failure).
`ASSIGN/ V1= SETROTABDATA("CENTER",NewValue,"V")`	V1 is a return code (1=success, 0=failure).
`ASSIGN/ V1= SETROTABDATA("CENTER",NewValue,"W")`	V1 is a return code (1=success, 0=failure).

VECTOR

- "VECTOR", - Sets the rotary table's IJK vector to the new value.
- "VECTOR",,"V" - Sets the IJK vector for rotary table V in a dual-table or stacked-table configuration to the new value.
- "VECTOR",,"W" - Sets the IJK vector for rotary table W in a dual-table or stacked-table configuration to the new value.

Examples:

`ASSIGN/ V2= SETROTABDATA("VECTOR",NewValue)`	V2 is a return code (1=success, 0=failure).
`ASSIGN/ V2= SETROTABDATA("VECTOR",NewValue,"V")`	V2 is a return code (1=success, 0=failure).
`ASSIGN/ V2= SETROTABDATA("VECTOR",NewValue,"W")`	V2 is a return code (1=success, 0=failure).

The [TABLE] argument is optional. If you do not specify table V or W, PC-DMIS does one of the following:

- If you are using a single-table or stacked-table configuration, it sets the new value for rotary table W.
- If you are using a dual-table configuration, it sets the new value for the rotary table that is activated on the **Active Rotary Table** toolbar. For more information about the toolbar, see "Active Rotary Table Toolbar".

PC-DMIS has two internal table definitions to accommodate dual-table and stacked-table configurations. For a single-table configuration, the second table definition is not actually used. Because it does exist internally, an error will not occur if you specify table V in a single-table configuration; however, this is not recommended. The values that the function sets are not generally useful because the table does not actually exist.

TUTORELEMENT

This function takes one parameter, either a number or a string (a string would be the ID of a feature).

TUTORELEMENT(<*PARAMETER*>)

This function works with the variable type, *Structures*. For explanations of structure and sub-elements, see "Structures".

Examples:

`ASSIGN/ E=TUTORELEMENT(1)`	Creates a single Tutor Element Structure
`ASSIGN/ WM=TUTORELEMENT(n)`	For any number over 1, this creates an array of `n` Tutor Element Structures
`ASSIGN/ CIR1E=TUTORELEMENT ("CIR1")`	Copies Data from feature CIR1 into the Tutor Element Structures.

The TutorElement structure currently has the following sub-elements:

Sub-Element	Description
ID	String of the Feature's ID
TYPE	INTEGER (FTYPE)
X, Y, Z	X, Y, and Z coordinate values
PR	Polar Radius
PA	Polar Angle
CX	I
CY	J
CZ	K
DM	Diameter 1
DM2	Diameter 2
DS	Distance from the origin
A	Angle
AXY	Angle in the XY plane
AYZ	Angle in the YZ plane

AZX	Angle in the ZX plane
F	Form Error
SDEV	Standard Deviation
TP	Position

Function Examples

Below are some different examples of functions that may help you in creating and using your own functions:

- Generic Function Example
- Functions Passed as Variables Example
- Function with Multiple Parameters Example
- Functions Creating Other Functions Example
- Functions As Members of an Array Example
- Functions Defined Recursively Example

Generic Function Example

```
ASSIGN/MYFUNC= FUNCTION ((X,Y,Z),X*3+Y*2+Z)
```

Creates a user-defined function and assigns it to the variable MYFUNC. The function takes three parameters, X,Y, and Z.

- X is multiplied by 3.
- Y is multiplied by 2.
- Z holds the passed value.

The total of X + Y + Z is what gets returned when values are passed into the function, as shown here:

```
ASSIGN/V1=MYFUNC(7,2,5)
```
This assigns V1 the value 30 by evaluating the parameters passed into the function MYFUNC(7,2,5).

- 7 is the parameter and is substituted where X occurs in the expression portion of the function definition. Thus, X*3 becomes 7*3, or 21.
- 2 is substituted where Y occurs. Thus Y*2 becomes 2*2, or 4.
- 5 is substituted where Z occurs.

The values are then all added together (21 + 4 + 5) and passed to V1.

Functions Passed as Variables Example

Functions can be passed as variables. The following example builds on the Generic Function Example above:

```
ASSIGN/NEWFUNC=MYFUNC
```
Sets the variable NEWFUNC to have the same function that MYFUNC has.

```
ASSIGN/V3=NEWFUNC(12,2,3)
```
Assigns V3 to have the value 43 from the evaluated expressions within the function (36 + 4 + 3).

Function with Multiple Parameters Example

Functions can have multiple parameters:

```
ASSIGN/ADDANDDOUBLE= FUNCTION ((A,B),2*(A+B))
```
Creates a function and assigns it to the variable ADDANDDOUBLE. The function takes two parameters, adds them together and then multiplies the result by 2.

```
ASSIGN/V2=ADDANDDOUBLE(4,5)
```
Assigns V2 the value 18. The parameters 4 and 5 are substituted into the expression portion of the function, thus becoming 2*(4+5).

Functions Creating Other Functions Example

Functions can create other functions.

```
ASSIGN/COMPOSE= FUNCTION ((F,G), FUNCTION ((X),G(F(X))))
```
Assigns COMPOSE to be a function that takes two functions as parameters and creates a new function using the two functions.

```
ASSIGN/ADD2= FUNCTION ((X),X+2)
```
Assigns ADD2 to be a function that adds two to the parameter passed in.

```
ASSIGN/ADD3= FUNCTION ((X),X+3)
```
Assigns ADD3 to be a function that adds three to the parameter passed in.

```
ASSIGN/ADD5= COMPOSE (ADD2,ADD3)
```
Assigns ADD5 to be a function composed of the functions ADD2 and ADD3.

```
ASSIGN/V5= ADD5 (3)
```
Assigns V5 to have the value V8.

Functions As Members of an Array Example

Functions can be members of an array.

```
ASSIGN/ANARRAY= ARRAY (3,FACTORIAL,"Hello World",ADD5)
```
Assigns ANARRAY to be an array of 4 elements : a number (3), a function (FACTORIAL), a string, ("Hello World"), and a function (Add5).

```
ASSIGN/V6=ANARRAY[2](4)
```
The second element of ANARRAY is the function FACTORIAL. The parameter 4 is passed in to this function and the result of 24 is assigned to V6.

```
ASSIGN/V7=ANARRAY[2](ANARRAY[4](ANARRAY[1]))
```
From the inside out: The first element of ANARRAY (3) is passed to the function of the fourth array element (Add5). The result, 8, is passed to the function of the second array element (FACTORIAL) and assigned to V7. V7 receives a value of 40320.

Functions Defined Recursively Example

Functions can be defined recursively, meaning they can be defined to call themselves.

```
ASSIGN/FACTORIAL= FUNCTION ((X), IF (X<=1,1,X* FACTORIAL (X-1))
```
Creates a function called factorial that takes one parameter. If the parameter is less than or equal to 1 it evaluates to 1, otherwise it evaluates to X multiplied by the FACTORIAL of X-1.

```
ASSIGN/V4= FACTORIAL (5)
```
Assigns V4 the value of 120 (5*4*3*2*1).

Example of a Line Feature Created from a Scan Segment

This topic provides an example of how to use PC-DMIS expression language, specifically the line segment functions, to export start and end point numbers for line segments within a scan and then to create your own line feature by using the extracted points within a constructed feature. You can use the same principles covered in this example to create an arc segment from a scan as well.

Suppose your measurement routine has a scan feature named SCN1 that looks like this:

```
SCN1=FEAT/SCAN,LINEAROPEN,SHOW HITS=NO,SHOWALLPARAMS=YES
   EXEC MODE=RELEARN, NOMS MODE=FIND
NOMS,CLEARPLANE=NO,SINGLE POINT=NO,THICKNESS=0

FINDNOMS=5,SELECTEDONLY=NO,USEBESTFIT=NO,PROBECOMP=YES,AVOID
ANCE MOVE=NO,DISTANCE=0,CAD Compensation=NO
   DIR1=VARIABLE,
   HITTYPE=VECTOR
   INITVEC=0,-1,0
   DIRVEC=1,0,0
   CUTVEC=0,0,1
   ENDVEC=0,-1,0
   PLANEVEC=-1,0,0
   POINT1=100,0,-5
   POINT2=70,0,-5
   MEAS/SCAN
   BASICSCAN/LINE,SHOW HITS=NO,SHOWALLPARAMS=YES
   <100,0,-5>,<70,0,-5>,CutVec=0,0,1,DirVec=1,0,0
   InitVec=0,-1,0,EndVec=0,-1,0,THICKNESS=0
   FILTER/NULLFILTER,
   EXEC MODE=RELEARN
   BOUNDARY/PLANE,<70,0,-5>,PlaneVec=-1,0,0,Crossings=2
   HITTYPE/VECTOR
   NOMS MODE=FINDNOMS,5
   ENDSCAN
   ENDMEAS/
```

To create a line from this scan you will need to use the LINESEGMENTSTARTINDEX and LINESEGMENTENDINDEX functions to pull out the data, like this:

```
   ASSIGN/LINESTARTINDEX=LINESEGMENTSTARTINDEX("SCN1",1,0.4,
0.1)
   ASSIGN/LINEENDINDEX=LINESEGMENTENDINDEX("SCN1",1,0.4,
0.1)
```

This tells PC-DMIS to go to the scan named "SCN1", and from its first line segment pull out the starting and ending index values that fall within the defined tolerances. It then assigns those index values to variables named LINESTARTINDEX and LINEENDINDEX.

Once you have the start and ending index values for the line segment assigned to variables, you can use those variables within a constructed line, like this:

```
LIN4=FEAT/LINE,RECT,UNBND
   THEO/100.225,0,-5.011,1,0,0
   ACTL/100.225,-0.005,-5.011,1,-0.0000388,0
   CONSTR/LINE,BF,2D,SCN1.HIT[LINESTARTINDEX..LINEENDINDEX],
,
   OUTLIER_REMOVAL/OFF,3
   FILTER/OFF,WAVELENGTH=0
```

Notice that in the highlighted code from the line feature above, PC-DMIS uses the starting and ending numbers you pulled out of the scan to create the feature:
`SCN1. HIT[LINESTARTINDEX..LINEENDINDEX]`

Operand Coercion

Operands can be coerced to other types using any of the coercion operators:

Integer Coercion

INT(<Expression>) - Coerces value of expression to type integer.

INT(4)	Evaluates to 4
INT(4.5)	Evaluates to 4
INT("Hello World")	Evaluates to 0
INT("2")	Evaluates to 2
INT("2.2")	Evaluates 2
INT("3 Blind Mice")	Evaluates to 3
INT("The 3 Blind Mice")	Evaluates to 0
INT("3, 4, 5")	Evaluates to 3
INT(MPOINT(0, 0, 1))	Evaluates to the distance of the point from the origin, in this case 1
INT(MPOINT(3, 4, 5))	Distance evaluates to 7.0711. This expression evaluates to 7.

Double Coercion

DOUBLE(<Expression>) - Coerces value of expression to type double

`DOUBLE(4)`	Evaluates to 4.0
`DOUBLE(4.5)`	Evaluates to 4.5
`DOUBLE("A String")`	Evaluates to 0.0
`DOUBLE("3.5")`	Evaluates to 3.5
`DOUBLE("3.5 inches")`	Evaluates to 3.5
`DOUBLE("The circle measures 3.5 inches in diameter ")`	Evaluates to 0.0
`DOUBLE(MPOINT(0,0,1))`	Evaluates to 1.0
`DOUBLE(MPOINT(3,4,5))`	Evaluates to 7.0711

String Coercion

STR(<Expression>) - Coerces value of expression to type string

`STR(4)`	Evaluates to "4"
`STR(4.5)`	Evaluates to "4.5"
`STR("Hello World")`	Evaluates to "Hello World"
`STR(MPOINT(3,4,5))`	Evaluates to "3, 4, 5"

Point Coercion

MPOINT(<Expression1>, <Expression2>, <Expression3>) - Coerces values of expressions to type point after coercing each expression to type double.

`MPOINT(1, 1, 1)`	Evaluates to point 1.0,1.0,1.0
`MPOINT(1.1, 1.1, 1.1)`	Evaluates to point 1.1, 1.1, 1.1
`MPOINT("1", "1", "1")`	Evaluates to point 1.0,1.0,1.0
`MPOINT(3, 4.5, "5.6")`	Evaluates to point 3.0, 4.5, 5.6

`MPOINT(MPOINT(1, 0, 0),`
`MPOINT(0,1,0),`
`MPOINT(3,4,5))`
	Evaluates to 1.0, 1.0, 7.0711

Operand Coercion and Mixed Type Expressions

The expression evaluator automatically coerces variables in mixed-type expressions. If the result of an expression is not what is expected because of automatic coercion, use of the coercion operators in some cases yields the desired result. Following are examples of automatic coercions in mixed-type expressions.

"CIR" + 1
Evaluates to "CIR1"

"2" + 2
Evaluates to 4

"The Value of 2+2 is " + 2 + 2
Evaluates to "The Value of 2+2 is 22". This is because PC-DMIS evaluates expressions left to right, and the left part of the expression is a string.

"The Value of 2+2 is " + (2 + 2)
Evaluates to "The Value of 2+2 is 4"

LINE1.XYZ > 2
Evaluates to 1 if the distance of the centroid of LINE1 from the origin is greater than 2

LINE1.XYZ > LINE2.XYZ
Evaluates to 1 if the centroid of LINE1 is further from the origin than the centroid of LINE2

LINE1.XYZ = LINE2.XYZ
Evaluates to 1 if the centroids of LINE1 and LINE2 are the same (no coercion occurs in this case)

DOUBLE(LINE1.XYZ) = DOUBLE(LINE2.XYZ)
Evaluates to 1 if the centroids are the same distance from the origin

11% 3.1
Evaluates to 2 (% is the modulo operator designed to work with integers. It returns the remainder from discrete division. 11%3 = 2.)

CIRCLE1.HIT [3.2].X
Evaluates to measured X value of third hit of Circle1. The argument 3.2 is automatically coerced to an integer with a value of 3.

ID Expressions

Many of the PC-DMIS commands use feature IDs as parameters. For example, constructed features use IDs to indicate which features are to be used as inputs for the constructed feature. ID expressions allow the user to refer to a specific instance of a feature, a group of similarly named features, an instance of a feature inside a call to a subroutine, or a feature in an external measurement routine.

Feature Array ID

Use a feature array id to refer to a specific instance of a feature or to a range of feature instances. For example, if the feature "Circle1" were located in a while loop that looped five times, then five instances of the circle would exist upon exiting the loop. To refer to an individual instance of the five instances of "Circle1", use feature array syntax as described under "Feature Arrays:" where "Circle1[1]" would refer to the first instance, "Circle1[2]" would refer to the second instance, etc.

To refer to a range of instances use the **..** notation. "Circle1[1..3]" refers to the 1st through 3rd instances of Circle1. "Circle1[3..5] refers to the 3rd through 5th instances of Circle1. "Circle1[1..5]" would refer to the 1st through 5th instances of Circle1. When a range of feature is referred to, the set is treated and behaves as a constructed set.

ID Wild Cards

Use ID Wild Cards to refer to a set of similarly named features. The two wild card characters are "*****" and "**?**". (See "Selecting Features Using Meta-character matching" in the "Editing the CAD Display" chapter for additional information.)

The asterisk '*' character refers to 0 or more instances of any character. To refer to the set of all features that start with the letters "CIR", use the expression ID "CIR*". This syntax creates a set of features that include all features with Ids that start with "CIR", such as "CIRCLE1", "CIRCLE2", "CIR3", or "CIR".

If CIR3 has several executions only the most recent measurement is used. To get the different instances of the executions, the following expression could be used: CIR?[1..3]

The question mark '?' character refers to a single instance of any character.

The ID expression "MY???1" would create a set of features that are six characters long, begin with "MY" and end with "1", such as "MYCIR1", "MYCON1", "MYLIN1", or "MYFT21".

IDs for Features Within Subroutines, Basic Scripts, or External Routines

Subroutines can be located within the current measurement routine or in an external measurement routine. When the subroutine is located in the same routine as the call to the subroutine, you can use the feature array ID syntax explained under "Feature Arrays:" to refer to individual instances of a feature created in the subroutine. However, when the subroutine is located in an external measurement routine, you can use the following syntax to refer to any features created in the subroutine: "<Call Sub ID>:<FeatID>".

For example, if a feature named "F1" were located in an external subroutine that was called from a Call Sub command with the id "CS1", then the ID expression "CS1:F1" could be used to refer to that feature.

This example merely illustrates the use of the syntax CS1.F1 and is not intended for use.

Routine 1: PLUS1.PRG

```
SUBROUTINE/PLUS1, A1 = 0, A2 = 0, A3 = 0

F1 =FEAT/POINT,RECT

THEO /A1+1,A2+1,A3+1,0,0,1

ACTL/3,1,1,0,0,1

MEAS/POINT,1

HIT /BASIC,A1+1,A2+1,A3+1,0,0,1,0,0,0

ENDMEAS/

ENDSUB/
```

Routine 2: TEST.PRG

```
CS1 =CALLSUB/PLUS1,D:\V30\WINDEBUG\PLUS1.PRG: 3,3,3,,

DIM D1= LOCATION OF POINT CS1:F1 UNITS=IN,$

GRAPH=OFF TEXT=OFF MULT=10.00 OUTPUT=BOTH

AX NOMINAL +TOL -TOL MEAS MAX MIN DEV OUTTOL

X 3.0000 0.0000 0.0000 3.0000 3.0000 3.0000 0.0000
0.0000

----#----

END OF DIMENSION D1
```

Basic scripts create and delete objects dynamically. Use the syntax "<Basic Script ID>:<Feat ID>" to refer to a feature created by a basic script. For example, if a basic script with ID "BS1" creates a feature with ID "F2", use the ID expression "BS1:F2" to refer to that feature.

You can use the attach command to attach external routines to PC-DMIS. To refer to features in the attached routine, use the following syntax: "<Attach Routine ID>:<Feat ID>". To refer to feature "F3" in the attached measurement routine with ID "GEAR1", use the expression, "GEAR1:F3". (For more information, see "Attaching an External Measurement Routine" in the "Adding External Elements" chapter.)

ID Expression Combinations

You can use array ID Expressions, Wild Card ID Expressions, and external subroutine, basic script, and external measurement routine ID Expressions in combination. For example, to refer to the third instance of all features that start with the letters "CIR" in an external measurement routine attached with the ID "BOLTPAT", use the ID expression " `BOLTPAT:CIR*[3]` ".

Also, you can use ID Expressions in regular expressions. Thus, the measured centroid of the above set of features could be assigned to variable with the following expression:

```
ASSIGN/V1=BOLTPAT:CIR*[3]. XYZ
```

Also, ID Expressions can be used in regular expressions. Thus, the measured centroid of the above set of features could be assigned to variable with the following expression:

```
ASSIGN/V1=BOLTPAT:CIR*[3]. XYZ
```

Accessing a Report's Object Properties

You can create your own custom report and label templates. PC-DMIS uses them to display report data inside a Report window (see **View | Report Window**). You use template editors to create the templates. The editors utilize a Visual Basic-like interface that you can use to insert, relocate, and size special components called "objects".

Each object consists of "properties" that define how it appears and what information it holds. Some of these properties are common to all other objects, some are common to only related objects, and others are unique to that specific object.

The PC-DMIS Expression Language can query the currently loaded report and store property values of a particular object in a variable. It can obtain values of type String, Integer, and Real by using this syntax:

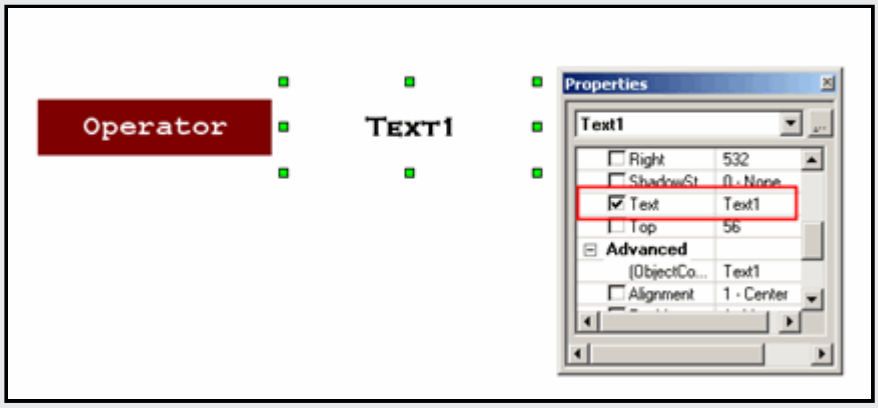
Property Query Syntax

```
ASSIGN/V1=Report.<Object Name>.<Property Name>
```

Report is a reference to the currently loaded report. <Object Name> is the object's unique name. <Property Name> is a valid property name for that object.

Example

Suppose that your report template has a text object called "Text1" that you want to use in the final report to display the operator's name. PC-DMIS stores the actual string of characters that represent the operator's name in the **Text** property of the object. By default, the text property (displayed text) initially has the value of "Text1" (see the figure below). Because this is a user-assigned property, the property's value changes when you type in the name during execution.



Properties dialog box that shows a selected object and the property to query

To use the Expression Language code to query this Text object's "Text" property and obtain the keyed-in data, you would use the following command:

```
ASSIGN/V1=Report.Text1.Text
```

In this code:

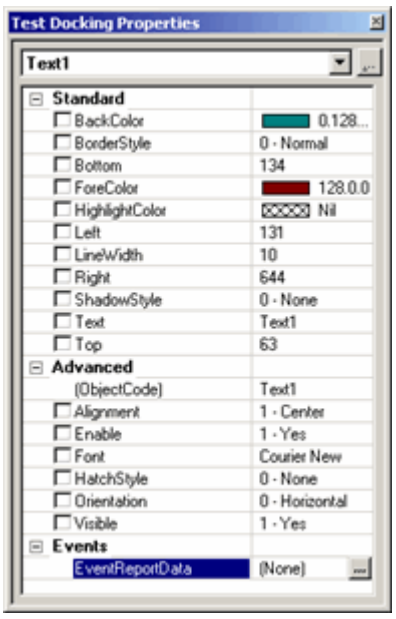
"Report" tells the code to look at the report loaded in the Report window.

"Text1" tells it to look for the object named "Text1".

"Text" tells it to look for the "Text" property within that object. The value of the "Text" property then gets passed into the V1 variable, which you could then further manipulate or display using the PC-DMIS Expression Language.

Finding Properties

To find the properties that are associated with a particular object, access the Report template in the Report template editor (**File | Reporting | Edit | Report Template**), select the object, and then right-click on the object to display its property sheet.



Property sheet for a Text object

The property sheet contains two columns. The left column displays the property name. The right column displays the current value. Be sure to use the exact property name in your expression code.

When you query property values, you may find that some properties return a seemingly useless numerical value. Generally, this happens when the property has a set list of available options. PC-DMIS returns an internal value for the selected property that does not relate to the displayed property.

For example, the **Text** object has an **Orientation** property with these values:

- 0 - Horizontal
- 1 - Vertical up
- 2 - Vertical down

However, if you obtain the value using PC-DMIS expression language, the software will instead return the following:

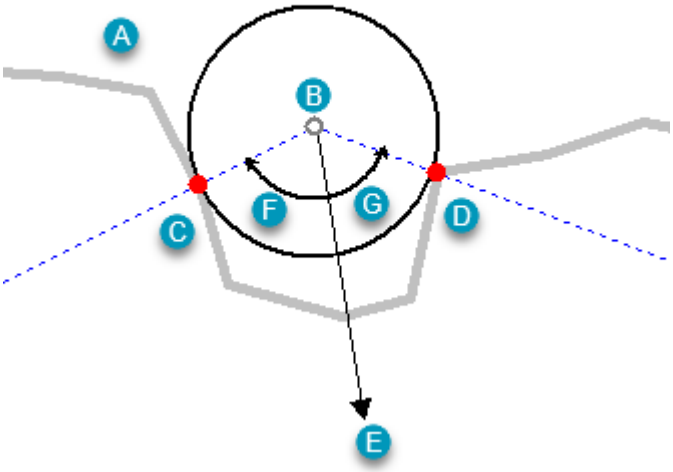
- 0 (for Horizontal)
- 900 (for Vertical up)
- -900 (for Vertical down)

It may require some trial and error to determine what returned values correspond with the value displayed on the property sheet.

Accessing Information from a Constructed Scan Minimum Circle

You can use PC-DMIS expressions to pull information from a circle feature that is constructed with a given radius at a minimum point along a linear scan. See the "Constructing a Circle at a Scan's Minimum Point" topic in the "Constructing New Features from Existing Features" chapter for more information.

When you construct a scan minimum circle feature, the circle ultimately uses a vector (termed the down vector) to contact the scan line. It only contacts the line in two places called contact points (CONTACTPOINT1 and CONTACTPOINT2). PC-DMIS can then use these points to determine the angles from the down vector to these contact points (CONTACTANGLE1 and CONTACTANGLE2). For example, consider this diagram:



A *- The scan line to which the circle is constructed.*
B *- The final XYZ position of the circle's centroid.*
C *- The contact point to the left of the Down Vector. It is termed CONTACTPOINT1.*
D *- The contact point to the right of the Down Vector. It is termed CONTACTPOINT2.*
E *- The Down Vector.*
F *- The angle from the Down Vector to CONTACTPOINT1. It is termed CONTACTANGLE1.*
G *- The angle from the Down Vector to the CONTACTPOINT2. It is termed CONTACTANGLE2.*

The expressions detailed below only function with this type of constructed circle feature. You can also use CONTACTPOINT2 in the syntax below to return the equivalent information using the second contact point instead.

```
ASSIGN/V1=CIR1. CONTACTPOINT1 . XYZ
```
Returns the XYZ point information for the circle's first contact point with the line, CONTACTPOINT1.

```
ASSIGN/V1=CIR1. CONTACTPOINT1 . X
```
Returns the X information for CONTACTPOINT1.

```
ASSIGN/V1=CIR1. CONTACTPOINT1 . Y
```
Returns the Y information for CONTACTPOINT1.

```
ASSIGN/V1=CIR1. CONTACTPOINT1 . Z
```
Returns the Z information for CONTACTPOINT1.

```
ASSIGN/V1=CIR1. CONTACTPOINT1 . IJK
```
Returns the IJK vector from CONTACTPOINT1 to the circle's centroid.

```
ASSIGN/V1=CIR1. CONTACTPOINT1 . I
```
Returns the I value from the above CONTACTPOINT1 IJK vector.

```
ASSIGN/V1=CIR1. CONTACTPOINT1 . J
```
Returns the J value from the above CONTACTPOINT1 IJK vector.

```
ASSIGN/V1=CIR1. CONTACTPOINT1 . K
```
Returns the K value from the above CONTACTPOINT1 IJK vector.

```
ASSIGN/V1=CIR1. CONTACTANGLE1
```
Returns the angle from the Down Vector to CONTACTPOINT1.

```
ASSIGN/V1=CIR1. CONTACTANGLE2
```
Returns the angle from the Down Vector to CONTACTPOINT2.

```
ASSIGN/V1=CIR1. CONTACTANGLE
```
Returns the sum of the absolute values of CONTACTANGLE1 and CONTACTANGLE2. It should be no greater than 180 degrees.

Adding External Elements

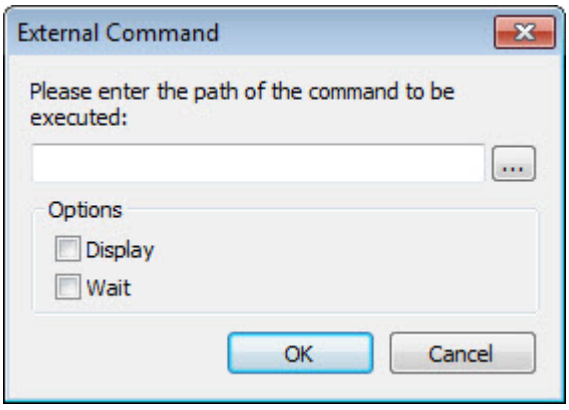
Adding External Elements: Introduction

This chapter discusses the various external elements that you can insert into your measurement routines. These include external applications, BASIC scripts, measurement routines, and other objects that further enhance your measurement routine's capability.

The main topics discussed in this chapter include:

- Inserting an External Command
- Inserting BASIC Scripts
- Attaching an External Measurement Routine
- Inserting External Objects

Inserting an External Command



External Command Dialog Box

Use the **Insert | External Command** menu option to insert a command into the Edit window that, when marked and executed, runs an external executable or batch file from the measurement routine.

- Normal DOS commands can be executed if they are put into a batch file.
- The command must be marked in the Edit window for PC-DMIS to execute the external command.
- A valid path and file name must be used.

- PC-DMIS halts the execution of the measurement routine and displays a message when it encounters an `EXTERNALCOMMAND/DISPLAY` command during execution. Click **OK** to continue measurement routine execution.

To insert an External Command

Select the **Insert | External Command** menu option. The **External Command** dialog box appears.

1. Specify an external command in the dialog box. To do this, either type the complete path for the file into the available box, or use the **...** button to find the file.
2. Select the **Display** check box if you want PC-DMIS to display a message informing you that measurement routine execution is paused when running an external command. Execution remains paused until you click **OK** on the message. See "Display Check Box" topic for more information.
3. Click **OK**. The command gets inserted into the Edit window.

The Edit window command line for this option reads:

```
EXTERNALCOMMAND/DISPLAYSTATE ; path name
```

DISPLAYSTATE - This toggle field controls whether or not PC-DMIS pauses execution and displays a message notifying you of an external execution. This field switches between `DISPLAY` and `NO DISPLAY`.

path name - This string represents the path and file name of the executable or batch file.

Display Check Box

If you select the **Display** check box in the **External Command** dialog box (**Insert | External Command**), PC-DMIS displays a message that lets you know that routine execution is paused in order to run the external command. PC-DMIS pauses execution until you click **OK** on the message.

Note that this message only appears if you have turned it on inside the **Warnings Display Options** dialog box.

To get this message to appear:

1. Press F5 to access the **Setup Options** dialog box.
2. From the **General** tab, click the **Warnings** button. The **Warnings Display Options** dialog box appears.

3. Select the **OK Execution paused in order to spawn a process** check box. Select **OK** to continue execution.

If you do not select the **Display** check box, PC-DMIS runs the specified external command without displaying any sort of message. PC-DMIS continues execution while the executable or batch file runs simultaneously. When not checked, the **Wait** check box becomes enabled. For more information, see "Wait Check Box".

Wait Check Box

The **Wait** check box in the **External Command** dialog box (**Insert | External Command**) is only available when the **Display** check box is not selected.

- When the **Wait** check box is selected, the execution of the measurement routine is paused until the external command finishes its operation.
- When the **Wait** check box is not selected, the measurement routine continues execution even if the external command hasn't finished its operation.

... button

The **...** button in the **External Command** dialog box (**Insert | External Command**) displays an **Open** dialog box. You can select the file name for the external command. Once you open the file, PC-DMIS inserts the full path into the **External Command** dialog box.

Creating an External Command as a Menu Item or Toolbar Item

PC-DMIS enables you to customize toolbars and menus to accept new menu items tied to .EXE, .BAT, and .BAS files. For information on how to do this, see the "Customizing the User Interface" topic in the "Navigating the User Interface" chapter.

Example - Using the External Command to Display a File

This example shows how to create a batch file (an external program) that works with the `EXTERNALCOMMAND` to open and display a file. For example, suppose you want to display an image file, but you don't want to use the **Insert | Report Command | External Object** menu option. You can use a command line (or DOS) prompt inside of a batch file to do this.

The advantage or disadvantage (depending on your needs) to this approach is that the image does not appear in the report at the end of measurement routine execution.

Step 1: Create a batch file to display the image:

1. Open a text editor, such as Notepad. On the first line, enter this command:

   ```
   start <PATHWAY>
   ```

   where <PATHWAY> is the complete path to the picture (for example, start d:\temp\mypart.gif).

   This command tells Windows to open the image file using its default image viewer application.

2. Save the file and give it a .bat filename extension.

Step 2: Link the External Command dialog box to the batch file:

1. Select **Insert | External Command**. The **External Command** dialog box appears.
2. Click the **...** button. An **Open** dialog box appears.
3. Under **Files of Type** list at the bottom of the **Open** dialog box, change the type to **BAT Files (*.bat)**.
4. Navigate to and select your batch file.
5. Click the **Open** button. The **Open** dialog closes, and the **External Command** dialog box now contains the path to the batch (.bat) file.

Step 3: Control what happens, and insert the command:

1. Choose either to display or not display a message that pauses the execution of the measurement routine. See "Display Check Box" for more information.

   - Select the **Display** check box from the **External Command** dialog box to display a message.
   - Clear the **Display** check box from the **External Command** dialog box to not display a message. When not checked, the **Wait** option becomes enabled. See "Wait Check Box" topic for more information.

2. Ensure that the **Link** check box is cleared.
3. Click **OK**. The `EXTERNALCOMMAND` gets inserted into the Edit window.

   ```
   EXTERNALCOMMAND/DISPLAY ; E:\BATCH\TEST.BAT
   ```

Step 4: Execute the routine:

1. Mark the resulting command line in the Edit window.
2. Execute your measurement routine.

PC-DMIS runs the specified batch program, displays the picture and, depending on what you selected in the **External Command** dialog box, it either pauses or continues the measurement routine while you view the picture.

Inserting BASIC Scripts

The Basic Language Extension to PC-DMIS provides a powerful extension to the software's functionality. Basic language scripts or applications may be written from within PC-DMIS (or imported from elsewhere) and linked to a button on a user-definable toolbar, allowing the execution of powerful macros. The version of Basic featured in supported versions of PC-DMIS provides all of the features of a high-level language, including custom dialogs (created using the built in Dialog Editor), ODBC support, and OLE support.

The ability to create and use basic scripts comes as a standard feature in PC-DMIS CAD and PC-DMIS CAD++. It is not available in PC-DMIS Pro.

The Edit window command line for a sample script reads:

```
 SCRIPT/FILENAME = C:\PCDMISW\sample.bas
FUNCTION/Main,SHOW=YES,,
ENDSCRIPT/
```

The **FILENAME=** field lets you specify the pathway to the BASIC file (.bas filename extension) that you want to insert and execute with the measurement routine.

The **FUNCTION/Main** field runs the "Main" subroutine. You can change this to specify a different subroutine or function in the BASIC file to run.

The **SHOW=** field lets you determine whether or not commands automatically generated by your Basic Script appear in your measurement routine after execution.

- When you set SHOW=NO, generated commands will not appear in Summary Mode, Command Mode, or DMIS Mode (commands still appear in the inspection report, however). Also, PC-DMIS will not save any generated commands with the measurement routine.
- When you set SHOW=YES, then generated commands appear in the measurement routine and PC-DMIS will save generated commands with the measurement routine. The default is SHOW=YES for measurement routine compatibility from previous versions.

The PC-DMIS *Basic Language Reference Manual* completely describes this add-on package. If you did not receive a copy of the documentation with your Basic Language package, contact your PC-DMIS software support representative.

To Insert a Basic Script as a Command

The **Insert | Basic Script** menu option displays the **Insert Basic Script** dialog box.

You can use this dialog box to add a basic script object to the measurement routine. Basic script objects contain the name of the basic script that should be executed when the basic script object is executed. Execution of the measurement routine does not continue until the basic script has executed. If the basic script creates any objects while executing, those objects will be inserted into the measurement routine and executed.

Objects inserted by Basic Scripts are highlighted in a different color than other objects to indicate that the basic script created them. For more information on basic scripts, see the PC-DMIS BASIC documentation.

To Insert a Basic Script as a Menu or Toolbar Item

You can use PC-DMIS to customize toolbars and menus to accept new menu items tied to .EXE, .BAT, and .BAS files. For information on how to do this, see the "Customizing the User Interface" topic in the "Navigating the User Interface" chapter.

Passing Variables To and From BASIC Scripts

From PC-DMIS code, you can only pass variables *to* BASIC scripts and not *from* BASIC scripts.

The only variable types that you can pass into BASIC scripts from PC-DMIS are:

- Integer
- String
- Double

Variables are passed as comma-separated values (known as arguments). You define these in the FUNCTION/ statement within the SCRIPT/FILENAME code block. The FUNCTION/ statement specifies not only the arguments, but also the subroutine within the script that takes the passed values. By default, this line initially reads:

```
FUNCTION/Main,SHOW=YES,,
```

This means that the subroutine named "Main" takes the arguments. `SHOW=YES` shows or hides the closing `ENDSCRIPT/` statement for the command block.

Notice the two commas following `SHOW=YES` above. These indicate a field where you may define your first argument. Type the value in the field and press the Tab key on your keyboard. PC-DMIS automatically adds "ARG1=" before the first value to indicate that it's the first argument. An additional comma is also added to allow for additional arguments. Any additional arguments have "ARG2=" and "ARG3=" and so on added as prefixes once you define the values.

Consider the examples below.

PC-DMIS variables only hold values during measurement routine execution; at learn time, PC-DMIS variables always have a value of zero.

Example 1: Using the Function Line to Pass Variables

The following command executes a BASIC script named TEST.BAS. It also, upon execution, passes the variables defined from the `FUNCTION/` line into the TEST.BAS script:

```
CS2=SCRIPT/FILENAME= D:\PROGRAM FILES\PCDMIS35\TEST.BAS
FUNCTION/ShowVars,SHOW=YES,ARG1=3,ARG2="Hello",ARG3=2.5,,
STARTSCRIPT/
ENDSCRIPT
```

Now here's the TEST.BAS script; on execution, it displays the passed in variables in their respective message boxes:

```
Sub ShowVars(IntVar As Integer, StrVar As String, DoubleVar
As Double)
   msgbox "The passed integer variable is " & IntVar
   msgbox "The passed string variable is " & StrVar
   msgbox "The passed double variable is " & DoubleVar
End Sub
```

Example 2: Using the GetVariableValue and SetVariableValue Methods to Pass Variables

The following example first uses PC-DMIS code to receive an integer value from the user and assigns it to the V1 variable.

```
C1=COMMENT/INPUT,Please type an integer value.
ASSIGN/V1=INT(C1.INPUT)
COMMENT/OPER,BEFORE SCRIPT: Variable is:
,V1
```

It then calls a BASIC script named TEST2.BAS.

```
CS1=SCRIPT/FILENAME=D:\PROGRAM FILES\PCDMIS35\TEST2.BAS
FUNCTION/Main,SHOW=YES,,
STARTSCRIPT/
ENDSCRIPT/
```

Here is TEST2.BAS:

```
Sub Main
  Dim App As Object
  Set App=CreateObject("PCDLRN.Application")
  Dim Part As Object
  Set Part=App.ActivePartProgram
  Dim Var As Object
  Set Var=Part.GetVariableValue("V1")
  Dim I As Object
  If Not Var Is Nothing Then
    Var.LongValue=Var.LongValue+1
    Part.SetVariableValue "V1",Var
    MsgBox"V1 is now: "&Var.LongValue
  Else
    Msgbox"Could Not find variable"
  End If
End Sub
```

This script takes V1 variable and, using the `GetVariableValue` and `SetVariableValue` automation methods, increments the V1 by one and then sets the new value for V1 in the measurement routine.

PC-DMIS then displays the changed variable in an operator comment.

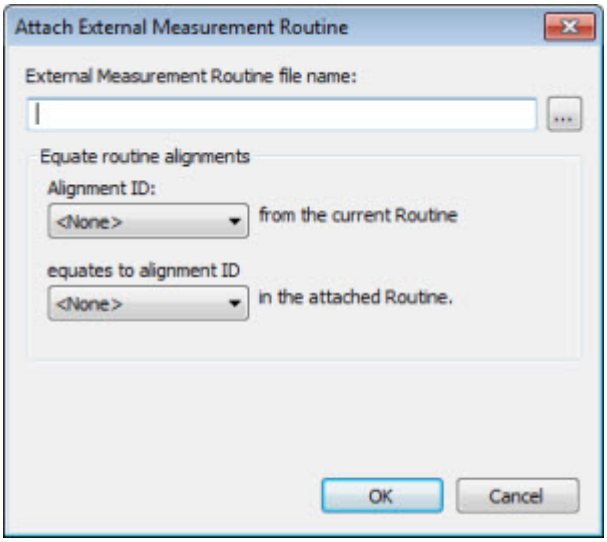
```
COMMENT/OPER,AFTER SCRIPT:Variable is now
,V1
```

Attaching an External Measurement Routine

When you attach an external measurement routine, you can only attach measurement routines created in valid versions of PC-DMIS.

For this version of PC-DMIS, the measurement routine must be created in PC-DMIS version 2021.1 up to this version of PC-DMIS.

The **Insert | Attach Measurement Routine** menu option opens the **Attach External Measurement Routine** dialog box. You can use this dialog box to attach a measurement routine to the current measurement routine. This does not mean that PC-DMIS actually attaches and executes all the command in the specified measurement routine. Instead, it attaches a pointer to the measurement routine, which enables you to access its dimensional and feature data. See "Using a Pointer to Reference Data".



Attach External Measurement Routine Dialog Box

This dialog box contains these options:

External Measurement Routine file name
Use this box to type the path for the measurement routine you are going to attach. If you prefer, you can use the **Browse** button (...), which also places the file name path into the box.

Equate Routine Alignments
Use this area to share alignments between two measurement routines by selecting them from the available lists. See "Equating an Alignment" in the "Creating and Using Alignments" chapter for additional information.

The **Attach Measurement Routine** menu option is especially useful when working in multiple arm mode. With this option, you can attach a measurement routine from the Arm2

system onto the Arm1 measurement routine. Attaching the measurement routine allows the sharing of data so that both arms can run off the same alignment, pass feature data from one measurement routine to another for calculations, and generally work in a cooperative manner. (See the "Using Multiple Arm Mode" chapter for more information on multiple arm mode.)

Using a Pointer to Reference Data

When you access an attached measurement routine, you often want to use data from that measurement routine. When you reference this data, you *must* reference the pointer (or variable) that contains the location of your measurement routine.

Suppose you're attaching TEST_A.prg to your current measurement routine. Your attach command would look something like this:

```
CS1=ATTACH/C:\PCDMISW\TEST_A.PRG, Machine=

EQUATE/LOCAL ALIGNMENT = A1, ATTACHED ALIGNMENT = A1
```

Notice the pointer, `CS1` . This pointer is used to extract data from the attached measurement routine.

Now, suppose you wanted to display the measured X value for feature F1 from TEST_A.prg inside your current measurement routine. You would use a statement like this.

```
COMMENT/OPER,"The X value for F1 from the attached
measurement routine is:"

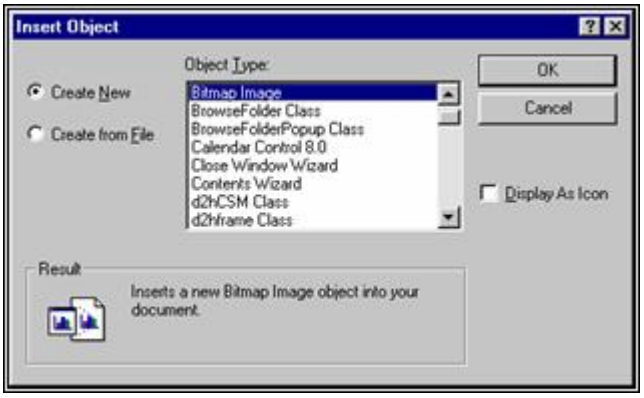
,CS1:F1.X
```

The code, `CS1:F1.X` , essentially tells PC-DMIS to look at TEST_A.prg, find feature F1, and display the X value. This is the way pointers are referenced inside PC-DMIS.

PC-DMIS also lists features from an attached measurement routine in the Construction or Dimension dialog box. PC-DMIS will display the attached measurement routine’s ID pointer within the Feature List box. A plus sign (+) appears to the left of the pointer. Clicking this plus sign expands or collapses a view of all the features in the attached measurement routine. After you expand the view to show all the features of the attached measurement routine, you can select any of those features to use in the construction or dimension process.

You cannot select the attached routine’s pointer. You can only select the expanded IDs associated with the pointer.

Inserting External Objects



Insert Object Dialog Box

The **Insert | Report Command | External Object** menu option enables you to enter various types of objects from other applications on your system into the Edit window. Types of objects that can be inserted depend on the applications installed on the computer system. Examples of objects that can be inserted include graphics, sound clips, movie clips, midi clips, documents, worksheets, and database tables.

Use external objects to import an instructional video, audio instructions, or written instructions into your measurement routine.

Be sure to place the Edit window in Command Mode when working with external objects.

Create New

The **Create New** option (**Insert | Report Command | External Object**) enables you to create a new file of a particular object type at a specified location in the Edit window. The object types are chosen from the **Object Type** list. Objects can only be placed just after or just before a feature in the measurement routine.

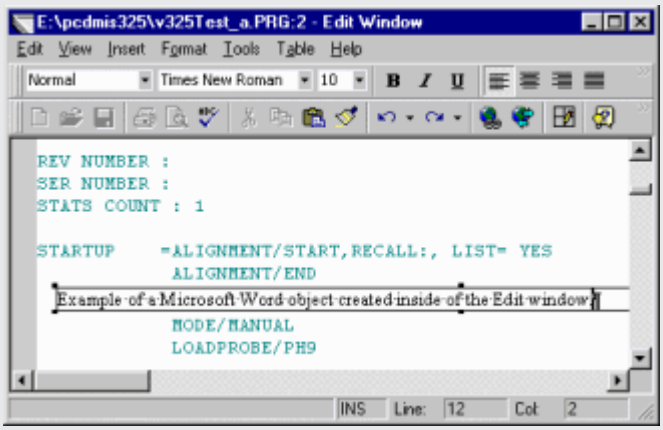
To create a new object and place it in the Edit window:

1. Select the **Create New** option.
2. Select the desired object type from the **Object Type** list. The object will appear in a box, bounded by small rectangular points within your Edit window. Use your mouse to drag the box to another location or resize the box using the small rectangles.
3. Double-click within the object**.** You will see that the application that runs that particular object opens in the Edit window.

4. Modify the object by using the tools specific to the inserted application.
5. When you are done, click on the portion of the Edit window that is *outside* of the inserted object.

Suppose you want to include a *new* word document in the Edit window:

1. Select the **Create New** option.
2. Select a word document object from the **Object Type** list.
3. Drag the object box with the mouse to a desired location within the Edit window.
4. Resize the box to the desired size.
5. Type the information within the word document object.
6. Click outside of the object to return to normal PC-DMIS Edit window functions. The word document will remain in the Edit window.



Example of a word document created in the Edit window. Notice how the Edit window's menus and toolbars are replaced with the menus and toolbars of the application that corresponds to the object you are creating.

Create from File

The **Create from File** option (**Insert | Report Command | External Object**) enables you to insert a previously-created file as an object into the Edit window.

To insert a previously-created object:

1. Select the **Create from File** option.

2. Type the directory path that contains the file you want to place as an object. You can also click the **Browse** button to navigate to the correct directory.
3. Select the file to insert as an object.
4. Click the **OK** button. The object now appears in the Edit window. Use your pointer to drag the box to another location or resize the box using the small rectangles.

Suppose you want to insert a previously-written word document into the Edit window that includes a set of instructions about operating the CMM.

To do that:

1. Select the **Create from File** option.
2. Navigate to the directory that contains the document.
3. Click the **OK** button. The document appears within the object box in the Edit window.
4. Use your pointer to move the object box to where you want it in the Edit window and resize it.

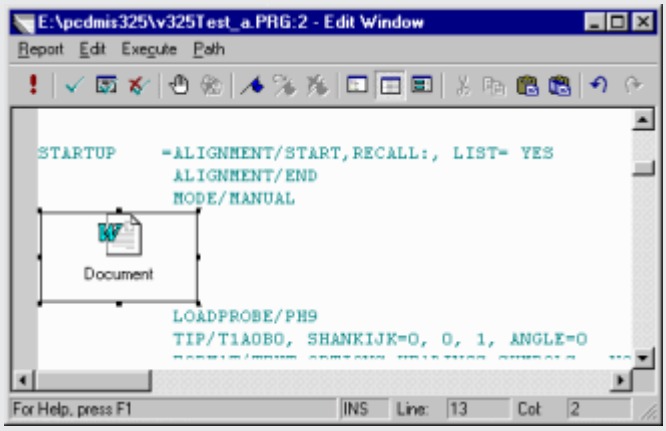
Link

When you select the **Create from File** option (**Insert | Report Command | External Object**), you have the opportunity to "link" your object to the Edit window. When you link your object back to its original file, any changes made to the original file are also applied to the external object in the Edit window.

Display As Icon

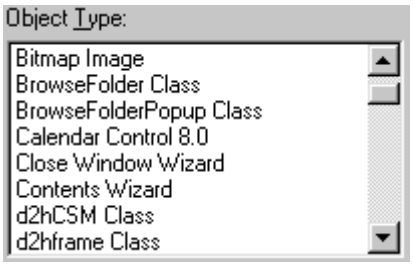
The **Display As Icon** check box (**Insert | Report Command | External Object**) enables you to display the imbedded object as an icon instead of displaying the information outright. Once you double-click on the icon within the Edit window, it will then activate.

Suppose you place a word document in the Edit window and select the **Display As Icon** check box. The word document appears as an icon. However, if you double-click on the icon, the imbedded application opens and displays the information contained in the word document.



Example of a word document object displayed as an icon

Object Type List



Object Type List

The **Object Type** list (**Insert | Report Command | External Object**) contains the object types available on your computer system. These vary from computer to computer depending on what application programs you have installed on your hard drive.

To choose an object type:

1. Use the scroll bar or UP ARROW and DOWN ARROW keys to find the object.
2. Select the object.
3. Click the **OK** button.

Marking External Objects for Execution

By default, external objects print and do not execute when you execute a measurement routine. However, with some objects, the desired action may be to execute and not print. For example, when embedding a graphic, the desired action may be to print the graphic to the report; while when embedding a sound or movie clip, the desired action may be to execute the object to play the clip at execution time.

External objects have four modes of execution:

1. Print - Don’t execute
2. Don’t print - Don’t execute
3. Don’t Print - Execute
4. Print - Execute

To switch between the different modes, press F3 while the insertion point is on the same line as the external object in the Edit window. PC-DMIS will use hash lines and borders to indicate the objects current mode of execution. See the examples below.

- Hash lines - diagonal lines that cross the graphic. When there are hash lines, the object will not print to the report.
- Hashed borders - diagonal lines that cross the border around the graphic. When a hashed border outlines the object, the object will execute.

Example	Behavior
No Hash Lines - No Hashed Border 	• Print • Don't Execute
Hash Lines - No Hashed Border 	• Don't Print • Don't Execute
Hash Lines - Hashed Border 	• Don't Print • Execute
No Hash Lines - Hashed Border 	• Print • Execute

The execute action is always the same action that occurs when an external object is double-clicked. For media clips, this default action is usually *play*. For most other objects, the default action is *edit*.

Play - Sound clips will play sound. Movie clips will play their movie, etc.

Edit - Objects that have a default action of edit will usually not be objects that would need to be executed. However, some application objects also have the ability to run custom basic scripts upon being activated. A Microsoft Word document or Excel spreadsheet are examples of this type of external object. With these types of objects and the PC-DMIS automation commands, it is possible to change the object using data from the measurement routine. For example, an Excel graph could be inserted inside a measurement routine that has a basic script that, when activated, would pull data out of the measurement routine using the PC-DMIS automation commands and adjust the graph accordingly before it was printed on the inspection report.

Displaying Files in a Different Way

An alternate way to display files is to use the PC-DMIS `EXTERNALCOMMAND` Edit window command. See "Example - Using the External Command to Display a File" for information.

Using Multiple Arm Mode

Using Multiple Arm Mode: Introduction

The Multiple Arm Mode was created to drive multiple arm CMMs. The Multiple Arm Mode is available as an add-on package. Currently, this version only supports a multiple arm mode of two arms. The two arms must be connected to separate computers with a version of PC-DMIS and the correct PC-DMIS license on each computer. These arms share a common alignment.

Later versions of PC-DMIS enable you to drive up to four machine arms from one version of PC-DMIS, using any combination of one to four computers.

While the measurement process for multiple arms is comparable to single arm units, PC-DMIS must be able to distinguish the arm that is taking the measurement when using a multiple arm system. The topics in this chapter explain how to do this.

The main topics in this chapter describe how to setup a multiple arm CMM, create measurement routines using multiple arms, and share the measurement routine among the participating arms. These topics are:

- Setting up a Multiple Arm CMM
- Creating a Measurement Routine Using Multiple Arm Mode
- Running the Arm1 Measurement Routine on Arm2
- Dialog and Message Boxes in Multiple Arm Mode
- Dual Arms with Wrists Calibration Example

PC-DMIS must be installed on all systems prior to running in Multiple Arm Mode.

In addition, the **World Axis** value in your PC-DMIS license on each machine must be configured appropiately to enable operation in Multiple Arm Mode, as follows:

- The primary computer's PC-DMIS license setting should detail how many secondary arms that will be driven by the primary computer. So, a primary computer driving three secondary arms would need to specify a value of 3.
- Each secondary computer's LMS license needs to be properly configured or the portlock should specify a value of 1.

Setting Up a Multiple Arm CMM

To setup a multiple arm CMM, follow these steps:

Step 1: Install PC-DMIS on All Computers

The first step needed to make this option accessible is to install PC-DMIS on all the computers that will drive the multiple arms. (See the documentation on software installation procedures if necessary.)

The Multiple Arm option must be programmed in all port locks. This should be available on all computers.

Step 2: Determine the Arm1 System

Determine the Arm1 system. In most cases, any arm controller can be used. However, if the multiple arm system has a rotary table, then the Arm1 system must be the controller that controls the rotary table.

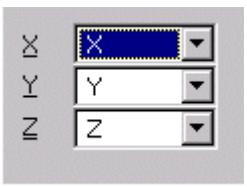
Label the participating arms in some way. Most users usually call them "ARM1" and "ARM2".

Step 3: Match the CMM Axes for Each Arm

The CMM axes for each arm must match. That is, the X+, Y+, and Z+ axes for all arms must go in the same direction.

If you need to change the axes assignments and directions:

1. Make sure you're running PC-DMIS in Online mode.
2. On the Arm2 computer, select **Edit | Preferences | Machine Interface Setup**. The **Machine Options** dialog box appears.
3. Select the **Axes** tab. This shows the X,Y, and Z axes combination boxes.



4. Use the **X**, **Y**, or **Z** list to reassign the axes of the connected CMM so that they match the axes of Arm1. Usually, only the X and Y axes will need modification.

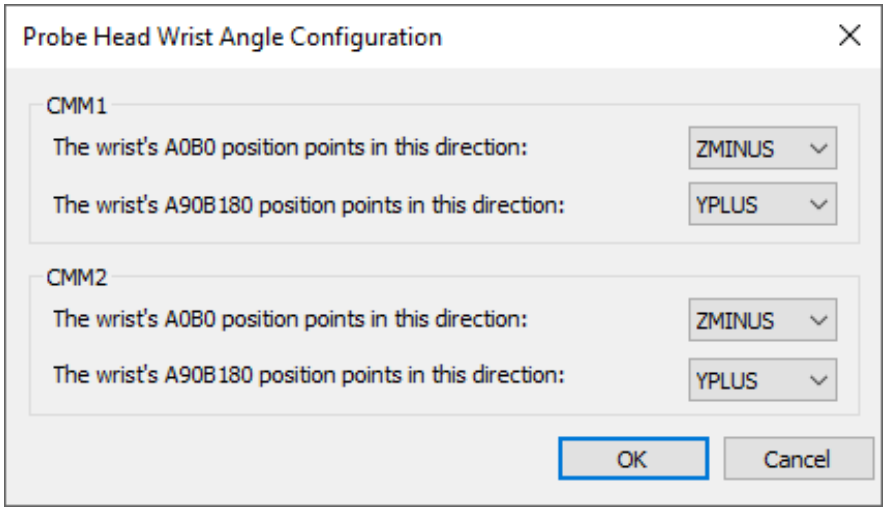
5. Click **Apply** to keep the changes.
6. Once the dialog box closes, exit PC-DMIS.
7. Restart PC-DMIS, and verify that the changes are correct by moving the axes for both arms in the same directions. Make sure the axis counters increment accordingly.

The numerical values in the counters will not match until you complete the multiple arm calibration.

Step 4: Configure Probe Head Mount Orientation

Once PC-DMIS is loaded on all systems, and the axes match for both arms, configure your probe head mount orientation:

1. Select **Edit | Preferences | Setup** to display the **Setup Options** dialog box.
2. Select the **Part/Machine** tab.
3. Click the **Probe Head Orientation** button. The **Probe Head Wrist Angle Configuration** dialog box appears.

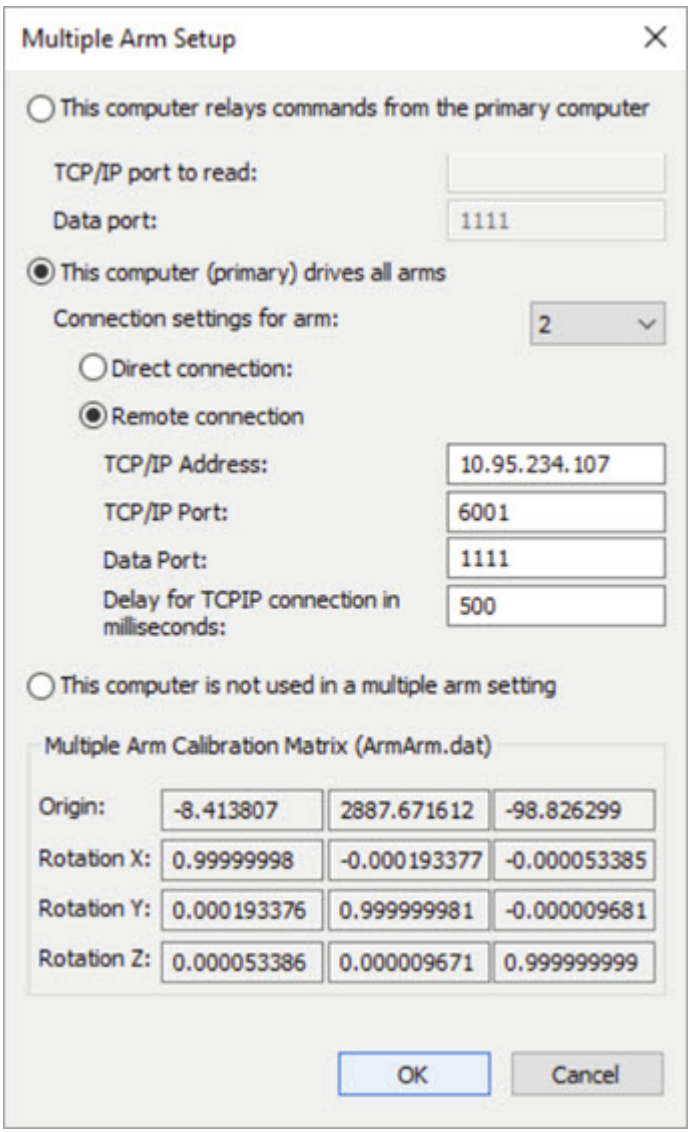


Probe Head Wrist Angle Configuration Dialog Box

4. Change the mount orientation as needed for each CMM arm.

Step 5: Setup the Multiple Arm Connection

The next step is to set up the multiple arm mode for the current computer. Select **Edit | Preferences | Multiple Arm Setup**. This menu option displays the **Multiple Arm Setup** dialog box.

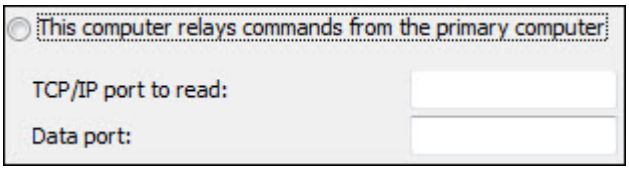


Multiple Arm Setup Dialog Box

Use this dialog box to determine if the current computer is the primary computer and drives the other arm or arms, or if the current computer is not the computer but relays commands from the primary computer.

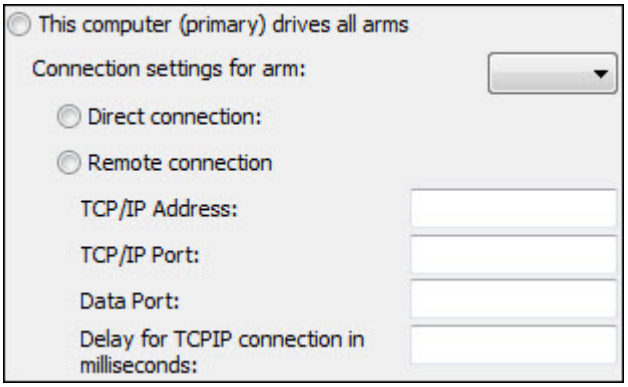
When you finish making changes to this dialog box and click **OK**, PC-DMIS displays a warning message that says that you need to restart PC-DMIS for your changes to take effect.

This computer relays commands from the primary computer



The **This computer relays commands from the main computer** option in the **Multiple Arm Setup** dialog box (**Edit | Preferences | Multiple Arm Setup**) enables the computer to be used with a non-primary arm (Arm2 or higher). In this case, it relays commands from the primary computer. You can choose to connect to the primary computer by defining the proper TCP/IP port and data port.

This computer (primary) drives all arms



The **This computer (primary) drives all arms** option in the **Multiple Arm Setup** dialog box (**Edit | Preferences | Multiple Arm Setup**) enables the computer to be the main computer that drives all the arms. You can choose to connect the computer to the other arms using either a direct connection or a remote connection.

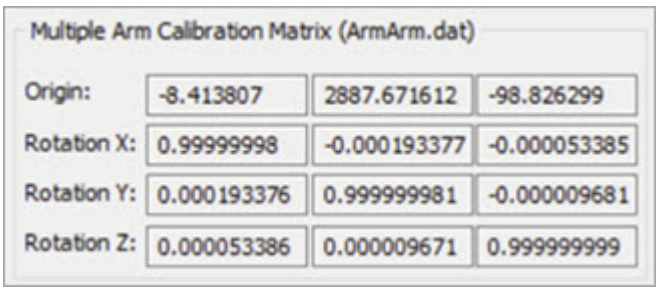
If you choose the **Remote connection** option, you need to fill out the available fields to establish the connection:

1. Select the arm from the **Connection settings for arm** list.
2. Type the IP address in the **TCP/IP Address** box.
3. Type the IP address's port number in the **TCP/IP Port** box.
4. Type the data port number in the **Data Port** box.
5. Specify the TCP/IP connection delay in the **Delay for TCPIP connection in milliseconds** box. This value is the number of milliseconds that PC-DMIS delays before attempting a TCP/IP connection to the specified arm from the current computer.

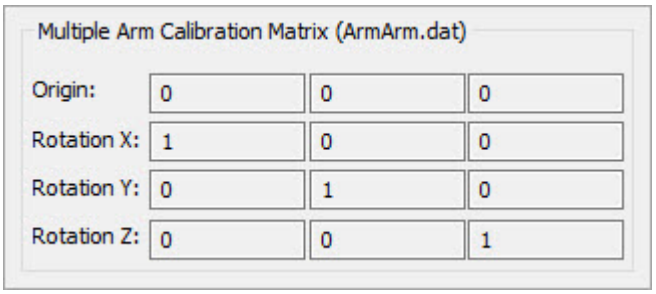
This computer is not used in a multiple arm setting

If the computer is not used in a multiple arm setup, select the **This computer is not used in a multiple arm setting** option in the **Multiple Arm Setup** dialog box (**Edit | Preferences | Multiple Arm Setup**).

Multiple Arm Calibration Matrix (ArmArm.dat)



This area displays the calibration data from the ArmArm.dat file which PC-DMIS creates after a multiple arm calibration. If PC-DMIS does not find an ArmArm.dat file, PC-DMIS populates this area with the identity matrix:



Each time you perform the multiple arm calibration routine, PC-DMIS updates the ArmArm.dat file with the new calibration values and populates the matrix with the new calibration data values.

Step 6: Connect the Computers

Now, you need to connect the computers so they can communicate with each other. You can either use a null modem serial cable between the computers, or, if the computers are connected to a network, you can use the network to communicate between them. The "Step 5: Setup the Multiple Arm Connection" topic enables you to configure these communication settings.

Once the computers are connected:

1. Start up PC-DMIS on the Arm2 and higher systems. Do *not* create a new measurement routine or activate a measurement routine. These systems are now ready.

2. Start up PC-DMIS on the Arm1 (primary) system. Create a new measurement routine (or activate one that is already available). If you are creating a new measurement routine, PC-DMIS automatically opens the **Probe Utilities** dialog box (**Insert | Hardware Definition | Probe**).

3. Either select or create a probe file that describes a probe on Arm1. Make sure that you add an AB angle for the tip you plan to use to calibrate the relationship between the two arms. *Don't calibrate the probe at this time*.

Step 7: Enter Multiple Arm Mode

Once you have set up the computers and are in a measurement routine, the **Operation | Enter Multiple Arm Mode** menu option becomes selectable from the Arm1 (primary) computer. Select this option.

PC-DMIS displays a check mark to the left of the **Operation | Enter Multiple Arm Mode** option. PC-DMIS also displays the **Active Arms** toolbar.

When PC-DMIS enters multiple arm mode, it attempts to establish a link between the multiple computer systems. This link coordinates the activities of all the arms.

Troubleshooting

If PC-DMIS cannot establish the link among the computers after it enters multiple arm mode, an error message appears and informs you of the arm that isn't responding. The following may cause this communication problem:

- PC-DMIS is not running on a computer
- An online measurement routine is active on an Arm2 or higher computer
- The cable connections (or other network connections) between the computers are not functioning
- Settings entered in the **Multiple Arm Setup** dialog box (**Edit | Preferences | Multiple Arm Setup**) are incorrect

Once you have a link between the multiple computers, you can calibrate the relationship between the arms.

Exiting the active measurement routine also removes PC-DMIS from multiple arm mode.

Step 8: Calibrate the Multiple Arm System

This step walks you through the calibration of the multiple arm system.

Prior to calibration and after PC-DMIS has been started on the computer systems, you must define any probes that will be used in the measurement process. PC-DMIS uses the theoretical data from the probes to calibrate the multiple arm system.

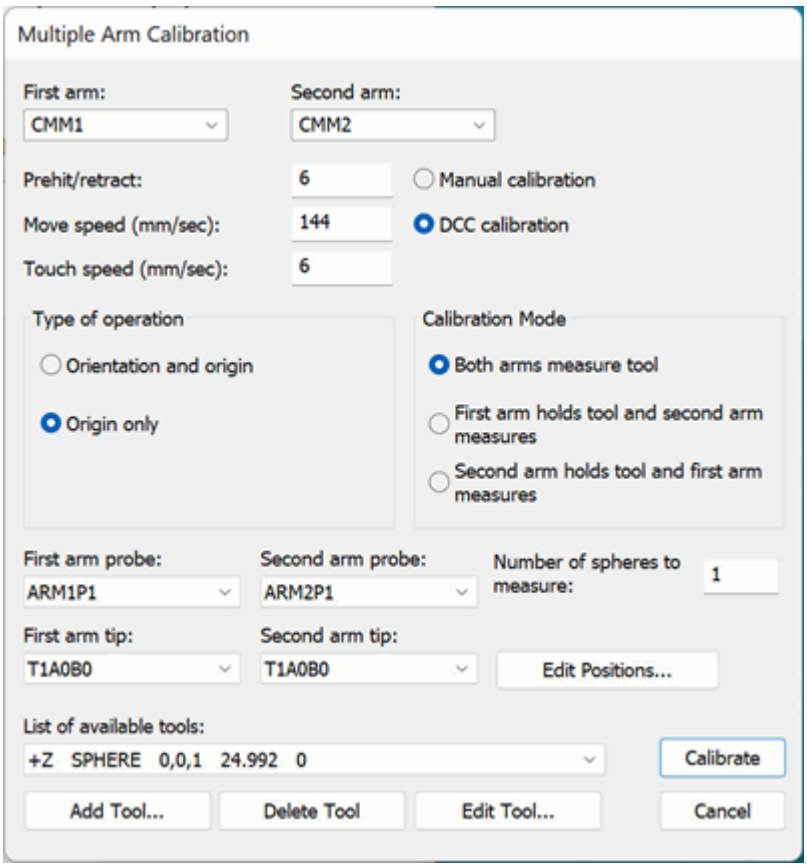
Do not calibrate the probes at this time. Only ensure they are properly defined and that you add an AB angle for the tip you plan to use to calibrate the multiple arm system.

In your measurement routine, you should have multiple `LOADPROBE` commands, one for each arm.

If you've attempted a multiple arm calibration previously then PC-DMIS has created *armtoarm.dat* files. It stores these where you installed PC-DMIS on both the Arm1 and Arm2 computers. You should delete or rename these files before proceeding so that data from previous calibration attempts doesn't negatively affect your current calibration process.

Follow these calibration procedures:

Part 1 of Calibration Procedure



Multiple Arm Calibration Dialog Box

1. Select the **Operation | Calibrate/Edit | Multiple Arm Mode** menu option (only available in Online mode). This displays the **Multiple Arm Calibration** dialog box.

2. Ensure that the correct probe files and tips are selected from the arm lists in the dialog box.

3. Ensure that the calibration tool you are using is available from the **List of available tools** list. The tool is only needed if you selected the **Both arms measure tool** option.

4. Define the **Prehit / Retract**, **Move speed**, and **Touch speed** values as desired. During calibration, these values supersede the same values listed in the **Measure Probe** dialog box (**Insert | Hardware Definition | Probe | Measure** button). In addition, they are shared by both arms to ensure that they operate using the same conditions during calibration:

    - **Prehit / Retract** - This defines a distance value away from the part or calibration tool. The speed of PC-DMIS decreases to the defined **Touch speed** while within this distance. It remains at the **Touch speed** until the hit is taken and the distance is reached again. At that point, PC-DMIS returns to the defined **Move speed**.

    - **Move speed** - This defines the speed that PC-DMIS uses to move the probe into position to take hits during multiple arm calibration.

    - **Touch speed** - This defines the speed that PC-DMIS uses to take hits during multiple arm calibration.

    Depending on the state of the **Display absolute speeds** check box on the Part/Machine tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**), the above **Move speed** and **Touch speed** boxes can either accept an absolute speed (mm/sec) or a percentage of the machine's defined top speed.

5. Choose what you want to calibrate by selecting either the **Orientation and origin** option or the **Origin only** option.

    - Selecting the **Orientation and origin** option creates a 3D transformation between the two arms to compensate for any out-of-squareness between the two arms. You must do this *at least once* (normally, this is done periodically every few months).

    - Selecting **Origin only** corrects only the origin between the two arms. You should do this type of calibration more frequently, based on probe calibration procedures. When calibrating your probe, PC-DMIS asks if you moved your tool. If you normally indicate to PC-DMIS that you haven't moved the tool, then you don't have to adjust your arm-to-arm origin. If you answer that you have

moved the tool, then after calibrating your probe tips, you should return to this dialog box and choose the **Origin only** type of arm-to-arm calibration.

With **Origin only**, make sure you are using calibrated tips.

6. Choose how you want to perform the calibration by selecting either **Manual calibration** or **DCC calibration**.

   - If you selected the **Manual calibration** option, PC-DMIS prompts you to measure each sphere position using the CMM 's jog box. Once you have taken the first hit on the top of the sphere, PC-DMIS takes the rest of hits in DCC Mode.
   - If you selected the **DCC calibration** option, you are prompted to supply the sphere positions. Once entered, the computer performs the calibration's motion control.

     WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

     Click the **Edit Positions** button to change the location of each sphere position by typing the X, Y, and Z coordinates. You may find it helpful to read the position of the active arm to fill in these three values. Be aware that clicking the **Done** button on your jog box can read the arm's current position.

You must first do at least one origin arm-to-arm calibration in Manual Mode to establish the basic relationship between the two arms. When you complete an arm-to-arm calibration, PC-DMIS generates an *armarm.results* file stored in the directory defined through the **Set Search Path** menu option (see the "Specifying Search Paths" topic in the "Setting your Preferences" chapter). This text file is viewable using any text editor. It shows how beneficial the spheres are once you have done the initial fit. In particular, it displays the "fitment error".

Fitment Error: During calibration, PC-DMIS transforms values from one coordinate system to another, attempting to "fit" a plane through all the spheres measured by a given arm. The values of this "fitment" is what is stored in the armarm.results file. This information may help to show the overall accuracy of the calibration.

7. Type a number in the **Number of spheres to measure** box. This value determines the number of spheres PC-DMIS measures for each arm. If you type a number of spheres greater than 1, PC-DMIS averages the measurements to create the origin.

- If you use the **Manual calibration** option, PC-DMIS prompts you to manually measure these positions.
- If you use the **DCC calibration** option, PC-DMIS automatically drives each arm to measure these positions. The minimum number of spheres is three.

Ensure that the spheres aren't in the same position. Otherwise, the calibration finishes with incorrect results.

8. Use the available options below to determine how PC-DMIS uses the arms to measure the tools.

Both arms measure tool

- If you select this option and you use **Manual calibration**, PC-DMIS prompts you to measure each sphere position with both arms.
- If you select this option and you use **DCC calibration**, PC-DMIS drives both arms to measure a sphere at each of the positions defined in the **Edit Calibration Positions** dialog box. Be sure to have the desired number of sphere positions actually present on the CMM since there is not enough time to physically move the sphere around between measurements.

First arm holds tool and second arm measures

- If you select this option and you use **Manual calibration**, PC-DMIS prompts you to move Arm1 to each position and then measure the spherical tool with Arm2.
- If you select this option and you use **DCC calibration**, PC-DMIS moves Arm1 to each of the given calibration positions and then commands Arm2 to measure the sphere at that position. For this option, you need a special sphere mounted onto the end of the arm.

Second arm holds tool and first arm measures

- If you select this option while using **Manual calibration**, PC-DMIS prompts you to move Arm2 to each position and then measure the spherical tool with Arm1.
- If you select this option while using **DCC calibration**, PC-DMIS moves Arm2 to each of the given calibration positions and then commands Arm1 to measure the sphere at that position. For this option, you need a special sphere mounted into the end of the arm.

9. Click **Calibrate** once this button becomes enabled. It remains disabled until you select all needed calibration parameters.

   If you select **Both arms measure tool**, you must provide the following items before the **Calibrate** button becomes available:

- A valid Arm1 probe file name and tip angle.
- A valid Arm2 probe file name and tip angle.
- A valid tool specified in the list of available tools.

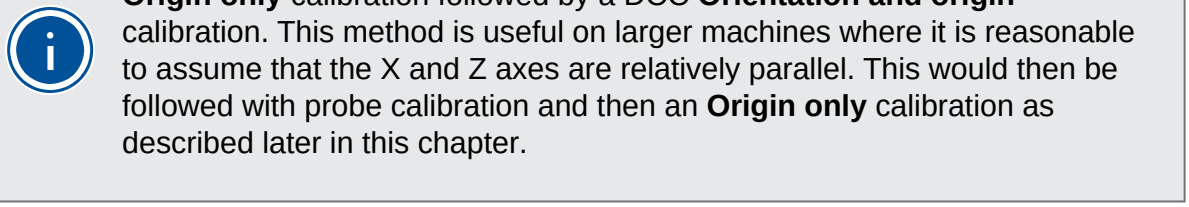
If you select **First arm holds tool and second arm measures**, you must provide the following items before the **Calibrate** button becomes available:

- A valid Arm1 probe file name and tip angle.
- A valid Arm2 probe file name and tip angle.
- The Arm1 tip type must be of type FIXEDBALL as specified in the probe.dat.

If you select **Second arm holds tool and first arm measures**, you must provide the following items before the **Calibrate** button becomes available:

- A valid Arm1 probe file name and tip angle.
- A valid Arm2 probe file name and tip angle.
- The Arm2 tip type must be of type FIXEDBALL as specified in the probe.dat.

10. Once you click this button, PC-DMIS begins the requested calibration. This creates an alignment between Arm1 and Arm2 by leveling, rotating, and setting the origin.
    - If you selected the **Manual calibration** option, you must begin by taking one point on the top of the tool. PC-DMIS automatically measures the rest of the points. Once you have measured the tool in the current position, PC-DMIS prompts you to move it to a new location on the table.
    - If you selected the **DCC calibration** option, PC-DMIS measures each of the given calibration sphere positions. Make sure the tool locations on the table are *not* co-linear (in a line). Position the tool locations as far as possible from each other, with at least one of the positions being raised up in the Z axis.



An alternate way to calibrate DCC machines involves performing a Manual **Origin only** calibration followed by a DCC **Orientation and origin** calibration. This method is useful on larger machines where it is reasonable to assume that the X and Z axes are relatively parallel. This would then be followed with probe calibration and then an **Origin only** calibration as described later in this chapter.

Part 2 of Calibration Procedure

Once you have completed the calibration described in Part 1, you need to calibrate the Arm1 and Arm2 probe files on the same calibration tool. This resets the origin relationship

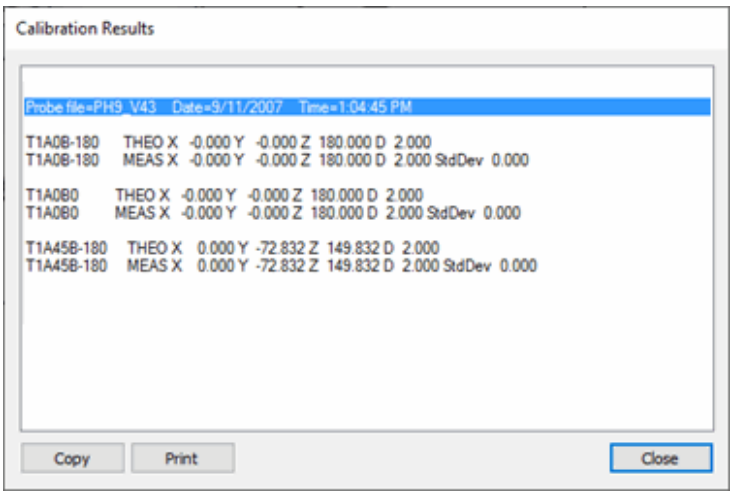
between the two tips. It doesn't change the level or the rotation of the alignment, only the origin. If you are using a PHS wrist, you need to do a wrist calibration with both arms on the common tool.

Follow this procedure:

1. Click the **Arm 1 Active** button on the **Active Arms** toolbar (**View | Toolbars | Active Arms**). Most users assign this button to the primary computer.
2. Access the **Probe Utilities** dialog box (**Insert | Hardware Definition | Probe**).
3. If PC-DMIS asks you if you want to load a new probe file, click **No**.
4. Calibrate the Arm1 probe (or do a wrist calibration if you are using a PHS). PC-DMIS prompts if the tool has been moved.
5. Click **Yes**, and follow the on-screen prompts.
6. When you complete the calibration, exit the **Probe Utilities** dialog box.
7. Click the **Arm 2 Active** button on the **Active Arms** toolbar. Most users assign this button to the Arm2 computer.
8. Access the **Probe Utilities** dialog box to calibrate the Arm2 probe (or do a wrist calibration if you are using a PHS).
9. This time when PC-DMIS prompts if the tool has been moved, click **No**.

Once you have calibrated both probe files in multiple arm mode, you are done with the calibration of the multiple arms. PC-DMIS copies the Arm2 file, the tool data, and the arm-to-arm transformation data to the Arm2 computer. This allows you to run Arm2 on its own as if it were an extension of the Arm1 coordinate system, or you can always run them together in multiple arm mode.

Viewing Calibration Results



If needed, you can access the calibration results by clicking on the **Results** button of the **Probe Utilities** dialog box. This displays the **Calibration Results** dialog box, which displays information about the calibrated tips of the related probe file. You can view the Arm2 calibration results in this same way on your Arm2 computer.

Performing an Automatic Calibration

In addition to the usual multiple arm calibration, you can perform an *automatic* calibration of the arms. PC-DMIS provides a command that automatically calibrates the current probe during measurement routine execution. PC-DMIS begins the calibration routine once it executes the command. To insert this command, select the **Insert | Calibrate | AutoCalibrate Multiple Arm** menu option.

The following command block is inserted into the Edit window:

```
AUTOCALIBRATE/MULTIPLEARM, ARM_THAT_MEASURES=BOTH,
MEASURE_MODE=DCC, OPERATION TYPE=ORIGIN,
QUALTOOL_ID=SPHERE3, MEASURE_AT_CENTER 1=<0,0,0>
ARM 1=CMM1, ARM 2=CMM2
```

A description of the items in this command block is given here:

ARM_THAT_MEASURES=
Indicates which arm performs the measurement (not which arm holds the tool). Choices are `BOTH` , `ARM2` or `ARM1` .

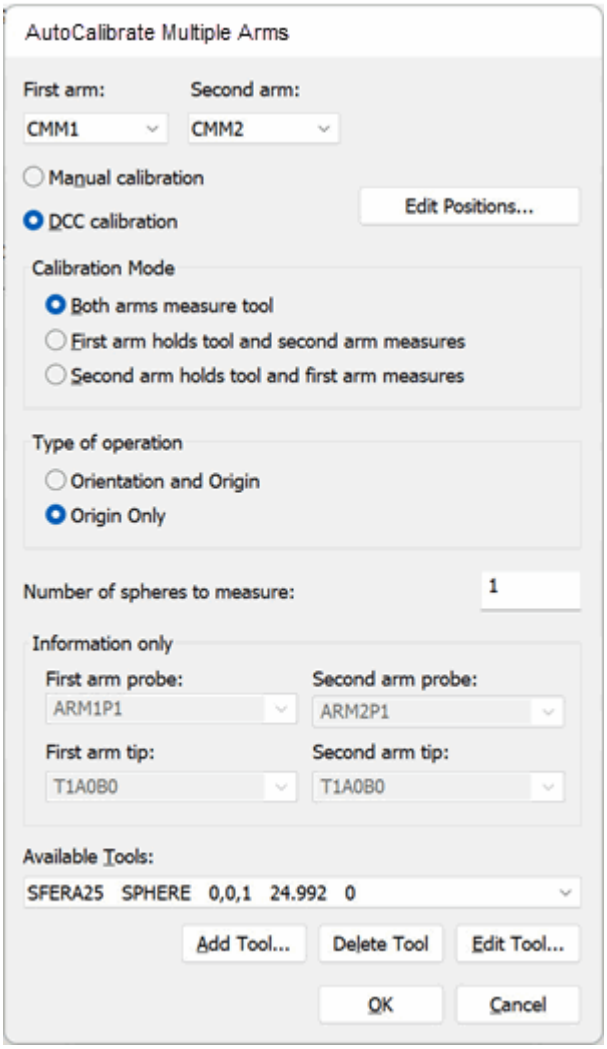
MEASURE_MODE=
Indicates whether the calibration is in `MANUAL` or `DCC` mode.

OPERATION_TYPE=
Indicates if calibration is for `ORIENTATION AND ORIGIN` or `ORIGIN` only.

QUALTOOL_ID=
Specifies the name of the qualification tool used.

MEASURE_AT_CENTER 1=
The X, Y, Z location to be used for measurement when using `CALIBRATION_MODE=DCC` . This is not present if the command is using `CALIBRATION_MODE=MANUAL` .

Press F9 to open the **AutoCalibrate Multiple Arms** dialog box.



AutoCalibrate Multiple Arms Dialog Box

Most of the items in this dialog box are the same as those used in the **Multiple Arm Calibration** dialog box (**Operation | Calibrate/Edit | Multiple Arm Mode**). The differences are listed below:

You cannot specify the probe and tip for Arm1 or Arm2. They are shown in the lists on this dialog box for information purposes only. The `AUTOCALIBRATE/MULTIPLEARM` command gets them from the content of the measurement routine in which the command is used.

First Arm Probe
For display only. This is determined by the `LOADPROBE` command for Arm1 that precedes the `AUTOCALIBRATE/MULTIPLEARM` command

First Arm Tip
For display only. This is determined by the `TIP` command for Arm1 that precedes the `AUTOCALIBRATE/MULTIPLEARM` command

Second Arm Probe
For display only. This is determined by the `LOADPROBE` command for Arm2 that precedes the `AUTOCALIBRATE/MULTIPLEARM` command

Second Arm Tip
For display only. This is determined by the `TIP` command for Arm2 that precedes the `AUTOCALIBRATE/MULTIPLEARM` command

Step 9: Calibrate the Multiple Arm Probe Files

Now that the system has been calibrated, you need to calibrate the multiple arm probe files.

For this calibration, you can:

- Calibrate any arm in any order.
- Use different calibration tools to calibrate the different arms.
- Calibrate Arm2 from the Arm2 computer and Arm1 from the Arm1 computer.
- Calibrate the Arm2 probe on the same calibration tool as the Arm1 probe.
- Only calibrate one arm at a time.

After this calibration, PC-DMIS synchronizes the probe files from the multiple computers the next time you enter multiple arm mode on the Arm1 computer.

Arm1 Probe File Calibration

If you want to calibrate the Arm1 probe file:

1. Select the **Arm 1 Active** icon from the **Active Arms** toolbar (**View | Toolbars | Active Arms**).
2. Access the **Probe Utilities** dialog box (**Insert | Hardware Definition | Probe**).
3. Follow existing procedures in the "Calibrating Probe Tips" topic of the "PC-DMIS CMM" documentation for information on how to calibrate probe files.

Arm2 Probe File Calibration

If you want to calibrate the Arm2 probe file:

1. Select the **Arm 2 Active** icon from the **Active Arms** toolbar (**View | Toolbars | Active Arms**).
2. Access the **Probe Utilities** dialog box (**Insert | Hardware Definition | Probe**).
3. Follow the existing procedures in the "Calibrating Probe Tips" topic of the "PC-DMIS CMM" documentation for information on how to calibrate probe files.

If you want to use a calibration tool different from the one used for the Arm1 probe file, select the SPHERE(ARM 2) tool during Arm2 probe calibration.

To select the SPHERE(ARM 2) tool:

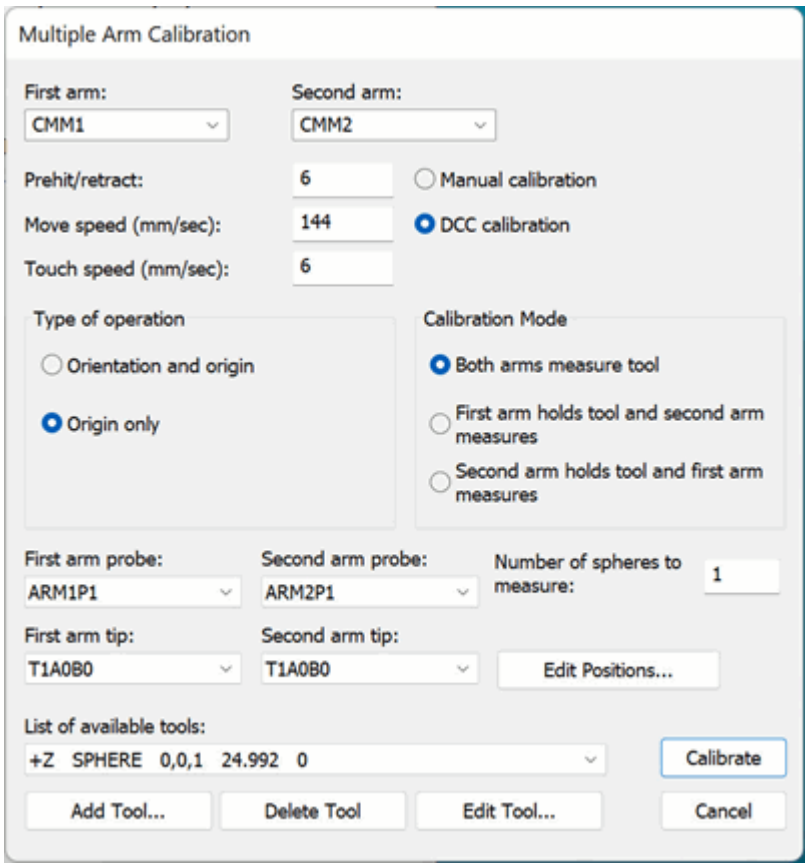
1. Select **Insert | Hardware Definition | Probe**.
2. Click **Measure**. The **Measure Probe** dialog box appears.
3. Click **Edit Tool**. The **Edit Tool** dialog box appears.
4. Select **SPHERE(ARM 2)** from the **Tool Type** list.
5. Click **OK** to confirm your choice. The SPHERE(ARM 2) information appears in the bottom of the **Measure Probe** dialog box.

Step 10: Set the Multiple Arm Origin

The final step in calibrating the multiple arm system is to set the origin between the two arms. You need to do this with calibrated probe files on both Arm1 and Arm2.

To set the multiple arm origin:

1. Open the **Multiple Arm Calibration** dialog box (**Operation | Calibrate/Edit | Multiple Arm Mode**).



Multiple Arm Calibration Dialog Box

2. Select the **Origin only** option.
3. In the **Number of spheres to measure** box, type the number of spheres you want to measure to establish the origin. If more than one sphere position is measured, PC-DMIS averages the positions to establish the origin.
4. Select the **Both arms measure tool** option.
5. Select the correct probe files and tips.
6. Select either the **DCC calibration** or **Manual calibration** option. If you select **DCC calibration**, make sure you define the correct sphere position using the **Edit Calibration Positions** dialog box.
7. From the **List of available tools**, select a tool that defines the correct diameter and orientation of the calibration tool to be measured.
8. Click the **OK** button.
    - If you selected the **Manual calibration** option, PC-DMIS prompts you to measure a single point on the sphere with the multiple arms. The rest of the points are then measured in DCC Mode around the sphere.
    - If you selected the **DCC calibration** option, PC-DMIS drives the arms to the sphere positions that are defined in the **Edit Calibration Positions** dialog box.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

Once you have calibrated all the probe files in multiple arm mode and set the arm-to-arm origin, the calibration process is complete.

After you finish your multiple arm calibration and perform a wrist calibration (see "Wrist Calibration" in the "Using a Wrist Device" chapter), you need to repeat the Origin Only wrist operation as discussed early on in "Step 8: Calibrate the Multiple Arm System".

PC-DMIS copies the Arm2 probe file, tool data, and arm-to-arm transformation data to the Arm2 computer. Arm2 is then capable of running on its own as if it were an extension of the Arm1 coordinate system. You also have the option of running them together in multiple arm mode. Each time you enter multiple arm mode (by selecting **Operation | Enter Multiple Arm Mode**), PC-DMIS synchronizes the following between the two computers:

- Probe file changes
- Wrist calibration changes
- Error map data changes
- Probe changer data
- Calibration tool data changes

Creating a Measurement Routine Using Multiple Arm Mode

Once you have defined and calibrated the probes, you can create the measurement routine. You create a multiple arm measurement routine like any other measurement routine with some differences. Mainly, in a multiple arm measurement routine, you need to assign specific arms to execute different commands and define exclusion zones so that the arms don't collide. The topics below describe how to do this:

Assigning a Command to an Arm

By default, PC-DMIS assigns new commands to the current active arm. You can use the **Active Arms** toolbar (**View | Toolbars | Active Arms**) to switch the current active arm or to execute only those commands tied to a specific arm.

Active Arms Toolbar

The **Active Arms** toolbar contains multiple arm icons with corresponding color coded check mark icons. Each arm icon corresponds to an arm on the machine.

	Arm1
	Arm2
	Execute on Arm1
	Execute on Arm2
	Move to Arm1 Start Point
	Move to Arm2 Start Point
	Execute From Start Point

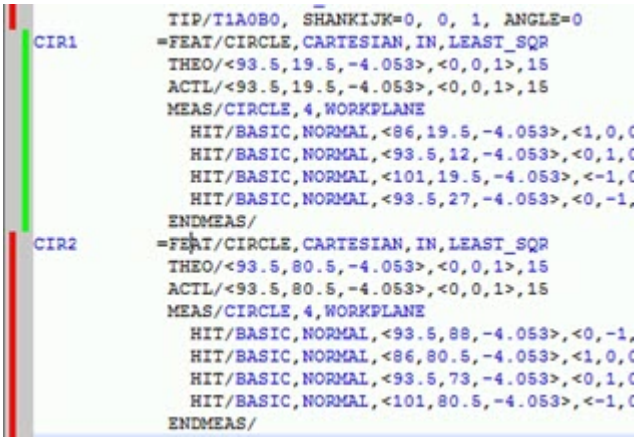
The *Arm(n)* icons (those with numbers) switches the current active arm.

The *Execute on Arm(n)* icons (those with check marks) executes only those commands associated with a specific arm.

The *Move to Arm(n) Start Point* icons move the cursor in the routine to the top of that arm's starting position.

The *Execute From Start Point* icon executes the routine for both arms at the currently defined start point.

Once Multiple Arm Mode is initiated, PC-DMIS inserts colored *vertical* lines into the left margin of the Edit window's Command Mode. This is used to identify the commands that are used for each arm. (In Summary Mode, PC-DMIS indicates commands assigned to the Arm2 with bold text.)



Edit window with green (feature CIR1) and red (feature LIN1) lines designating Arm2 and Arm1 portions respectively

- Features assigned to Arm1 are indicated using the red line.
- Features assigned to Arm2 are indicated using the green line.
- Features assigned to multiple arms are indicated using multiple colored lines.

Colored *horizontal* bars (instead of vertical) signify that the commands affect both arms and neither arm is allowed to execute this command until both arms have executed all prior commands. This type of command (usually a branching or alignment command) is executed by both arms at the same time.

Assigning Existing Commands to a New Arm

The **Toggle Multiple Arm Markings** menu item is only available on systems that have entered into multiple arm mode.

If you have commands assigned to a particular arm and you want to assign them to a different arm, do the following.

1. Place the Edit window into Command Mode.
2. Select the Edit window command you want to add.
3. Select **Operation | Toggle Multiple Arm Markings**.

When you select this option, PC-DMIS connects all of the highlighted commands to the other arm.

- If you don't highlight any commands, PC-DMIS connects the command where the cursor resides in the Edit window.
- You can assign most commands to be executed by Arm1, Arm2, or both arms. For example, you could create a `PREHIT` or `ALIGNMENT` command that applies to both Arm1 and Arm2, or to just one of the arms.

- You cannot assign certain commands to multiple arms. These include *features*, *hits*, *dimensions*, and *probe commands*.

Multiple Arm Measurement Routine Execution

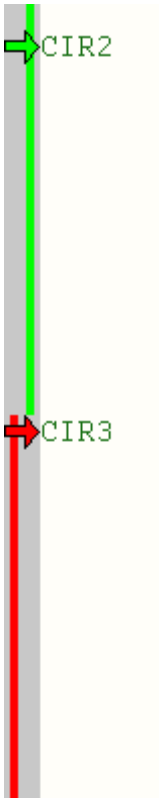
Unless you choose to execute just the commands assigned to a particular arm, when you execute the measurement routine, the routine flow continues as it normally does from the top of the Edit window to the bottom. Each arm executes the commands assigned to it.

When you execute in multiple arm mode, Arm2 runs a little behind Arm1. This type of delay is expected.

Setting Start Points for Multiple Arms

You can assign start points for the current arm by selecting the **Set Start Point** icon ( ) on the **Edit Window** toolbar. This is also accomplished by right-clicking in the Edit window in Command Mode and selecting it from the shortcut menu.

To set multiple start points, change the current learn arm before you click the **Set Start Point** toolbar icon.



A special start point arrow will appear in the left margin of the Edit window in a color that corresponds to the active arm color on the **Active Arms** toolbar (**View | Toolbars | Active Arms**).

The screen capture to the left shows that Arm1, in red, will begin execution at CIR3 while Arm2, in green, will begin execution at CIR2.

If you cancel execution, PC-DMIS automatically moves the start points for each arm to the command where the execution was cancelled for each arm.

Start points tell PC-DMIS to begin the routine's execution at that point when you select the **File | Partial Execution | Execute From Start Points** menu option. For information on using start points, see the "Setting Start Points" topic in the "Editing a Measurement Routine" chapter.

Be aware that if the current tip for that location in the routine does not match the current orientation of the probe head, PC-DMIS does not go back to execute the tip command above it in order to change the tip orientation.

Causing an Arm to Wait to Prevent Collision

Sometimes you may want one arm to wait until the other arm has finished measuring in an area that is overlapping. This is usually to prevent a collision between the arms. There are two different commands to prevent this.

You cannot use the `MOVE/SYNC` command within a Move Exclusion zone.

Using a Move Sync Command

You can put `MOVE/SYNC` commands at the beginning and end of a measurement sequence where you want to make sure that only one arm is moving. See "Inserting a Move Sync Command" in the "Inserting Move Commands" chapter for additional information.

Using a Move Exclusive Command

You cannot use the `MOVE/SYNC` command within a Move Exclusion zone.

You can use the `MOVE/EXCLUSIVE_ZONE` command.

- The advantage of using this method is that PC-DMIS only makes one of the arms wait if the other arm is in its zone.
- The disadvantage is that you need to put `MOVE/EXCLUSIVE_ZONE` commands around all the blocks of commands that command an arm into the overlapped area in the middle of the dual arm volume.

To use this command:

1. Find the sequence of commands that causes one of the arms to enter into an overlapped portion of the CMM volume.
2. Place a `MOVE/EXCLUSIVE_ZONE=ON` command at the start of the sequence.
3. Place a `MOVE/EXCLUSIVE_ZONE=OFF` at the end of the sequence.

Use the `MOVE/EXCLUSIVE_ZONE=ON` command to specify two corner points that form a 3D zone. PC-DMIS reserves this zone for the arm that is assigned the command. If the other arm is already in the requested zone, then PC-DMIS waits until the first arm is out of the way and exits the contested space with a `MOVE/EXCLUSIVE_ZONE=OFF` command. See the "Inserting a Move Exclusion Zone Command" topic in the "Inserting Move Commands" chapter in the PC-DMIS documentation for additional information.

Using Temperature Compensation with Multiple Arm Calibration

A thermocouple is a thermoelectric couple that measures temperature differences.

If you're compensating for temperature on the CMMs, you need to insert two temperature compensation commands into the routine - one command for Arm1 and another command for Arm2. Also, only the thermocouple for the part which is attached to the Arm1 controller is used for recording the part temperature.

In addition to having the STP file (Serv1.stp) in the appropriate directory on the Arm2 computer, you must also ensure that another STP file for Arm2 (named Serv1s.stp) resides in the corresponding directory on the Arm1 computer. To do this, copy Serv1.stp from the Arm2 computer, rename it to Serv1s.stp and place it on the Arm1 computer.

Synchronizing Arms for TEMPCOMP Commands

Once you have the TEMPCOMP commands inserted, you need to ensure that the arms are synchronized. To do this, insert two MOVE/SYNC commands, one before and one after the TEMPCOMP command assigned to Arm2, as shown here:

```
MOVESPEED/ 100
FLY/ON,3
TEMPCOMP/ORIGIN=0,0,0,Material Coeff=0.0000115,Reference Temp=20
  ,Hi Threshold=40,Lo Threshold=10,Sensor num=3
  ,X Axis Temp=21.141,Y Axis Temp=22.7843,Z Axis Temp=23.3941,Part Temp=21.6783
LOADPROBE/TEST_MASTER
MOVE/SYNC
TEMPCOMP/ORIGIN=0,0,0,Material Coeff=0.0000115,Reference Temp=20
  ,Hi Threshold=40,Lo Threshold=10,Sensor num=3
  ,X Axis Temp=,Y Axis Temp=,Z Axis Temp=,Part Temp=21.3603
MOVE/SYNC
LOADPROBE/TEST_MASTER
TIP/T1A0B0, SHANKIJK=0, -1, 0, ANGLE=0
LOADPROBE/TEST_SLAVE
TIP/T1A0B0, SHANKIJK=0, 1, 0, ANGLE=180
```

The highlighted items in this graphic show the two MOVE/SYNC commands around the TEMPCOMP command for Arm2

- The first MOVE/SYNC command provides the correct sequence for writing temperature values to the report. This ensures that temperature values are displayed for Arm1 first.
- The second MOVE/SYNC command prevents Arm2 from measuring until Arm1 finishes obtaining the part's temperature.

For more information on MOVE/SYNC, see "Inserting a Move Sync Command" in the "Inserting Move Commands" chapter.

For more information on temperature compensation, see the "Compensating for Temperature" topic in the "Setting Your Preferences" chapter.

Running the Arm1 Measurement Routine on Arm2

If you need to run your Arm1 measurement routine on Arm2, you can run PC-DMIS in Reverse Axes mode. This mode internally reverses the sign of the X and Y axes, making the Y axis positive towards the center of the machine and the X axis opposite the Arm1 X axis.

All existing probe files, wrist maps, tool changers, and other calibration and error comp files are usable in this mode without any change.

Calibrations done in either normal or Reverse Axes mode are correct and usable in either mode.

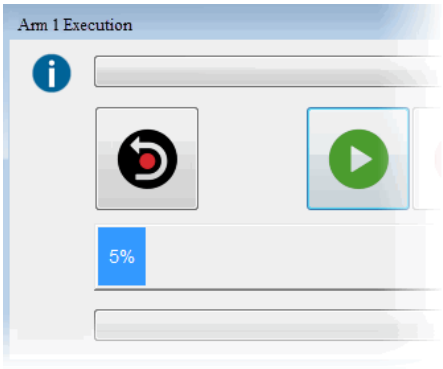
To add an icon that runs PC-DMIS in Reverse Axes mode

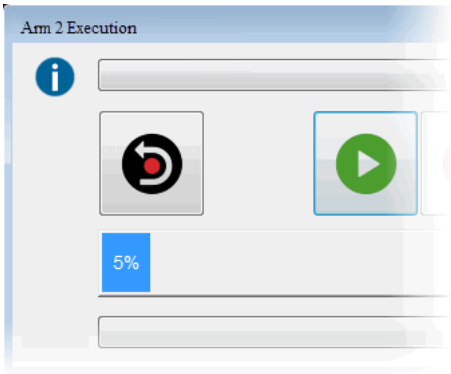
1. Use Windows Explorer and navigate to the directory where you want to add the icon.
2. From Windows Explorer's **File** menu, select **New** | **Shortcut**. A **Create Shortcut** wizard appears and prompts you to enter the path to the routine.
3. In the **Command Line** box, either type the complete path to the PC-DMIS executable file, or use the **Browse** button to navigate to and select the file. The default path is "C:\Pcdmisw\Pcdlrn.exe".
4. Once you have the path in the **Command Line** box, place your cursor at the end of the path, type a space, and then type a **/r** or **-r** switch. This switch notifies PC-DMIS to run in Reverse Axes mode. You can also combine this with Operator mode by adding a **–o** or **/o** switches to the command line.
5. Click **Next**.

6. In the **Select a Name for the Shortcut** box, type something like "PC-DMIS Reverse Axes Mode".
7. Click **Finish**. The new icon appears.

Dialog and Message Boxes in Multiple Arm Mode

Once you enable Multiple Arm Mode for your measurement routine, any dialog boxes or message boxes that are related to a specific arm contain an "Arm 1" or "Arm 2" identifier in their captions, like these **Execution** dialog boxes:





Dialog and message boxes that are affected include:

- **Execution** dialog box (**File | Execute**)
- **Probe Changer** dialog box (**Edit | Preferences | Probe Changer**)
- Info messages
- Warning messages
- Error messages

Dual Arms with Wrists Calibration Example

This advanced topic assumes you have a solid working understanding of PC-DMIS, including such concepts as probe angles, calibrations, the autocalibrate command, move point commands, multiple arm mode, and other concepts.

This topic provides a typical calibration example to show the steps needed to calibrate a dual-arm horizontal machine with different extensions on the wrist and with a probe changer. After a full calibration, additional steps explain how to create two measurement routines that will automate the calibration steps so you can more quickly perform the calibration when needed. Some steps are described generally and assume that as an advanced user, you are already familiar with the underlying principles needed.

This example uses CW43L_Multiwire wrists with short, medium, and long probe extensions containing TP2/TP6 probes. Your actual procedure will differ.

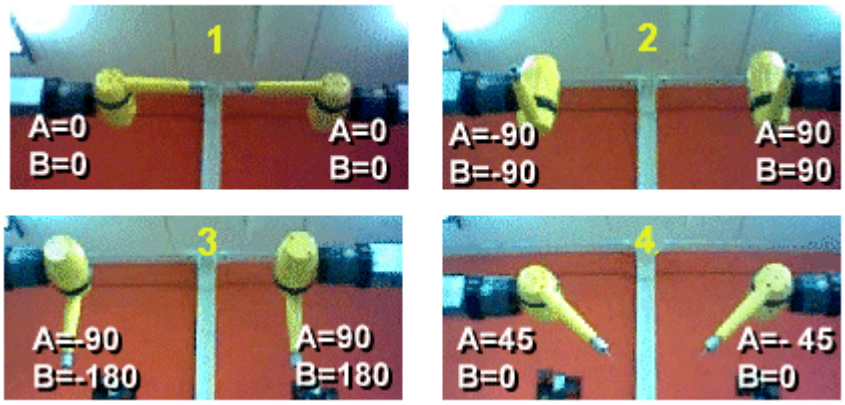
Before you begin, make sure the following has taken place:

- The machine has been properly compensated. This compensation data must reside in the Leitz controller for both the arms.
- You understand the importance of temperature compensation.

  Be sure to take into account how temperature will affect your calibration, and compensate as needed.

  The coefficient of expansion of the part (or in this case the calibration sphere) is zero. For more information, see "Compensating for Temperature" in the "Setting Your Preferences" chapter.

- Both arms have been properly assembled and aligned.
- A technician should have corrected any possible skew that may have occurred during the assembly and mechanical levelling of the wrists. Data from this correction should have been stored in the controller in the COSDAT.
- You should understand the wrist orientations on each arm. Each wrist when positioned at specific angles determines the orientation of that wrist's head compared with the machine's axes. The following example demonstrates some angles used on a PRIMA machine:



Example showing angular positions and the corresponding orientation values for each arm.

Long extensions are often useful on vertical machines and wrists. If you use a very long extension, you'll need to create a map for that extension. These machine types are highly accurate, and it takes several hours to finish a mapping on this type of machine.

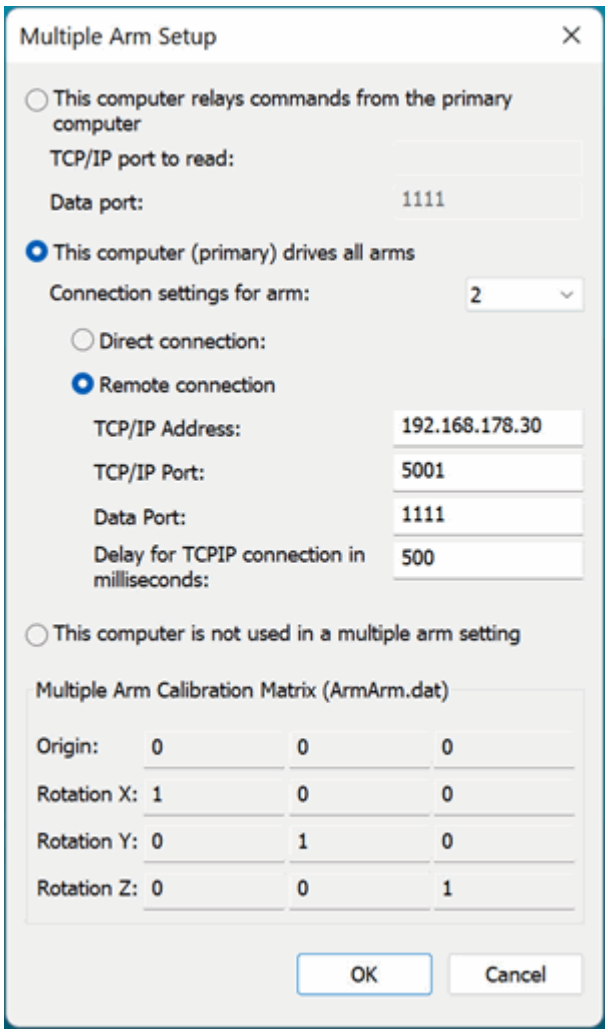
Step 1: Define Connection Info and Configure Angles

Since the two arms use different orientations, you need to properly configure the setup parameters to reflect this.

Set Up the Primary Computer

On your primary computer, modify the **Multiple Arm Setup** dialog box with these options:

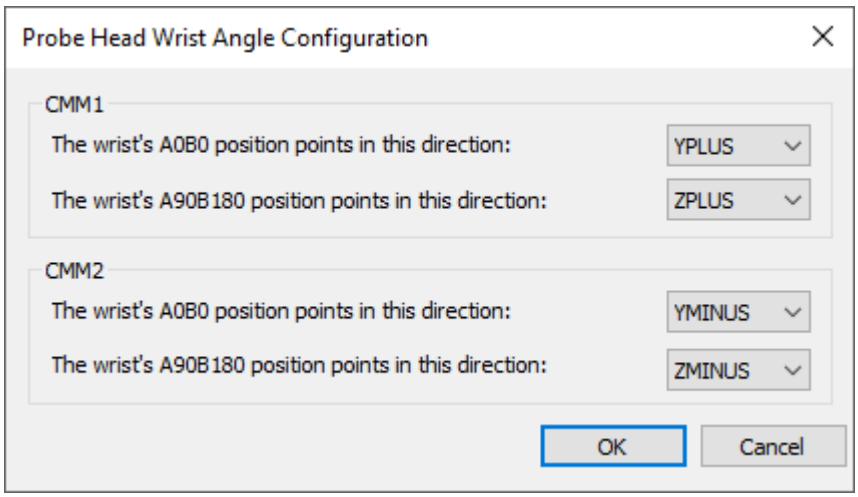
1. To access this dialog box, select **Edit | Preferences | Multiple Arm Setup**.
2. Mark the **This computer (primary) drives all arms** option.
3. Choose **2** from the **Connection settings for arm** list.
4. Choose **Remote connection**. Set the connection values to the secondary machine: **TCP/IP Port**, **Data Port**, and **Delay for TCPIP connection in milliseconds**.
5. Click **OK** to close the **Multiple Arm Setup** dialog box.



Multiple Arm Setup Dialog Box

Also, modify the **Probe Head Wrist Angle Configuration** dialog box with these options:

1. To access this dialog box, select **Edit | Preferences | Setup**, the **Part/Machine** tab, and then the **Probe Head Orientation** button.
2. In the **CMM1** area, set the wrist's A0B0 position to point in YPLUS direction. Set the A90B180 position to point in ZPLUS.
3. In the **CMM2** area, set the wrist's A0B0 position to point in the YMINUS direction. Set the A90B180 position to point in ZMINUS.
4. Click **OK** to close the **Probe Head Wrist Angle Configuration** dialog box.
5. Click **OK** to close the **Setup Options** dialog box.



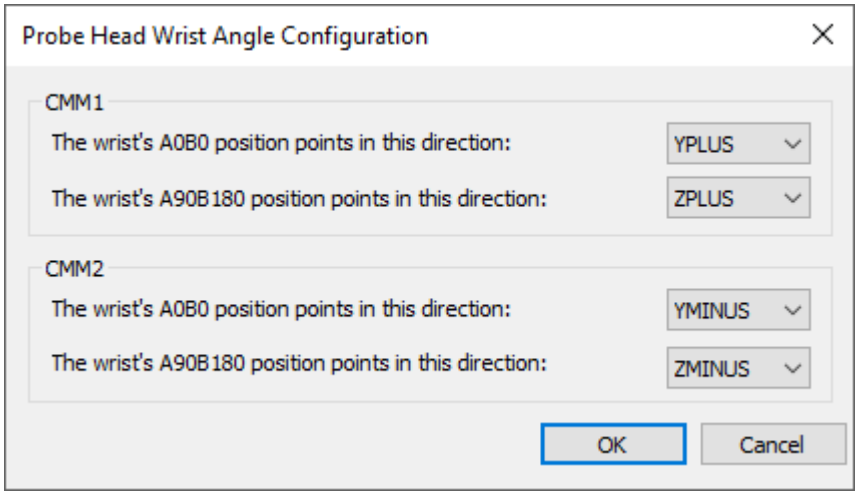
Probe Head Wrist Angle Configuration Dialog Box

Set Up the Secondary Computer

On the secondary computer, modify the **Multiple Arm Setup** dialog box, and click the **This computer relays commands from the primary computer** option.

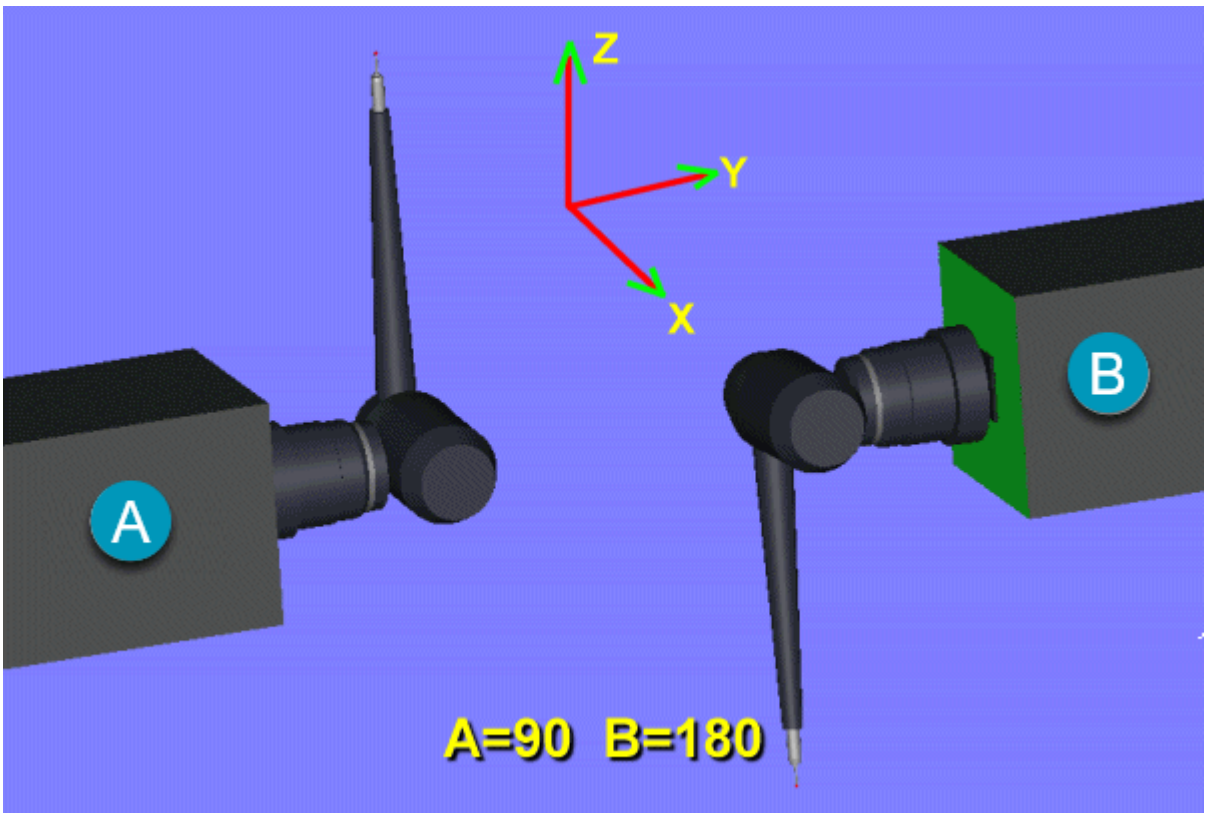
Modify the **Axis** tab of the **Machine Options** dialog box (**Edit | Preferences | Machine Interface Setup**) with these options:

- Set the **X** list to **-X**
- Set the **Y** list to **-Y**
- Set the **Z** list to **Z**



Probe Head Wrist Angle Configuration Dialog Box

The angles are now set up as shown here:



A. *Arm1*

B. *Arm2*

Angles with DEA Wrists

If you're using a machine with DEA wrists, use the PC-DMIS Settings Editor to modify these entries *on both computers* to the following values:

- `DEAWrist = 1`
- `RotateWristFromController = TRUE`
- `FlipBAxis = TRUE`
- `AaxisMax = 181`
- `AaxisMin = -181`

> The `AaxisMax` and `AaxisMin` entries define the allowed amount of angular rotation for the wrists. For very long extensions, you should not exceed +/- 124 degrees.

On the primary LEITZ computer (arm 1), set these entries:

- `AxisX = 0`
- `AxisY = 2`

- `AxisZ = 4`

On the secondary LEITZ computer (arm 2), set these entries:

- `AxisX = 1`
- `AxisY = 3`
- `AxisZ = 4`

Note on Different Configurations

If you need to configure your machine differently from a conventional DEA machine; for example, if you want to use the wrist convention used in the PHS Renishaw, you would need to set the following parameters. They are then stored in the JSON file:

1. In the **Machine Options** dialog box for arm 1 (computer 1), set the **B offset** value to -180.
2. In the **Probe Head Wrist Angle Configuration** dialog box, specify the proper axes associated with the wrist rotations.

The figure below shows the values you should change along with some sample wrist rotations at the noted angles:

The next step provides information on backing up your files.

Step 2: Backup and Delete Files

Before you continue with the calibration, be sure to back up the following items on both computers:

- The entry settings
- The *.PRB, and the *.Results files
- These data files: abcalib.dat, abcalib_CMM2.dat, abcomp.dat, abcomps_CMM2.dat, aboutput.dat, aboutput_CMM2.dat, wristm.dat, wrists_CMM2.dat, armarm.dat, tool.dat, toolc.dat

The PC-DMIS Settings Editor provides the ability to back up entry settings and user data files. See the "Working with Backup Files and User Data" topic in the PC-DMIS Settings Editor documentation for information on backing up important files.

You may have to back up some files manually. See the "Understanding File Locations" topic for information on where the above file types are stored in case you need to do this.

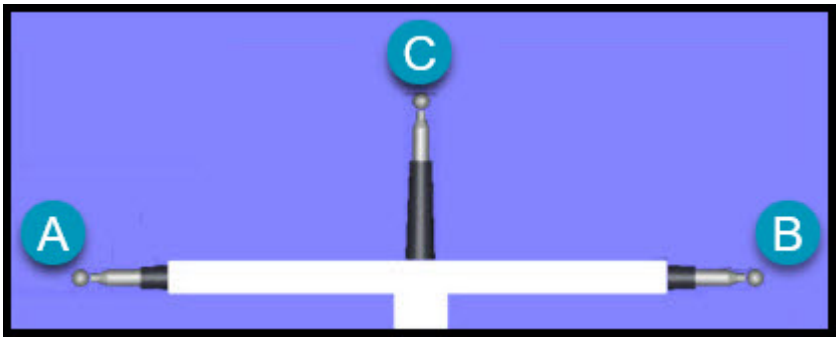
Now that you have backed up the above files, you should delete the original ones (keep the backed-up ones as needed). This ensures that you're starting with a fresh setup and that previous calibration data won't affect the current calibration.

The next step provides information on creating the basic arm-to-arm relationship.

Step 3: Create a Basic Arm-to-Arm Relationship

In this step, you'll create a measurement routine, define your probes, define your calibration spheres, and then perform an initial calibration to establish a basic relationship between the two arms. This calibration consists of machines containing wrists with probe extensions at a length of 332 mm. This will result in a calibration of medium accuracy. The probe changer will not be used at this point.

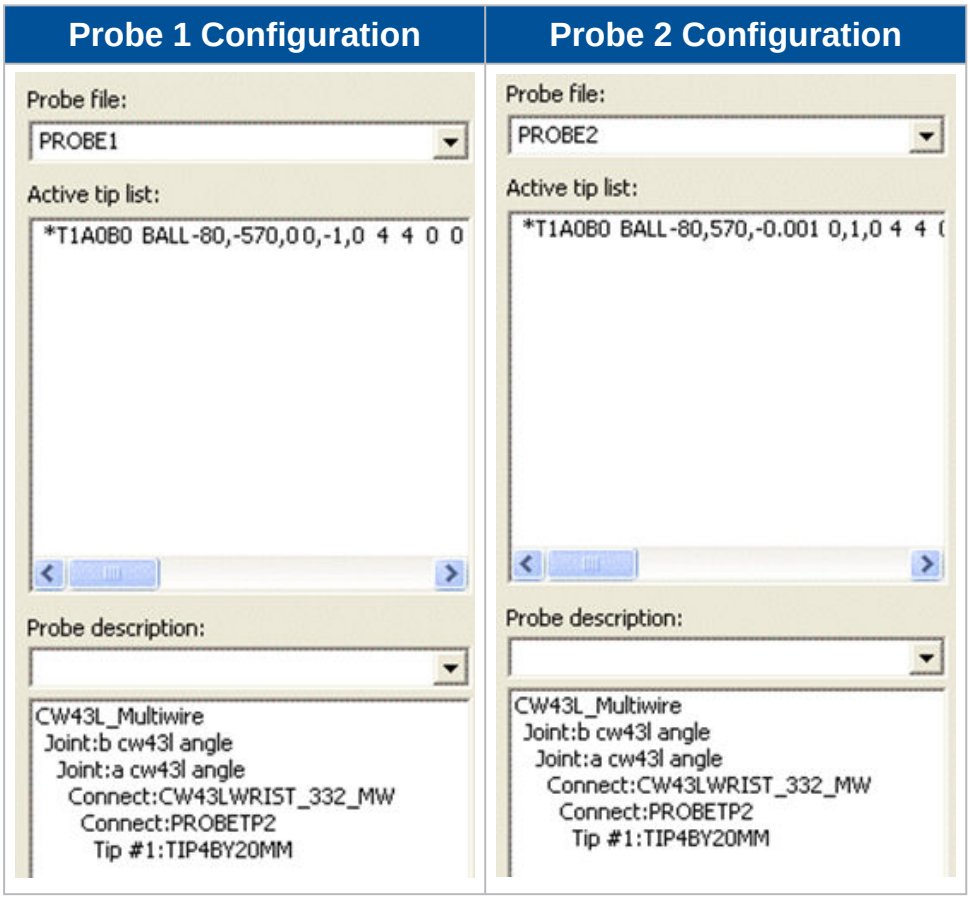
Three calibration spheres mounted on a cross-like fixture with 15 mm calibration spheres will be used for this calibration, like this:



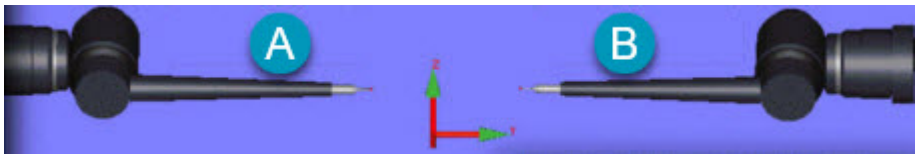
(A) - Sphere 1
(B) - Sphere 2
(C) - Sphere 3

Create a New Measurement Routine

Create a new measurement routine and then load or create the two probe files, PROBE1 and PROBE2, into your measurement routine.

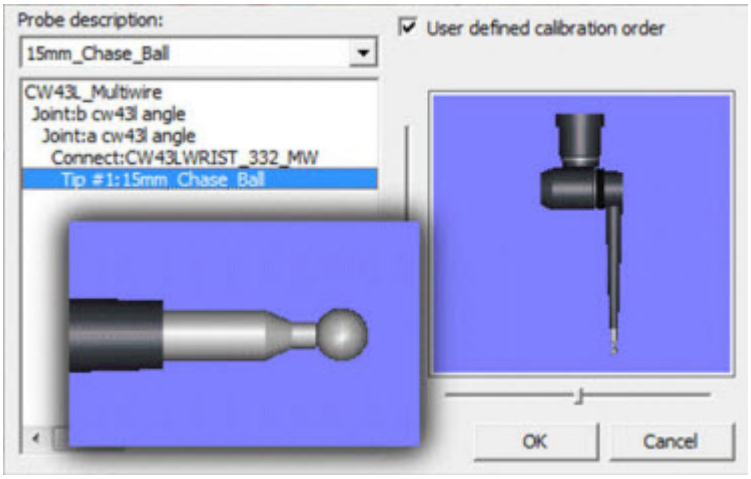


They should look like this:



(A) - Probe 1
(B) - Probe 2

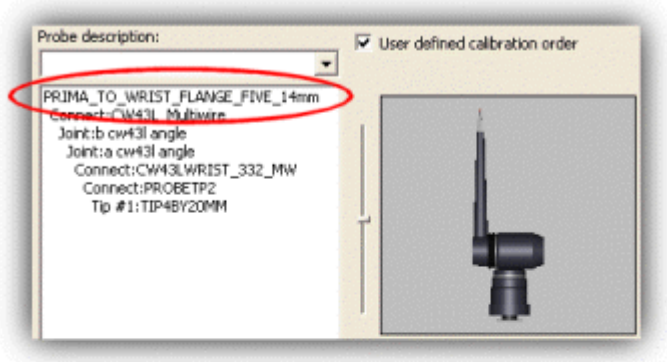
Load in a third probe file, name it PROBALL, and give it a 15 mm fixed rigid ball, like this:



Your measurement routine should look like this:

```
STARTUP    =ALIGNMENT/START,RECALL:,LIST=YES
            ALIGNMENT/END
            MODE/MANUAL
            PREHIT/6
            RETRACT/6
            CHECK/6,1
            MOVESPEED/ 80
            TOUCHSPEED/ 5
            SCANSPEED/80
            FORMAT/TEXT,OPTIONS, ,HEADINGS,SYMBOLS, ;NOM,TOL,MEAS,DEV,OUTTOL, ,
            LOADPROBE/PROBE1
            TIP/T1A0B0, SHANKIJK=0, 0, 1, ANGLE=0
            LOADPROBE/PROBE2
            TIP/T1A0B0, SHANKIJK=0, 0, 1, ANGLE=0
            LOADPROBE/PROBALL
            TIP/T1A0B0, SHANKIJK=0, 0, 1, ANGLE=0
                              END OF MEASUREMENT FOR
      PN=2010MR1_Test                 DWG=                SN=
   TOTAL # OF MEAS =0      # OUT OF TOL =0      # OF HOURS =00:00:00
```

If your physical structure of the probe and arm are not displayed in the **Probe Utilities** dialog box (**Insert | Hardware Definition | Probe**), be sure to edit the USRPROBE.DAT so that the dialog box displays the necessary hardware. For information on data files, see "Understanding Data Files" topic in the "Setting Your Preferences" chapter.



USRPROBE.DAT

Example usrprobe.dat file edited to contain a flange between the arm and wrist

Define the Calibration Spheres

1. Access the **Add Tool** dialog box:

- Select **Insert | Hardware Definition | Probe**.
- Click the **Measure** button.
- Click the **Add Tool** button.

2. In **Tool ID**, type SPHERE3.
3. In **Tool type**, choose SPHERE.
4. In the **Shank vector IJK** boxes, type 0,0,1.
5. In the **Diameter/Length** box, type 15.875.
6. Click **OK** to close the **Add Tool** dialog box.
7. Repeat steps 2 through 6 to define the SPHERE1 calibration sphere. Use 0,-1,0 for the vector.
8. Repeat steps 2 through 6 to define the SPHERE2 calibration sphere. Use 0,1,0 for the vector.
9. The information is stored and written to your Tools.dat file.
10. Click **Cancel** to close the **Measure Probe** dialog box.
11. Click **Cancel** to close the **Probe Utilities** dialog box.

Do a Preliminary Calibration

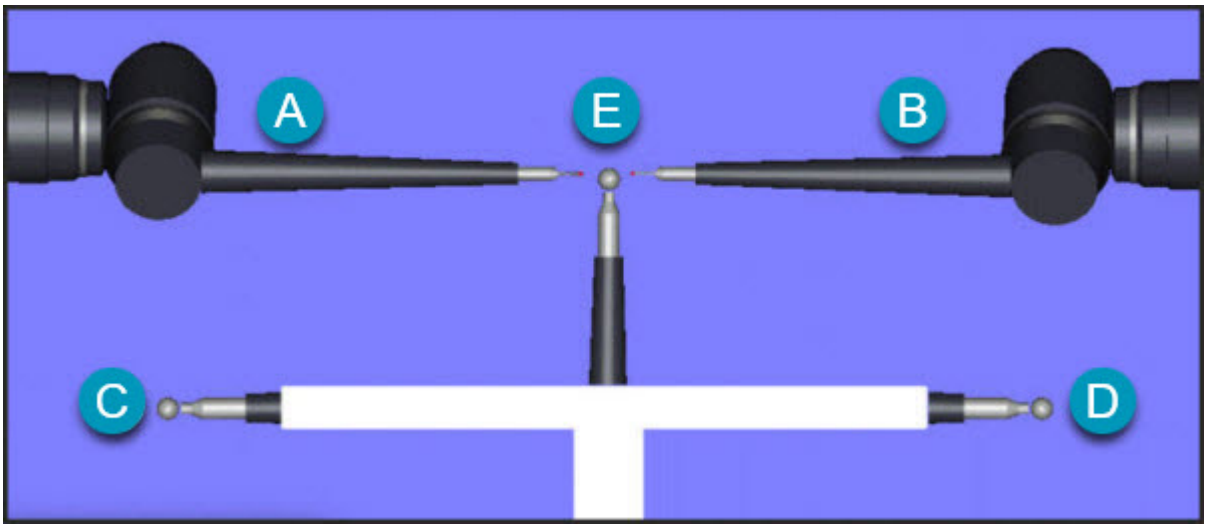
You need to perform a preliminary calibration on SPHERE3 in order to temporarily map the two arms. You can do this calibration without needing to calibrate the actual probe tips for PROBE1 and PROBE2.

1. Access the **Multiple Arm Calibration** dialog box by selecting **Operation | Calibrate/ Edit | Multiple Arm Mode**.
2. Set the **First arm** list to CMM1.
3. Set the **Second arm** list to CMM2.
4. Choose the **Both arms measure tool** option.
5. Type a value of 1 in the **Number of spheres to measure** box.
6. Choose the **Manual calibration** option.
7. Choose the **Origin only** option.
8. Set **First arm probe** to PROBE1.
9. Set **First arm tip** to T1A0B0.

10. Set **Second arm probe** to PROBE2.
11. Set **Second arm tip** to T1A0B0.
12. Choose **SPHERE3** from the list of available tools.
13. Click **Calibrate**. Follow any on-screen prompts.

When the calibration finishes, your Probe Readouts window for arm 1 and arm 2 should contain nearly identical X and Z values.

Before Calibration	After Calibration



Following a Preliminary Calibration on SPHERE3
(A) - PROBE 1
(B) - PROBE 2
(C) - Sphere 1
(D) - Sphere 2
(E) - Sphere 3

You've successfully calibrated SPHERE3 in order to temporarily map arms 1 and 2. The calibration information is stored within an ArmArm.dat file.

The next step provides information on initiating a more accurate calibration.

Step 4: Initiate a More Accurate Calibration

In this step, you will perform a more accurate calibration to define the alignment of the axes between arm 1 and arm 2.

1. Swap out the TP2 tip on the arm 1 extension with a 15 mm tip.

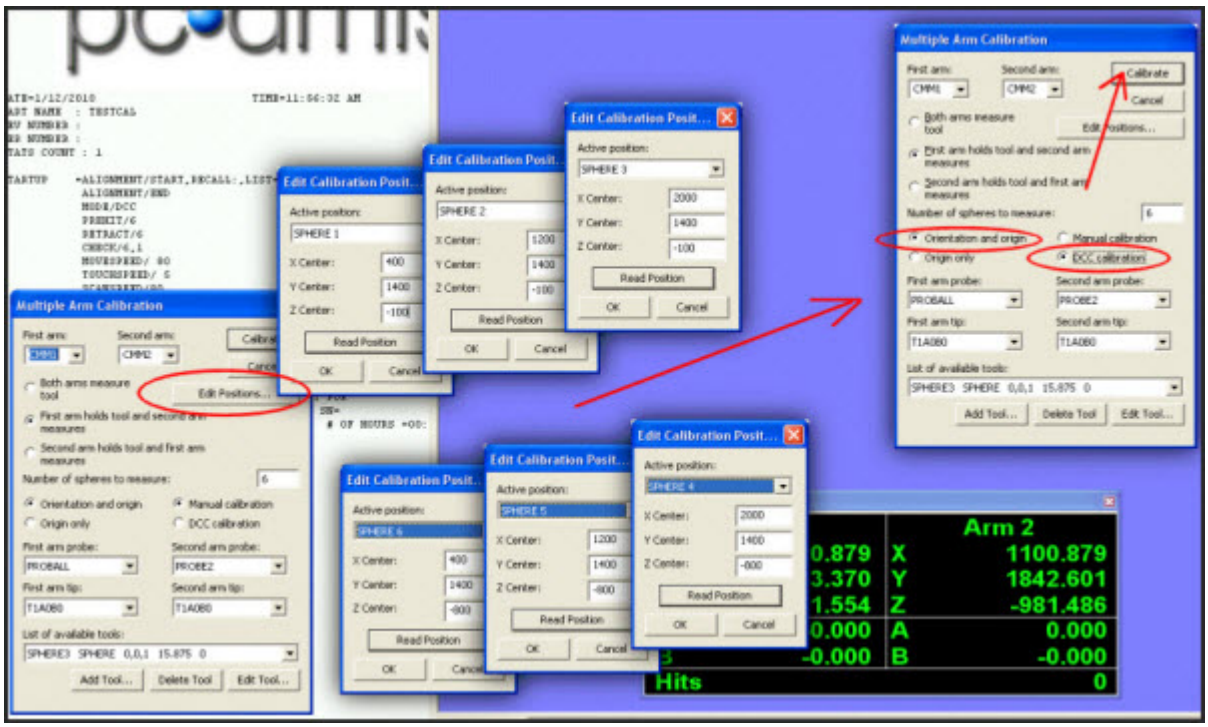
2. In the **Multiple Arm Calibration** dialog box (**Operation | Calibrate/Edit | Multiple Arm Mode**), make sure the following are set:

    - For **First arm probe**, select the PROBALL probe.
    - For **Second arm probe**, select the PROBE2 probe.
    - For **Number of spheres to measure**, define how many spheres PC-DMIS will measure with each arm. For this example we'll use a value of 6. But for your machine, you may want to choose a different number based on the dimensions of your machine. A value of 9 is good. 12 is the maximum. The higher the number, the greater the accuracy, but you'll also experience an increase in calibration time with more spheres during the DCC calibration.

3. Calculate the orientation plane so that the sphere of arm 1 will move on a plane lying on the Y center line of the machine. This will allow arm 2 to later reach the ball in all positions. To do this:

    - Manually move arm 1 to the six sphere positions specified in the **Multiple Arm Calibration** dialog box.
    - From the **Multiple Arm Calibration** dialog box, click **Edit Positions** and correct each sphere position as needed to improve the distribution. This may be needed since the positions are not perfectly aligned nor evenly distributed on the vertical plane.
    - You may find it helpful to read the position of the active arm to fill in the X, Y, Z coordinates. The **Read Position** button automatically uses the current X, Y, Z position of the arm.

4. Choose the **Orientation and Origin** option.
5. Choose the **DCC calibration** option.
6. Click **Calibrate**. The armarm.dat file is regenerated with a more accurate mapping from this calibration.



Different dialog boxes showing the settings used.

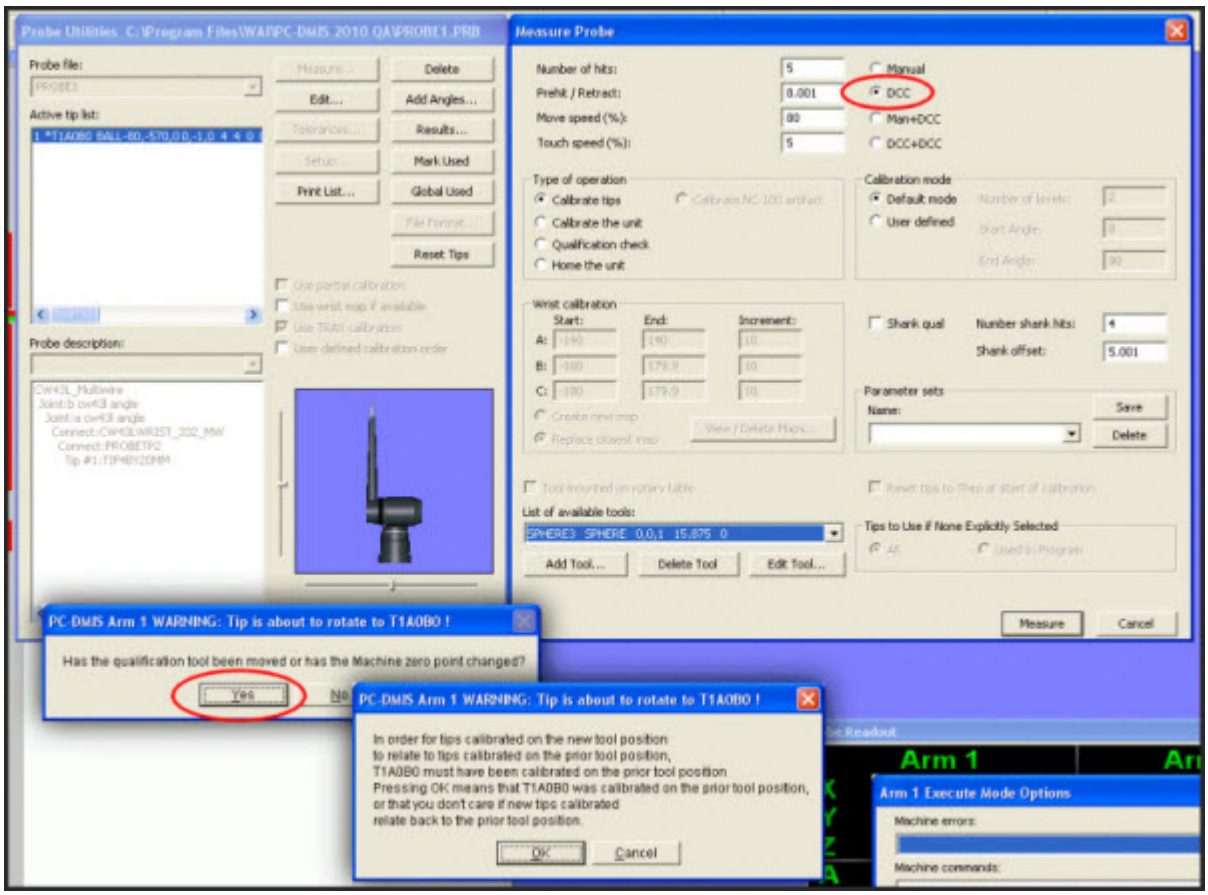
The next step provides information on performing the DCC calibrations.

Step 5: Performing a DCC Calibration

DCC Calibration of SPHERE3 Using Arm 1

Continue the calibration in DCC Mode for arm 1 measuring SPHERE3. This is the center sphere on the calibration fixture.

1. Swap out the 15 mm tip on the Arm 1 extension with the TP2 tip.
2. In the **Measure Probe** dialog box (**Insert | Hardware Definition | Probe | Measure** button) for the PROBEALL probe, choose **DCC**.
3. In the **List of available tools**, choose SPHERE3.
4. Click **Measure**.
5. When PC-DMIS asks if the qualification tool has moved or the machine zero point has changed, click **Yes**.



Different dialog boxes showing the settings used.

DCC Calibration of SPHERE1 Using Arm 1

1. In the **Measure Probe** dialog box, in the **List of available tools**, choose SPHERE1.
2. Ensure that the IJK orientation of this calibration sphere is correctly set to 0, -1, 0.
3. Click **Measure**.
4. When PC-DMIS asks if the qualification tool has moved or the machine zero point has changed, click **Yes**.

DCC Calibration of SPHERE2 using Arm 2

1. Access the **Measure Probe** dialog box for PROBE2, the probe on Arm 2.
2. In the **Measure Probe** dialog box, choose **DCC**.
3. In the **List of available tools**, choose SPHERE2.
4. Ensure that the IJK orientation of this calibration sphere is correctly set to 0, 1, 0.
5. Click **Measure**.
6. When PC-DMIS asks if the qualification tool has moved or the machine zero point has changed, click **Yes**.

The next step provides information on mapping the wrists of Arm 1 using SPHERE1.

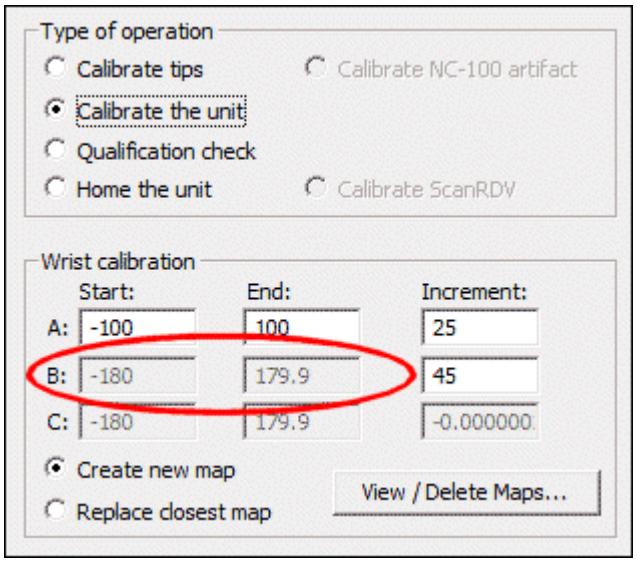
Step 6: Map the Wrists of Arm 1 using SPHERE1

At this point, you have a probes for both arms defined. You've also defined the orientation between the arms. Now, you need to map available wrist angles you'll be using.

1. Check to see the ability to use wrist maps is already enabled. You can do this by accessing the **Probe Utilities** dialog box for a probe that has a wrist. If you see the **Use wrist map if available** check box, this functionality is enabled. If you don't see it, check to ensure that the `DeaWrist` entry is set to 1.

2. Access the **Measure Probe** dialog box (**Insert | Hardware Definition | Probe | Measure** button) for PROBE1 and set these options and values:

    - In the **Type of operation** area, choose **Calibrate the unit**.
    - In **Calibration Mode**, choose **User defined**.
    - The boxes in the **Wrist calibration** area should now be editable.
    - Choose **DCC + DCC**. This is needed for long extensions.
    - For the A angle values (the probe's pitch), define the following: For **Start A**, type -90; for **End A**, type 90; and for **Increment**, type 30.
    - In the B angle values (the probe's roll), define the following: For **Start B**, type -180; for **End B**, type 180; and for **Increment**, type 45. Note that you cannot adjust the A and B angles. You can only adjust the increment.



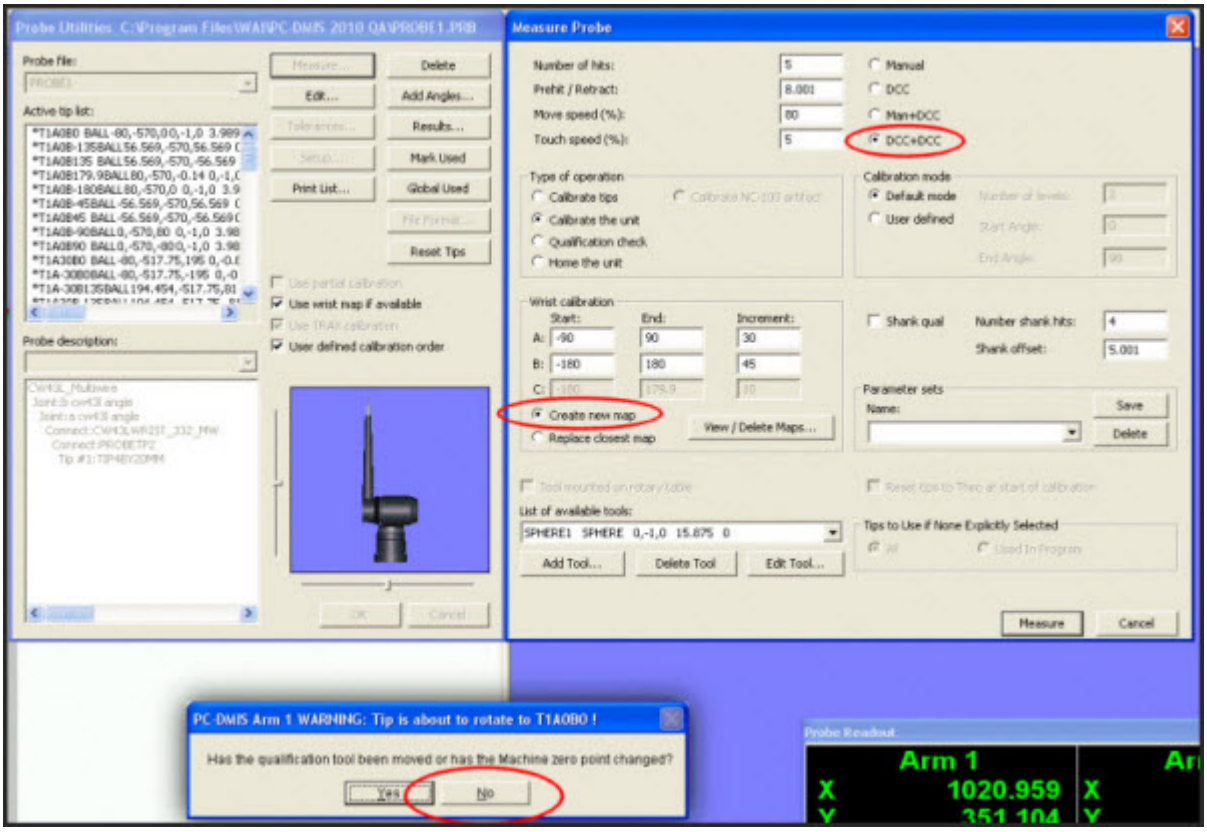
Wrist Calibration area with B angles disabled in version 2012 and later.

    - Choose **Create new map**.

> For increased precision in your calibration, you can decrease the increment value. This increases the time. For shorter extensions, the value of 30 and 45 is a medium value.

3. For **List of available tools**, choose SPHERE1.
4. Click **Measure**.
5. When PC-DMIS asks if the qualification tool has been moved or the machine zero point changed, click **No**.

Arm 1 starts to measure all the positions defined in the dialog box. Generally, this lasts approximately an hour, but it depends on the speed of the machine and the size of your probe's extension. A shorter extension is faster.



Different dialog boxes showing the settings used.

The next step provides information on mapping the wrists of Arm 2 using SPHERE2.

Step 7: Map the Wrists of Arm 2 Using SPHERE2

Repeat Step 6, but instead use Arm 2 with SPHERE 2. After both arms have calibrated the wrist angles, the following files are created or modified with the latest calibration data:

- *. PRB

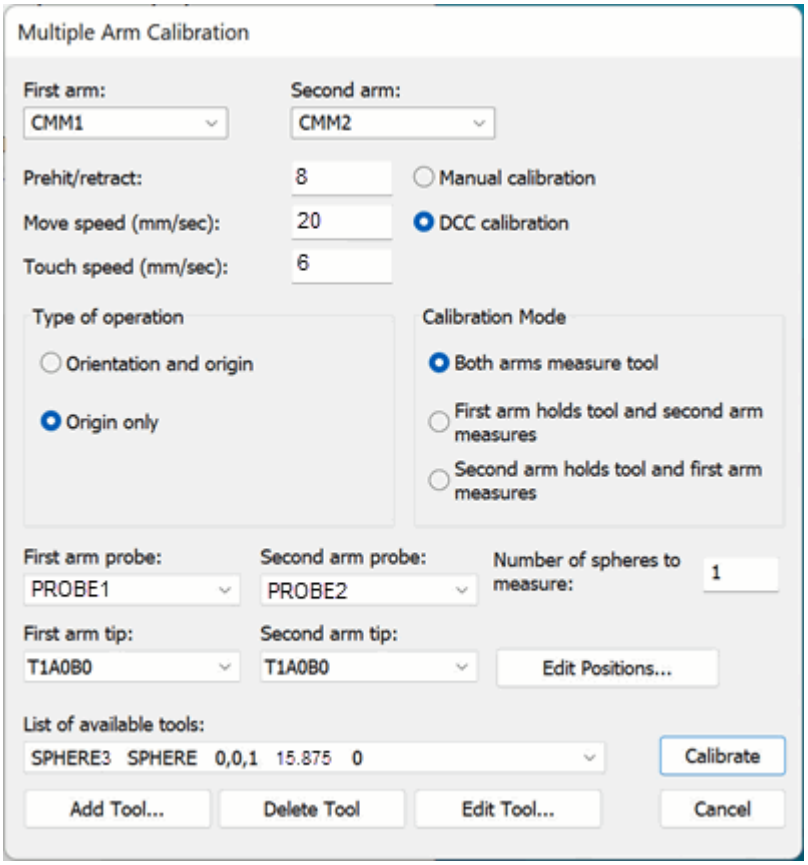
- *. Results
- abcalib.dat and abcalib_CMM2.dat
- abcomps.dat and abcomps_CMM2.dat
- aboutput.dat and aboutput_CMM2.dat
- wrists.dat and wrists_CMM2.dat
- toolc.dat and toolc_CMM2.dat
- armarm.dat
- tool.dat

The next step provides information on mapping the origin between arms.

Step 8: Map the Origin Between Arms

In the previous steps, you created a basic relationship between arm 1 and arm 2. They were mainly used to establish the orientation. The origin between arms was not established because the mapping didn't exist then. Now that the wrist mapping is done for both arms, you can now map the origin. This will generate two maps, one for each arm.

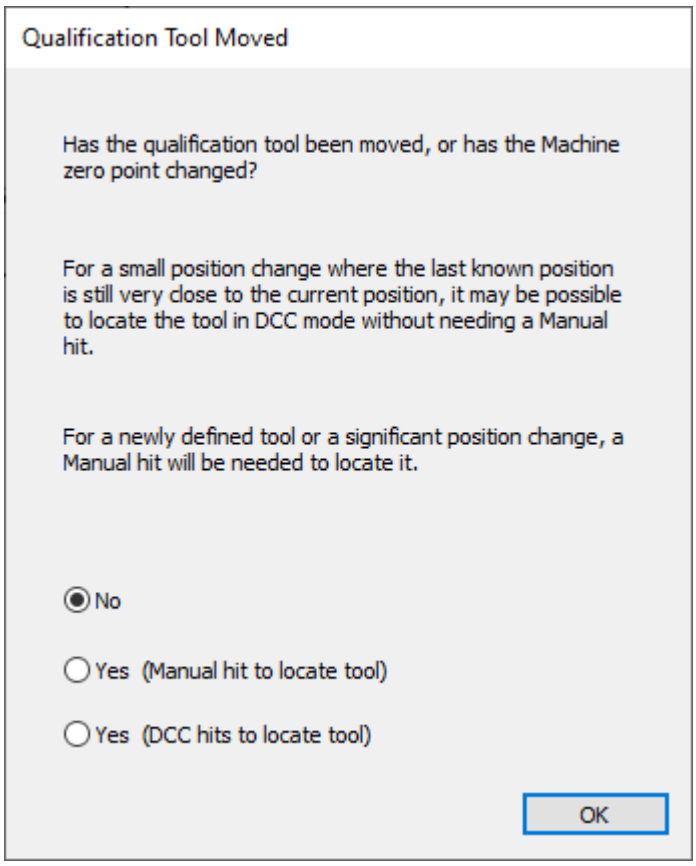
1. From the **Multiple Arm Calibration** dialog box (**Operation | Calibrate/Edit | Multiple Arm Mode**), set the following:
    - Choose **Both arms measure tool**.
    - Set **Number of spheres to measure** to 1.
    - Choose **Origin only**.
    - In **First arm probe**, choose PROBE1 and set the **First arm tip** to T1A0B0.
    - In **Second arm probe**, choose PROBE2 and set the **Second arm tip** to T1A0B0.
    - In **List of available tools**, choose SPHERE3.



Multiple Arm Calibration dialog box showing the settings used.

2. Click **Calibrate**.

3. When PC-DMIS asks if the qualification tool has been moved or the machine zero point changed, click **No**. Since the calibration spheres are almost always located in the same position of the machine (it's screwed in place), you can choose **No**. PC-DMIS doesn't care if the spheres are off by some tenth of a millimeter.



The next step provides information on performing a test measurement.

Step 9: Perform a Test Measurement

At this point, do a test measurement to ensure that everything is set up correctly and to see if the accuracy is good.

1. Use a test part, something like a 700 mm sized test block.
2. Tilt the part in 3D space.
3. Measure the part using an alignment.
4. Reposition it in different locations inside the machine volume.
5. Measure with a single arm.
6. Measure with both arms.
7. Compare the results against measurements done on separate, single-arm machines.

The next step provides information on mapping the other extensions.

Step 10: Map the Other Extensions

Some machines come with three extensions: short, medium, and long. For your first calibration, it's best to use a short extension. If you have other extensions to use on each arm, you would need to perform a mapping for each additional extension. Since you have already created a mapping using the shortest extensions, you need to now do mappings of the other two extensions (long and medium extensions for both arms).

This step is needed before we can calibrate and use probe changers that will hold the different extensions.

Your probes should be named or renamed using a format that corresponds to the different extension lengths and the different arms.

For example, this procedure uses the following:

- ARM1_1 is the short extension on arm 1
- ARM1_2 is the medium extension on arm 1
- ARM1_3 is the long extension on arm 1
- ARM2_1 is the probe with the short extension on arm 2
- ARM2_2 is the medium extension on arm 2
- ARM2_3 is the long extension on arm 2

PC-DMIS supports multiple maps. You can potentially even have a separate map for each probe. But having so many maps is very impractical, given the work and attention needed for a single mapping procedure. So, when possible, try to group similar probe lengths together so that they use a single map. However, you should create a new map if the range between probe extensions is very large.

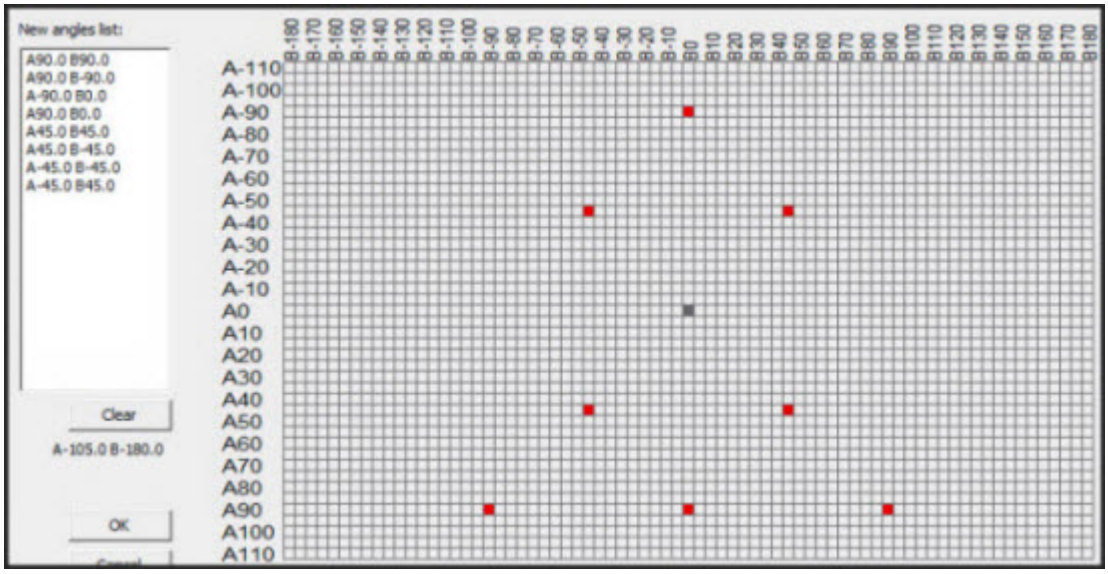
Map the Long Extensions

Two new maps are needed for the long extension. To do this, create a new map by repeating Step 6, Step 7, and Step 8; this time however, use the probes with the long probe extensions.

Map the Medium Extensions

For the medium extensions, you can update the extensions to an existing map.

1. Access the **Probe Utilities** dialog box (**Insert | Hardware Definition | Probe**) for the probes with the medium extensions, and using the **Add New Angle** dialog box add at least 9 angular positions. This defines the calculation of the new offset, due to variation in the extension. These are some good recommended angles to use: [0,0] [90,90] [90,-90] [-90,-90] [-90,90] [45,45] [45,-45] [-45,-45] [-45,45]



Add New Angle dialog box showing the suggested angles.

2. Access the **Measure Probe** dialog box.
3. Choose **Calibrate tips**. Since you are updating an existing map, not creating a new one, you'll see that **Calibrate the unit** and **Create new map** are both grayed out.
4. Click **Calibrate**.

The next step provides information on calibrating the probe changers.

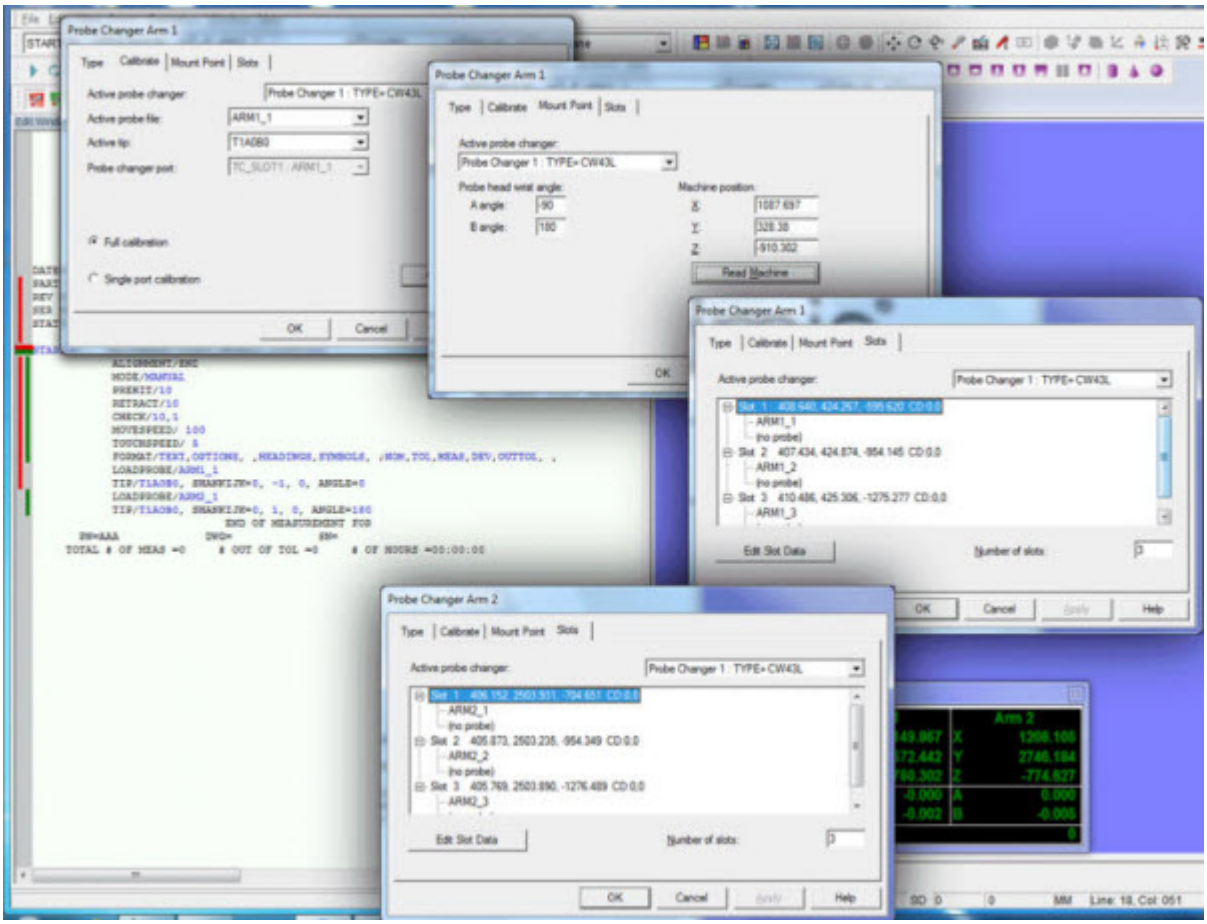
Step 11: Calibrate the Probe Changers

> **!** Before you calibrate the probe changer, make sure that all tips have been calibrated and the relationships between the arms is also established.

Since you'll have multiple extensions (three for each arm is the minimum), you'll need to do a probe changer calibration to support the loading and unloading of probe extensions with the probe changer. It is assumed that you already know how to do the probe changer calibration.

Follow your existing procedure to calibrate the probe changers. If you want to see how some probe changers are calibrated, see the "Defining Probe Changers" topic here.

If you're planning to use a laser probe on your probe changer, you can devote a slot on the probe changer rack to that particular component. To do this, use the `CW43LThirdAxisTCSlot` entry in the PC-DMIS Settings Editor.



The next step provides information on setting up routine files for automatic use.

Step 12: Setup Routine Files for Automatic Use

With the previous steps completed, the dual arm setup is now ready to use. The tips are calibrated and related for both arms as well as with the probe changers.

However, there are times when you'll need to adjust the calibration or correct the offset (for example if you need to replace a damaged tip or if you want to substitute a different tip). Repeating the previous manual steps would be very time consuming. For this reason, it makes sense to use an automated approach. All you'd have to do is run a routine and PC-DMIS would automatically perform the procedures you did previously.

Before doing this, you should be very familiar with PC-DMIS operations.

Create two empty measurement routines:

1. AUTO_MAPS.PRG - This measurement routine is used to create a complete automatic mapping with all probes. It'll measure many angles around the calibration sphere to create all the needed mappings. If you need to run this measurement routine, it'll still take a long time to run (approximately one hour per arm), but at least the process will be automated.

2. AUTO_UPDATE.PRG - This measurement routine is used to update probes when, for example, a tip crashes and you need to update the calibration of a single tip. In this case you just need to have one update measurement routine that uses AUTOCALIBRATE commands. This measurement routine is much shorter to run as it involves only measuring a few orientations on the calibration sphere and is used to adjust the mapping for a new tip.

For now, just create the measurement routines. You'll add content to them in later steps.

The next step provides information on adding commands to AUTO_MAPS.PRG.

Step 13: Add Commands to AUTO_MAPS.PRG

You do not need to create an arm-to-arm map for every extension. While a single map is insufficient for good accuracy, you can obtain good accuracy with two maps. It's better to do one mapping of the short extension followed by one with the long extension. This step will help you build the AUTO_MAPS.PRG routine for the recommended two maps.

Define Parameter Sets for Probe Extensions in AUTO_MAPS.PRG

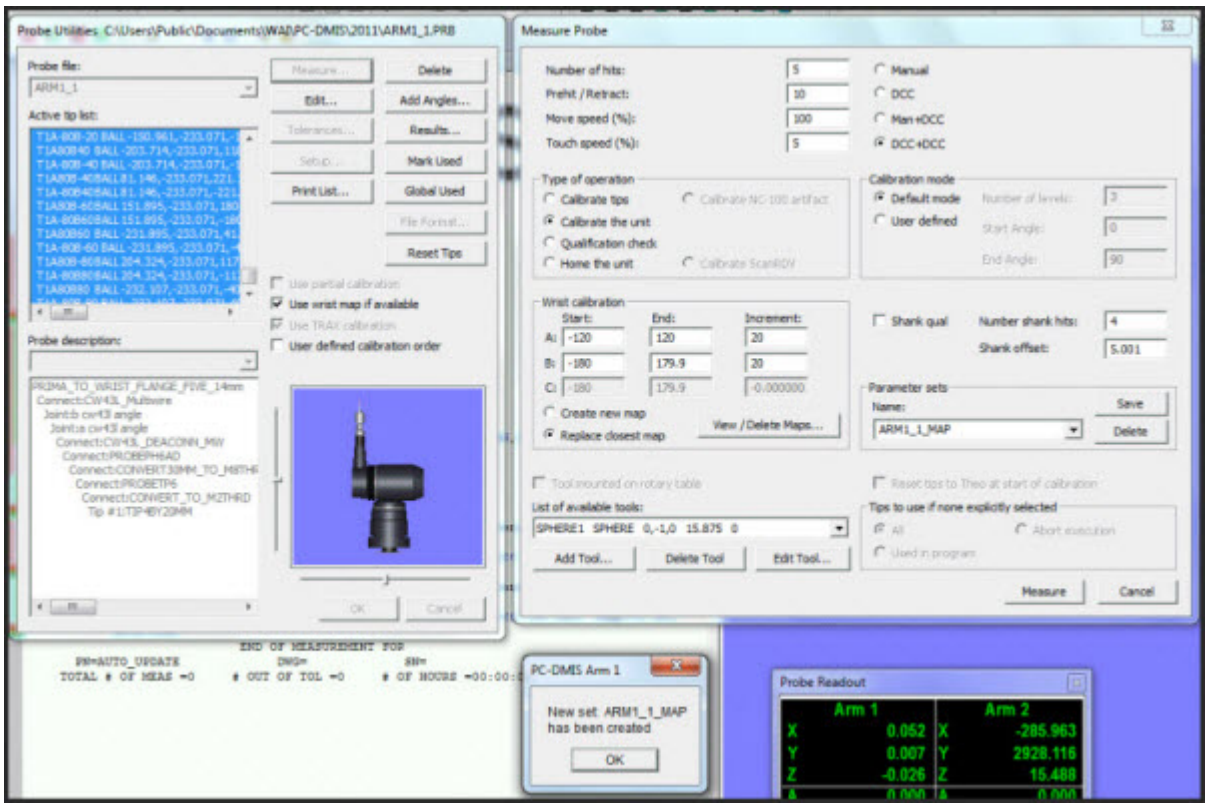
1. Access AUTO_MAPS.PRG and place the Edit window in Command Mode.

2. Start with the ARM1_1 probe. Access the **Measure Probe** dialog box (**Insert | Hardware Definition | Probe | Measure** button) for that probe.

3. Define all the parameters you need in this dialog box to create a new arm-to-arm mapping of that probe.

4. Choose **Replace closest map** in the **Wrist Calibration** area.

5. In the **Parameter Sets** area, give the set a name by typing in the **Name** box the name of the probe with a "_MAP" suffix appended (for example, "ARM1_1_MAP").



Example of Parameter Set creation

6. Click **Save**. A parameter set is created for ARM1_1 probe. Click **OK** to close the message box.
7. Repeat 2-6 for each probe, creating a parameter set for each.
8. When finished, you should have these six parameter sets:

   ARM1_1_MAP - For the probe named ARM1_1 (the short extension on arm 1)

   ARM1_2_MAP - For the probe named ARM1_2 (the medium extension on arm 1)

   ARM1_3_MAP - For the probe named ARM1_3 (the long extension on arm 1)

   ARM2_1_MAP - For the probe named ARM2_1 (the short extension on arm 2)

   ARM2_2_MAP - For the probe named ARM2_2 (the medium extension on arm 2)

   ARM2_3_MAP - For the probe named ARM2_3 (the long extension on arm 2)

You only need to create parameter sets for the number of extensions you have on each arm. For example, if you only had two extensions on each arm, you would end up with a total of four parameter sets.

This means, you can now use an AUTOCALIBRATE command to call one of these parameter sets. When the AUTOCALIBRATE statement executes, PC-DMIS will generate a new arm-to-arm mapping with all settings stored in the called parameter set.

Add Preliminary Commands into AUTO_MAPS.PRG

1. Access AUTO_MAPS.PRG.
2. Add in a TEMPCOMP command (temperature compensation) for arm 1. If you're calibrating inside of a climate-controlled environment, the temperature compensation commands aren't needed. See "Compensating for Temperature" and "Using Temperature Compensation with Multiple Arm Calibration".
3. Add a MOVE/SYNC command.
4. Add in a TEMPCOMP command for arm 2.
5. Type a MOVE/SYNC command after the TEMPCOMP command blocks.
6. Type a LOADPROBE/ARM1_1 command to load the probe with the short extension on arm 1. Assign the command to arm 1.
7. Type a LOADPROBE/ARM2_1 command to load the probe with the short extension on arm 2. Assign the command to arm 2.
8. Type a LOADPROBE/ARM1_3 command to load the probe with the long extension on arm 1. Assign the command to arm 1.
9. Type a LOADPROBE/ARM2_3 command to load the probe with the long extension on arm 2. Assign the command to arm 2.

Insert AUTOCALIBRATE Commands for Short and Long Probe Maps in AUTO_MAPS.PRG

1. Access AUTO_MAPS.PRG.
2. Place the cursor after the LOADPROBE commands for the short probes.
3. Insert an AUTOCALIBRATE command (choose **Insert | Calibrate | AutoCalibrate Probe**).
4. Press F9 on the command. The **Calibrate Probe** dialog box appears.
5. In the **Parameter set** list, choose the parameter set for the short probe on arm 1. This is ARM1_1_MAP.
6. Click **OK**. The command updates to use the selected parameter set.
7. Assign the command to arm 1.
8. Repeat 3-6 for the short probe on arm 2. This is ARM2_1_MAP. Assign the command to arm 2.
9. Place the cursor after the LOADPROBE commands for the long probes.
10. Repeat 3-6 for the long probe on arm 1. This is ARM1_3_MAP. Assign the command to arm 1.

11. Repeat 3-6 for the long probe on arm 2. This is ARM2_3_MAP. Assign the command to arm 2.

12. Type a MOVE/SYNC command at the end of the routine.

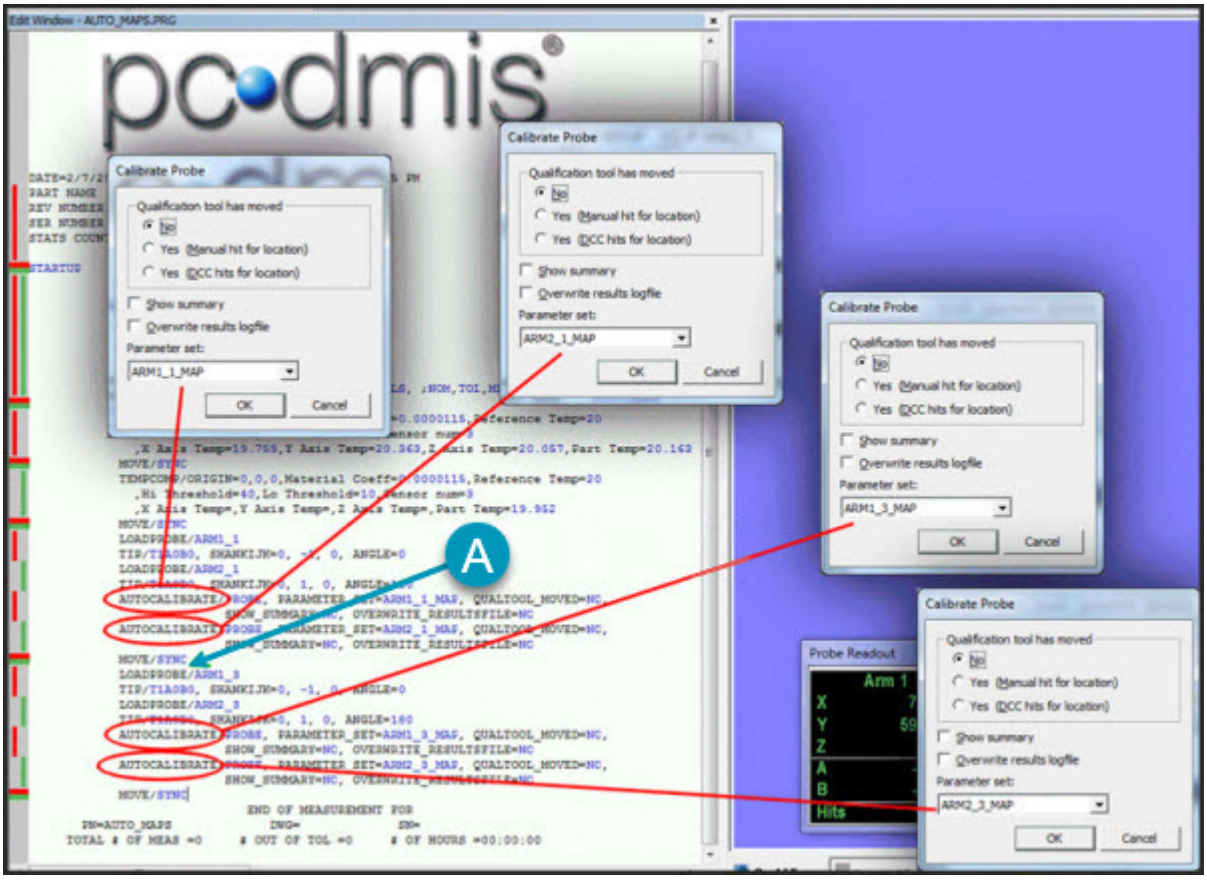
Insert Moves Between Short and Long Probe Maps in AUTO_MAPS.PRG

1. After the AUTOCALIBRATE commands for the short probes and before the LOADPROBE command for the long probes, type a MOVE/SYNC command.

2. After the MOVE/SYNC command, ensure that the tips' angles are adjusted appropriately for drop off at their respective probe changers. You can do this by inserting moves appropriate to your machine's dimensions and arm and probe changer setup.

This completes the information needed for the AUTO_MAPS.PRG.

Your routine should now be organized like this:



Sample AUTO_MAPS.PRG Routine. Safety moves are inserted after the MOVE/SYNC, indicated by green arrow (A).

Notes on using AUTO_MAPS.PRG

You would run this routine to recreate the arm-to-arm mapping in these instances:

Whenever your normal maintenance schedule requires that your mappings should be updated.

Whenever you need to use an entirely new probe. In that case, you would need to add in the LOADPROBE statements for the new probe.

- Whenever your wrist is remounted (for example, after a technician adjusts its electronic compensation).
- Whenever data is lost or corrupted or you're not sure if the mapping is correctly generated.
- Whenever a room situation changes that alters the thermal compensation (for example, if moving the machine out of a climate controlled room).
- Whenever the physical structure of the machine changes.

Before you run this routine, delete old maps. Use the **View | Delete maps** button located in the **Wrist calibration** area of the **Measure Probe** dialog box to do this.

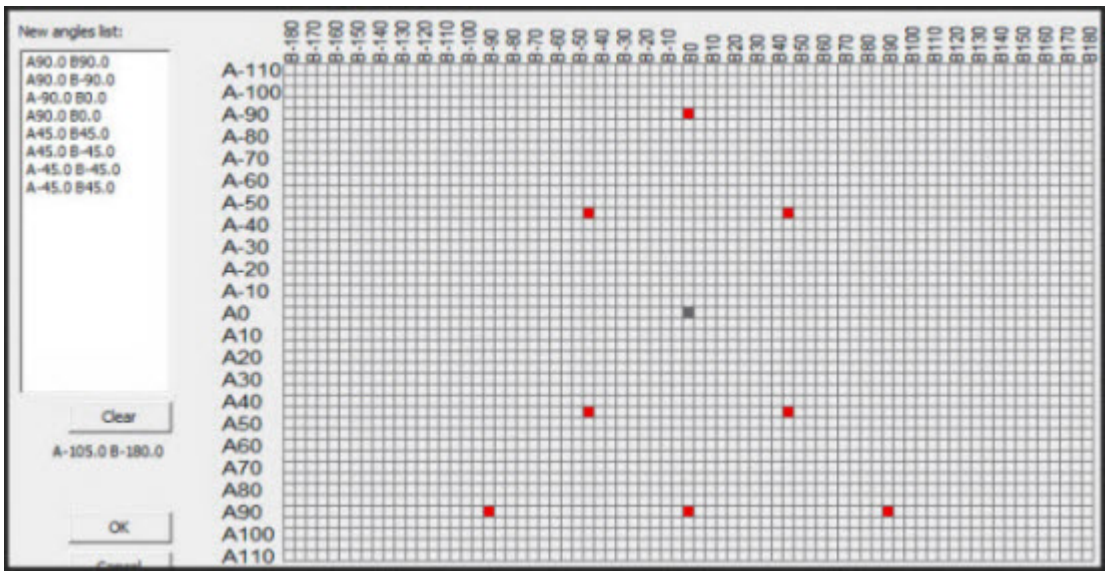
If you're using long extensions, and you aren't running at maximum speeds, expect a minimum of 3-4 hours to run the entire routine. This time is just an estimate, as it depends on your individual machine dimensions, the length of the extensions, and speed percentage used.

The next step provides information on adding commands to AUTO_UPDATE.PRG.

Step 14: Add Commands to AUTO_UPDATE.PRG

Using Step 13 as a guide, do the following:

1. Add in the preliminary commands (`TEMPCOMP` , `MOVE/SYNC` , and `LOADPROBE` commands).
2. In this case, you'll need a `LOADPROBE` commands for all probes (short, medium, and long extensions).
3. Press F9 and ensure **Use wrist map if available** is marked for each. Click **Add Angles**.
4. Use the **Add New Angles** box for each probe, and add in at least 9 angles for the desired probe. These angles are recommended as they result in a sufficiently precise distribution: [0,0] [90,90] [90,-90] [-90,0] [-90,0] [45,45] [45,-45] [-45,-45] [-45,45]

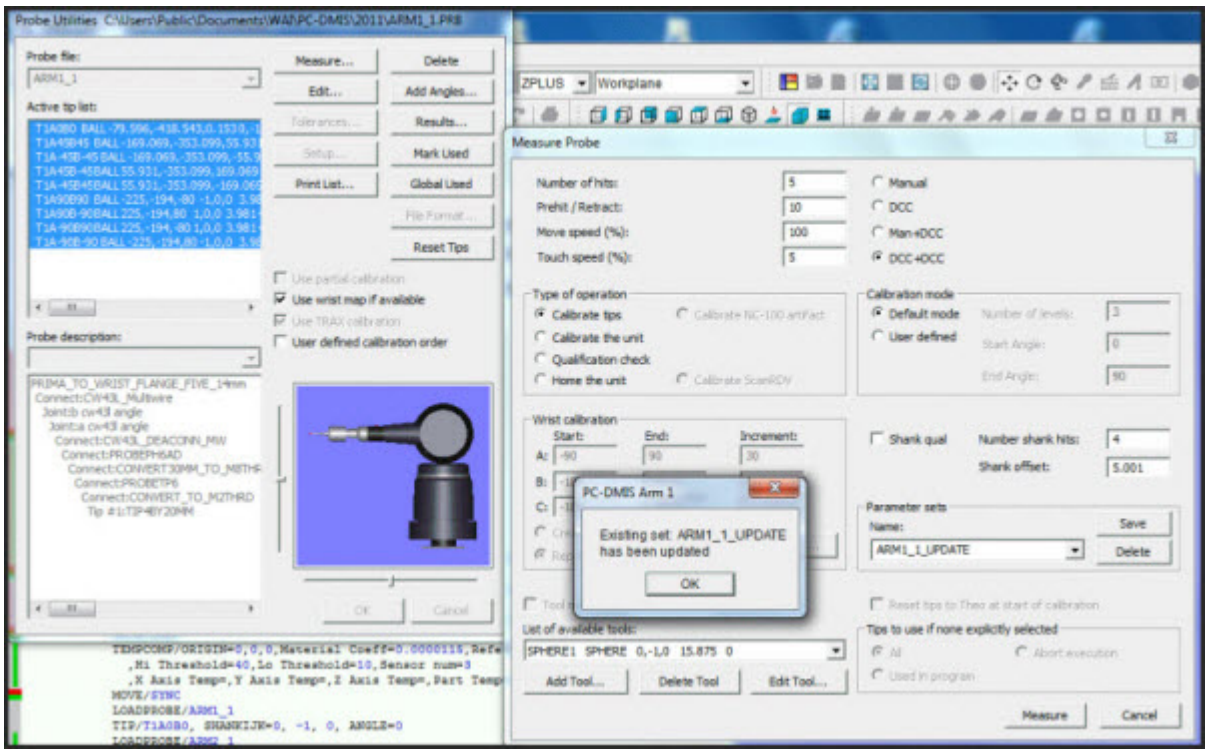


Add New Angle dialog box showing the suggested angles.

For increased precision, you can increase the angles to 17, but this lengthens the execution time of the update.
The recommended 17 angles for this wrist are:
([0,0] [90,0] [90,-45] [90,-90] [90,-135] [90,45] [90,90] [90,135] [-90,0] [45,-20] [45,-65] [45,-110] [45,-155] [45,25] [45,70] [45,115] [45,160])

5. Access the **Measure Probe** dialog box and define parameter sets for each probe. Ensure that **DCC + DCC** and **Calibrate tips** are selected.

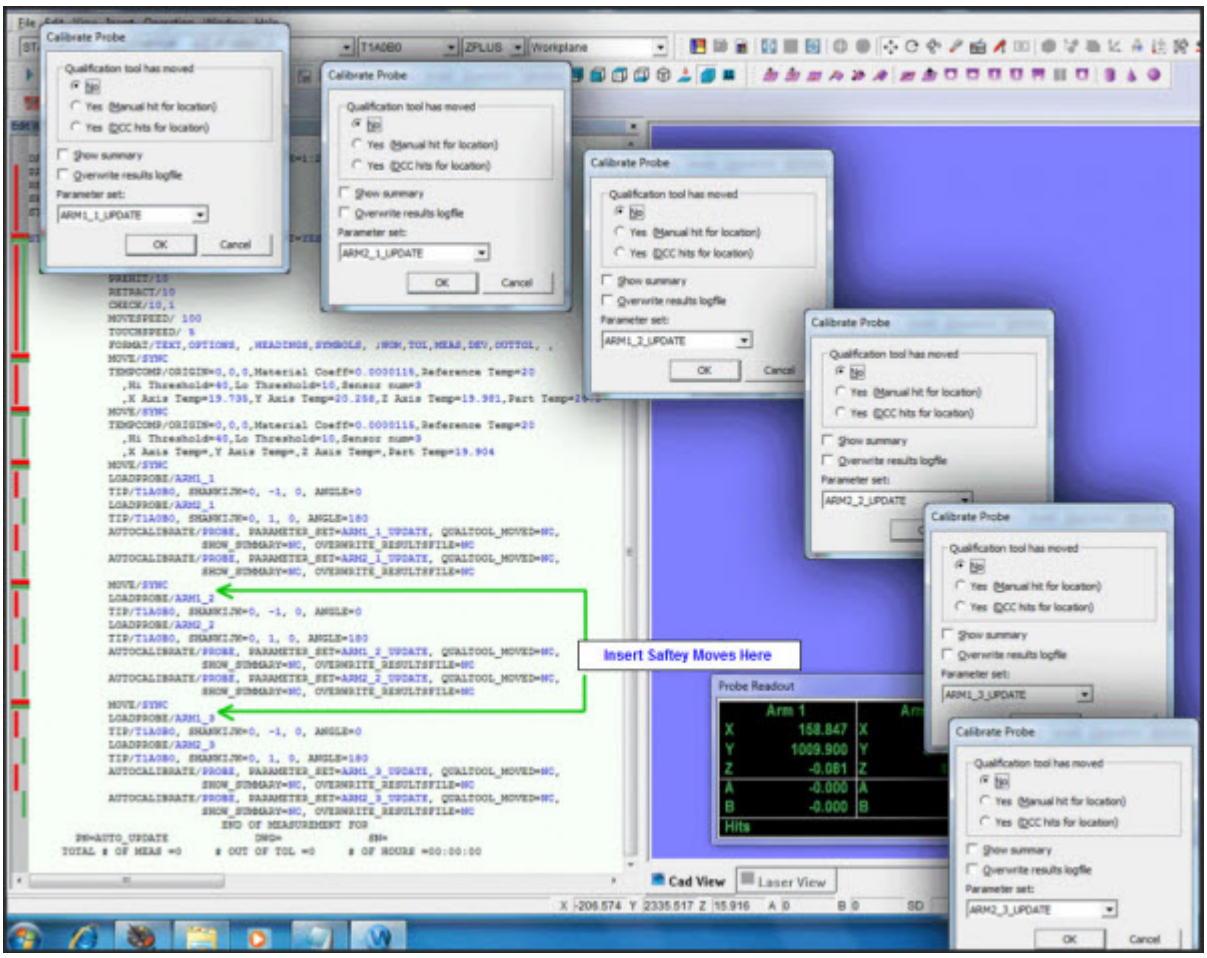
6. Name each parameter set by basing it off the probe name and adding on an "_UPDATE" suffix. For example, ARM1_1 would have a parameter set named ARM1_1_UPDATE.



Example of Parameter Set creation

7. After each set of `LOADPROBE` commands, insert two `AUTOCALIBRATE` commands that correspond to the parameter sets for those loaded probes.
8. Insert a `MOVE/SYNC` command after each `AUTOCALIBRATE` pair.
9. Between each `AUTOCALIBRATE` pair, after the `MOVE/SYNC` command, insert some safety move commands to prevent against possible crashes when the arms move to swap probes in and out of the probe changer.

At this point your measurement routine should be organized like this:

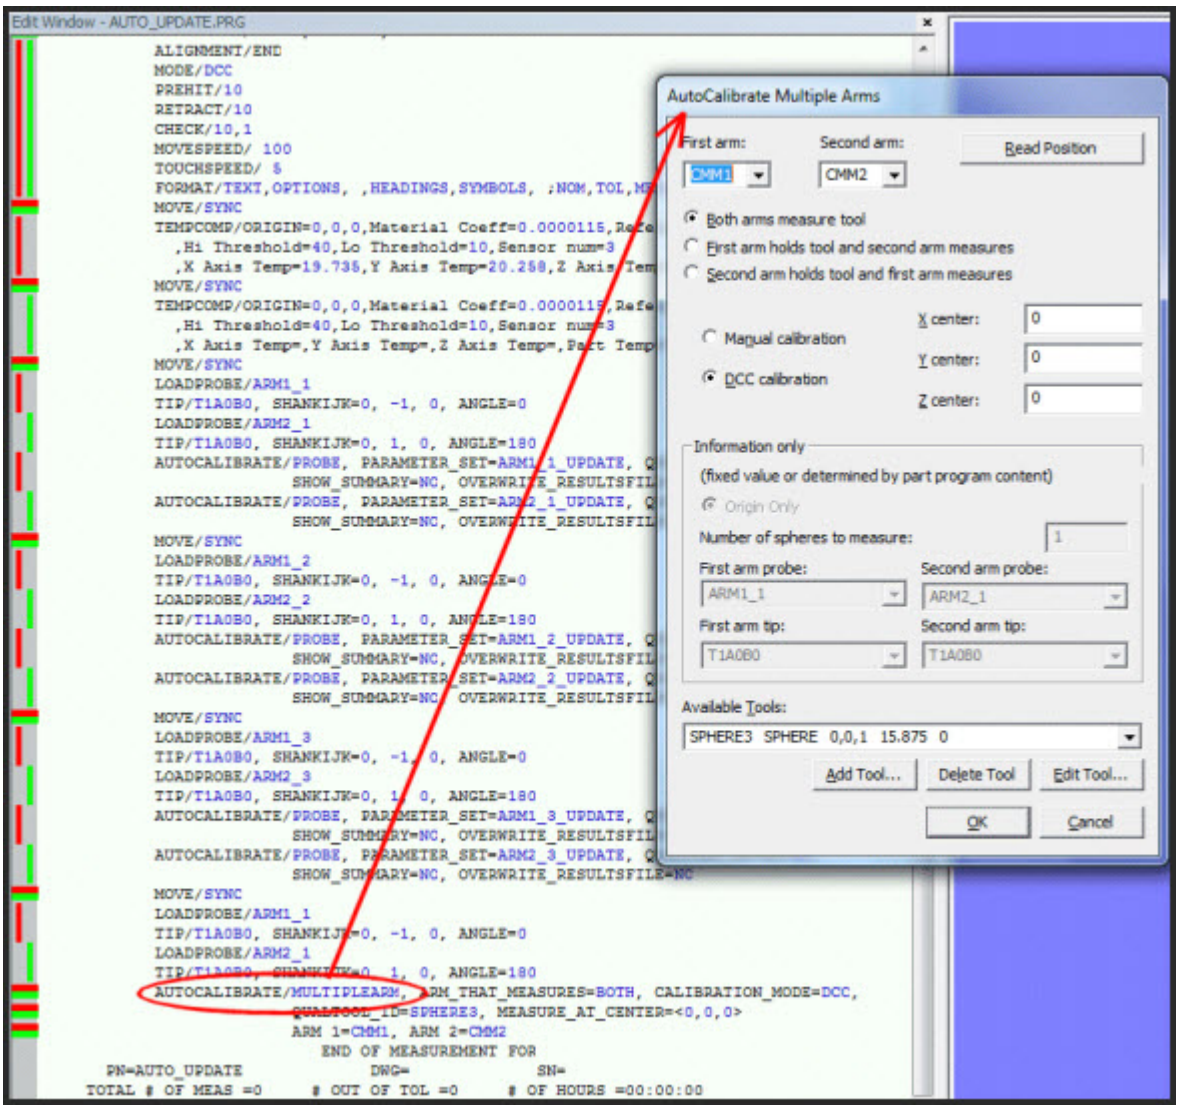


A sample AUTO_UPDATE.PRG measurement routine.

Continue by adding these commands:

1. Go to the end of the measurement routine, add in a `LOADPROBE` command for ARM1_1 and for ARM2_1.
2. Insert an `AUTOCALIBRATE/MULTIPLEARM` command and press F9. The **AutoCalibrate Multiple Arms** dialog box appears.
3. For **First arm**, choose CMM1. For **Second arm**, choose CMM2.
4. Choose **Both arms measure tool**.
5. Choose **DCC calibration**.
6. Choose SPHERE3 from the **Available Tools** list.

This last piece causes the short extension on both arms to go and measure SPHERE3 in order to adjust the relationship one last time between arm 1 and arm 2. Generally, you only need to use this final command after perhaps a month machine usage (or after many measurements) to occasionally adjust the offset and improve accuracy.



AutoCalibrate Multiple Arms Dialog Box

Before running this final portion of the measurement routine, be sure to place calibration spheres (SPHERE1, SPHERE2, and SPHERE3) back on the table.

Notes on using AUTO_UPDATE.PRG

You would run this measurement routine to update the mapping for a specific tip in these instances:

- Whenever you want to adjust the accuracy of the machine.
- Whenever you want to adjust a tip or need to add a new tip.

This measurement routine is used more frequently than AUTO_MAPS.PRG.

A typical `AUTOCALIBRATE` command with update parameters and 1 extension can be done using the Execute Block command.

Running the entire measurement routine for all probe extensions and using the recommended nine angles takes about 30 minutes.

Navigating and Displaying Multiple Windows

Navigating and Displaying Multiple Windows: Introduction

This chapter describes how to use the Window menu to navigate between and view multiple open measurement routines.

The main topics in this chapter include:

- Switching Between Open Measurement Routines
- Arranging Open Windows
- Giving Open Windows the Focus

Switching Between Windows of Open Measurement Routines

Here are some ways you can switch between windows of the active measurement routine:

Click the Next or Previous options: Select the **Next** (**Window | Next**) or **Previous** (**Window | Previous**) menu options to switch to the next or previous window of the currently active measurement routine. When you've reached the end of all the windows, selecting **Next** again does nothing.

Click on a list of open measurement routines: At the very bottom of the **Window** menu, PC-DMIS displays a list of all open measurement routines. You can select which measurement routine you want to have the focus by selecting the file's name from the list.

Click on a title bar: If a file's Edit window or Graphic Display window title bar is showing, click on the title bar to switch to that measurement routine. Cascade or tile the windows for the active measurement routine by selecting the appropriate option from the **Window** menu.

Arranging Open Windows

The following menu options allow you to arrange all open windows for the active measurement routine. These menu options do not affect the Edit window until you remove the Edit window from its docked position by right-clicking on the Edit window and deselecting the **Docking View** menu option.

Cascade

Stacks the windows one on top of the other with just the title bars showing and places the window with the focus on the top of the stack.

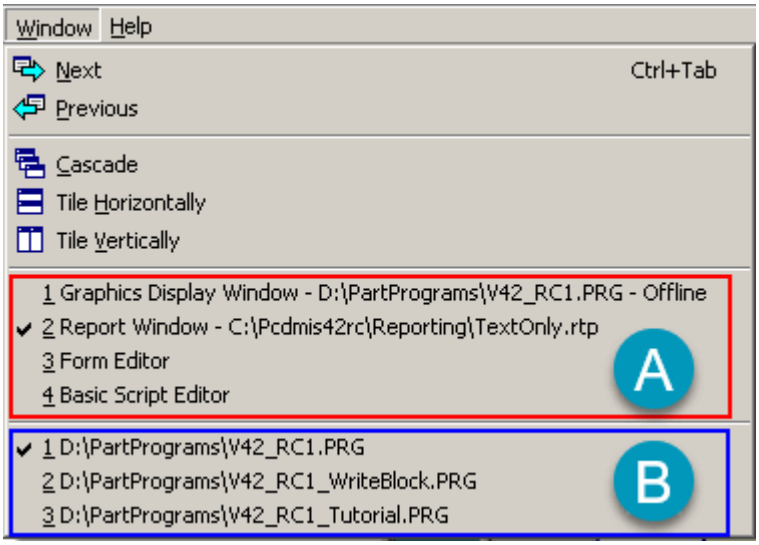
Tile Horizontally

Tiles the windows horizontally and places window with the focus on the top.

Tile Vertically

Tiles the windows vertically and places the window with the focus on the left.

Giving Open Windows the Focus



Sample Window Menu

A. This section shows the list of open windows for the current measurement routine.

B. This section shows the list of open measurement routines.

Above the list of measurement routines, PC-DMIS also lists all open windows in the **Window** menu. Select the window from this menu to give that window the focus.

Working in Offline Mode

Working in Offline Mode: Introduction

PC-DMIS in Offline mode enables you to prepare and debug measurement routines without using a CMM. The ability to program offline has become increasingly important over the last several years. Users of CMMs have become more aware that, to fully realize their investments in CMMs, their equipment must be used to measure parts and not write routines to measure parts.

CMM manufacturers' first attempts at adding offline programming capabilities involved cumbersome and specialized text editors. These products, although of limited use, spurred user interest in offline programming. Driven by this interest, several CAD vendors developed products that allowed users to use CAD models to generate measurement routines.

Although these products were vastly superior to text editors, they had a major cost disadvantage. Since each CMM vendor has their own specific measurement language or languages that were constantly changing or being replaced, the expense of developing and maintaining these products put them out of the reach of all but a few well-financed users.

This situation brought about the development of the DMIS specification, which is a generic CMM language. DMIS allowed CAD vendors to develop measurement routine programming packages that were targeted toward a single language instead of many, which greatly reduced their costs. These savings were passed on to their customers, and offline measurement routine programming became a viable option for a large group of CMM users. However, there was still one problem: What about CMM users whose CAD vendors did not support, and did not plan to support, offline measurement routine programming?

Although many mainframe CAD vendors, driven by major customers, have introduced DMIS extensions to their products, PC-based CAD vendors with their diverse customer bases have shown little interest in this area. Many CMM users, particularly small shops, use PC-based CAD systems exclusively. PC-DMIS brings offline programming capabilities to this group.

With PC-DMIS, programmers who use standard IGES models, which virtually every CAD vendor supports, can generate measurement routines on an inexpensive PC or PC clone without going near a CMM. These measurement routines can then drive any CMM that either runs PC-DMIS or supports the DMIS specification.

The techniques for programming offline are much the same as those used for programming in Online mode. However, as might be expected, the methods used to

qualify probes, take measurements, and debug routines differ from those in Online mode. This appendix describes PC-DMIS programming techniques in Offline mode.

The main topics in this chapter include:

- PC-DMIS Offline Prerequisites
- Offline Probes
- Setting Probe Depth
- Measuring Features Offline
- Executing and Debugging Measurement Routines Offline

PC-DMIS Offline Prerequisites

To use PC-DMIS in Offline mode, CAD data in the form of an IGES model, a DES file, a DXF file, or X,Y,Z,I,J,K data must be available. The "Importing CAD Data or Feature Data" topic in the "Using Advanced File Options" chapter has information on how to import these files into the PC-DMIS system.

IGES Entities Supported

IGES Entity	Description
100	CIRCLE/ARC
102	COMPOSITE CURVE
104	CONIC ARC
106	COPIOUS DATA (multiple point line)
108	PLANE
110	LINE
112	PARAMETRIC SPLINE CURVE (with curves and surfaces option)
114	PARAMETRIC SPLINE SURFACE (with curves and surfaces option)
116	POINT
118	RULED SURFACE (with curves and surfaces option)
120	SURFACE OF REVOLUTION (with curves and surfaces option)
122	TABULATED CYLINDER (with curves and surfaces option)
124	TRANSFORMATION MATRIX
126	RATIONAL B-SPLINE CURVE (with curves and surfaces option)

128	RATIONAL B-SPLINE SURFACE (with curves and surfaces option)
140	OFFSET SURFACE
144/142	TRIMMED SURFACE (with curves and surfaces option)
402	ASSOCIATIVITY INSTANCE
408/308	SUBFIGURE
410	VIEW

PC-DMIS is compatible with IGES 3.0, 4.0, and 5.1.

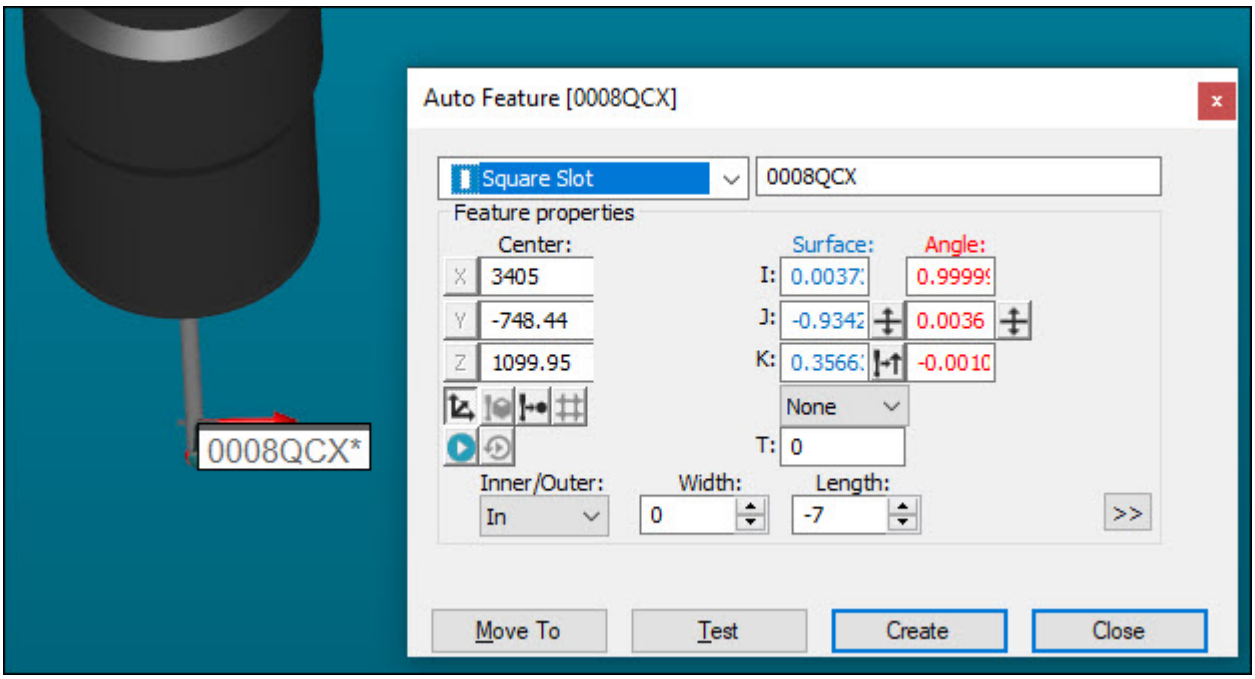
DXF Input

PC-DMIS reads in a DXF (Drawing Interchange File) file as CAD data to be used to create measurement routines. This file format does not support text. It only supports feature data.

This option is not part of standard module of PC-DMIS. Please contact your PC-DMIS software representative if you are interested in purchasing this add-on package.

DES Input

PC-DMIS can read in a DES (Data Exchange Standard) file as CAD data to be used to create measurement routines. The data can come in as feature or fixture data. If it is feature data, after you import, you can click on the feature label in the Graphic Display window to define the type of feature. PC-DMIS displays the **Auto Feature** dialog box for the feature type with the values filled in from the DES point:



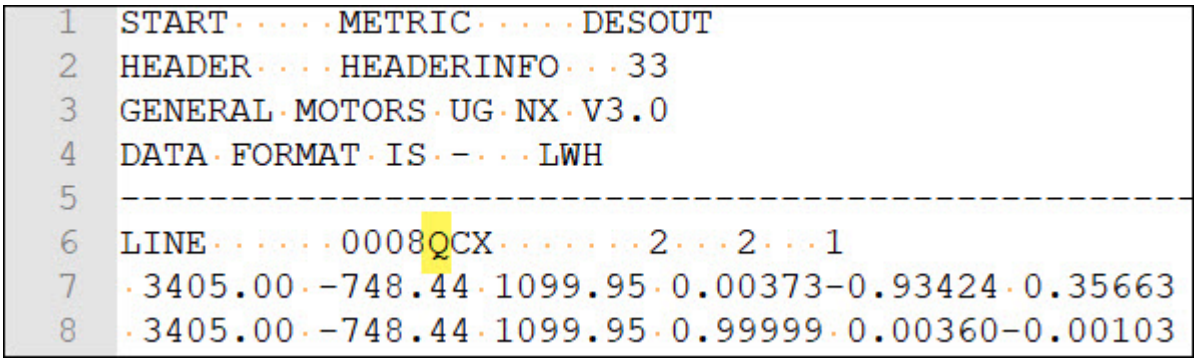
Example showing DES feature interpreted as a square slot feature.

PC-DMIS gets the feature type from the fifth character position of the feature label. So, if the DES feature label is 0008QCX, the character in the fifth position is a Q. These are the available characters and how PC-DMIS interprets them:

CHARACTER	DES Type	PC-DMIS Feature Type
S	Surface	Vector Point
T	Trim	Edge Point
H	Hem Edge	Edge Point
P	Profile	Vector Point
I	Intersection	Vector Point
X	Hole	Circle (in)
Y	Stud	Round Slot
Z	Slot	Circle (out)
V	Square	Square Slot
W	Hexagon	Circle (in)
Q	Square	Square Slot
R	Reference	Vector Point
G	Gap	Edge Point
F	Flush	Vector Point
L	Parallelism	Vector Point

D	Differential	Vector Point

Note that if you open the DES file in a text editor, the fifth character on the feature label is identical to the fifteenth (15) column of the data type LINE:



Example of a DES file with the 15th character highlighted.

For more information in importing a DES file, see "Importing a DES File" in the "Using Advanced File Options" chapter.

XYZ ASCII File

PC-DMIS can read in any ASCII file that contains XYZ (and possibly IJK) data. The file should contain the nominal (theoretical) inspection points that need to be measured.

For detailed information on XYZ ASCII files, see "Importing an XYZIJK File" in the "Using Advanced File Options" chapter.

Offline Probes

When PC-DMIS is in Offline mode, you can use all of the probe definition and calibration capabilities as you can in Online mode. However, you can only enter values. You cannot make measurements. (For example, you cannot actually measure a calibration artifact to find the diameter of a probe.)

For information on how to define a probe, see "Defining Probes" in the "Defining Hardware" chapter.

We recommend that you use the same probe configuration in the offline measurement routine as the online measurement routine.

Setting Probe Depth

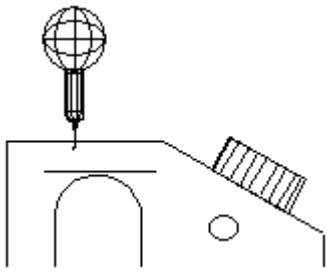
To program measurements in Offline mode, it is important to set the depth of the probe at a specified distance (in relation to the surface of the current workplane). PC-DMIS offers several methods to set the probe's depth.

PC-DMIS must be in Program Mode to use any of these techniques.

Setting Approximate Probe Depth

In most circumstances, it is only necessary to set an approximate probe depth to properly measure a feature. To use PC-DMIS in Offline mode to do this:

1. Position the mouse cursor on the drawing at the desired depth for hit taking.
2. Right-click at the current location. PC-DMIS then redraws the probe in its new position.



Setting Probe Depth

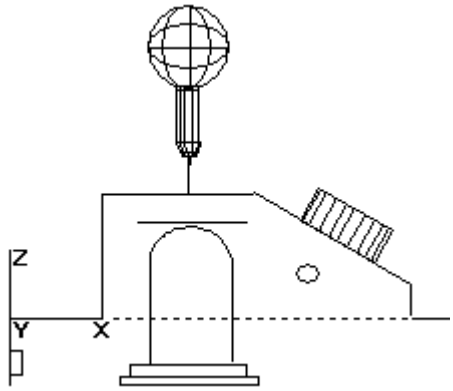
Setting Probe Depth on a Feature

To position the probe on a specific feature (i.e., a plane):

1. Move the cursor close to the feature.
2. Click the right mouse button.

PC-DMIS "snaps" the probe to the closest CAD element and displays the message: "Precise Depth Set on".

The Status bar displays the current number of hits and the probe's location.



Example showing the setting of the precise probe depth on a feature.

Setting Probe Depth on a Sphere

PC-DMIS offers two procedures that allow you to set the probe depth on a sphere. Where the probe is located in relation to the centerline of the drawing determines where the hit is taken on the sphere. If the probe is below the centerline, PC-DMIS takes the hit on the bottom of the sphere. To take a hit on the top of the sphere, the probe depth must be set above the centerline.

For additional information on the following procedures, see "Measuring Features Offline".

Three-Dimensional Procedure

To set the precise depth on a three-dimensional spherical surface:

1. Move the animated probe to the desired circle.
2. Hold down the right mouse button.
3. Release the mouse button. The precise depth is set on the sphere.

PC-DMIS positions the probe on the side of the feature where the mouse button was first held. This determines the type of feature that is measured. If the probe snaps to the outside of a circular CAD element, the hits are placed outside the circle. If the probe snaps to the inside of the same element, the hits are placed inside the circle. The circle’s three-dimensional origin must be the same location as the sphere’s center.

Once the precise depth has been set, all the points that are generated snap on to the spherical surface.

Two-Dimensional Procedure

When you use a two-dimensional drawing, PC-DMIS requires at least two views of the sphere. The sphere should be visible as a circle (or arc) in both views.

1. Set the precise depth for two of the axes using one of the views. PC-DMIS displays this message: "Precise Depth Set on". See "Setting Probe Depth on a Feature" for setting the precise depth.

2. Use the second view to set the precise depth for the third axis. PC-DMIS displays this message: "Precise Depth Set on Sphere". This procedure finds the true three-dimensional center point of the sphere.

Once you have set the precise depth, all the points that are generated snap on to the spherical surface.

Setting Probe Depth on a Cone

PC-DMIS offers two procedures that allow you to set the probe depth on a cone. For additional information on the following procedures, see "Measuring Features Offline".

Three-Dimensional Procedure

To set the precise depth on a conical surface, PC-DMIS requires that two CAD circles (or arcs) on the cone be displayed. It is suggested that you use two views of the surface for this procedure, but it is not required. (Isometric views are also a viable way to set the probe depth on a cone.)

1. Set the precise depth for one end of the cone using one of the circles. PC-DMIS displays this message: "Precise Depth Set on."

2. Set the precise depth for the other end of the cone using the second circle. PC-DMIS displays this message: "Precise Depth set on Cone."

Once the precise depth is set, all the points that are generated snap on to the conical surface. Single hits can be taken on cones by holding down the left mouse button. Click the left mouse button to prompt PC-DMIS to take equally-spaced hits around the cone.

Two-Dimensional Procedure

To set the precise depth on a conical surface in two-dimensional drawings, PC-DMIS requires that you define the length between the two circles (as described above). Because these circles are at the same depth, it is necessary to also define the precise depth of a line. This can be either a straight line or a line on the edge of the cone. After you set the precise depth on the circles, hold down the right mouse button next to the line that is to be used for the length.

Once you have set the precise depth, all the points that are generated snap onto the conical surface. To take single hits on cones, hold down the left mouse button. Click the left mouse button to prompt PC-DMIS to take equally-spaced hits around the cone.

Keying in Probe Depth

It is sometimes necessary to set the probe at some specific location in space. To do this:

1. Click on the X, Y, Z portion of the Status bar while in Program Mode (or select the **Operation | Move To** option described in the "Inserting Move Commands" chapter)

to open the **Auto Move Point** dialog box. The default setting indicates the probe's current location.

2. Change the X, Y, Z to the desired values. If you mark the **Store Move** check box, you can add the `MOVE POINT` command to the routine. You can also select the **Increment moves** check box and the **OK to Move** check box.

3. Once the new X, Y, or Z values are entered, click on **Done** and PC-DMIS moves the animated probe to the new position.

Measuring Features Offline

PC-DMIS offers several methods for you to program measurement routines in Offline mode:

- You can hold down the left mouse button to take a hit.
- You can press the Alt + "-" (minus) keys to remove the last hit as long as the measurement process isn't complete.
- You can press the End key to complete the measurement process. PC-DMIS continues to accumulate hits in the hits buffer until you press the End key.

Automatic Measurements

Based upon the IGES definition of circular and linear feature types, PC-DMIS can make some assumptions about the way they should be measured. Take advantage of these assumptions to speed up the measurement routine programming process.

Circular Features

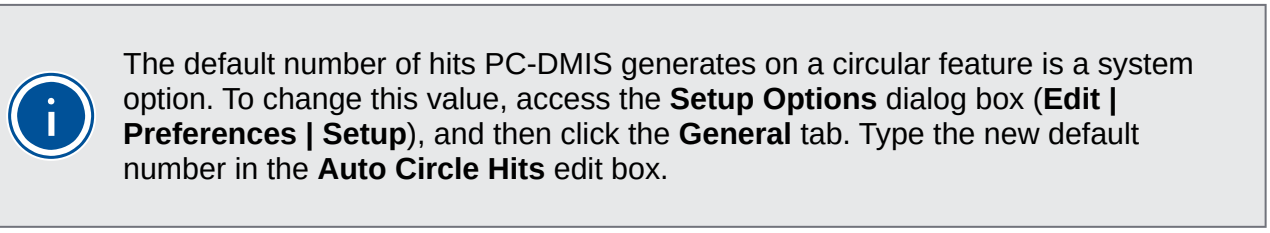
PC-DMIS can automatically generate hits for circles, cylinders and arcs. To do this:

1. PC-DMIS must be in Program Mode.
2. Move the pointer close to the circumference of the feature.
3. Click the left mouse button. PC-DMIS then generates equally spaced hits on the feature at the current probe depth. (See "Setup Options: General Tab" in the "Setting Your Preferences" chapter for setting the number of hits for circles.)

Follow these measurement rules for circular features.

- For an inside diameter (ID), place the cursor just inside the feature.

- For an outside diameter (OD), place the cursor just outside the feature.
- To automatically program cylinders, take at least two sets of hits at different probe depths.
- When programming an arc, PC-DMIS spaces the hits along the length of the arc.
- To measure a sphere or a cone, first set precise depth on the sphere or cone before generating any hits. See "Setting Probe Depth on a Sphere" and "Setting Probe Depth on a Cone".



The default number of hits PC-DMIS generates on a circular feature is a system option. To change this value, access the **Setup Options** dialog box (**Edit | Preferences | Setup**), and then click the **General** tab. Type the new default number in the **Auto Circle Hits** edit box.

Linear Features

The default number of hits PC-DMIS generates on a linear feature is a system option. To change this value, access the **Setup Options** dialog box (**Edit | Preferences | Setup**), and then click the **General** tab. Type the new default value in the **Auto Line Hits** edit box.

PC-DMIS can automatically generate hits for lines and planes. To do this:

1. PC-DMIS must be in Program Mode.
2. Move the pointer close to the line.
3. Click the left mouse button.

Follow these rules for measuring linear features:

- PC-DMIS generates equally spaced hits along the length of the line at the current probe depth. (See "Setup Options: General Tab" in the "Setting Your Preferences" chapter for setting the number of hits for lines.)
- The cursor must be placed on the side of the line where the hits are to be taken.
- To automatically program planes, at least *two sets* of hits at different probe depths must be taken.

Surface Features

You can use the UV scan to automatically place points on a surface along its UV direction. In Program Mode and Surface Mode, press the left mouse button on the surface you want to select. A dialog box opens where you can enter the start and end UV values and specify the number of points along each UV direction.

Discrete Measurements

Automatic measurements speed up the programming process, but it is sometimes necessary due to either part geometry or feature type to precisely place hits on a feature. There are two techniques for placing hits.

Placing Hits on a Surface

In many instances you need to precisely position the hits on a surface (such as a plane, sphere, or cone measurement). To do this:

1. Move the cursor to the position where you wish to take the hit.
2. Hold down the left mouse button (do not move the mouse).
3. Release the button. PC-DMIS programs the hit at that point.

You must hold the pointer in one position while holding down the button. Otherwise, PC-DMIS may misinterpret your intention. If the probe tip snaps onto a feature after the button is released, instead of the surface, then the mouse was moved during the process. In that case, press the Alt + "-" (minus) key combination to remove the hit and begin again.

You must set the precise depth before you place discreet hits on a cone, sphere, or plane.

Placing Hits on a Feature

In many instances you need to precisely position hits on a feature other than a plane. To do this:

1. Move the cursor close to the position where you wish to take the hits.
2. Hold down the left mouse button.
3. Move the probe towards the position where you want to take the hit. (the probe *must* be moved at least 1/8" on the screen).
4. Release the button.

PC-DMIS "snaps" the hit onto the feature. PC-DMIS locates the hit on the side of the feature where you positioned the cursor when you first held down the mouse button.

Ending a Measurement

To end a measurement in Offline mode, press the END key.

Executing and Debugging Measurement Routines Offline

The execution of measurement routines in PC-DMIS in Offline mode behaves the same as in Online mode. The Edit window provides immediate access to all of the commands in a measurement routine, which makes it as easy to fine-tune an offline measurement routine as a routine done on a CMM. For an overview of the many edit options in PC-DMIS, see the "Editing a Measurement Routine" chapter.

Pay careful attention to the probe animation to detect collisions and misplaced hits. The best way to do this is to use the probe path and collision detection functionality to determine collision points between the probe and the part.

The **Operations | Graphic Display Window | Collision Detection** menu option provides an animated graphical representation of the probe's path along the part. This tool for probe path editing can help you when programming measurement routines in Offline mode.

To access the **Collision Detection** option:

1. In the Edit window, mark the features you want to use in the probe path. (See "Marking Commands for Execution" in the "Editing a Measurement Routine" chapter.)

2. Select the **View | Path Lines** option. PC-DMIS displays the path lines of the probe created during the learning portion of the measurement routine.

3. Select **Operation | Graphic Display Window | Collision Detection**. PC-DMIS moves an animated probe along the path lines. It shows any collisions in red on the part and in the **Collision Detection** dialog box. Once execution finishes, a **Collision List** dialog box shows where any collisions occurred. The "Showing, Animating, and Moving Path Lines" topic in the "Editing the CAD Display" chapter has additional information on how to use path lines and detect collisions.

Manipulating Animation and Execution Speeds

You may also find it helpful to manipulate animation and execution speeds while you debug measurement routines. Several settings exist so that you can fine-tune these speeds to meet your needs. For information on these settings, see the "Setup Options: Animation tab" topic in the "Setting Your Preferences" chapter.

Using Inspection Plans in PC-DMIS

Using Inspection Plans in PC-DMIS: Introduction

The following topics describe how to create a measurement routine from your Inspection Plan inside of PC-DMIS:

- Importing an Inspection Plan from Planner
- Mapping Features to Sensors
- Importing an Inspection Plan from Legacy PC-DMIS Planner

These other topics explain how to update your measurement routine later by using the Change Management, how PC-DMIS uses path optimization, void detection, and clearance moves inside the measurement routine:

- Updating Inspection Plans with the Change Manager
- Optimizing the Path
- Void Detection
- Inserting Clearance Moves Automatically

Importing from Planner (.plancad, .planxml, .xml)

You can import the Inspection Plan from Planner into PC-DMIS by importing a .planxml or .xml file exported from Planner. The .planxml or .xml file contains XML elements with the inspection plan information.

To import a .plancad, .planxml, or .xml file:

1. Select **File | Import | Inspection Plan** to open the **Import** dialog box.
2. From the file type list, select the file type that filters the current folder. If you select **All Plan Files**, you can import a .plancad, .planxml, or .xml file.

- If you import a .PlanCAD file, the software imports both the plan features and the embedded CAD model.
- If PC-DMIS detects changes in the original .PlanCAD file that you're referencing, it asks if you want to use the Change Manager to handle those changes. For information on the Change Manager, see "Updating Inspection Plans with the Change Manager".

Your file to import should have the same measurement units as the measurement routine that takes the import. If the files don't have the same measurement units, you can still import the file, but the measurement routine ends up with incorrect information. For example, if you have a circle with an X value of 4 inches in the file to import, the software imports it as 4 millimeters if the measurement routine that takes the import expects millimeters.

3. Click **Import** to import the inspection plan and create a measurement routine from it. For .plancad and .planxml files, once you click **Import**, the software opens the **Sensor Mapping** dialog box so that you can map features to sensors. For more information, see the "Mapping Features to Sensors" topic.

PC-DMIS uses entries to determine the settings for the imported features. You can use the Measurement Strategy Editor or the **Auto Feature** dialog box to modify these settings.

Mapping Features to Sensors

You can use the **Feature - Sensor Mapping** dialog box to assign or map features to probes (sensors). A sensor with a mapped feature measures that feature during execution.

To open the **Feature - Sensor Mapping** dialog box, do one of the following:

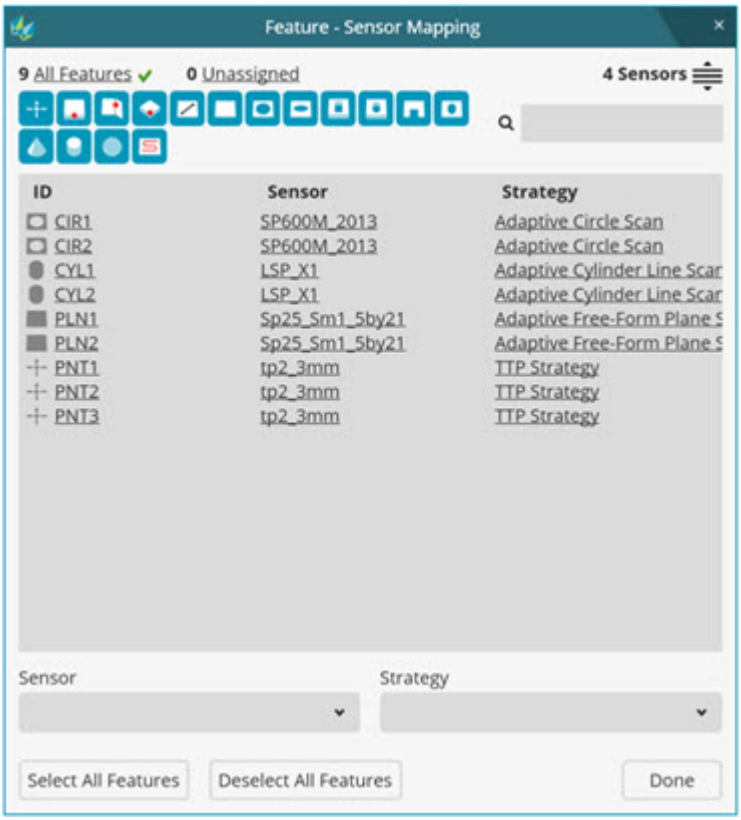
- Select **Edit | Preferences | Feature - Sensor Mapping**.

  The software opens an empty dialog box. You can then use QuickFeatures to populate the dialog box. For more information on QuickFeatures, see "Creating QuickFeatures" in the "Creating Auto Features" chapter.

  If the menu item is disabled, be sure to close any instances of the Measurement Strategy Editor.

- Select **File | Import | Inspection Plan**. Then choose a supported inspection plan file type (.plancad or .planxml) and click **Import**.

The software populates the dialog box with the features in the inspection plan. You can then use QuickFeatures to populate the dialog box with additional features.



Feature - Sensor Mapping Dialog Box

To Assign a Feature to a Sensor

1. In the Edit window, position the cursor after the `LOADPROBE` command. If the cursor is not positioned after the command, QuickFeature selection is possible, but the **Edit** window will not be populated with the selected features.

2. From the **Feature - Sensor Mapping** dialog box, from the feature list, select one or more features. You can then use the feature icons to filter by feature type. The software highlights the features that you select from this list in the Graphic Display window. Press the Shift key and position your mouse pointer over a feature in the Graphic Display window. Then click the feature to add it to the list. The features are not added to the Edit window until you click **Done**.

   > You can use the Shift key to select multiple sequential features and the Ctrl key to select multiple non-sequential features. Each selected feature is highlighted in the Graphic Display window.

3. From the **Sensor** list, select the probe to which you want to assign the selected feature or features. Any new features added to the list are also assigned this sensor.

4. If you want to use a specific strategy for those features, from the **Strategy** list, choose a strategy.

5. Click **Done** to complete the mapping and to continue the import process.

> Be patient while the software does post processing and finishes the import. This process can take a long time. On a standard test computer, 18 features mapped to two probes took about a minute.

6. Once the software finishes the import, the Edit window shows `LOADPROBE` commands for each probe you selected. After each `LOADPROBE` command, the Edit window shows the features that you mapped to that probe.

To Organize Features by Sensor Order

You can also define a probe order and organize your imported features according to that order.

1. From the **Feature - Sensor Mapping** dialog box, start to assign features as usual according to the above procedure.

2. Before you click **Done**, click the **Sensors Ordering** button (top right of dialog box) to open the **Sensors Ordering** dialog box. This dialog box shows a list of the current mapped probes.

3. For one or more probes, select the probe, and then drag and drop (or click the up and down arrows) to change the probe order.

4. From the **Sensor Ordering** dialog box, click **Done** to use the order when PC-DMIS finishes the import.

5. From the **Feature - Sensor Mapping** dialog box, click **Done** to finish the import.

6. Once the software finishes the import, the order of `LOADPROBE` commands matches the probe order you defined in the **Sensors Ordering** dialog box.

Description of the Feature - Sensor Mapping Dialog Box

All features - This text selects all the features in the feature list. It also shows the number of features.

Unassigned - This text selects those features that you have not yet assigned to a sensor.

Sensors - This text shows the current number of sensors in the sensor list. The **Sensors Ordering** button next to **Sensors** opens the **Sensors Ordering** dialog box. You can use the **Sensor Ordering** dialog box to define a sensor order and organize your imported features according to that order.

- The search box filters the feature list by the text you type here.

- The feature icons filter the feature list. Features that match the selected icons appear in the feature list.

Feature list - This list shows all the imported features in the inspection plan, along with the sensor and strategy assigned to them. Click any of the column headers to rearrange the list in alphanumeric order based on that column. When you click **Done**, the features are organized in the same order in the Edit window with the `LOADPROBE` command for the selected sensor added.

The features list contains these columns:

> **ID** - This column shows a symbol and name for each imported feature.
>
> **Sensor** - This column shows the sensor name assigned to that feature.
>
> **Strategy** - This column shows the current strategy for the feature. If nothing appears here, then the software uses the default strategy for that feature. For information on how to define strategies, see "Using the Measurement Strategy Editor" topic in the "Setting Your Preferences: Introduction" chapter.

Sensor - This list shows all the sensors available to the measurement routine.

Strategy - This list shows all the available strategies.

Select All Features - This text selects all the features in the feature list.

Deselect All Features - This text deselects all the features in the feature list.

Done - This button applies the feature to sensor mapping as shown in the **Feature - Sensor Mapping** dialog box.

Importing a Legacy Planner Inspection Plan (.ip)

To import a Planner Inspection Plan as an .ip file, perform the following tasks first:

- Define Parameters and Rules
- Perform an optimization step on the imported plan
- Ensure that the probe won’t collide with the part by inserting proper move commands

Once you have completed these tasks, you can then execute your imported inspection plan as a newly-created PC-DMIS measurement routine.

If you have problems using the PC-DMIS Planner commands inside PC-DMIS, ensure that there is an *InsPlan.dll* file located in the directory where you installed PC-DMIS.

Inspection Plan Default File (.ipd)

You must have an Inspection Plan Default file or .ipd to import a .ip file into PC-DMIS. The "Legacy Planner Parameters" topic provides more information on this file.

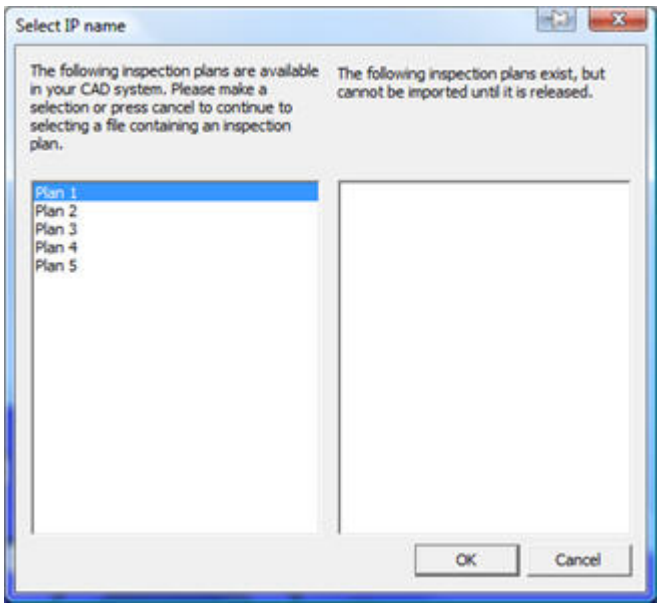
Once you've performed the above preparatory steps, you can import the legacy inspection plan and any rules by importing an inspection plan's .cad file that has the inspection plan embedded in it or by importing a previously-exported inspection plan.

To import an embedded Inspection Plan from a CAD file:

1. Select **File | Import | CAD**. The **Open** dialog box appears.

   When importing a CAD file using the **CAD by Reference** menu option, PC-DMIS updates the file accordingly if any changes were made to the IP CAD file by the legacy PC-DMIS Planner application.

2. Browse to and select the needed IP CAD file, and click **Import**. PC-DMIS imports the IP CAD file.
3. Select **File | Import | Inspection Plan**. The **Select IP name** dialog box appears.



Select IP name Dialog Box

4. Select the needed Inspection Plan, and click **OK** or click **Cancel** to browse to and select an exported Inspection Plan via the **Open** dialog box.

5. Follow any on-screen instructions.

    - Select the **IPD** file that will be applied to the imported Inspection Plan if you have not previously selected it. See the "Legacy PC-DMIS Planner Parameters and Rules" topic for more information.

    - If the insertion point is not at the end of the measurement routine, you are prompted to move the cursor to the end of the measurement routine before continuing.

    - If the CAD file comes from a CATIA v5 model, any comments associated with a feature in the eTool data of the CATIA model are imported as Feature Locator Text for the feature. Note that eTool is a proprietary format used by Chrysler. For information on Feature Locator Text, see the "Providing and Using Feature Locator Instructions" topic in the PC-DMIS CMM documentation.

    - Specify the **Optimize Path** options and click **OK**, or click **Skip** to ignore this step. See "Optimizing the Path" for more information.

    - Specify the options for "Inserting Clearance Moves Automatically" and click **OK** to complete this process or click **Cancel** to skip this step.

To import an Inspection Plan from an exported .ip text file:

1. Select **File | Import | Inspection Plan**. An **Import** dialog box appears.

2. Browse to the directory containing your file with an .ip filename extension.

3. Select the inspection plan, and click **Import**.

4. Follow any on-screen instructions.

- Select the **IPD** file that will be applied to the imported Inspection Plan if you have not previously selected it. See the "Legacy PC-DMIS Planner Parameters and Rules" topic for more information.
- If the insertion point is not at the end of the measurement routine, you are prompted to move the cursor to the end of the measurement routine before continuing.
- Specify the **Optimize Path** options and click **OK**, or click **Skip** to ignore this step. See "Optimizing the Path" for more information.
- Specify the options for "Inserting Clearance Moves Automatically" and click **OK** to complete this process or click **Cancel** to skip this step.

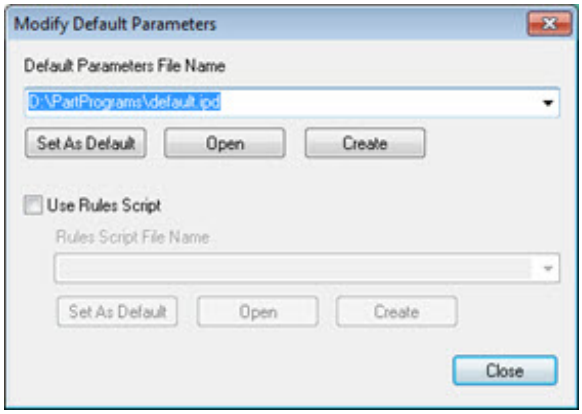
Once you've imported your inspection plan, the imported commands are preceded by a start comment that provides the following basic information for the imported inspection plan:

- Date and time
- The .ip file name with path
- The .ipd file name and path

An end comment indicates the end of the imported inspection plan.

Legacy Planner Parameters

You can use **Edit | Preferences | Inspection Plan Defaults** menu option to open the **Modify Default Parameters** dialog box. You can use this to edit the inspection plan default parameters file (.ipd).



Modify Default Parameters Dialog Box

The Inspection Plan Defaults File (.ipd)

An inspection plan defaults (.ipd) file determines the following:

- The parameters for an inspection plan imported into the software.

- The parameters for Auto features, Constructed Features, and Dimensions.
- How to take hits from features within the inspection plan.
- How to display comments and features.

During an .ip import, if you modify an .ipd file to contain feature parameters and sets it as the default, the software modifies the settings. It then adds the new feature and uses the settings to determine its properties.

The Inspection Plan Rules File (.ipr)

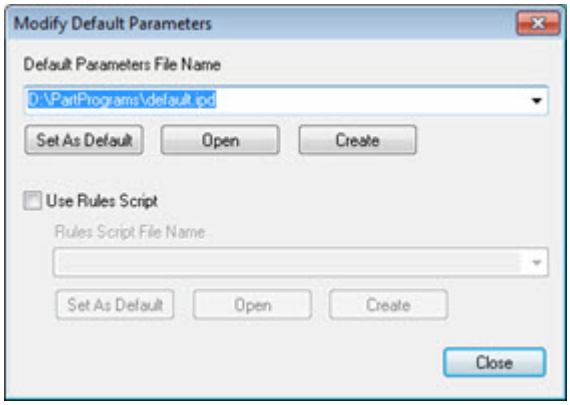
An inspection plan rules (.ipr) file is a Basic script that tells the software how to perform automatic processes on the inspection plan when its imported. Rules can be modified for certain criteria. For example, the number of hits taken on a circle based upon the diameter of the circle and so forth.

Before importing an inspection plan from a CAD file or an .ip or .xml file, you need to set up these files to apply to imported inspection plans.

Creating and Modifying an Inspection Plan Default (.ipd) File

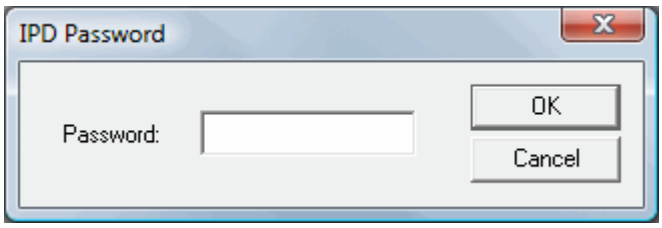
To create a new .ipd file or make changes to an existing .ipd file, follow this procedure:

1. Select the **Edit | Preferences | Inspection Plan Defaults** menu option to display the **Modify Default Parameters** dialog box.

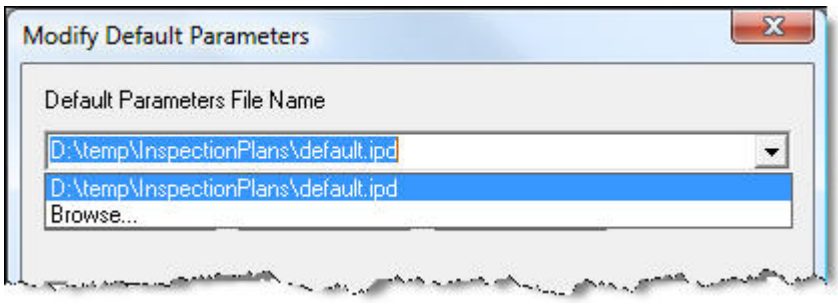


Modify Default Parameters Dialog Box – PC-DMIS Planner Default File

If password protection is enabled for PC-DMIS settings, you need to type the correct password into the **IPD Password** dialog box to proceed. The password is case-sensitive. For more information on password protection, see the "Password" topic discussed under the "Setup Options: General Tab" topic in the "Setting Your Preferences" chapter.



2. From the **Modify Default Parameters** dialog box, in the **Default Parameters File Name** list, select the file that you want to use. If the file isn't listed, click **Browse** to locate and open one from your directory.

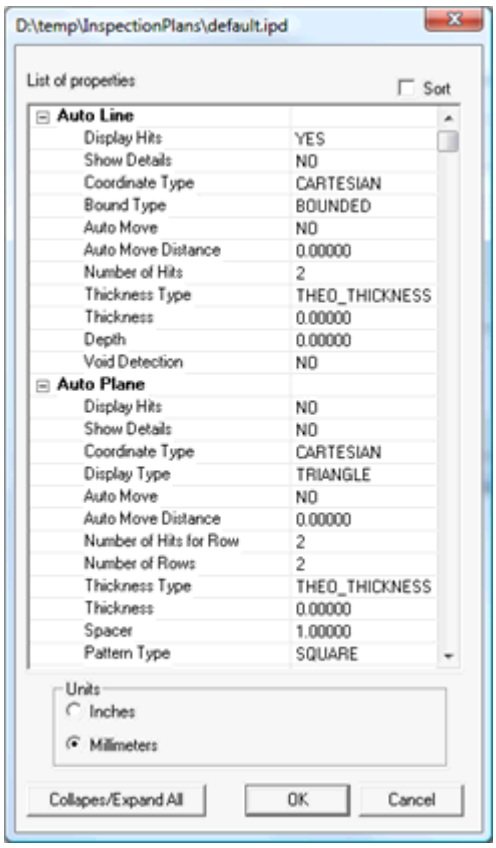


Default Parameters File Name List - Default.ipd

> The default path and file name used for your .ipd file is stored in the `Parameters File` entry in the **Planner** section of the Settings Editor. If no file name is specified, PC-DMIS uses the default value of <PC-DMIS Install Directory>\default.ipd.

3. Decide if you want to edit parameters on an existing .ipd file or edit parameters on a new one.

   - If you want to open and modify an existing .ipd file, click the **Open** button to show the **Default Parameters** dialog box for the selected .ipd file.
   - If you want to create a new .ipd file, click **Create** to show the **Default Parameters** dialog box for the new .ipd file.



Default Parameters

4. To edit a property, from the right column, click on that property's value to show a drop-down list.

5. Select the drop-down list, and choose a different value. These values may represent distance, amount, or some measured value. You can select values from option lists or toggle fields.

    - Option lists provide a list of choices relevant to the associated item.

    - Toggle fields provide only two choices, such as ON/OFF, YES/NO, or TRUE/FALSE.

6. If you want to sort the **List of properties** alphabetically, click the **Sort** check box.

7. Select either **Inches** or **Millimeters** to determine how units are displayed in the **Default Parameters** dialog box. PC-DMIS also converts imported Inspection Plans to the specified units if they are different from the Inspection Plan units.

8. Click the **Collapse/Expand All** button to collapse or expand the **List of properties**.

If you do not achieve the desired results for imported Inspection Plan items, you may need to update the needed parameter and recreate the .ipd file. Also, note that .ipd files are only compatible with the version in which they were created. For example, an .ipd created for PC-DMIS 4.2 is not compatible with PC-DMIS 4.3.

9. Click **OK** to open the **Save As** dialog box, or click **Cancel** to abort any changes that have been made.
10. Click **Save** to save the .ipd file.
11. If you want to make the file listed in the **Default Parameters File Name** box the default file, click **Set as Default**. This copies any inspection planner settings for plan features contained in that file and sets the equivalent default entries to those settings.
12. Click **Close**.

Updating Inspection Plans with the Change Manager

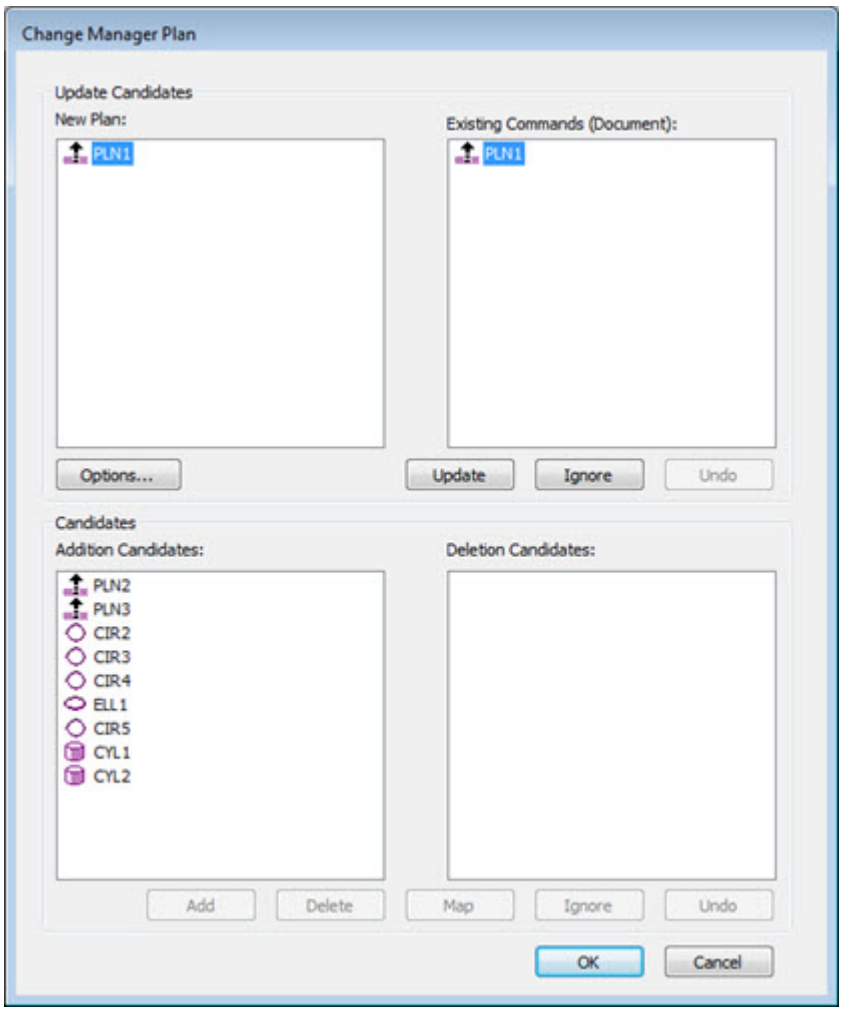
While this documentation specifically addresses Inspection Plans, it also applies to updating measurement routine files created from Datalog files as well.

The Change Manager Plan updates a measurement routine you created from a previously-imported version of your plan with the latest version of your plan. The Change Manager CAD compares the measurement routine's feature values with those in the CAD. You can then update the measurement values based on the CAD values if necessary.

The number of decimal places that Change Manager uses follows the current measurement routine's units. If the routine is in mm, Change Manager uses three decimal places. If it is in inches, Change Manager uses four decimal places.

Updating a Measurement Routine from an Inspection Plan

1. Select the **File | Change Manager | Plan** menu item to open an **Import** dialog box.
2. You can import a .planxml or .xml file created from Planner or an .ip file created from the legacy Planner.
3. Choose the plan to import, and click **Import** to convert the file and show the **Change Manager Plan** dialog box:



Change Manager Plan Dialog Box

4. You can double-click on a feature name from any list to show its parameters for that feature in order to compare values before updating your measurement routine.

5. Use the following controls to process the differences in the measurement routine and the imported plan.

    - **Options** - Opens the **Change Management Options** dialog box. See "Change Management Options".

    - **Update** - This updates the selected feature into the **Existing Commands** from the **New Plan**. If you select a feature from one list, the software highlights the corresponding feature from the other list. You can select more than one feature at a time to update. This button also updates any associated dimensions.

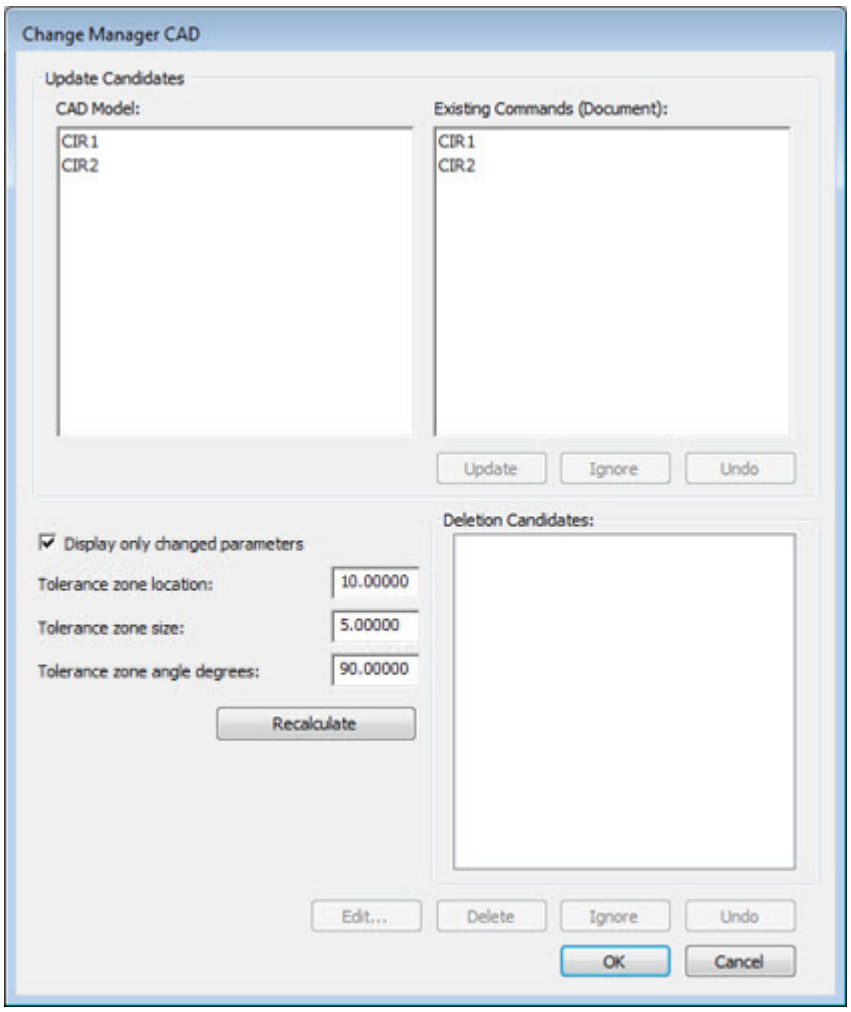
    - **Ignore** - The selected feature is ignored for update into the **Existing Commands** from the **New Plan** when you click this option. Selecting a feature from one list will highlight the corresponding feature from the other list. You can select more than one feature at a time to ignore.

    - **Undo** (under **Existing Commands** area) - This is available only after you use **Update** or **Ignore**. This reverts the last change made.

- **Add** - This adds the selected feature from the **Addition Candidates** list to the bottom of the existing plan. You can select more than one feature at a time to add.
- **Delete** - The selected feature from the **Deletion Candidates** list is deleted from the existing plan when you click this option. You can select more than one feature at a time to delete.
- **Map** - This is available only when you select one feature from both the **Addition** and **Deletion Candidate** lists. This replaces the selected **Deletion Candidate** feature with the selected **Addition Candidate** feature. This does not allow multiple selections. You can map both like and unlike feature types (for example, circle to a point or point to a point).
- **Ignore** - This ignores (removes) the selected feature from the **Deletion Candidates** list, but it does not delete the feature from the existing plan when you click this option. You can select more than one feature at a time to ignore. Any feature that you remove from the list remains in the measurement routine.
- **Undo** (under **Deletion Candidates** area) - This is available only after **Add**, **Delete**, or **Map** has been processed. This button reverts the last change made.

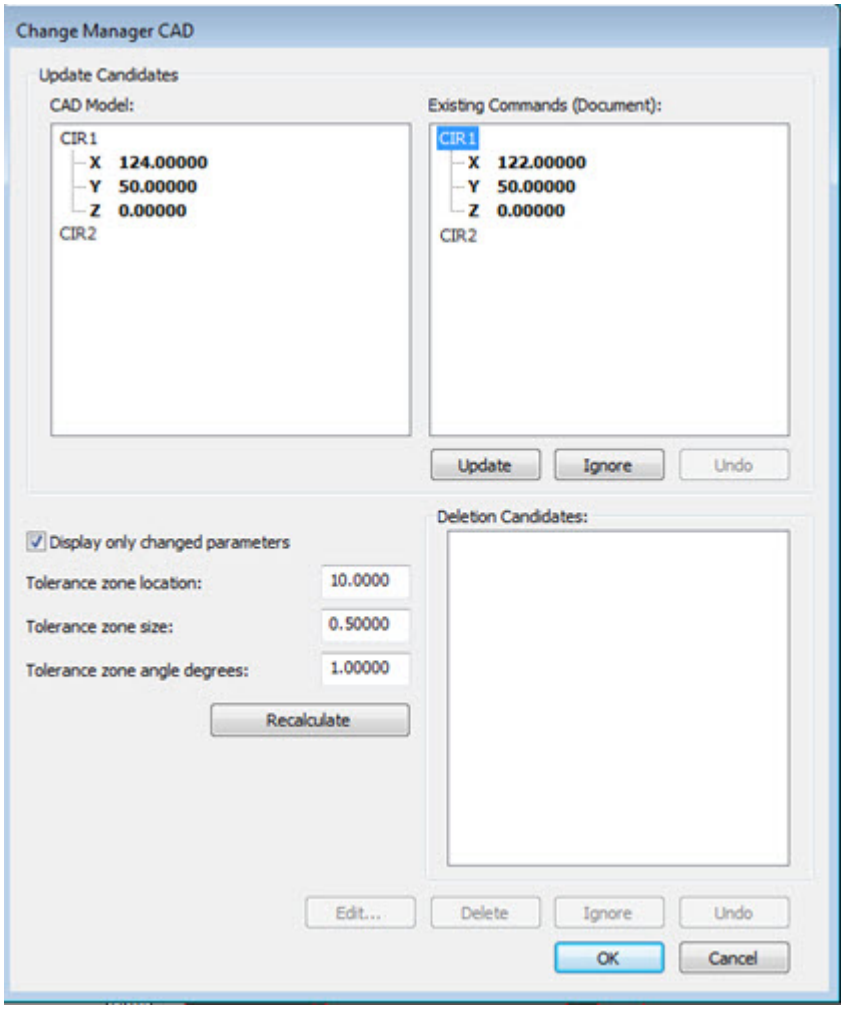
Updating a Measurement Routine from a CAD Model

1. Import a CAD model into your measurement routine (**File | Import | CAD**) or open a measurement routine that already contains a CAD model (**File | Open**).
2. Select the **File | Change Manager | CAD** menu item to open the **Change Manager CAD** dialog box:



Change Manager CAD Dialog Box

3. If the software finds differences between the CAD and command feature components, it lists the features in the dialog box. It displays the CAD features in the **CAD Model** area and the measurement routine features in the **Existing Commands (Document)** area of the dialog box. Double-click any of the listed features to display its components.



Change Manager CAD dialog box showing feature component values

4. Click the **Update** button to change the measurement routine's feature component values to those of the CAD's. This button also updates any associated dimensions.

   The **Change Manager CAD** dialog box functions the same as the **Change Manager Plan** dialog box, except for the following items:

   - The **Add** button and the **Addition Candidates** section are not available.
   - The **Edit** button for the **Deletion Candidates** section displays the edit dialog box for the selected feature in the **Deletion Candidates** list so that you can edit the feature instead of just deleting or ignoring it.
     - Select the **IPD** file to apply to the imported Inspection Plan if you have not previously selected it. See "Legacy PC-DMIS Planner Parameters and Rules" for more information.
     - If the insertion point is not at the end of the measurement routine, the software prompts you to move the cursor to the end of the measurement routine before continuing.

- Specify the **Optimize Path** options and click **OK**, or click **Skip** to ignore this step. See "Optimizing the Path" for more information. Review the optimization and close the **Optimize Path Workflow** dialog box.
- Specify the options for "Inserting Clearance Moves Automatically" and click **OK** to complete this process, or click **Cancel** to skip this step.

- If the tolerances have changed, click the **Recalculate** button to recalculate using the new tolerances. PC-DMIS then reviews the settings to determine which features are close enough to the CAD model to be considered the same.

The **Change Management Options** functions described for the **Options** button are integrated into the **Change Manager CAD** form.

Centering and Highlighting Features

You can also use the **Change Manager CAD** dialog box to **Center** a feature or **Highlight** and **UnHighlight** features you need to change or delete. This can help you to better see where changes in a CAD model have been made or how you should update your measurement routine to match a new CAD model.

To access this functionality, from the **Change Manager CAD** dialog box (**File | Change Manager | CAD**), right-click on any feature name in any of the lists (CAD Model, Existing Commands or Deletion Candidates) to display the options.

The options perform the following functions:

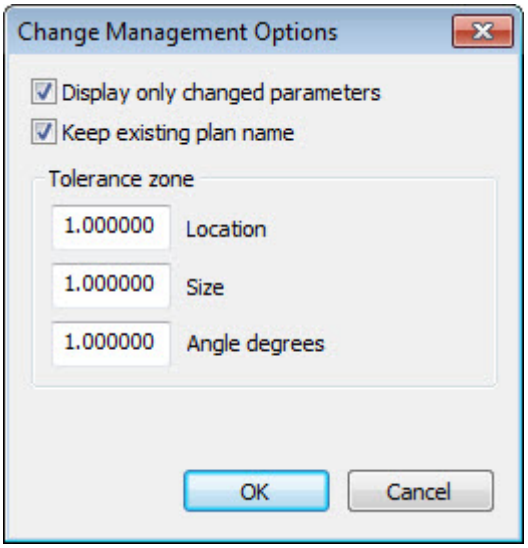
- **Center in CAD** - This centers the selected feature location in the CAD Window.
- **Highlight in CAD** - This highlights the selected feature in the CAD window. You can only highlight one feature at a time, and you cannot highlight any feature in the CAD Model list if the feature does not currently exist in the measurement routine.
- **UnHighlight in CAD** - This clears the highlight on the feature in the CAD window.

Reloading a CAD File

If the software doesn't automatically detect a modified CAD model and reload it in the Change Manager (which can happen if the original native CAD file is moved from its known location), you can use **File | Change Manager | Reload CAD** to manually tell the Change Manager to reload the CAD model.

PC-DMIS uses entries to determine the settings for the imported features. You can use the Measurement Strategy Editor or the **Auto Feature** dialog box to modify these settings.

Change Management Options



Change Management Options Dialog Box

To access this dialog box:

1. Select the **File | Change Manager | Plan** menu item.
2. From the inspection plan **Import** dialog box, navigate to the inspection plan file to import, and click **Import**.
3. Click **Options** to display the **Change Management Options** dialog box.

The following options are available:

Display Only Changed Parameters - This displays only the changed parameters for expanded features in the lists of the **Update Candidate** area.

Keep existing plan name - This retains feature names in the existing plan. Otherwise the software replaces the feature name with the feature name from the imported plan.

Tolerance Zone - You can use this area to define the tolerance values the software should use to evaluate the features. The software shows the features that are within tolerance in the **New Plan** and **Existing Plan (Program)** lists. The software evaluates the following feature dimensions:

- **Location** - Provides the tolerance for *location* evaluation.
- **Size** - Provides the tolerance for *size* evaluation.

- **Angle Degrees** - Provides the tolerance for *angle* evaluation.

Optimizing the Path

Once you have created a measurement routine (or imported one from an Inspection Plan), the Edit window contains commands to measure features on your part. The software originally adds the features in the order that you select them. However, this may not be the most efficient order to use.

With the **Optimize Path Workflow** dialog box (**Edit | Optimize Path**), you can have PC-DMIS optimize the order in which it measures the features in your measurement routine. PC-DMIS can also recommend the ideal tip angles for the different features on the part.

Optimize Path can provide significant savings in execution time.

Optimize Path works only with routines that use touch probes. It does not work with routines that use vision or laser devices.

You can access the **Optimize Path Workflow** dialog box at any time to perform path optimizations on all or part of your measurement routine. This dialog box optimizes the order in which PC-DMIS measures the features and what tip angles it uses and when.

For information on how to use this functionality, see these topics:

- Path Optimization Procedure
- The Optimize Path Workflow Dialog Box

Path Optimization Procedure

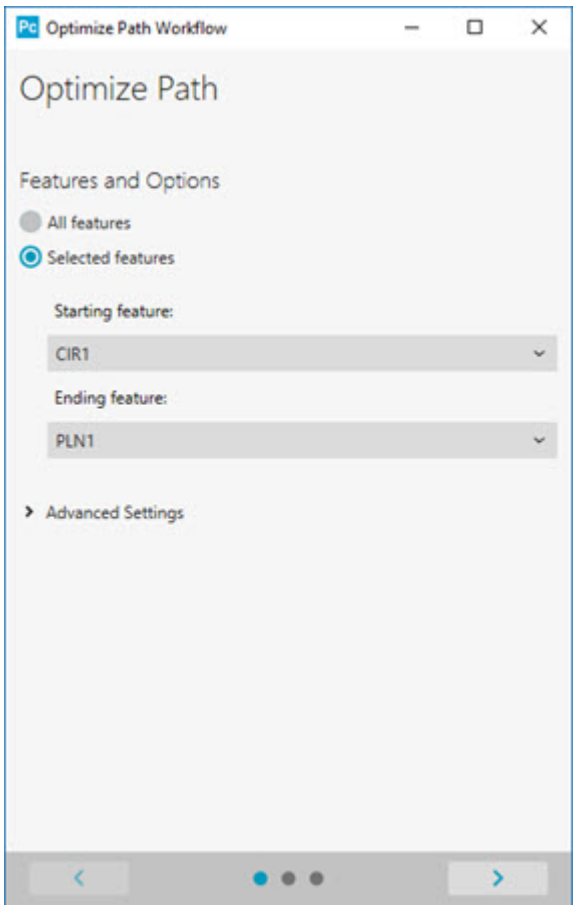
This topic shows the procedure to optimize the path with the **Optimize Path Workflow** dialog box. It uses the default options.

This dialog box uses three panels. The dots at the bottom indicate the panels and which panel you're on. From left to right, these dots indicate panels 1, 2, and 3.

Step 1 - Set Options (Panel 1)

Panel 1 shows options you can select, as well as advanced settings.

1. Select **Edit | Optimize Path**, or click **Path Optimizer** ( ) from the **QuickMeasure** toolbar. This opens the **Optimize Path Workflow** dialog box and changes the Edit window to show Command Mode. For information on the dialog box, see "The Optimize Path Workflow Dialog Box".



Optimize Path Workflow dialog box (Panel 1)

2. On panel 1, from the **Features and Options** area, decide to optimize the path for all the features (**All features**) or a subset range of features (**Selected features**).

   A. If you choose **Selected features**, from the **Starting feature** list, choose a start feature. You can also choose the feature directly from the Graphic Display window.

   B. If you choose **Selected features**, from the **Ending feature** list, choose an end feature. You can also choose the feature directly from the Graphic Display window.

> You can also open the dialog box with the starting and ending features already selected if you choose them first from the Edit window.
>
> 1. From the Edit window, select the first feature in the range.
> 2. Press Shift.
> 3. Select the last feature in the range.
> 4. Select **Edit | Optimize Path**.

3. If you need to do so, modify items under **Advanced Settings**.

4. Click the next button ( ) to move to panel 2 in the dialog box. This initiates the path optimization process and shows a progress bar.

> The path optimization makes permanent changes to your measurement routine. Make sure you're satisfied with the options in the first panel before you start the process on panel 2.
>
> *Once the optimization process finishes, the only way to revert it is to choose* **File | Quit** *and close the modified routine without saving it.*
>
> The previous button ( ) only remains active until the optimization process finishes. Once the process finishes, you cannot go back to the first panel.

Step 2 - View the Results (Panel 2)

Panel 2 shows how much the path improved.

1. On panel 2, review the circle graph and the **Shorter** value.

2. Click the next button ( ) to move to panel 3.

Step 3 - Cleanup Uncalibrated or Missing Tips (Panel 3)

Panel 3 shows the number of features without tips and the number of uncalibrated tips.

If you have features without tips:

1. From the **Features without tips** list, click on each feature to see that feature in the Graphic Display window and to see an optimum tip angle.

2. Use the area above the **Features without tips** list (the area with the **Use only calibrated** check box), and define a tip for the feature. This area behaves the same as the **Select Tip** toolbar in the "Using Toolbars" chapter.

3. Click **Apply** to evaluate the new tip against the remaining features in the list. If this new probe tip can measure any of these features, PC-DMIS assigns it to that feature and then removes the feature from the **Features without tips** list.

4. If you want to re-optimize the path based on the new tips, mark the **Perform routing** check box and click **OK**.

5. Once you click **OK**, the **Optimize Path Summary** dialog box closes, and the **Auto Insert Moves** dialog box opens. Use this dialog box to automatically insert `MOVE/`

`POINT` commands between features. For more information, see "Inserting Clearance Moves Automatically" in the "Inserting Move Commands" chapter.

If you have uncalibrated tips:

1. From the **Uncalibrated Tips** area, click on a tip and click **Calibrate tip** to open up the **Probe Utilities** dialog box.
2. From the **Probe Utilities** dialog box, click **Measure** to begin the calibration. For information on how to use the **Probe Utilities** dialog box to calibrate the tip, see "Measure" in the "Defining Hardware" chapter.

When you're done, click finish ( ) to close the **Optimize Path Workflow** dialog box.

Step 4 - Apply Clearance Moves

If the **Auto Insert Moves** dialog box opens, you can use this dialog box to insert moves between features. For information, see the "Inserting Clearance Moves Automatically" topic in the "Inserting Move Commands" chapter.

Step 5 - Check for Collisions

It's always a good idea to check for collisions whenever your measurement routine changes. For more information, see "Detecting Collisions" in the "Editing the CAD Display" chapter.

During Optimization

During path optimization, PC-DMIS accounts for machine volume as the optimization makes the following default modifications:

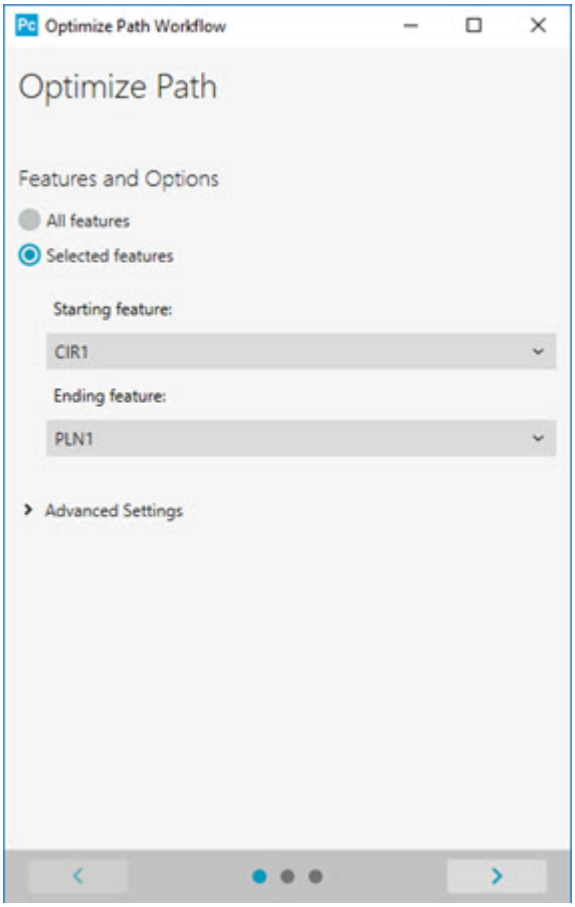
- PC-DMIS sorts the features by the tips used to measure them. However, PC-DMIS does not sort across `ALIGNMENT` or `LOADPROBE` commands.
- PC-DMIS also sorts features inside of groups.
- PC-DMIS removes all `MOVE/POINT` commands, but preserves any motion commands or other parameters that may affect measurement, such as retract distance, prehit distance, and so on.
- PC-DMIS determines the best path for the probe to take based on distances between features and the tip change.
- PC-DMIS adds dimensions at the end of the measurement routine.
- PC-DMIS adds constructed features as soon as possible.
- PC-DMIS ensures that features that have the RMeas option are not measured prior to their related features.

- PC-DMIS then determines the best tip angle for each feature. For example, the optimal tip angle for a cylinder is based on the cylinder vector, which may or may not correspond to an exact tip angle.
- If PC-DMIS cannot find an appropriate tip, it assigns a tip of T?A?B? to that feature in the measurement routine. It then adds this feature to the **Features without tips** in panel 3.

The items under **Advanced Settings** in panel 1 can affect the above path optimization process and procedure. For information on these settings and their effects, see "Advanced Settings" in "The Optimize Path Workflow Dialog Box - Panel 1".

The Optimize Path Workflow Dialog Box

To access the **Optimize Path Workflow** dialog box, choose **Edit | Optimize Path**.



Optimize Path Workflow Dialog Box

With this dialog box, PC-DMIS can reorder the measurement routine's commands to create the most efficient path for the probe to take. At the end of this process, PC-DMIS can also recommend optimal tip angles for the features in your routine. For the procedure that goes with this dialog box, see "Path Optimization Procedure".

This dialog box uses three panels. The dots at the bottom indicate the panels and which panel you're on. From left to right, these dots indicate panels 1, 2, and 3.

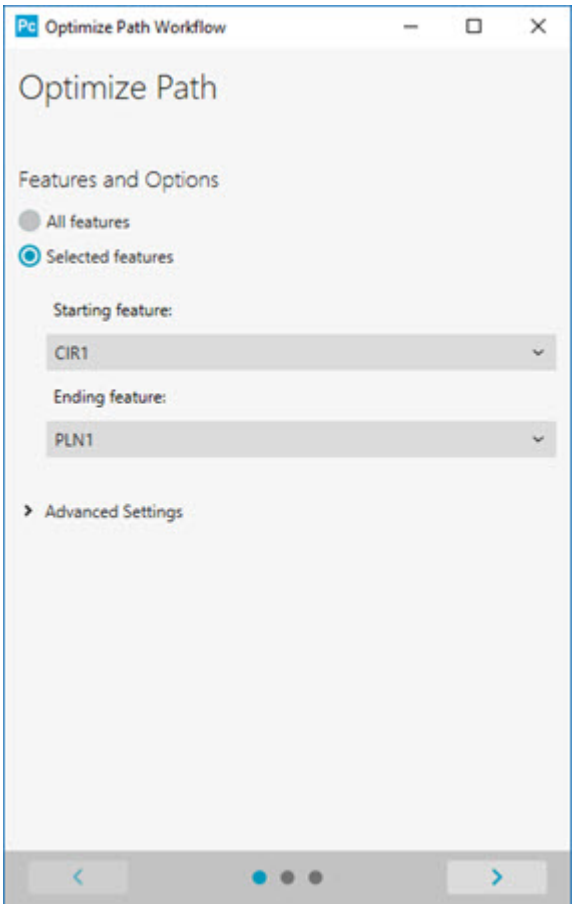
When the dialog box opens, it shows panel 1.

The topics for the panels show all the items on the dialog box.

When you access this dialog box for the first time, PC-DMIS positions it on top of the Edit Window. You can then move or size the dialog box. When you next open the dialog box, the software remembers its latest position and size.

The Optimize Path Workflow Dialog Box - Panel 1

Panel 1 contains the options for the path optimization. In this panel, you can decide to optimize the path for all the features or just a subset of features based on a selected range of features.



Optimize Path Workflow Dialog Box (Panel 1)

Features and Options area - With this area, you can decide what features receive the path optimization:

All features - This option makes the path optimization occur for all the features in the measurement routine.

Selected features - The option makes the path optimization occur for only a range of features in the measurement routine.

Starting feature - This is the first feature in a range of features. You can also choose the feature directly from the Graphic Display window.

Ending feature - This is the last feature in a range of features. You can also choose the feature directly from the Graphic Display window.

Advanced Settings

These values are persistent. This means if you change these values, the next time you open the dialog box, the software pulls in the values for these items from the JSON file.

Tip Changes area - With this area, you can decide if and how PC-DMIS adds tip changes during optimization.

Add tip changes - This switch determines whether PC-DMIS automatically inserts tip changes during the optimization. If you turn this switch off, the **Use only defined tips** and **Ask if tip not found** switches are disabled.

Use only defined tips - This switch determines whether PC-DMIS only uses defined tips to measure features. If PC-DMIS cannot find an appropriate tip then it assigns a tip of T?A?B? to that feature in the measurement routine. It then adds this feature to the **Features without tips** in panel 3 of the dialog box after the optimize path process finishes (for more information, see "The Optimize Path Workflow Dialog Box - Panel 3"). If you turn off this switch, PC-DMIS uses undefined tips. Prior to execution, PC-DMIS requires that you calibrate any undefined tips.

Ask if tip not found - This switch determines whether PC-DMIS prompts the operator if it cannot determine the optimal tip for a given feature. This lets the operator manually specify the most appropriate tip.

Filter tips - This switch filters tips so that PC-DMIS considers only those tips with angles that are within the **Filter angle** value. The **Filter angle** value defines a maximum range for considered tip angles. If you don't filter the tips, PC-DMIS considers all available tips.

Dimensions area - With this area, you can decide when to insert dimensions from your inspection plan into the measurement routine.

Insert at end - This option inserts dimensions at the end of all the measured features.

Insert as soon as possible - This option inserts dimensions as soon as possible after each measured feature.

Sorting features and groups area - With this area, you can decide how PC-DMIS handles sorting features and sorting features in groups.

Reorder features - This switch determines whether PC-DMIS sorts the features during the optimization. This enables the following two options.

If you turned on **All features** under **Features and Options**, then this sorts all features. If you chose **Selected features** then PC-DMIS only sorts that selected range of features. The default value for this switch is on.

Reorder features inside of groups - This switch determines whether PC-DMIS sorts features inside of `GROUP` commands during the optimization. If you don't choose to sort inside groups, the software doesn't sort features in groups. Instead, it only sorts the groups themselves as if they were a single feature. The default value for this switch is off.

Sort Inside Groups - This linked text opens a **Sort Inside Groups** dialog box that contains all the `GROUP` commands in the measurement routine. You need to mark the check box next to each group you want to sort. The software sorts inside groups with the inner-most group first. It handles each group as a single feature to its parent group.

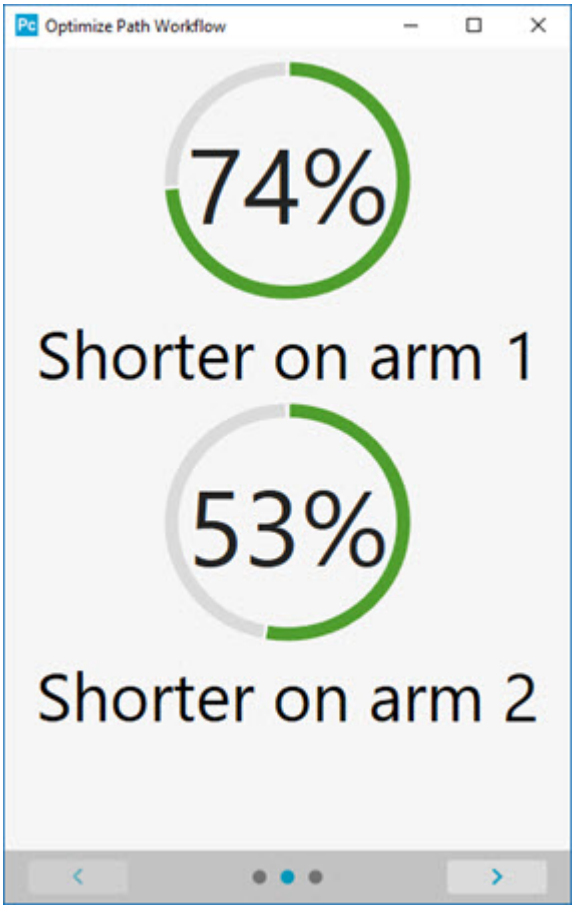
The Optimize Path Workflow Dialog Box - Panel 2

Panel 2 of the **Optimize Path Workflow** dialog box shows the result of the path optimization. It shows a percentage value. The path is that percentage shorter after the optimization.

PC-DMIS calculates the total path length before and after optimization to get this value.

Panel 2 showing the optimization summary for a single-arm machine.

If you use multiple CMM arms to measure the part, it shows the percentage shorter for each arm:



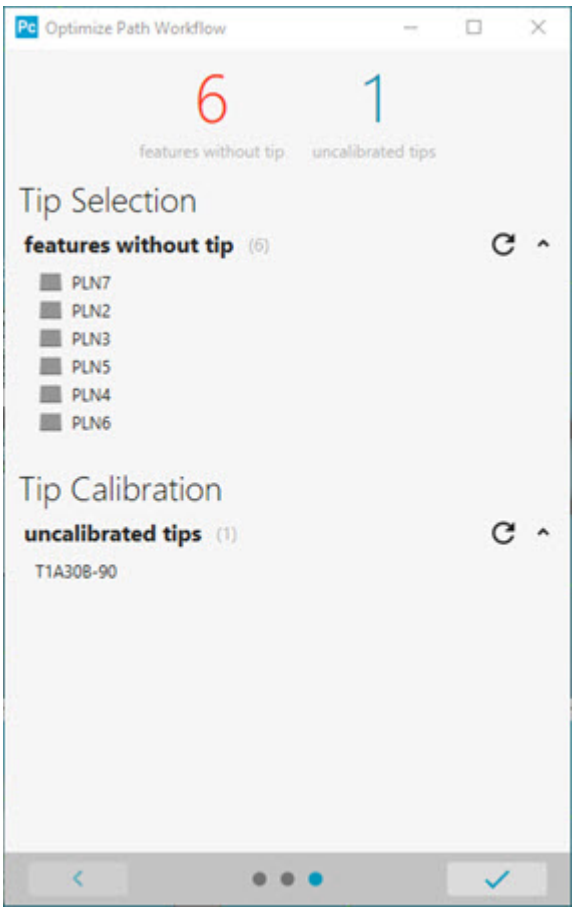
Panel 2 showing the optimization summary for a dual-arm machine.

- The previous button shows panel 1. However it only remains active until the optimization process finishes. Once the process finishes, you cannot go back to the first panel, and you cannot undo the changes the process makes.

- The next button shows panel 3 where you can work with uncalibrated or missing tips.

The Optimize Path Workflow Dialog Box - Panel 3

Panel 3 of the **Optimize Path Workflow** dialog box shows features without tips and uncalibrated tips. You can use this panel to resolve those items.

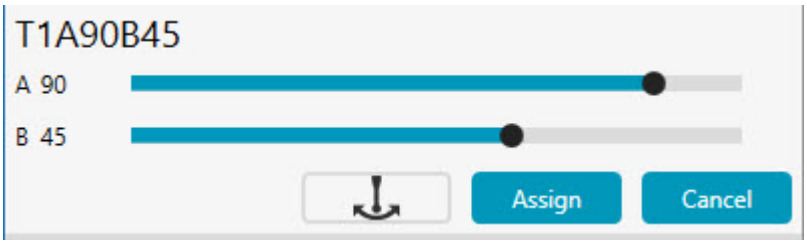


With this panel, you can do the following:

- Define probe tips for features without tips
- Calibrate uncalibrated probe tips

Features without tip list - This option shows the list of features that need a tip command. The number in parentheses shows the number of items in the list. It corresponds to the red number at the top of the panel.

You can click on a feature in this list to get a recommended tip. A mini window slides into view. This window initially suggests the best tip and angles to use to measure that feature:



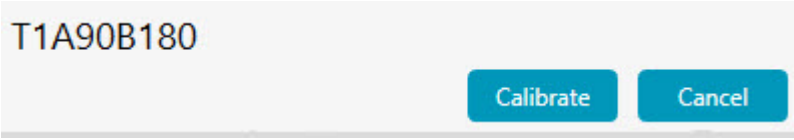
A and **B** sliders show the current angle. You can also use them to modify the A and B angles for the tip. A **C** slider may also appear if your probe supports C angles.) You may want to use these sliders to tweak the angles. The animated probe shows the current orientation in the Graphic Display window.

Find Optimum Tip Angles - This sets the slider bars back to the optimal tip angles for that feature.

Assign - Assigns the final tip angle to the feature and closes the mini window.

Tip Calibration list - This shows the list tips that need calibration. The number in parentheses shows the number of items in the list. It corresponds to the blue number at the top of the panel.

You can click on a tip to calibrate it. A mini window slides into view. This window contains these items:



Calibrate - This closes the mini window and opens the **Probe Utilities** dialog box so that you can calibrate the probe tip. You can use the **Measure** button on the **Probe Utilities** dialog box to calibrate the probe. For more information, see "Calibrating Probe Tips" in the PC-DMIS CMM documentation.

Attempt to find valid tip - This attempts to find a valid tip for the feature.

- The small triangle buttons turn blue when you hover your pointer over them. They collapse or expand the lists.

- Closes the **Optimize Path Workflow** dialog box and opens the **Auto Insert Moves** dialog box to automatically insert clearance moves between features.

Void Detection

Void Detection prevents hits from being taken in empty spaces (such as holes). This functionality has been added to these Auto Features:

- Auto Surface Point
- Auto Edge Point
- Auto Line
- Auto Plane
- Auto Circle
- Auto Round Slot
- Auto Cylinder

- Auto Cone

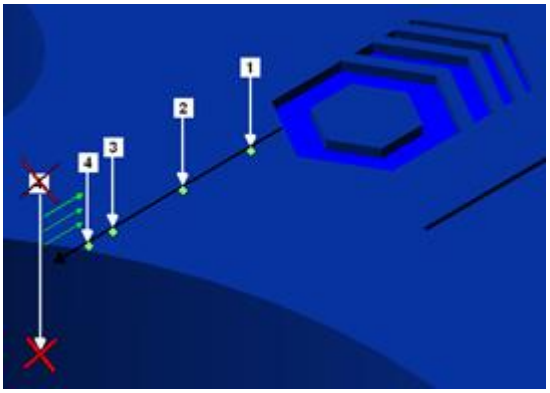
Without Void Detection, an Auto feature may place hits in holes and other empty spaces in the CAD surface and the part.

PC-DMIS automatically applies void detection to the generation of the probe hits when you create a supported Auto feature by using the parameters from the corresponding **Auto Feature** dialog box (**Insert | Feature | Auto**) such as **# hits**, **Start Angle**, and **End Angle** for an auto circle. Any probe hits that would normally fall into a void are moved so that they reside on the surface of the selected feature.

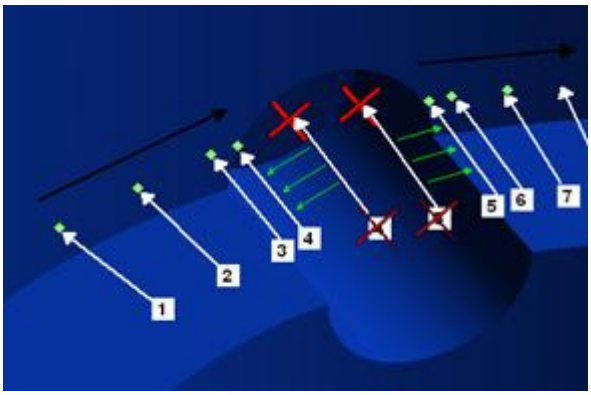
- For an Auto Plane feature, you can determine this distance, termed a "boundary offset", from any edge. This boundary offset is specified inside the **Void detection** area of the **Auto Move Properties** tab of the Probe Toolbox.
- For the other supported Auto features, this distance is the tip's radius value.

Requested sample hits for Auto Circles or Auto Cylinders are also automatically generated with Void Detection.

The following examples show when Void Detection would be useful for accurately and safely measuring an Auto feature. Hits denoted with an "X" are determined to be voids and are corrected to the edge of the Auto feature surface.



Example showing the void detection for an Auto Plane feature.



Example showing the void detection for an Auto Cylinder feature.

Void Detection can be turned On or Off using the **Void Detection** toggle on the dialog box. For details on the toggle, see the "Void Detection Toggle" topic in the "Creating Auto Features" chapter.

Inserting Clearance Moves Automatically

Once you import or create features and perform a path optimization, you need to ensure that your probe won't collide with your part during measurement. PC-DMIS contains menu options in the **Operation | Graphic Display Window | Clearance Moves** submenu that insert clearance moves automatically as `MOVE/POINT` commands to help avoid unintentional collisions with the part. These menu items under the **Clearance Moves** submenu are discussed below.

For more information on how to detect collisions, see "Detecting Collisions" in the "Editing the CAD Display" chapter.

Using a Wrist Device

Using a Wrist Device: Introduction

PC-DMIS provides complete support for calibrating and using infinitely indexable wrist devices such as the Renishaw PHS, the DEA CW43, and the DEA CW43L as well as devices provided by other manufacturers.

The main topics in this chapter include:

- Wrist Installation
- Tip Calibration
- Calibrate the Unit
- Qualification Check
- Home the Unit
- Using the Wrist in a Measurement Routine
- Calibrating and Using a CJoint Device

Wrist Installation

If a wrist is installed on your CMM, PC-DMIS adds A and B axes to the Probe Readouts window where the X, Y, and Z values are normally displayed. The wrist option must be enabled in the PC-DMIS license for wrist support to be available. In addition, you may need to set certain entry values. Because of the variety of infinite wrists and interfaces supported, you should consult with your software vendor for specifics on what PC-DMIS entries need to be changed (see the "Modifying Setting Entries" appendix for information on using the PC-DMIS Settings Editor to modify entries).

PC-DMIS automatically queries the controller and determines that the wrist is present.

Notes for Renishaw PHS with Leitz Interface

When you are using the kinematics mount for the Renishaw wrist, you need to set the `RenishawKinematicMount` entry to 1 in the **Option** section of the PC-DMIS Settings Editor. For information on modifying entries, please view the "Modifying Setting Entries" appendix.

When the system starts, PC-DMIS asks if the PHS Wrist is mounted on the CMM. PC-DMIS only asks this question when the controller has just been powered on. Once you inform PC-DMIS what is on the end of the arm, it does not ask the question again until it senses the controller has been shut down and restarted. When you have the wrist mounted, PC-DMIS adds A and B axes to the Probe Readouts window. This is in addition to the X, Y, Z axis readouts that are normally displayed.

The Probe Readouts window does not reflect the value changes until you run PC-DMIS after click **Yes** to the question regarding the PHS Wrist.

Tip Calibration

Tip calibration assumes that you have already calibrated the wrist. It does not need to be done for the tip that is used to calibrate the wrist. Tip calibration is done automatically for the tip used to calibrate the wrist.

The purpose of tip calibration is to calculate the distance from the last joint's center point (A joint) to the tip center. Theoretically, measuring one tip AB combination is sufficient for PC-DMIS to compute this distance once the wrist is calibrated. However, to get better accuracy, it's a good idea to measure more than one AB combination so that PC-DMIS can average the computed tip offsets.

New Probe File

Once you have calibrated the wrist, you can change the tip attached to the wrist and do a tip calibration.

To calibrate a new tip on the wrist:

1. Access the **Probe Utilities** dialog box by selecting the **Insert | Hardware Definition | Probe** menu option.
2. Make sure the probe description matches the new tip that you have loaded.
3. Select one or more AB combinations from the **Active Tip** list that correspond to this new tip. If a desired AB combination is not in the list, you can add it by selecting the **Add Angles** button. You must select at least one AB combination from the tip list in order to calibrate the tip. If you select more than one, PC-DMIS averages the results to get a more accurate tip offset.
4. Once you select the desired tips, click the **Measure** button. The **Measure Probe** dialog box appears for you to set the number of hits; the prehit and retract values; and the speeds.
5. From the **Options to Calibrate** area, select the **Calibrate Tips** option.

6. Set any other desired parameters. For more information on the **Measure Probe** dialog box, see the "Measure" topic.

7. Click the **Measure** button.

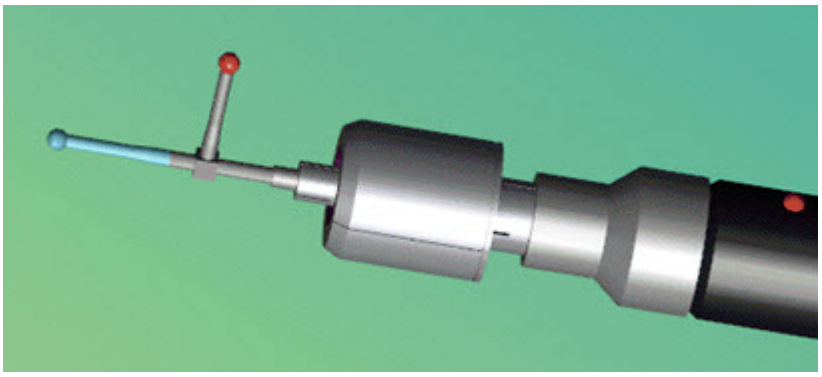
PC-DMIS begins to measure the sphere with the selected AB angle combinations.

Calibrating a "L"-Shape Star Probe with a Wrist Map

If you need to calibrate a star probe that uses a wrist map, you must perform a specific sequence of operations. You must also pay particular attention when you set the wrist rotation angles. Consider this example which shows how to calibrate a typical "L"-shape star probe configuration with a wrist map:

Overview

A star probe is not always composed of all five tips. Star probes often have only two tips. One tip connects along the central axis of the wrist. The second tip connects to an empty connection point to form an "L"-shape configuration like this:

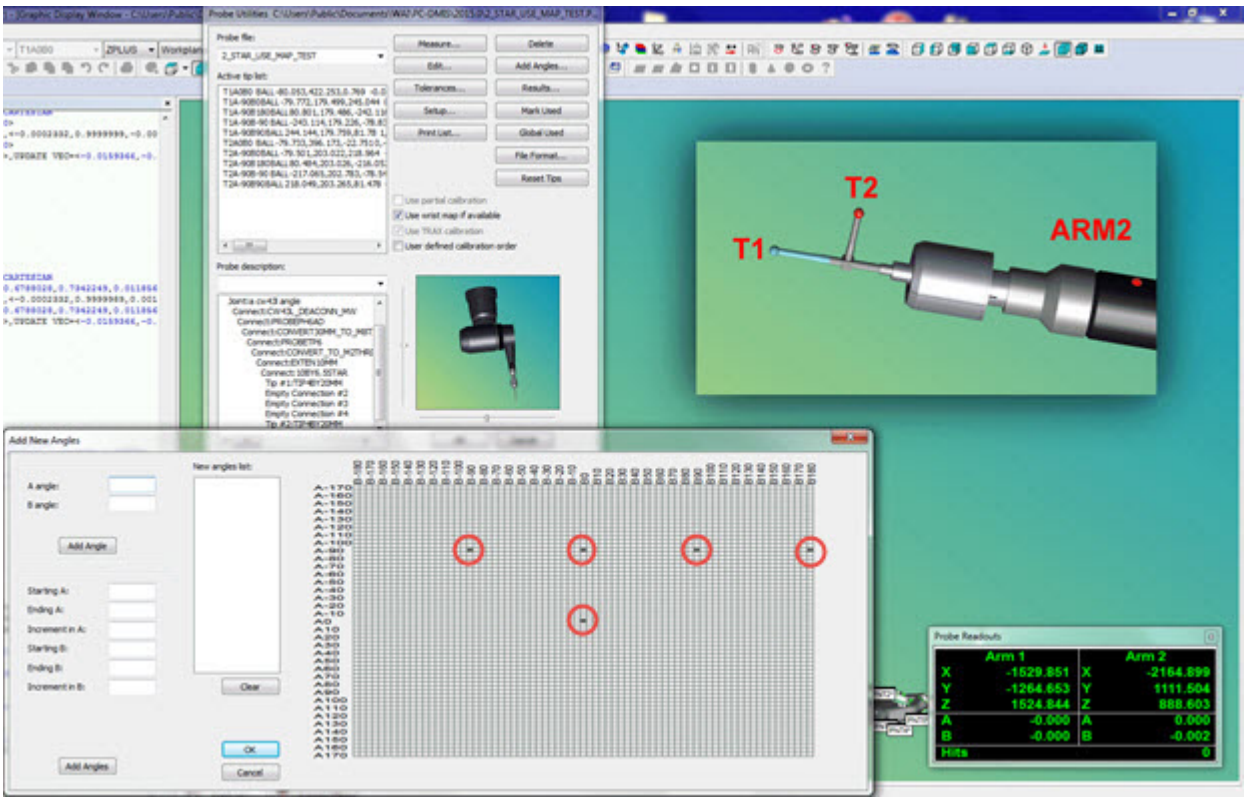


Example of an "L"-shaped star probe formed from two tips

To calibrate the star probe, you must define at least five wrist rotations (AB angles) and then measure the calibration tool with those rotations.

The wrist must already be mapped. Also, from the **Probe Utilities** dialog box (**Insert | Hardware Definition | Probe**), you must mark the **Use wrist map if available** check box. This ensures that PC-DMIS uses the wrist map and takes a sufficient number of measurements on the calibration tool to calibrate the star probe.

Define Wrist Five Rotation Angles



Example of a star probe defined with five wrist rotations (AB angles)

- On the ARM2 arm, the wrist holds a probe that has two tips: T1 (the central tip) and T2 (the side tip). These form an "L" configuration.
- When the wrist rotates to A = 0 and B = 0, T1 has a Y- direction, and T2 has Z+ direction.

You already start with one AB wrist rotation on your current tip. To get the minimum of five wrist rotations, you need to add four more wrist rotations that to later measure the calibration sphere. This provides the best distribution of points during the calibration process.

When you define the four rotations, you can unintentionally define rotation values (AB angles) that can calibrate T1, but cannot calibrate T2. To avoid this, take care to choose the most suitable values for the direction of the T2 tip.

You should choose rotation angles that allow T2 to always touch the calibration tool but won't collide with the tool's stem.

To accomplish this, the above example adds these wrist angles:

- A = -90, B = 0
- A = -90, B = 180
- A = -90, B = -90
- A = -90, B = 90

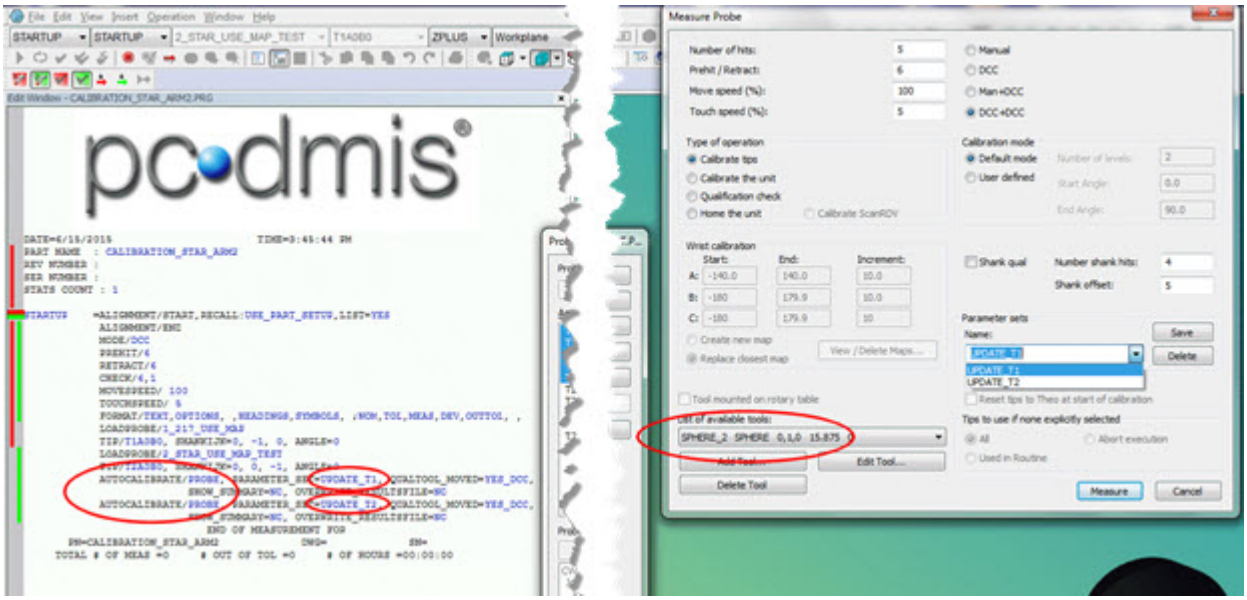
With these additional wrist angles, during calibration T2 always touches the calibration sphere, but it never collides with the calibration sphere's stem.

Once PC-DMIS detects these new tips in the **Active tip list**, it automatically creates an additional five tips. This gives you a total of ten tips: five tips with an identifier of "T1", and five tips with an identifier of "T2".

Calibrate Mapped Wrist

Once the ten wrist rotations appear in the **Active tip list**, you can calibrate them. To calibrate, you must measure the calibration sphere separately for each group of T1 and T2 tips.

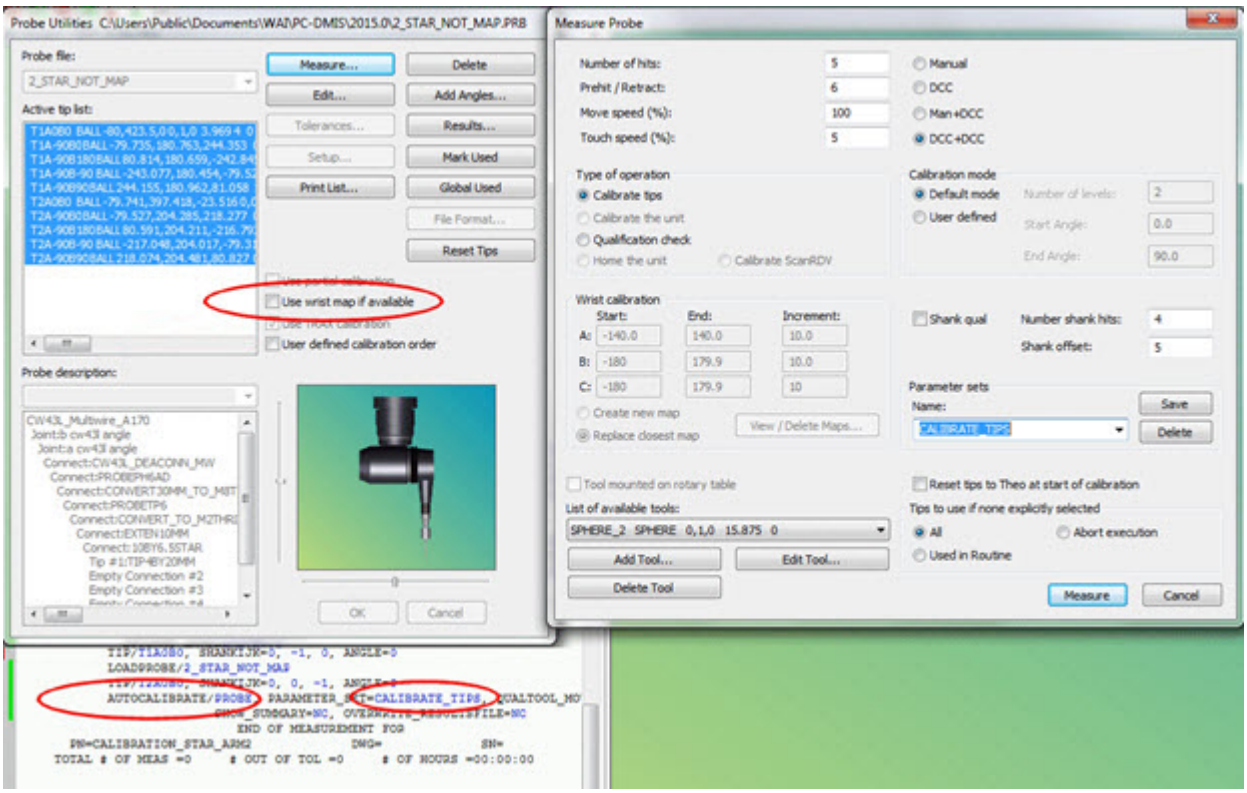
You can use the `AUTOCALIBRATE` command to invoke the parameter sets for each group. The image below shows two parameter sets (UPDATE_T1 and UPDATE_T2) that combine the respective rotations for T1 and T2:



Example of a Star Probe with parameters UPDATE_T1 and UPDATE_T2

Calibrate Non-Mapped Wrist

If the star probe was calibrated without a mapped wrist, you can calibrate the T1 and T2 tip list in the traditional method.



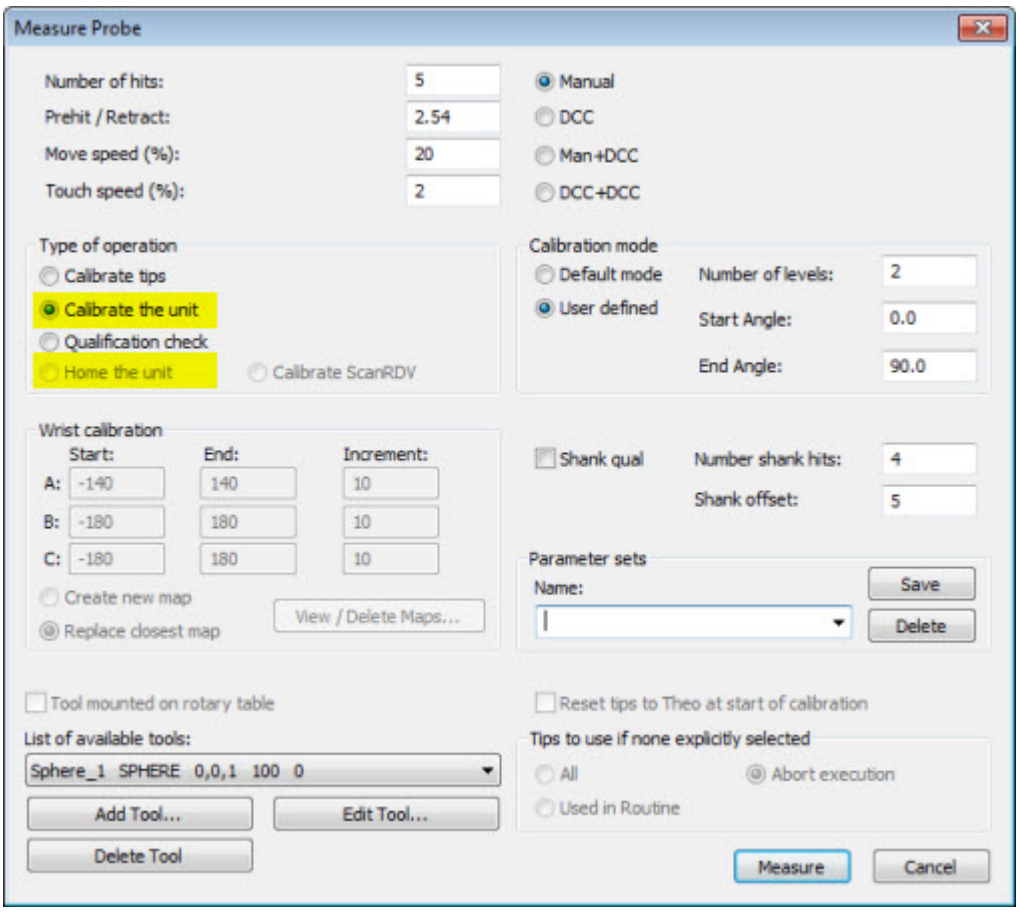
Example of a Star Probe without a wrist map

You can use a custom parameter set with the `AUTOCALIBRATE` command to measure all ten tips in the list on the calibration sphere.

The example above shows a parameter set named CALIBRATE_TIPS for this purpose.

Calibrate the Unit for Infinite Wrist Devices

When you have an indexable wrist on the CMM, PC-DMIS allows the **Calibrate the Unit** and **Home the Unit** options in the **Type of Operation** area of the **Measure Probe** dialog box.



Measure Probe dialog box showing Calibrate the unit and Home the unit option.

This wrist calibration is only done with a single stylus, not star probes. After PC-DMIS completes this calibration, you can use any angular position of the wrist in new probe files by calibrating a minimum of one probe angle. For additional information, see "Calibrate the Unit" under the "Type of Operation area" topic. See the "Calibrating Probe Tips" topic in the PC-DMIS CMM documentation for general information about calibrating probes.

The **Calibrate the Unit** option calibrates the wrist. It only works with single-arm configurations. It measures several angles on a sphere to determine the internal distances within the wrist itself. Once this information is calculated, PC-DMIS uses it to accurately predict the tip position at any A, B angle pair. This allows you to use any A, B angle in your measurement routine without calibrating each individual position.

Be sure you type your desired measurement values in the **Measure Probe** dialog box for the sphere measurement, and select the qualification tool *before* you measure with the **Calibrate the Unit** option selected. From the **Measure Probe** dialog box, you can set the number of hits, the probe prehit and retract distances, and various speeds used in the measurement process. For more information on the **Measure Probe** dialog box's options, see "Measure" in the "Defining Hardware" chapter.

Wrist Calibration

In order to calibrate the wrist, you need to measure at least three A angle positions and at least three B angle positions for a total of nine sphere measurements (each A angle position must be measured at every B position). The **Wrist calibration** area of the **Measure Probe** dialog box gives you the ability to specify the angles for calibrating both the A and the B axes. The first three options are for calibrating the A joint.

For information on using the **Wrist calibration** area to define the AB angle positions, see the "Wrist Calibration area" topic in the "PC-DMIS CMM" documentation.

When using a Renishaw PHS, every time there’s an interruption in electrical power to the PHS controller, you must either perform a wrist calibration; or in the **Measure Probe** dialog box, from the **Type of Operation** area, select **Home the Unit** and click **Measure** again.

Caution When Using SP600 Probes

For most probe types on an infinite wrist, the wrist device calibrates a zone of angles and approximates the rest. However, if you have an SP600 probe on an infinite wrist, the SP600 probe needs its own deflection matrix. You must, therefore, calibrate each AB tip angle that wasn't part of the original mapping process or suffer inaccurate results in your measurements.

Calculate Error Map

Normally, wrist devices are calibrated at relatively small increments (such as 20 degrees). When you calibrate an infinitely indexable wrist, and you select the **Calibrate the Unit** check box on the **Measure Probe** dialog box, PC-DMIS automatically creates a wrist error (wrist map) compensation file named *abcomp.dat*. It uses the file to correct for angular errors in the wrist. The error map increases the accuracy of the wrist which allows PC-DMIS to interpolate the probing offsets for probing positions not previously calibrated.

After PC-DMIS calculates the error map, it stores the results on your computer’s hard drive so that any time you use the wrist, it takes advantage of the improved angular accuracy. You should only calculate the error map periodically (once a week or less), or as necessary. When calculating the error map, PC-DMIS also performs a valid wrist and tip calibration for the currently loaded probe file.

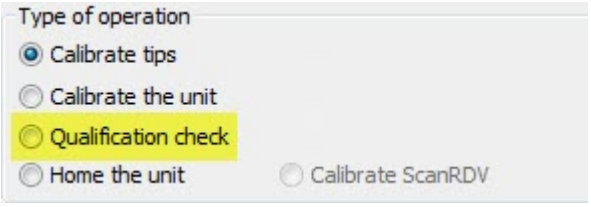
You should do a wrist calibration each time the mounting of the wrist changes. You should also refer to your hardware and vendor information for all appropriate times to map a wrist since this can change based on the construction of your device and the manufacturer's recommendations.

Once you complete the calibration of your infinitely indexable wrist device and a wrist error map file exists, you need to tell PC-DMIS to use the error map file. To do this, from the **Probe Utilities** dialog box, select the **Use Wrist Map If Available** check box. For information on this check box, see the "Use Wrist Map If Available check box" topic in the "Defining Hardware" chapter. You can then create and use any position of new probe files with a minimum number of calibrations.

To do this, create a new probe file and perform a normal tip calibration using at least one probe position on the qualification tool that maintains a link to the probe file used during the **Calibrate the Unit** process. However, you need to use more than one probe position for this calibration to provide a better "fitting" of the probe offset data to the wrist error matrix. This is especially true if you intend to utilize several wrist positions in the new probe file.

Failure to maintain a link to the probe file used during wrist mapping results in measurement errors.

Qualification Check



Type of Operation Area - Qualification Check Option

After you calibrate the unit, a qualification check is recommended, but not required. When you perform a qualification check, it provides you with information on the general accuracy of the wrist calibration and future measurements. You can also use a qualification check to check the errors of new tips added to new probe files.

Qualification Check Explained

When you perform a full calibration of your system, it establishes the relationship between the measurement system and a reference standard. For example, when you calibrate a probe tip on a reference sphere and store the probe tip's exact center.

A qualification check is a subsequent, shorter test where the same artifact (reference sphere) is measured again and the new results are compared to the stored calibration values.

- If the differences (for example, in X, Y, and Z position, or in a combined 3D distance like PR) are within the allowed limits, the probe, stylus, and machine configuration is qualified for use. The previous calibration is considered still valid.
- If the differences exceed those limits, the system is no longer qualified and a new full calibration is required.

During a full calibration of your system, PC-DMIS stores the reference center of the calibration sphere.

The qualification check measures that sphere center again to generate the deviation values in X, Y, and Z. These three deviation values define a vector (ΔX, ΔY, ΔZ). PR is the length or magnitude of that vector and is defined as:

$$PR = \sqrt{(\Delta X)^2 + (\Delta Y)^2 + (\Delta Z)^2}$$

The PR value defines how far in 3D space the current measured physical center of the reference sphere has moved from the calibrated center. It represents the overall 3D shift of the ruby tip since the last calibration. For example, the shift might be due to a bent stylus after a crash.

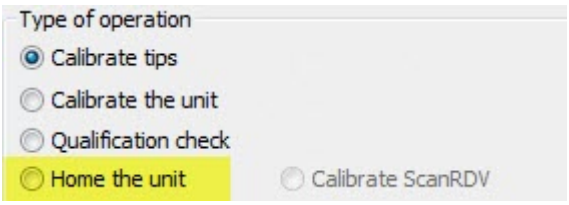
If the PR value is within the allowed limit, the probe tip is still qualified.

If the PR value exceeds the limit, your probe tip is no longer qualified and you must recalibrate it.

To perform a qualification check:

1. Access the **Probe Utilities** dialog box by selecting the **Insert | Hardware Definition | Probe** menu option.
2. On the **Probe Utilities** dialog box, from the **Active Tip** list, select the angles you wish to use for the qualification check. You should select probe angles both used and not used in the wrist calibration.
3. Click the **Measure** button to open the **Measure Probe** dialog box.
4. Provide the parameters you wish to use during the calibration check including selecting the appropriate calibration tool.
5. From the **Type of Operation** area, select the **Qualification Check** option.
6. Click the **Measure** button.
7. Follow any on-screen instructions.

Home the Unit



Type of Operation Area - Home the Unit Option

Some wrist devices, such as the Renishaw PHS, do not have predefined zero positions and use potentiometers instead of scales to position the wrist. These types of wrist devices need to have the zero redefined every time power to the probe head controller is interrupted. To redefine the wrist zero position, you may choose the **Calibrate the Unit** option (For information see the "Tip Calibration" topic discussed in this chapter) or the **Home the Unit** option.

Selecting **Home the Unit** calculates the angular error offset from the previously calculated wrist zero position by qualifying one or more probe angles on a previously calibrated sphere position. The advantage of this is you can use a minimum of one probe tip angle thereby making the process much faster than a wrist calibration.

Since PC-DMIS averages the errors of the homing procedure to provide a more accurate adjustment to the wrist error map, you use more than one probe angle to accomplish the **Home the Unit** operation.

To perform a **Home the Unit** operation, follow these steps:

1. To open the **Probe Utilities** dialog box, select the **Insert | Hardware Definition | Probe** menu option.
2. Select the same probe file that was used to calibrate the unit.
3. From the **Active Tip** list, select the angles that you wish to use for the calibration check.
4. Click the **Measure** button to open the **Measure Probe** dialog box.
5. Provide the parameters that you wish to use during the calibration check. Also select the same calibration tool used during the Calibrate the Unit operation.
6. From the **Type of Operation** area, select the **Home the Unit** option.
7. Click the **Measure** button.

After calibrating the unit and prior to homing the unit, do not move the calibration sphere. If it is moved, you must re-calibrate the unit (for information on calibrating the unit, see the "Tip Calibration" topic in this chapter).

Using the Wrist in a Measurement Routine

On machines that support it, PC-DMIS automatically senses when the wrist has been rotated with the jog box. The tip offsets are dynamically updated based on the current AB angles. That is, the XYZ readout displays the current tip position as it is being rotated. There are four ways (discussed below) to add a new AB tip combination into a measurement routine.

Once you have added a new AB tip combination into your measurement routine by using one of the options below, PC-DMIS displays the active tip as programmed in the measurement routine in **Probe Tips** list on the **Settings** toolbar (**View | Toolbars | Settings**). The selected item is the same as the `TIP/` command above where the cursor is in the Edit window.

To move the wrist to this AB angle combination, from the **Settings** toolbar, pull down and choose the probe from the **Probe Tips** list. PC-DMIS asks if you want to rotate the probe. A **Yes** response rotates the wrist to the desired position. This is useful when you want to go back and insert measurements and moves into the measurement routine.

Option 1

In the **Probe Utilities** dialog box (**Insert | Hardware Definition | Probe**), select the **Add Angles** option. You can use this option to key in new AB angle pairs to the probe file. If the tip is already calibrated, then the new AB combinations are also calibrated and made ready to use. Once you leave the **Probe Utilities** dialog box, you can use these new AB combinations by selecting them from the **Probe Tips** list located on the **Settings** toolbar (**View | Toolbars | Settings**).

Option 2

Manually jog the wrist to the desired AB angles using the jog box. When you reach the desired position, press the **Store Move** button on the jog box, or take a manual probing. The current AB angles are read automatically. If the A or B angles have changed by more than the PH9 **Wrist Warning Delta** value available on the **Part/Machine** tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**) then PC-DMIS automatically adds the current AB angles to the **Probe Tips** list and inserts a `TIP/` command in the measurement routine. The new `TIP/` command is added to the measurement routine before the stored move or manual probing. When the measurement routine is then executed, PC-DMIS first changes the tip before moving to the programmed location.

For information on the **Wrist Warning Delta** option, see the "Automatically Adjust Probe Head Wrist" topic in the "Setting your Preferences" chapter.

Option 3

Type a `TIP/` command in the Edit window. Once you finish editing the vector, PC-DMIS calculates the best AB combinations that put the tip shank parallel to that vector.

The **Auto Wrist** icon in the **Measurement Properties** area in the **Auto Feature** dialog box is available if your measurement routine has a wrist probe. You can use this icon to enable PC-DMIS to determine the best wrist position to use when an Auto feature is measured. For more information, see "Auto Wrist".

Calibrating and Using a CJoint Device

PC-DMIS provides complete support for calibrating and using a three continuous axes wrist obtained by mounting a CJoint device on the DEA CW43L wrist.

If a CJOINT is installed on your DEA CW43L wrist, PC-DMIS adds A, B, and C axes to the X, Y, and Z values that are normally displayed in the Probe Readouts window.

The following sub topics are available to help you calibrate your CJoint device.

- Tip Calibration Information
- CJoint Calibration Procedure for Infinite Third Axis Wrist Devices
- Calculate Error Map for CJoint

CJoint Tip Calibration Information

The purpose of tip calibration is to calculate the distance from the second joint's center point (the A joint’s center) to the star probe’s tip center. You may want to measure more than one AB combination so that PC-DMIS can average the star tip offsets computed, resulting in better accuracy in reaching the sphere when the CJoint calibration cycle is performed.

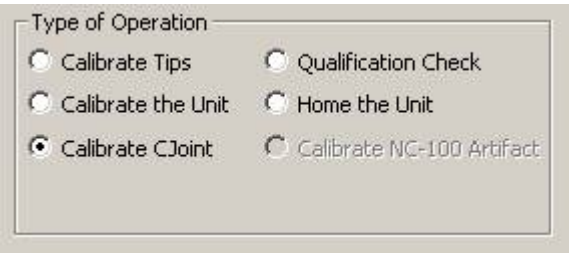
Before proceeding, verify the following:

- You should already have calibrated the AB wrist device; and the files named *acomp(s).dat* and *wrist(m)(s).dat* should exist on your computer’s hard drive.
- You need to mount a star probe on the CJoint device with the tip pointing in the X+ direction. PC-DMIS uses this tip to calibrate the CJoint. Tip calibration in this case does need to be done.

You can also obtain the AB calibration map with the CJoint mounted on the wrist. This increases the accuracy of angle position computations for any A, B, and C angle combinations.

CJoint Calibration Procedure for Infinite Third Axis Wrist Devices

The **Calibrate CJoint** option allows you to calibrate the third axis of the wrist. Once this information is calculated, PC-DMIS uses it, together with the AB calibration data, to predict the tip position at any A, B, and C angle combinations for a probe that needs to be installed on a CJoint device.



Type of Operation Area - Calibrate CJoint Option

To Calibrate using the CJoint Option

1. Ensure that you have already performed the preliminary steps discussed in the "CJoint Tip Calibration Information" topic of this chapter.
2. Select **Insert | Hardware Definition | Probe** to display the **Probe Utilities** dialog box.
3. Click the **Measure** button to open the **Measure Probe** dialog box.
4. From the **Type of Operation** area, select the **Calibrate CJoint** option. Selecting this item enables the **Wrist Calibration** area if the appropriate wrist entries from the **Option** section in the PC-DMIS Settings Editor are set to 1 (either `DEAWrist` or `RENISHAWWrist`).
5. Ensure that you have a star probe configuration connected, with a tip pointing in the X+ direction.
6. From the **Available Tools** list, select a sphere qualification tool.
7. Type the desired measurement values for the sphere qualification.
8. Set the number of hits, the probe pre-hit and retract distances, and various speeds.
9. Fill out the **Wrist Calibration** area. In order to calibrate the C joint, you need to measure at least three C angle positions. This gives you the ability to specify the angles for calibrating the A, B, and C axes. The **Start**, **Increment**, and **Angle** boxes for the **C** row are for calibrating the C joint.
    - **C Angle Start** defines the starting C angle used for the calibration of your wrist's C joint. The default value is -180.
    - **C Angle End** defines the ending C angle used for the calibration of your C joint. The default value is 180.
    - **C Angle Increment** defines the angle increment between the starting and ending C angles. Angles are calibrated for your C joint device for the starting, ending, and additional angles based on the increment value. For example, an increment angle of 10 degrees adds angles for calibration every 10 degrees between the starting and ending angle. The default value is 10.

Be sure that the wrist's **A Angle Start** and **B Angle Start** are set to 0 when you calibrate a C joint device.

10. When you are ready, click the **Measure** button to start the calibration process.

Calculate Error Map for CJoint

Normally, wrist devices are calibrated at relatively small angle increments (such as 20 degrees). When you calibrate a continuous third axis of a wrist, with the **Calibrate CJoint** option selected, PC-DMIS automatically creates a wrist error compensation file named *ccomp(s).dat* that it uses, together with *abcomp(s).dat*, to correct for angular errors in the three axes wrist.

After calculating the error map, the results are stored on your computer’s hard drive so that any time you use the wrist, it will take advantage of the improved angular accuracy.

Recalculating the Error Map

Generally, you should only need to calculate the error map periodically (once a week or less). However, you should perform a wrist calibration each time the mounting of the wrist changes and at other times recommended by hardware and vendor information. This varies based on device construction and manufacturer recommendations.

Working in Operator Mode

Working in Operator Mode: Introduction

The Operator Mode limits the options that will be available when operating PC-DMIS. Once the restrictions are in place, the operator can only open and execute the measurement routine.

To start PC-DMIS in Operator Mode, from the **Start** menu, select **All Programs | <Version> | <Version> Operator** , where <version> represents your PC-DMIS version.

When PC-DMIS launches in Operator Mode, only the options necessary to run the measurement routine are available.

The main topics in this chapter include:

- File Open Options
- Operator Mode Menu Options
- Using the Marked Sets Window in Operator Mode

File Open Options

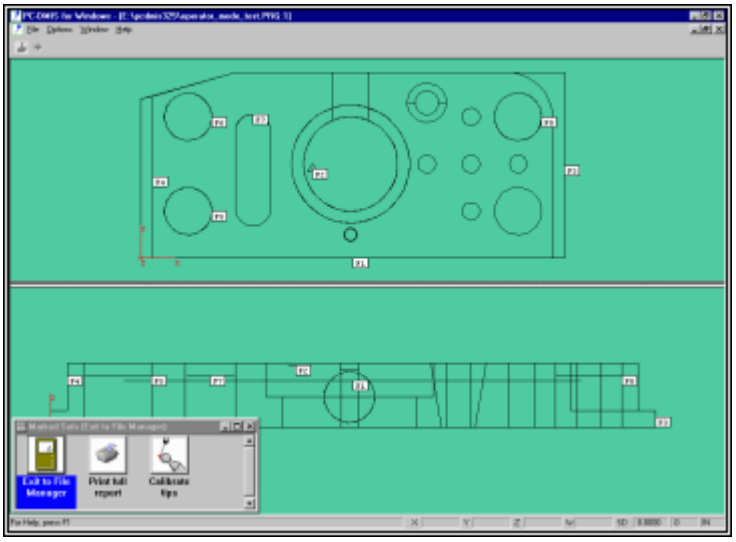
The **Open** dialog box (**File | Open**) is a standard Windows file open dialog. You can activate a measurement routine in Operator Mode by double-clicking the measurement routine file name or by selecting the measurement routine file name and clicking the **Open** button.

The following options have been *disabled* from this dialog box in Operator Mode:

- **Importing to PC-DMIS**, accessible when *not* in Operator Mode by right mouse clicking on a measurement routine and selecting Import to PC-DMIS from the pop-up list.
- **Exporting from PC-DMIS**, accessible when *not* in Operator Mode by right mouse clicking on a measurement routine and selecting Export from PC-DMIS from the pop-up list.
- **Editing the Part Name**, Serial Number, or Revision Number on the measurement routine's PC-DMIS property page, accessible when *not* in Operator Mode by right mouse clicking on a measurement routine and selecting Properties from the pop-up list.

Operator Mode Menu Options

Once a measurement routine has been activated, the main PC-DMIS screen is displayed with the following menu options.



Graphic Display window in Operator Mode

File

The **File** menu allows you to open an existing measurement routine, close the current measurement routine, export the current measurement routine, or exit the software.

Open

The **File | Open** menu option allows you to switch between measurement routines anytime by invoking the **Open** dialog box and allowing you to select a different measurement routine. If the measurement routine you select is different from the currently executing part, PC-DMIS automatically saves and closes the active measurement routine before loading the newly selected measurement routine. If however, you try to select and initiate the active measurement routine a second time from the **Open** dialog box, PC-DMIS offers two choices:

- Discard all changes made to the active measurement routine since the last Save operation and reload the selected measurement routine without the changes.
- Cancel the entire operation and return to the **Open** dialog box.

You can only have one measurement routine open at a given time in Operator Mode.

Close

Selecting **File | Close** closes the measurement routine and saves the measurement values of any executed marked sets.

Quit

Selecting **File | Quit** closes the current measurement routine *without saving* any recently taken measurement values from executed marked sets. Only pre-existing data will be retrievable.

Export

To export your current measurement routine, choose the **File | Export** menu option. This will display the **Export Data** dialog box. Select the data type to export as, and a directory location, and then click **OK**. For more information on exporting, see "Exporting CAD Data" in the "Using Advanced File Options" chapter.

Exit

To quit PC-DMIS, all other routines, and log off the computer, choose the **File | Exit** menu option. PC-DMIS automatically saves the current measurement routine before exiting.

Edit

The **Edit** menu option allows you to access the **Probe Readouts Setup** dialog box. You can use this dialog box to set up how information is displayed. See the "Setting Up the Probe Readouts Window" topic in the "Setting your Preferences" chapter for information.

View

The **View** menu allows you to show or hide the following windows while in Operator Mode:

Graphic Display window – Selecting this option shows and hides the Graphic Display window. See "The Graphic Display window" in the "Navigating the User Interface" chapter.

Preview Window – Selecting this option shows and hides the Preview window. See "Using the Preview Window" in the "Using Other Windows, Editors, and Tools" chapter.

Probe Readouts – Selecting this option shows and hides the Probe Readouts window. See "Using the Preview Window" in the "Using Other Windows, Editors, and Tools" chapter.

Marked Sets Window – Selecting this option shows and hides the Marked Sets window. See "Using the Marked Sets window" in the "Using Other Windows, Editors, and Tools" chapter. See "Using the Marked Sets Window in Operator Mode".

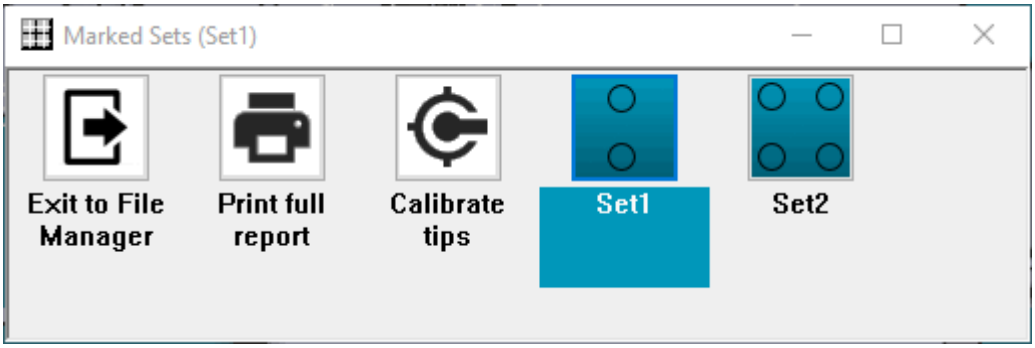
Window

The **Window** menu provides operations to manage multiple open measurement routines and windows. See the "Navigating and Displaying Multiple Windows" chapter.

Help

The **Help** menu provides all the menu items as in PC-DMIS's standard mode of operation.

Using the Marked Sets Window in Operator Mode



Marked Sets Window

As soon as you open a measurement routine, the Marked Sets window automatically launches. The following options are available to the Marked Sets window in Operator mode:

- Exit to File Manager
- Print full Report
- Calibrate Tips
- Any Predefined Marked Sets

Exit to File Manager

The **Exit to File Manager** button displays the **Open** dialog box. From the dialog box, select a measurement routine to open.

Print Full Report

The **Print full report** icon prints the complete report to the output source that was setup in the "learning" portion of the measurement routine.

If the output is sent to a file, it is saved in an RTF format. If this is the first inspection report to be saved since powering up the system, PC-DMIS requires you to enter a value in the **New File #** box. If **Auto** is checked, after the initial file is saved PC-DMIS saves all future files incrementally from the initial number that was entered (as long as the system has not been powered down). The displayed number can be changed at any time simply by entering another value.

To print the current Edit report, choose the **Print Full Report** button (or press F4). The Edit window output is sent to the printer and/or a pre-selected file.

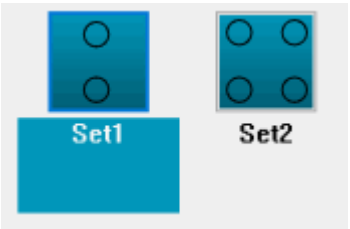
Calibrate Tips

The **Calibrate Tips** button calibrates all tip angles for all probes in the current measurement routine. This process informs PC-DMIS of the location and diameter of each probe tip.

PC-DMIS does not track the calibration of probes. Be sure to verify that a probe is re-calibrated if it is changed in any way.

Predefined Marked Sets

Predefined marked sets may appear in your Marked Sets window. These are features that have been programmed and marked for execution by the measurement routine programmer and are combined into a set for the operator to execute.



Example of predefined marked sets.

To execute and measure features in a marked set, simply click on the set from the Marked Sets window and follow any instructions provided by PC-DMIS.

Using Shortcut Keys and Shortcut Menus

Using Shortcut Keys and Shortcut Menus: Introduction

This appendix covers shortcuts to many of the menu options, dialog boxes, and commands that you can use in PC-DMIS. Using shortcuts can help speed up your programming time and increase productivity and efficiency.

The main topics covered in this appendix are:

- Shortcut Keys Reference
- Shortcut Menus Reference

Shortcut Keys Reference

This table provides a reference of the available shortcut keys in the English language. If the description of a shortcut key is preceded by *italicized text*, the item in italicized text must be the active window or focused item for the shortcut key to function properly. For specific information regarding the function of each option, see the appropriate section of the documentation.

Non-English Shortcut Keys: Since keyboards differ from language to language, some shortcut keys may not be the same for non-English builds of PC-DMIS. To see what shortcuts are associated with a non-English build of PC-DMIS, on the **Customize** dialog box, consult the **Keyboard** tab. To access the **Customize** dialog box, right-click on the toolbar area and select **Customize**. For information on using the **Keyboard** tab, see "Customizing Shortcut Keys" in the "Navigating the User Interface" chapter.

Key	Description	Key	Description	Key	Description
F1	Accesses the online Help.	Ctrl + A	*Edit window:* Selects all text. Form and Report Editors: Selects all the objects.	Ctrl + F1	Places PC-DMIS into Translate Mode.
F2	*Edit window:* Opens the **Expression Builder** dialog box if the cursor is on a line that allows expressions.	Ctrl + C	*Edit window:* Copies the selected text. Form and Report Editors: Copies the selected objects.	Ctrl + F2	*Graphic Display window:* Places PC-DMIS into 2D Rotate Mode. *Edit window:* If in Command Mode, this shortcut inserts or removes a bookmark on the current line.
F3	*Edit window:* Marks or unmarks the command for execution. If your cursor resides on an External Object, F3 switches between print and execute modes.	Ctrl + D	Deletes the current feature.	Ctrl + F3	Places PC-DMIS into 3D Rotate Mode and opens the **Rotate** dialog box.
F4	*Edit window:* Prints the contents of the Edit window.	Ctrl + E	Executes the selected feature or command (for those commands that support this shortcut).	Ctrl + F4	Places PC-DMIS into Program Mode.
F5	Accesses the **Setup Options** dialog box.	Ctrl + F	Opens the **Auto Features** dialog box.	Ctrl + F5	Places PC-DMIS into Text Box Mode.

Key	Description	Key	Description	Key	Description
F6	Accesses the **Font Setup** dialog box.	Ctrl + G	Inserts a `READPOINT /` command into the Edit window.	Ctrl + Tab	Switches between certain open windows to make the next window active. For example, the Basic Script Editor window, Graphic Display window, and the Report Window. The windows must be open for this to work.
F7	*Edit window:* Within a selected toggle field, cycles forward to the next alphabetical entry.	Ctrl + J	*Edit window:* Jumps to a referenced command.	Ctrl + Shift	Hides the selected graphical analysis arrow.
F8	*Edit window:* Within a selected toggle field, cycles backwards to the last alphabetical entry.	Ctrl + K	Saves the selected dimension in the Edit report.	Ctrl + End	*Edit window:* Moves the cursor to the end of the current measurement routine.

Key	Description	Key	Description	Key	Description
F9	*Edit window:* Opens the dialog box associated with the command at the cursor's position. (For the `MODE` command in the Edit window, this key switches between the DCC Mode and Manual Mode.)	Ctrl + L	Executes the currently selected block of commands.	Ctrl + Home	*Edit window:* Moves the cursor to the beginning of the current measurement routine.
F10	Opens the **Parameter Settings** dialog box.	Ctrl + M	Inserts a `MOVEPOINT` command into the Edit window.	Ctrl + Alt + A	Opens the **Alignment** dialog box.
F12	Opens the **Fixturing Setup** dialog box.	Ctrl + N	Creates a new measurement routine.	Ctrl + Alt + L	Creates an automatic alignment using the QuickAlign functionality.
Shift + Right-click	Opens the **Scale Drawing** dialog box.	Ctrl + O	Opens a measurement routine.	Ctrl + Alt + P	Opens the **Probe Utilities** dialog box.

Key	Description	Key	Description	Key	Description
Shift + Tab	*Edit window:* Moves the cursor backwards to the previous user-editable field.	Ctrl + P	Prints the Graphic Display window.	Ctrl + Click	In Text Box Mode, performing this action on a feature or label ID in the Graphic Display window moves your cursor to that feature in the Edit window. Performing this action with the **Analysis** dialog box open selects any associated dimensions.
Shift + Arrow	Highlights all text as the cursor moves.	Ctrl + Q	*Edit window:* Executes the current measurement routine.	Ctrl + Shift + H	*Edit window:* Highlights the selected feature in the Graphic Display window.
Shift + F5	*Edit window:* Changes a dimension's hit display between the Cartesian and polar coordinates. A 'P' character indicates polar display mode.	Ctrl + R	Opens the **Rotate** dialog box.	Ctrl + Shift + U	*Edit window:* Clears the highlight of the selected feature from the Graphic Display window.
Shift + F6	*Edit window:* If in Command Mode, opens the **Color Editor** dialog box.	Ctrl + S	Saves the current measurement routine.	Up Arrow	*Edit window:* Moves the cursor to next available element above the current position.

Key	Description	Key	Description	Key	Description
Shift + F10	*Edit window:* Accesses the **Jump To** dialog box.	Ctrl + T	*Edit window:* Assigns the current command (or selected commands) to Arm1, Arm2, or both arms.	Down Arrow	*Edit window:* Moves the cursor to next available element below the current position.
END	Ends the measurement of a feature. *Edit window:* Moves the cursor to the end of the present line.	Ctrl + U	*Edit window:* Executes the measurement routine from the cursor's location.	Right Arrow	*Edit window:* Moves the cursor to next available element to the right of the current position. In Summary Mode, this shortcut expands a collapsed list.
Home	*Edit window:* Moves the cursor to the beginning of the present line.	Ctrl + V	*Edit window:* Pastes the Clipboard's contents. Form and Report Editors: Pastes the copied objects.	Left Arrow	*Edit window:* Moves the cursor to next available element to the left of the current position. In Summary Mode, this shortcut collapses an expanded list.
Tab	*Edit window:* Moves the cursor forward to the next user-editable field.	Ctrl + X	*Edit window:* Cuts the selected text. Form and Report Editors: Cuts the selected objects.	Alt + "-" (minus)	Pressing Alt and then the minus key deletes the last hit in the hit buffer.

Key	Description	Key	Description	Key	Description
Esc	Aborts any process (other than data entry) if pressed prior to pressing the Enter key.	Ctrl + Y	*Edit window:* Resumes a previously cancelled execution.	Alt + C	Displays the **ClearanceCube** dialog box.
Delete	*Edit window:* See 'Backspace'.	Ctrl + Z	Activates the Scale to Fit function.	Alt + H	Accesses the Help menu.
Backspace	*Edit window:* Deletes any highlighted characters. If nothing is highlighted, then functions as in a normal editor. If the item cannot be deleted, an error message is displayed.	Ctrl + Enter or Return	*Edit window:* In Summary Mode, this keyboard shortcut allows you to select a command to add to the Edit window.	Alt + J	*Edit window:* Jumps back from a referenced command.
Enter or Return	*Edit window:* Creates a new blank line that is automatically deleted if not completed before the cursor is moved from the line. Selects a command.	Ctrl + Click	*Graphic Display window:* Multi-selects CAD objects (like surfaces). If a CAD object is already selected, this shortcut deselects that object.	Alt + P	*Graphic Display window:* Draws the current path of the probe for the entire measurement routine.
Shift + F4	Opens the Machine Interface Setup.	Ctrl + Left-mouse drag	Makes the dialog box or toolbar drag without docking into the interface when you release the mouse.	Alt + Shift + P	*Graphic Display window:* Draws the current path of the probe for the features immediately before and after the cursor position.

Key	Description	Key	Description	Key	Description
Shift + Right-click	*Report Window Label Object:* Displays the **Report** dialog box.	Ctrl + Right-mouse drag (Also click and drag the center wheel button)	*Graphic Display window:* Rotates the CAD model in 3D.	Alt + F3	*Edit window:* Opens the **Find** dialog box.
Shift + Click	*Graphic Display window:* Creates an Auto feature based on the highlighted CAD element.	Ctrl + Shift + F	*Edit window*: This works only in Command Mode. This option toggles the display of selected feature commands and their IDs in the Graphic Display window. You can also use this on a GROUP command to toggle the display of features within the group.	Alt + Backspace	*Edit window:* Undoes the last action taken in the Edit window.

Key	Description	Key	Description	Key	Description
Ctrl + F6 or Ctrl + Shift + F6	Switches between certain open windows to make the next window active. For example, the Graphic Display window and the Report Window. The windows must be open for this to work.	Alt + Click	*Graphic Display window:* With the **CAD Assembly** dialog box open, if you press and hold the Alt key and then left-click a CAD object in the Graphic Display window, this shortcut highlights its corresponding component in the tree view.	Shift + Backspace	*Edit window:* Redoes the last undone action in the Edit window.
				Alt + Right-mouse drag	*Graphic Display window:* Rotates the CAD model in 2D.
				Alt + Click	*Graphic Display window:* Toggles the marked status of the underlying feature in the Edit window.

Command Mode Shortcut Keys

Summary Mode Shortcut Keys

Shortcut Menus Reference

Shortcut menus are contextual menus that appear when you right-click on certain areas of the user interface. This section explains how to access the various shortcut menus and what the various menu options do.

Shortcut Menus in Standard Windows Dialog Boxes

Beyond the standard commands that exist in the Standard Windows dialog boxes (such as the **Open**, **Save**, and **Print** dialog boxes), PC-DMIS, in certain circumstances, adds additional functionality to shortcut menus. Many of these are explained in the "Using Basic File Options" and "Using Advanced File Options" chapters.

When opening, saving, or using other file operations, right-click on the measurement routine file name listed in the dialog box to bring up these shortcut menu options.

PC-DMIS Import
Imports data from an input file into the selected measurement routine. See "Importing CAD Data or Feature Data" in the "Using Advanced File Options" chapter.

PC-DMIS Export
Exports data to an output file from the selected measurement routine. See "Exporting CAD Data or Feature Data" in the "Using Advanced File Options" chapter.

Open
Opens a measurement routine. See "Opening Existing Measurement Routine" in the "Using Basic File Options" chapter.

Cut
Cuts a measurement routine and moves it to the Clipboard; this is used with Windows **Paste** command to place the cut file into another folder.

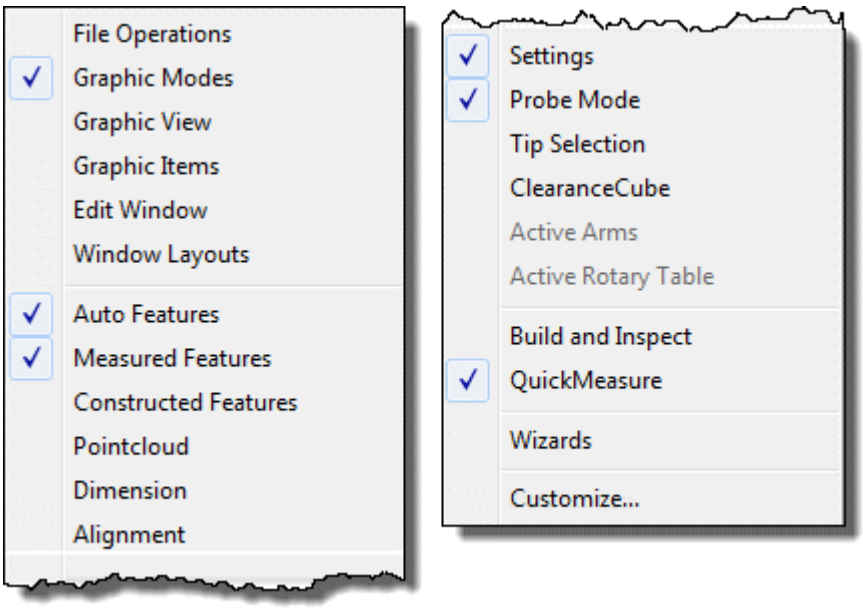
Copy
Copies a measurement routine to the Clipboard; this is used with the **Paste** command to place the copied file into another folder. See "Performing File Operations" in the "Using Basic File Options" chapter.

Rename
Renames a measurement routine.

Delete
Deletes a measurement routine. See "Performing File Operations" in the "Using Basic File Options" chapter.

Shortcut Menus on the Toolbar Area

When you right-click on the **Toolbar** area, PC-DMIS displays a list of the toolbars and other options that you can instantly access. These options include:



The following options are available:

File Operations
Adds or removes the File Operations toolbar to or from the toolbar area.

Graphic Modes
Adds or removes the Graphic Modes toolbar to or from the toolbar area.

Edit Window
Adds or removes the Edit Window toolbar to or from the toolbar area.

Window Layouts
Adds or removes the Window Layouts toolbar to or from the toolbar area.

Auto Features
Adds or removes the Auto Features toolbar to or from the toolbar area.

Measured Features
Adds or removes the Measured Features toolbar to or from the toolbar area.

Constructed Features
Adds or removes the Constructed Features toolbar to or from the toolbar area.

Pointcloud
Adds or removes the Pointcloud toolbar to or from the toolbar area.

Dimension
Adds or removes the Dimension toolbar to or from the toolbar area.

Alignment
Adds or removes the Alignment toolbar to or from the toolbar area.

Settings
Adds or removes the **Settings** toolbar to or from the toolbar area.

Probe Mode
Adds or removes the **Probe Mode** toolbar to or from the toolbar area.

Tip Selection
Adds or removes the **Select Tip** toolbar to or from the toolbar area.

ClearanceCube
Adds or removes the **ClearanceCube** toolbar to or from the toolbar area.

Active Arms
Adds or removes the **Active Arms** toolbar to or from the toolbar area.

Active Rotary Table
Adds or removes the **Active Rotary Table** toolbar to or from the toolbar area.

Build and Inspect
Adds or removes the **Build and Inspect** toolbar to or from the toolbar area.

QuickMeasure
Adds or removes the specific **QuickMeasure** toolbar (CMM QuickMeasure Toolbar, Portable QuickMeasure Toolbar, Vision QuickMeasure Toolbar, QuickCloud Toolbar) to or from the toolbar area.

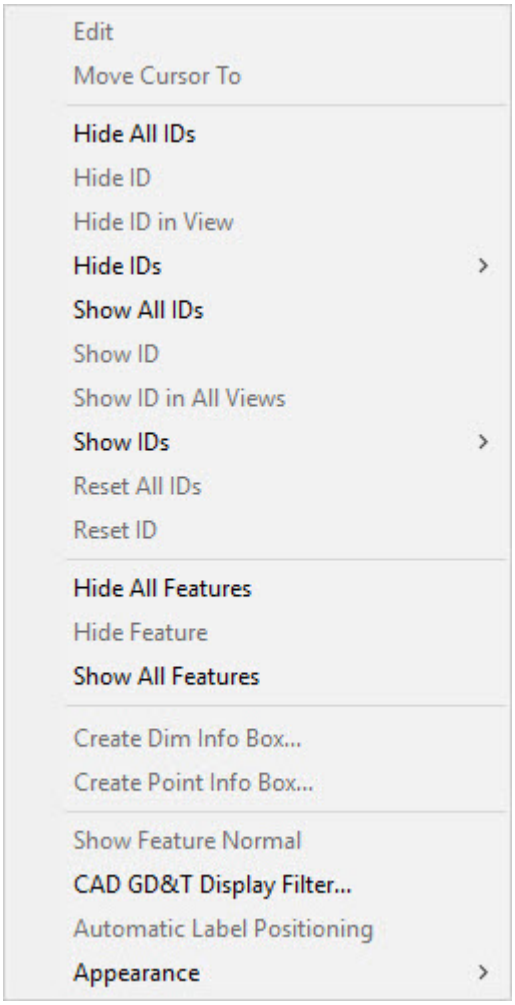
Wizards
Adds or removes the **Wizards** toolbar to or from the toolbar area.

Customize
Customizes the toolbars and the menus to meet specific needs. See "Customizing the User Interface" in the "Navigating the User Interface" chapter.

For information on these toolbars, see the "Using Toolbars" chapter.

Shortcut Menus in the Graphic Display Window

The following shortcut menu is available inside the Graphic Display window (**View | Graphic Display Window**) when you right-click on empty space.



Option	Discussed in Topic
Edit	Feature Shortcut Menu
Move Cursor To	Feature Shortcut Menu
Hide All IDs	Feature Shortcut Menu
Hide ID	Feature Shortcut Menu

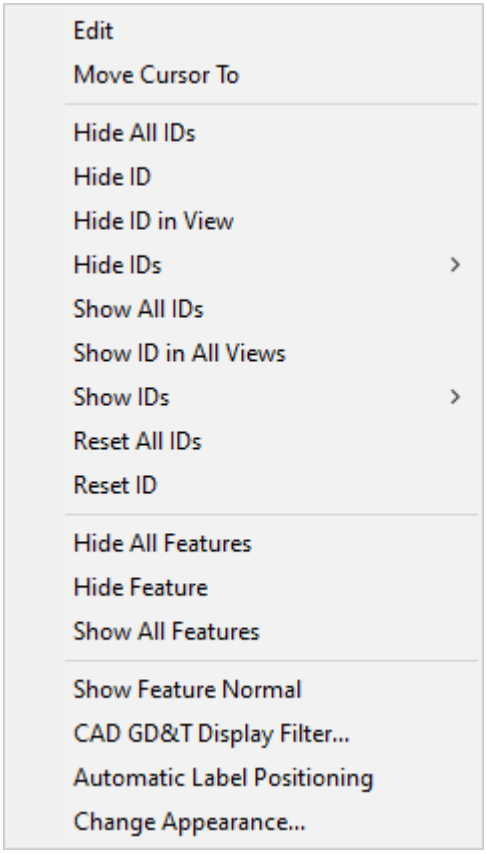
CAD GD&T Display Filter	Feature Shortcut Menu
Automatic Label Positioning	Feature Shortcut Menu
Appearance	Feature Shortcut Menu

Additional menu options become available only if you right-click on specific areas. For more information, see the topics below.

Feature Shortcut Menu

To access this shortcut menu, from the Graphic Display window, right-click on a feature ID label, Diminfo box, Pointinfo box, or CAD GD&T callout. You can also see many of these options if you right-click anywhere in the Graphic Display window.



Right-clicking on a GD&T callout displays many of these same menu items; however, only the "show" and "hide" menu items function in this context.

The following options are available:

Edit
This menu option opens the appropriate dialog box for the underlying command in the Edit window so that you can use the dialog box to edit that command.

For Dimension Info boxes with legacy graphics labels, this opens the **Edit Dimension Info** dialog box as usual. For information, see "Inserting Dimension Info Boxes" in the "Inserting Report Commands" chapter.

For Dimension Info boxes with new graphics labels, this opens the **Properties** dialog box for that label so that you can see the pathway to the underlying template in the **Template Path** field.

You can change what graphics labels the software uses with the **Use legacy graphics labels** check box in the **Feature Appearance** dialog box. For more information on this dialog box, see the "Editing Feature Appearance" topic in the "Editing the CAD Display" chapter.

Move Cursor To
Select this menu option to move the Edit window's cursor to this feature's command line in the Edit window. This *only* affects the location of the cursor in the Edit window; the location of the probe in the Graphic Display window remains unchanged.

Hide All IDs
Hides all Feature Labels, Dimension Infos, and Point Infos for all features.

Hide ID
This menu option hides a single ID label in the Graphic Display window. A hidden label still exists; it's merely hidden from view.

An ID Label in this topic refers to any number of identification labels. They could be any of the following:

- Feature ID
- Dimension info text box
- Point info text box
- Feature Control Frame
- CAD GD&T callout

Hide ID in View
This hides the selected feature's ID label only in the current view. In other views, it remains visible.

An ID Label in this topic refers to any number of identification labels. They could be any of the following:

- Feature ID
- Dimension info text box
- Point info text box
- Feature Control Frame
- CAD GD&T callout

Hide IDs
This submenu lets you hide the different feature ID labels. ID labels that you hide still exist and are merely hidden from view.

You can choose to show or hide these types of ID labels:

- **Feature Labels** - Hides all Feature Labels for all features.
- **Feature Labels visible in view** - Hides all Feature Labels for all features visible in the current view.
- **Dimension Infos** - Hides all Dimension Infos for all features.
- **Point Infos** - Hides all Point Infos for all features.

Show All IDs
Shows all Feature Labels, Dimension Infos, and Point Infos for all features.

Show ID in All Views
This shows the selected feature's ID label in all views.

An ID Label in this topic refers to any number of identification labels. They could be any of the following:

- Feature ID
- Dimension info text box
- Point info text box
- Feature Control Frame

Show IDs
This submenu lets you show the different feature ID labels. For information, see the Hide IDs documentation above. The show menu items do the opposite of those "hide" menu items.

Reset All IDs
This option moves all ID labels back to their original locations next to their respective features.

Reset ID
This option moves a single ID label back to its original location next to the feature.

Hide All Features
This option hides all features on a part and removes them from the Graphic Display window. The features still exist and are merely hidden from view.

Hide Feature
This option hides a single feature and removes it from the Graphic Display window. The feature still exists and is merely hidden from view.

Show All Features
This option displays all previously hidden features in the Graphic Display window.

- If you select **Hide All Features**, **Hide Feature**, and **Show All Features**, the icon also turns on or off in the Summary Mode Edit window.
- If you select **Hide ID** and **Show ID**, the icon turns on or off only for the Point Infos, Dimension Infos, Datums, Pointclouds, Mesh, and Basic scan commands but not for the features.

Show Feature Normal
For information, see "Show Feature Normal Option" in the "Editing the CAD Display" chapter.

CAD GD&T Display Filter
This menu option displays a dialog box allowing you to filter what CAD GD&T callouts are displayed. It appears in the shortcut menu if your CAD model contains embedded CAD GD&T information. See "Working with CAD GD&T Callouts" in the "Editing the CAD Display" chapter.

Automatic Label Positioning
This menu option allows you to perform a one-time automatic positioning of feature ID labels around the edges of the current view.

Change Appearance
This menu option opens the **Change Label Options** dialog box. With this dialog box, you can change the appearance of the different labels in the Graphic Display window. There are three different label types: feature ID labels, Dimension Info boxes, and Point Info boxes.

The dialog box contains these items:

Background Color
This box opens a **Color** dialog box so that you can change the label's background color.

Background Transparency
This slider or the box to its right adjusts the transparency level of the label's background color. The value can be from 0 (opaque) to 100 (completely transparent).

Line Color
This box opens a **Color** dialog box so that you can change the label's border color.

Show Shadow
This check box displays a small shadow under the label.

You can choose to apply your changes to all label types or to just the current label type.

To make your changes the default settings, click the **Default** button.

Feature Shortcut Menu Additions in Text Box Mode

In Text Box Mode ( ), PC-DMIS adds these additional options to the standard feature shortcut menu:

Show ID
Shows the label of the selected feature. (This is only available if you right-click near a feature with its label hidden.)

Create Dim Info Box
This option creates a Dimension Information text box from the highlighted feature. An **Edit Dim Info** dialog box appears and shows the available dimensions from which you can create the Dimension info text box.

If no dimensions are associated with the feature, PC-DMIS automatically creates a default Location dimension for the feature (see "Dimensioning Location" in the "Using Legacy Dimensions" chapter). For information on how to use the **Edit Dimension Info** dialog box, see "Inserting Dimension Info Boxes" in the "Inserting Report Commands" chapter.

Create Point Info Box
This menu option creates a Point Info text box from the highlighted feature. An **Edit Point Info** dialog box appears and shows the feature (and any available dimensions) from which you can create the Point Info text box. For information on how to use the **Edit Point Info** dialog box to create a Point Info text box, see "Inserting Point Info Boxes" in the "Inserting Report Commands" chapter.

To access these added options:

1. Select the **Text Box Mode** icon. For information, see "Text Box Mode" in the "Editing the CAD Display" chapter).

2. Right-click on a feature or feature's ID label in the Graphic Display window to display the shortcut menu.

Dimension/Point Info Menu in Text Box Mode

When in Text Box Mode ( ), if you right-click on a Dim Info box or Point Info box, PC-DMIS adds these two options to the standard feature shortcut menu:

Edit
This option allows you to edit the selected Dimension Info or Point Info text box. A slightly modified **Edit Dimension Info** or **Edit Point Info** dialog box opens. In addition to the standard buttons along the bottom of the dialog box, an additional **Apply To All** button is available.

Click **Apply To All** to have any changes made in the dialog box apply to *all* Dimension Info or Point Info boxes:

Only the changes made from the original to the modified info box will be applied across all Dim Info or Point Info boxes. Settings on the original info box that already differ from other info boxes will not be applied to the other info boxes.

For additional information see "Inserting Dimension Info Boxes" in the "Inserting Report Commands" chapter.

Delete
Select this menu option to delete the selected dimension or point info text box. The corresponding POINTINFO or DIMINFO command in the Edit window will also be deleted.

To access these added options:

1. Select the **Text Box Mode** icon (see "Text Box Mode" in the "Editing the CAD Display" chapter).
2. Right-click on a **Dim Info** or **Point Info** box in the Graphic Display window.

Related Topics

Layout

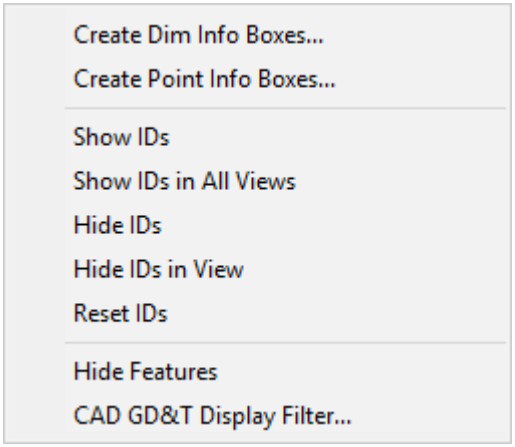
Box-Select Shortcut Menu

This shortcut menu only works in **Text Box Mode**.

To access this menu, follow these steps:

1. From the **Graphic Modes** toolbar, select the **Text Box Mode** icon ( ). (For information on this mode, see "Text Box Mode" in the "Editing the CAD Display" chapter.)
2. Box-select one or more features to select all graphical features or feature ID labels inside the box.

A shortcut with these options appears:



The following options are available:

Create Dim Info Boxes
This menu option creates Dimension Info text boxes from the selected features.

PC-DMIS displays the **Edit Dimension Info** dialog box for one of the highlighted features. The dialog box shows the available dimensions from which you can create the first Dimension Info box.

Once you select the desired options in the **Edit Dimension Info** dialog box, click either the **OK** or **Create** button (**Apply** button when editing) to create the Dim Info boxes.

PC-DMIS creates the first Dim Info box from any selected dimensions in the **Edit Dimension Info** dialog box.

PC-DMIS then creates subsequent info boxes from all dimensions associated with each feature.

If no dimensions are associated with any of the features, PC-DMIS creates a default Location dimension for that feature (see "Dimensioning Location" in the "Using Legacy Dimensions" chapter). For information on how to use the **Edit Dimension Info** dialog box, see "Inserting Dimension Info Boxes" in the "Inserting Report Commands" chapter.

Create Point Info Boxes
Select this menu option to create Point Info text boxes from the highlighted features. PC-DMIS displays the **Edit Point Info** dialog box for one of the highlighted features. This dialog box shows the feature (and any available dimensions) from which you can create the Point Info text box.

Once you've selected the desired options in the **Edit Point Info** dialog box, select the **OK** or **Create** button (**Apply** button when editing) to create the info boxes.

PC-DMIS creates the first info box from the selected feature or dimension (or dimensions) in the **Edit Point Info** dialog box. PC-DMIS creates the

subsequent Point Info boxes from all dimensions associated with each feature and the feature itself. A Point Info box is created for all dimension and feature hits. For information on how to use the **Edit Point Info** dialog box to create a Point Info text box, see "Inserting Point Info Boxes" in the "Inserting Report Commands" chapter.

Show IDs, Hide Ids
Select one of these menu options to show or hide all the selected features' ID labels. If you choose to hide the ID labels, the ID labels still exist and are merely hidden from view.

Show IDs in All Views
This option shows all the selected ID labels in all of the available Graphic Display window view panes.

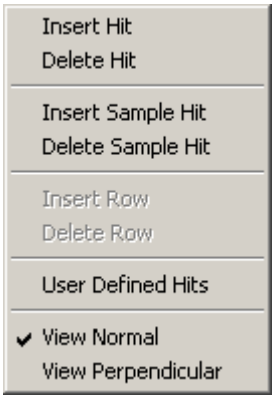
Hide IDs in View
This option hides all the selected ID labels in the current Graphic Display window view pane.

Reset Ids
This option moves all selected ID labels back to their original locations next to their respective features.

Hide Features
This option hides all selected features on a part, removing them from the Graphic Display window. The features still exist and are merely hidden from view.

CAD GD&T Display Filter
This menu option displays a dialog box allowing you to filter what CAD GD&T callouts are displayed. It appears in the shortcut menu if your CAD model contains embedded CAD GD&T information. See "Working with CAD GD&T Callouts" in the "Editing the CAD Display" chapter.

Auto Feature Path Lines Shortcut Menu



To access this shortcut menu, select the **Show Hit Targets Toggle** button inside an **Auto Feature** dialog box (**Insert | Feature | Auto | <Feature Type>**).

The following options are available:

Insert Hit
Inserts an additional hit into the Auto feature.

Delete Hit
Deletes the selected hit from the Auto feature.

Insert Sample Hit
Inserts a sample hit for the Auto feature.

Delete Sample Hit
Deletes the selected sample hit from the Auto feature.

Insert Row
When working with a feature that uses multiple rows of hits, such as a cylinder or cone, this inserts another row of hits.

Delete Row
When working with a feature that uses multiple rows of hits, such as a cylinder or cone, this deletes the selected row of hits.

User Defined Hits
This menu option becomes automatically selected whenever you manually make a change to a hit or path using the mouse.

If you then deselect this menu option, PC-DMIS reverts your change back to what it was before.

Additionally, if you have this option selected for a hit and then change to the feature's perpendicular view with **View Perpendicular**, you can adjust the depth or height for that specific hit.

View Normal
This changes the CAD view of the feature to a top-down view.

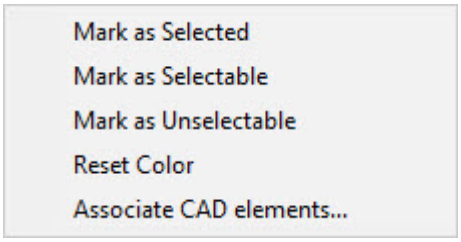
View Perpendicular
This changes the CAD view of the feature to a side view, ideal for defining a feature's depth or adding additional levels of hits.

CAD GD&T Callouts Shortcut Menu

You can use this shortcut menu to set CAD GD&T Callouts to different colors to better communicate the state of the current callout (selected, selectable, or unselectable).

To access this menu, the software must be in GD&T selection mode. To enable this mode, from the **Graphic Modes** toolbar, enable **GD&T selection mode** .

You can then right-click on a CAD GD&T callout to see the menu options:



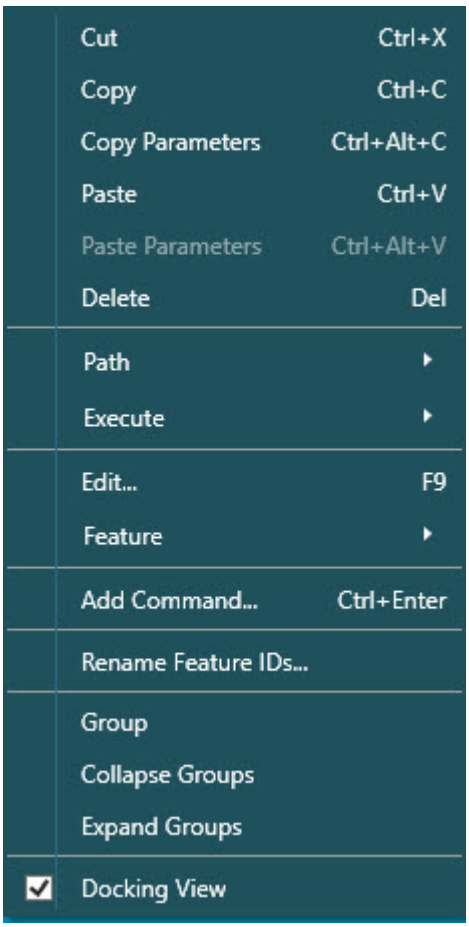
- **Mark as Selected** - This changes callout's color to a gray color to signify that you have selected this callout.
- **Mark as Selectable** - This changes the callout's color to the selectable color to signify that this callout is available for selection.
- **Mark as Unselectable** - This changes the callout's color to the invalid (unselectable) color to signify that this callout is invalid and cannot be selected.
- **Reset Color** - This changes the color of callout's color back to original color when you imported the model.
- **Associate CAD elements** - This opens a dialog box so that you can manually link GD&T CAD callouts to CAD elements on the model. For more information, see "Associating CAD GD&T Callouts with CAD elements" under "Working with CAD GD&T Callouts" in the "Editing the CAD Display" chapter.

Shortcut Menus in the Edit Window

The PC-DMIS Edit window contains the following shortcut menus depending on which Edit window mode you select.

Summary Mode Command Shortcut Menu

When you select a command item in the Edit window's Summary Mode (see "Working in Summary Mode" in the "Using the Edit Window" chapter) and right-click on the command item, the command shortcut menu appears. This menu has the following options:



Summary Mode Command Shortcut Menu

The following options are available:

Cut (Shortcut Key stroke: Ctrl + X)

This option cuts the selected command to the Clipboard and removes the command from the measurement routine.

Copy (Shortcut Key stroke: Ctrl + C)

This option copies the selected command to the Clipboard.

Copy Parameters (Shortcut Key stroke: Ctrl + Alt + C)

This option copies the selected parameters to the Clipboard.

Paste (Shortcut Key stroke: Ctrl + V)

This option pastes a command that you previously cut or copied from the Clipboard and places it below the selected command.

Paste Parameters (Shortcut Key stroke: Ctrl + Alt + V)

This option pastes the copied parameters from the Clipboard into the Edit window at the cursor position.

Delete (Shortcut Key stroke: Del)

This option deletes the selected command and any sub-commands out of the measurement routine.

Path | Path Lines

This option shows only the path lines for a range of selected features. See "Showing, Animating, and Moving Path Lines" in the "Editing the CAD Display" chapter.

Path | Collision Detection

This option shows path lines and performs the collision detection for a range of selected features. See "Detecting Collisions" in the "Editing the CAD Display" chapter.

Path | ClearanceCube | Off

Turns the ClearanceCube feature to Off.

Path | ClearanceCube | On

Turns the ClearanceCube feature to On.

Path | ClearanceCube | Starting Face

This option enables you to select the Starting Face to align the ClearanceCube to. The options are -X, +X, -Y, +Y, -Z, +Z, and Off.

Path | ClearanceCube | Ending Face

This option enables you to select the Ending Face to align the ClearanceCube to. The options are -X, +X, -Y, +Y, -Z, +Z, Use Tip Vector, and Off.

Path | Optimize Path

This option only appears if you right-click on a `GROUP` command. It performs a path optimization on the features inside of the group. For more information, see "Path Optimization for Single Arm with Touch Probe" in the "Using Inspection Plans in PC-DMIS" appendix.

Execute | Execute From Cursor

This option starts the measurement routine at the point of the current cursor location.

Execute | Execute Block

This option executes a designated block of code.

Edit (Shortcut Key stroke: F9)

This option displays the dialog box for the current command object.

Feature | Update Nominals From CAD

This option updates the measurement routine nominals with the imported CAD nominals.

Feature | Override FindNoms

This option overrides the default FindNoms behavior of PC-DMIS during Learn mode and Execute mode. For more information, see "Overriding Found Nominals" in the "Editing a Measurement Routine" chapter.

Feature | Reset Measured Values to Nominal

This option sets all measured values to the measurement routine nominal values.

Feature | Center in CAD

This option pans and rotates the part's CAD model as needed to center the current feature in the Graphic Display window. Once centered, the feature flashes a few times. You cannot undo this pan-and-rotate operation.

Feature | Highlight in CAD (Shortcut Key stroke: Ctrl + Shift + H)

This option highlights the selected feature in the Graphic Display window. It also shows and highlights the feature label if it is hidden. To clear the highlight of the first feature, highlight a second feature.

Feature | UnHighlight in CAD (Shortcut Key stroke: Ctrl + Shift + U)

This option clears the CAD feature that you highlighted through the **Highlight in CAD** menu item.

Feature | Move Probe to Feature

This option moves the animated probe in the Graphic Display window to the CAD element for the selected feature. It becomes available for selection only in Offline mode and only if you first select a feature command. Other commands are not supported.

Feature | Move To SPH_Tip1

This option only appears when you right-click on an Auto feature. It moves the probe to the center of the selected Auto feature. This action functions the same as the **Move To** button in the **Auto Feature** dialog box (**Insert | Feature | Auto | <Feature Type>**).

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

Feature | Test SPH_TIP1

This option only appears when you right-click on an Auto feature. It performs a test execution of the selected Auto feature. This action functions the same as the **Test** button in the **Auto Feature** dialog box.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

Add Command (Shortcut Key stroke: Ctrl + Enter)

This option enables you to add a command to the Edit window from the **Add Command** dialog box.

STEP 1: Use the search box to type the first few letters of the command. PC-DMIS displays the filtered list.

STEP 2: Select the command from the list.

STEP 3: Press either Ctrl + Enter or Enter to place the new command into the Edit window.

- Press Ctrl + Enter to place the command after the command block used to open the shortcut menu.
- Press Enter to place the command inside the command block used to open the shortcut menu. The Enter key only functions in this manner if the command you are adding is a type of command that PC-DMIS can insert into another command block. Otherwise, PC-DMIS inserts it after the current command.

Rename Feature IDs

This option enables you to rename multiple feature IDs at the same time.

Group

This option inserts the list of contiguous commands into a user-defined group.

Collapse Groups

This option collapses all expanded user-defined groups. Other expanded items remain expanded.

Expand Groups

This option expands all collapsed user-defined groups. Other collapsed items remain collapsed.

Docking View

This option determines whether or not the Edit window is docked or undocked.

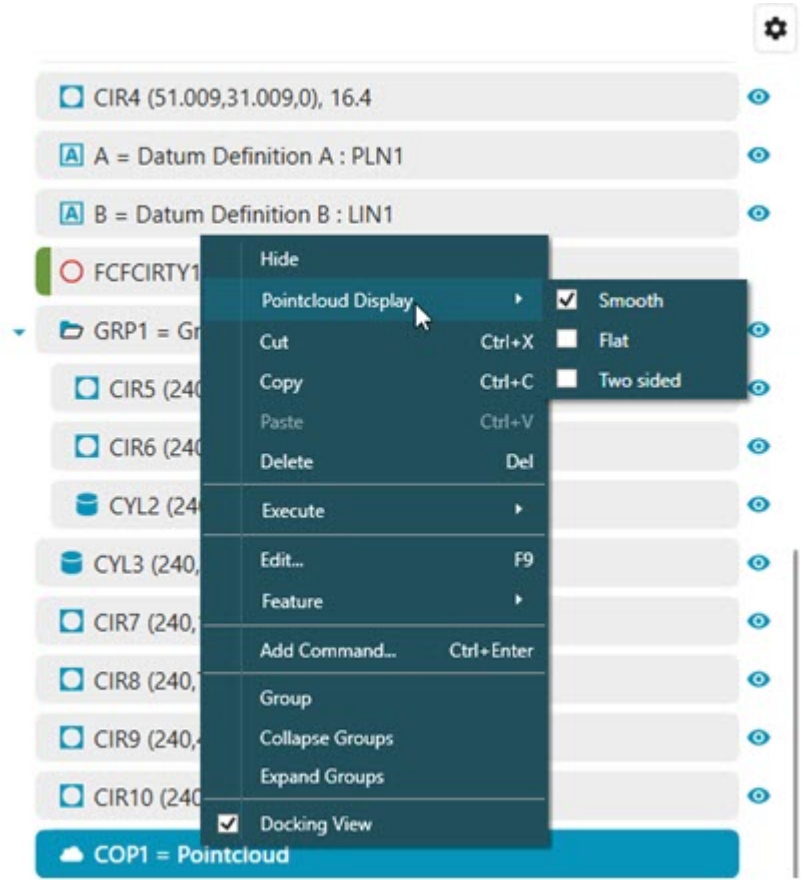
- If you deselect this option, the Edit window floats over the Graphic Display window.
- If you select this option, you can dock the Edit window to the sides or top or bottom of the Graphic Display window.

  For details on how to dock and undock user interface elements, see "Docking and Undocking User Interface Elements".

When you select a command item in the Edit window in Summary Mode (see "Working in Summary Mode" in the "Using the Edit Window" chapter) and right-click on the command item, the options on the command shortcut menu change according to the type of command you selected: general, pointcloud, pointcloud cross section operator, or Mesh.

Pointcloud Commands

The following shortcut menu appears for pointcloud commands:



Pointcloud Command Shortcut Menu

The following options are available:

Show or **Hide**

This option toggles the labels between shown and hidden. This option is also available for the Mesh commands.

Pointcloud Display

- **Smooth** - This option provides a shaded appearance using the defined COP color.
- **Flat** - This option shows the COP in a non-shaded graphical view. This selection requires the least amount of graphical memory.
- **Two sided** - This option shows a shaded appearance where the scanned side of the part is the defined COP color, and the non-scanned side is a contrasting color.
- **Mesh display** - This option shows the pointcloud as a Mesh display.

The **Mesh display** option is only available if you have the Mesh license and you scanned the COP using the **Mesh display** option (Portable only). For details, see "Pointcloud Display Section" in the PC-DMIS Laser documentation.

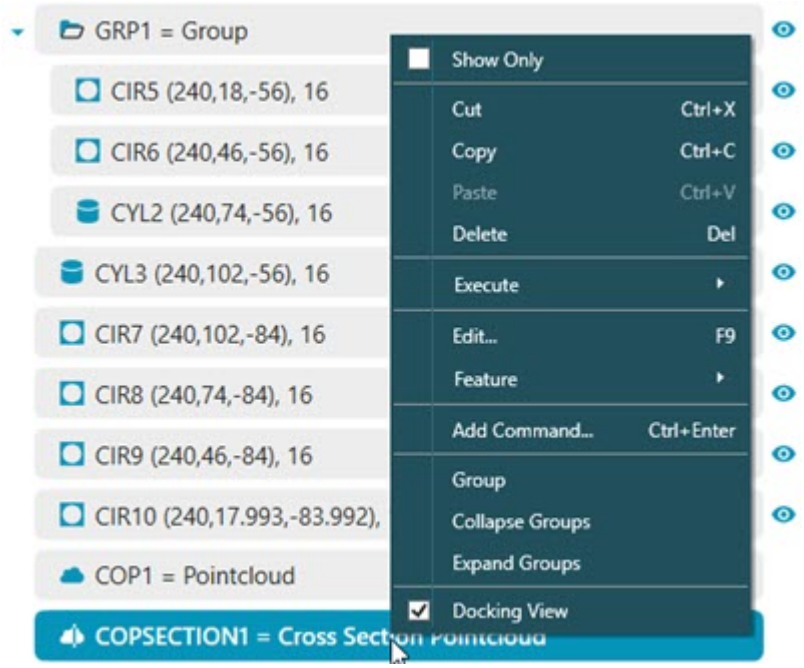
The **Mesh display** is a display setting only. The underlying data is a pointcloud.

However, the mesh display is lost, and the display reverts to points if you edit the COP (for example, if you perform any COP operation on the pointcloud).

For more information about the **Pointcloud Display** options, see "Pointcloud Graphical Representation" in the PC-DMIS Laser documentation.

Pointcloud Cross Section Operator Commands

The following shortcut menu appears for pointcloud cross section operator commands:



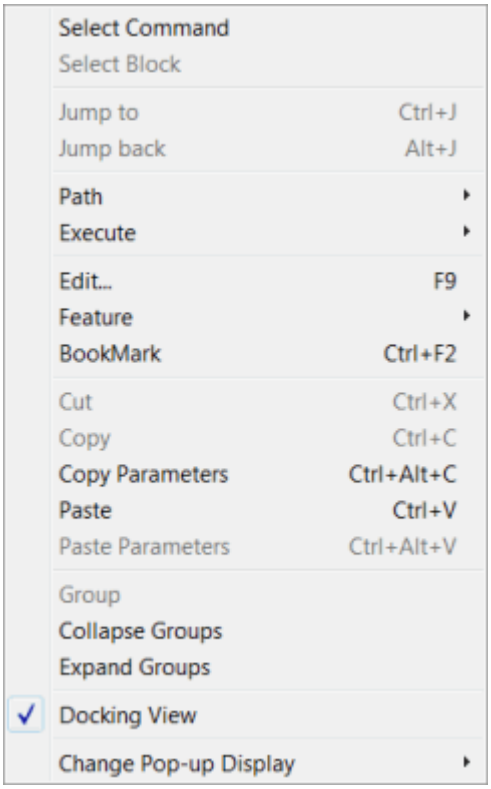
Pointcloud Cross Section Operator Command Shortcut Menu

Show Only

This option displays the 2D view of the selected cross section. When you enable the option, PC-DMIS displays a check mark to the left of it. For more information, see "2D View of Cross Sections" in the PC-DMIS Laser documentation.

Command Mode Shortcut Menu

The following shortcut menu options are available when PC-DMIS is in Command Mode. For information on these modes, see "Working in Command Mode" in the "Using the Edit Window" chapter.



The following options are available:

Select Command
This option highlights the command that the mouse is positioned over.

Select Block
If the mouse is over a start or end block object, it selects the entire block.

Jump To <Feature> (Shortcut Key stroke: Ctrl + J)
This option jumps from the current command to the referenced feature ID.

Jump Back (Shortcut Key stroke: Alt + J)
This option jumps back to the command that you were at before when you selected the **Jump To** option.

Path | Path Lines
This option shows only the path lines for a range of selected features. See "Showing, Animating, and Moving Path Lines" in the "Editing the CAD Display" chapter.

Path | Collision Detection

This option shows path lines and performs the collision detection for a range of selected features. See "Detecting Collisions" in the "Editing the CAD Display" chapter.

Path | ClearanceCube | Starting Face

The **ClearanceCube | Starting Face** option determines what ClearanceCube face PC-DMIS moves to before measuring the feature. The available settings are -X, +X, -Y, +Y, -Z, +Z, and Off.

Path | ClearanceCube | Ending Face

The **ClearanceCube | Ending Face** option determines what ClearanceCube face PC-DMIS moves to after measuring the feature. The available settings are -X, +X, -Y, +Y, -Z, +Z, and Off.

Path | Optimize Path

This option only appears if you right-click on a `GROUP` command. It performs a path optimization on the features inside of the group. For more information, see "Optimizing the Path" in the "Using Inspection Plans in PC-DMIS" appendix.

Execute | Mark (Shortcut Key stroke: F3)

This option toggles the mark state of the object for execution. For more information on marking, see "Mark" in the "Editing a Measurement Routine" chapter.

Execute | Set as Start Point

This option determines the starting location at which measurement routine execution begins when you select the **File | Partial Execution | Execute From Start Points** menu option. See "Setting Start Points" in the "Editing a Measurement Routine" chapter.

Execute | Execute From Cursor

This option starts execution from the current location of the insertion point in the Edit window.

Execute | Execute Block

This option executes the currently marked block of commands.

Execute | Breakpoint

This option inserts a breakpoint at the cursor's location. For more information on breakpoints, see "Using Breakpoints" in the "Editing a Measurement Routine" chapter.

Edit (Shortcut Key stroke: F9)

This opens the dialog box that enables you to edit the command that the cursor resides on.

Feature | Update Nominals From CAD

This option updates the routine Nominals with the imported CAD Nominals.

Feature | Override FindNoms

This option accesses the **Override FindNoms** dialog box so that you can override the default find nominals behavior for the points you right-clicked on in the Edit window. See "Overriding Found Nominals" in the "Editing a Measurement Routine" chapter.

Feature | Reset Measured Values to Nominal

This option sets all measured values to the routine nominal values.

Feature | Center in CAD

This option pans and rotates the part's CAD model as needed to center the current feature in the Graphic Display window. Once centered, the feature flashes a few times. You cannot undo this pan and rotate operation.

Feature | Highlight in CAD

This option highlights the selected feature in the Graphic Display window. It also shows and highlights the feature label if it is hidden. Highlighting a second feature clears the highlight of the first feature.

Feature | UnHighlight in CAD

This option clears the highlighted CAD feature made using the **Highlight in CAD** menu item above.

Feature | Move Probe to Feature

This option moves the animated probe in the Graphic Display window to the CAD element for the selected feature. It becomes available for selection only in Offline mode and only if you first select a feature command. Other commands are not supported.

Feature | Hide Feature(s)

This option toggles the display of selected feature commands and their IDs in the Graphic Display window. You can also use this on a GROUP command to toggle the display of features within the group.

The shortcut for this is Ctrl + Shift + F.

Feature | Test <Feature>

This option only appears when right-clicking on an Auto feature. It performs a test execution of the selected Auto feature. This functions the same as the **Test** button in the **Auto Feature** dialog box.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

Feature | Move To <Feature>

This option only appears when right-clicking on an Auto feature. It moves the probe to the center of the selected Auto feature. This functions the same as the **Move To** button in the **Auto Feature** dialog box.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

BookMark (Shortcut Key stroke: Ctrl + F2)

This option inserts a bookmark at the cursor's location. For more information on bookmarks, see "Using Bookmarks" in the "Editing a Measurement Routine" chapter.

Cut (Shortcut Key stroke: Ctrl + X)

This option cuts the selected Edit window text to the Clipboard. For more information on how to cut in the Edit window, see "Cut" in the "Editing a Measurement Routine" chapter.

Copy (Shortcut Key stroke: Ctrl + C)

This option copies the selected Edit window text to the Clipboard. For more information on how to copy in the Edit window, see "Copy" in the "Editing a Measurement Routine" chapter.

Paste (Shortcut Key stroke: Ctrl + V)

This option pastes text from the Clipboard into the Edit window at the cursor's location. For more information on how to paste in the Edit window, see "Paste" in the "Editing a Measurement Routine" chapter.

Group

This option inserts the list of contiguous selected commands into a user-defined group.

Collapse Groups

This option collapses all expanded user-defined groups. Other expanded items remain expanded.

Expand Groups

This option expands all collapsed user-defined groups. Other collapsed items remain collapsed.

Docking View

See the description given in the "Summary Mode Command Shortcut Menu".

Change Pop-up Display | Expression Value

1. Select **Expression Value**.
2. Let your cursor rest over an expression.
3. A small pop-up window appears and displays the current value of the expression.

Change Pop-up Display | Data Type Information

1. Select **Data Type Information**.

2. Let your cursor rest over a data field.

3. A small pop-up window appears and displays information about that data field, including the data type description, data type number, and type index.

The information displayed in this pop-up window can be used with the GETTEXT expression. See the "Using Expressions and Variables" chapter.

Change Pop-up Display | Command Information

1. Select **Command Information**.

2. Let your cursor rest over any Edit window command.

A small pop-up window appears and displays command description information and the command type number. The information displayed in this pop-up window can be used with the GETCOMMAND expression. See the "Using Expressions and Variables" chapter.

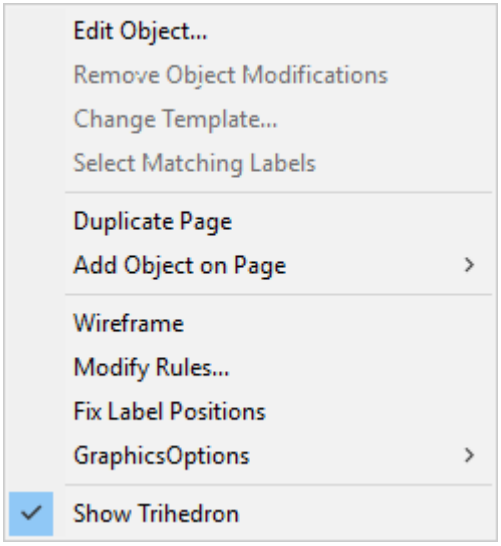
Object

This menu option remains unavailable for selection until you insert an external object into the Edit window. For information on how to do this, see "Inserting External Objects" in the "Adding External Elements" chapter.

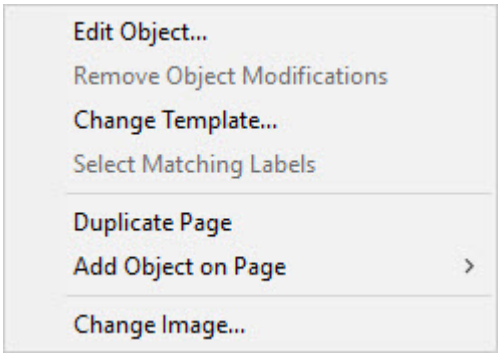
Once you select the inserted external object in the Edit window and then right-click on it, this menu changes to reflect options unique to that particular object. These may include options such as opening the object, editing the object, or modifying the object's properties.

Shortcut Menus in the Report Window

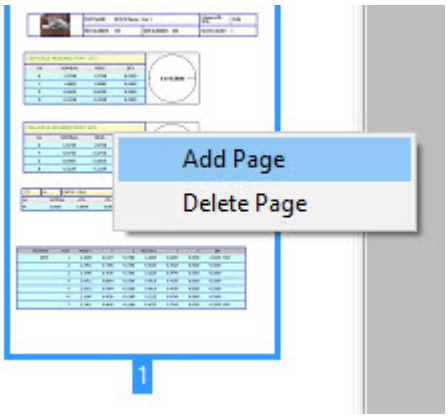
If you right-click in the Report window, PC-DMIS displays a shortcut menu with menu items that affect how objects appear in the Report window. Certain menu items only appear if you right-click on specific underlying objects in the Report window. The various menu items you can access from the Report window's shortcut menu are discussed in the table below:



Report Graphic Display - Shortcut Menu



Report Header - Shortcut Menu



Shortcut menu with mouse pointer over a custom report's thumbnail image in the Preview Pane

Edit Object
This option allows you to modify the current object in the Report window from its default state.

- If you right-click on a label object in the Report window, the **Label Properties** dialog box appears, so that you can modify that label.

- If you right-click on the TextReportObject (essentially any white space text at the end of your report or any non-table-like reporting text), the **Report** dialog box appears so that you can determine what gets included in your report.

You can press **Shift** and right-click on any label object to display the **Report** dialog box.

For more information, see "Changing the Report Window's Contents" in the "Reporting Measurement Results" chapter.

Hide Selected Labels
This option hides any selected labels used with the CadReportObject. Select the labels you want to hide and then right-click on one of the selected labels for this menu item to appear. To select multiple labels at a time, drag a box around the desired labels with the mouse or hold down the Ctrl key and click on the desired labels.

Show Hidden Labels
This option shows all hidden labels. Right-click on the CadReportObject for this menu item to appear.

Remove Object
This option removes a selected label object or section cut profile object that you added using the **Add Object on Page** submenu.

You should not use the **Delete** key when you try to remove selected objects; doing so deletes selected commands in the Edit window instead.

Remove Object Modifications
This option returns the object you right-click on to its original state and removes any modifications you may have made using the **Edit Object** menu item or made resizing or repositioning supported objects.

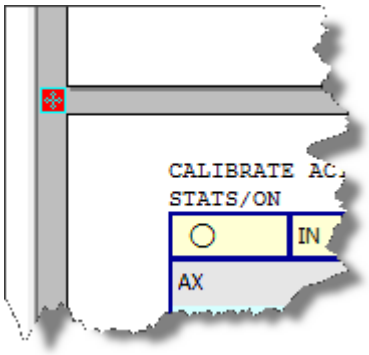
Change Template
This option displays an **Open** dialog box, so that you can change the template used to display and format the data from the underlying command. Only those templates specified to work with the command appear in the dialog box.

If you have multiple labels selected when you use this option (such as after you use the **Select Matching Labels** menu item), PC-DMIS applies the label change to all the selected labels.

Select Matching Labels
This option appears when you right-click on a label. This option selects all labels on the current page that use the same label template as the label on which you clicked.

Duplicate Page
This option creates an identical page of the one on which you right-click immediately following the current page. You may find this helpful to organize labels that can't fit on one page across multiple pages.

Duplicated pages show a red cross icon at the top-left area of the page.

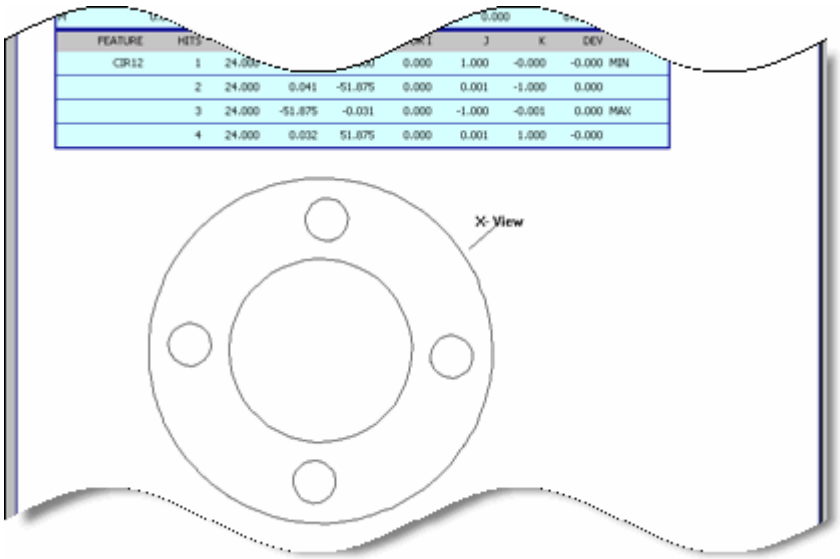


Example of a cross icon indicating a duplicated page.

To remove a duplicated page, right-click on it and select **Remove Duplicated Page**.

Remove Duplicated Page
This option only appears in the menu when you right-click on a previously duplicated page. Select it to remove the duplicated page from the report.

Add Object on Page | Section Cut Profile
This option inserts a section cut profile of your part model into the report.



A sample section cut profile.

After you select this option, use your mouse and drag a box in the Report window to insert the section cut profile. For detailed information, see the information in the "SectionCutObject" topic in the "Reporting Measurement Results" chapter.

You can use this method to insert multiple cutaway views into your report.

Change Image
This option only appears in the menu when you right-click on a header label template (such as FILE_HEADER.LBL). When you choose this option, you can use an **Open** dialog box to choose a new image for the report's header. After you locate the new image and click **Open**, the report uses that image. This action also updates the underlying label template (.lbl) with the new image.

Add Object on Page | Custom Label
This menu item lets you insert a custom label object on the fly into the active report. This type of label insertion process is not tied in any way to the Rule Tree Editor.

Select this menu item and then drag a box in the Report window. An **Open** dialog box appears so that you can insert a selected label template on the fly into the current page of the report.

Remove CAD Report Object Pan/Zoom/Rotate MOD
This menu item lets you remove just pan, zoom, and rotate modifications for the CadReportObject. Other modifications (such as section cuts, various label definitions, solid or wire displays and so forth) are not affected.

Select Labels
This menu item allows you to easily select multiple labels across different sections in your report.

When you select this item, PC-DMIS displays the **Select Labels** dialog box. This dialog box displays the labels in your report that are tied to a CadReportObject. Select any labels from this dialog box; when you click **OK** on the dialog box, PC-DMIS selects the corresponding labels in the report.

You can limit the labels that appear in the dialog box by feature type, dimension type, or all commands.

For more information, see "Changing the Report Window's Contents" in the "Reporting Measurement Results" chapter.

Wireframe
This menu item toggles the display of the selected CadReportObject by displaying the model as either a wireframe or a solid. This menu item only appears if you right-click on a CadReportObject in your report.

Modify Rules
This menu item displays a simplified version of the **Rule Tree Editor** dialog box. You can use the **Disable** or **Enable** options on this dialog box to turn rules on or off.

Show Previously Unused Labels
This menu item works with labels on a CadReportObject in a duplicated page.

If you turn off a set of labels on the CadReportObject on one page and then duplicate that page, you can use this menu item on the duplicated page to get it to show the labels not used on the original page.

Fix Label Positions
This menu item creates a position modification for each label so that the next time you open the report, PC-DMIS won't recalculate label positions.

GraphicsOptions | None
This menu item hides all labels on the CADReportObject.

GraphicsOptions | Labels
This menu item shows all labels on the CADReportObject.

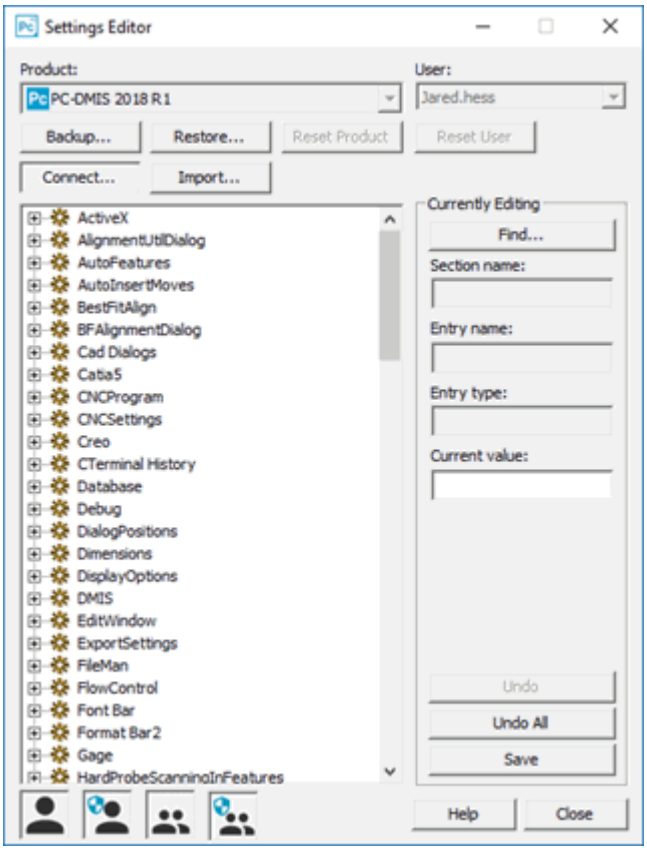
Add Page (applies to Custom Reports only)
This menu item adds a new page to the end of your custom report.

Delete Page (applies to Custom Reports only)
This menu item deletes that page from your custom report. You must always have at least one page in your report.

Modifying Setting Entries

Modifying Setting Entries: Introduction

You can use the PC-DMIS Settings Editor application to change entries that control various PC-DMIS settings.



Settings Editor Dialog Box

To launch the PC-DMIS Settings Editor and its documentation:

1. Close the PC-DMIS application if open.
2. Access the PC-DMIS **Settings Editor** shortcut from the program group where you installed PC-DMIS.
3. Once the Settings Editor opens, click **Connect** to have it connect to the main application. This may take some time.
4. Once the Settings Editor connects, press F1 (or click the **Help** button) to get information on how to use the Settings Editor.

   For more information, see the "PC-DMIS Settings Editor" documentation.

If this is your first time using the Settings Editor since PC-DMIS was installed, PC-DMIS needs to remain open as you click **Connect**. After the first connection succeeds, you can later run the Settings Editor by itself.

Glossary

95 % Confidence Factor
Given a Gaussian distribution (or filter) of errors, an adequate number of hits, and the resulting standard deviation, you can be 95% confident that the actual dimension will be less than the measured value.

AB angles
The position of these A and B axes determine the angles a probe will use during tip calibration. These are also referred to as AB positions. * A is the vertical wrist angle. A = 0 when the tip is pointing straight down, and it is normal to the probe. * B is the rotation angle. B = 0 will vary according to machine type and brand and also probe head type.

Active Tip
The active tip refers to the part of the probe (also referred to as the stylus) that is currently loaded for use. Several tips can be considered active at a time and are referenced in the Active tip list.

Active Tool
This refers to the calibration tool that is used to calibrate the active tip. See also Tool.

ACTL
This means Actual, meaning the "measured" size or location information as opposed to the "theoretical" size or location information.

Actual Point (APT)
Out of the multiple readings that the controller takes during the probing cycle, the Actual Point is the one that is returned from the controller.

Alignment Block
This is a section of measurement routine code in the Edit window beginning with the "Label = ALIGNMENT/START,..." command line and continuing to the "ALIGNMENT/END" command line.

Alignment offset
This is the distance of the part from the X, Y, and Z (0, 0, 0) location.

Alignment Rotation Feature
This Rotate button (found in Alignment dialog box) allows you to rotate the part about a particular axis. This is used for creating alignments.

Analog Probe
This type of probe is an electronic device capable of performing a continuous contact scan of a part's surface without having to leave the part's surface in order to record measurement data. When not performing scans, the probe functions similar to a Touch Trigger Probe (TTP).

Anti-aliasing
A technique used in computer software to smooth jagged edges that appear on curved or diagonal lines drawn on a computer screen.

Arguments
These are conditions used in a subroutine or equation, such as an IF THEN statement. IF a certain argument (or condition) is met THEN a certain result follows.

Assignment
Assignment is the process of giving the value of an operation, set of operations, or a real number to a variable and is accomplished by use of the assignment operator (=). The assignment operator is automatically created when the assignment option is selected (from the menu bar, select the Assignment option).

Asterisk (*) Meta-Character
The asterisk (*) meta-character will match, or take the place, of any character or characters in a search.

Autojoint
A connection where a key is used to engage the male and female halves of this coupling. You manually use a key to engage and disengage the Autojoint for systems with no probe racks. For rack systems, this is done with a rack-and-pinion-style device to turn the key.

Axes
This is plural for axis. See Axis.

Axis
An axis is one of the reference lines in a system of coordinates. The various axes (plural for axis) are XPLUS, XMINUS, YPLUS, YMINUS, ZPLUS, and ZMINUS. An axis can also be defined as the derived median line along the length of a cylinder, cone, slot, or ellipse.

Axis Counters
These are digital readout hardware devices connected to your machine that give a readout of the machine's axes X, Y, and Z positions.

Ball Tip
Tip shaped as a small ball.

Balloon IDs
See "Characteristic IDs".

Baricenter
The center of gravity for a hole of any shape.

Basic Script
A basic script is a series of basic commands written in the programming language BASIC.

Baud
This is the rate at which data can be transmitted or received by a computer. This is usually defined as a number of bits per second (bps).

Bend Radius
This is essentially an outside cylinder (pin) measurement for sheetmetal. It measures the center location and size.

Best Fit
This is a mathematical process that calculates feature or alignment parameters by minimizing certain error conditions between measured and theoretical points or features.

Best Guess Algorithms
These are mathematical calculations that PC-DMIS uses to determine what feature type is being measured based on the number of hits taken. Based on the results of the calculations, PC-DMIS makes its best guess to determine the feature type. Incorrect guesses can be overridden using the Override command on the main menu.

Block Edit
This refers to moving a portion of text from one area of the Edit window to another area.

Boss
A "boss" is usually an external cone or cylinder that has a flat top to it that a bolt may thread into. Sometimes this is also termed as a "Stud".

Boundary Crossings
This numerical value (used in the Number of Boundary Crossings box) tells PC-DMIS how many times the probe's ball center can cross the given condition's surface (planar, spherical, cylindrical) before stopping a given scan. Once the ball center crosses the condition's surface for the nth time (where n = the number entered), then the scan stops.

Boundary Plane
The Boundary Plane is created perpendicular to the Boundary Plane Vector with the same XYZ coordinates as the start point of the scan. The Boundary Plane is often used to determine when to stop a scan by indicating a maximum number of times the scan may cross the boundary plane.

Boundary Plane Vector
The Boundary Plane Vector is determined initially by the direction from the start point of a scan to the direction point of the scan.

Boundary Points
These are sample points which will determine the limits of the area to be contained within a scanned line or surface.

Box Tolerancing
Box tolerancing is a variation of box-selecting. Box tolerancing can be performed with an open Dimension dialog window and box-selecting a group of measured features. The tolerance options in the Dimension Dialog box can then be used to apply the same tolerances to all of the features that are selected.

Box-Selecting
Box-selecting is a function within the Graphic Display area that allows you to draw a box with the mouse around a group of features. This highlights those features in a Feature ID list box.

Branching
Branching is the path (not the probe path but the logical path or flow that an executing measurement routine takes) followed during execution of a measurement routine which may be variable as a result of some logical statement, such as IF, ELSEIF, ELSE, DO, and WHILE, that causes the measurement routine to execute differently depending on the value of some input or variable that is computed or measured in the measurement routine.

CAD Coordinates
The position, expressed as X, Y, and Z values, of a feature in a CAD file.

CAD file
A CAD file is a graphical image file created using Computer Aided Drafting which contains information about a part or parts and their features' dimensions, orientations, and sizes. These files are usually saved in one of the following formats: IGES, DFX, DES, STEP, and XZYIJK.

Cal Wrist

Abbreviation for Calibrate Wrist. Used to calculate the probe head offsets for each wrist position that is used.

Calculate Boundary
Abbreviation for Calculate Boundary Points. Used with Perimeter Scans to determine the limits of travel during the scanning operation.

Calibration
This process simply tells PC-DMIS the location and diameter of the probe tip. It is also referred to as "qualification".

Calibration Tool
A Calibration Tool is a calibrated artifact used to qualify a probe tip. It is normally a precision tooling ball. It is also known as a "Qualification Tool".

Capability
This is a calculated number based on measured data and the tolerances (USL and LSL). It tells you how well a process can produce parts with respect to the specified tolerances.

Capability in Equation Form
It is the minimum between: (USL-XBarBar)/(3*sigma) and: (XBarBar - LSL)/(3*sigma). Where XBarBar is the mean of the subgroup's means for the data in consideration. In order for the process to be labeled as "capable", the calculated capability (above equation) must be greater than the user entered capability threshold. If a process is not capable it is considered "incapable".

Capability Threshold
This is the number by which the process's capability is determined. The capability and the capability threshold are two different values.

Car Body Alignment
Most Car Body (and Aircraft) alignments have a coordinate system that is off in space. In the case of a car, it is usually down in the lower center of the car, under the instrument panel. Dimensioning of features takes place from that point.

CD
Collision Detection.

Centroid
The center most point of a feature.

Characteristic IDs
Circular labels on a blueprint next to a GD&T callout. Also, referred to as "Balloon IDs".

Characteristic Point
This is a measurement used by the NC-100 video probe that is essentially an Angle Point measurement. It has two measurement types.1) Measures a point at the intersection of two surfaces (this measurement type is most like an angle point).2) Measures two points, one on each surface at a specified distance from the intersection.

Child
A 'child' is a command that is dependent upon another command in order to function.

Circ Move
Circular Move.

ClearP

An abbreviation for Clearance Plane. It is also a command entered in the Edit window to define the plane the probe must clear to avoid collision with the part.

Cmk
Machine capability process. This value is used to determine how well a given process can match the specification limits for the process.

CMM
Coordinate Measuring Machine.

Collision Tolerance
Indicates a measurable value from the surface of the CAD data. It is designed to alert you to any collisions between the probe and part.

Column locator
Another term for "Gripper".

Column passing lane
The column passing lane is a small corridor behind the usable fixture volume where columns are moved from one arm to the other and pulled from the rack for placement on the machine table.

Comm
Communications port.

Continuous Contact Scanning
A Continuous Contact Scan can be performed only when using either an analog probe, hard probe, or some laser probes and optical probes. In this type of scan the probe tip is brought in contact with the surface of a part and moved in a linear fashion without leaving the surface of the part until the scan or a portion of the scan is complete.

Controller
Every CMM has a controller. The controller drives the servos to move the machine, reads the scales to keep track of the position, interfaces to the actual probe, etc. A given CMM (or machine) can have any one of several different types of controllers.

Coordinate System
A coordinate system consists of an origin and X,Y, and Z axes.

Coplanar
Coplanar means that features reside in the same plane.

Cpk
Process capability index. This value is used to determine how well a given process can match the specification limits for the process.

CTE
Coefficient of Thermal Expansion

Cut Plane
The Cut Plane is a theoretical plane which is created perpendicular to the Cut Plane Vector with the same XYZ coordinates as the start point of the scan. The Cut Plane is used to enable a scan to be created with all points being at the same level relative to the Cut Plane Vector.

Cut Plane Vector
The cut plane vector is the cross product of the initial touch vector and the line between the start and end boundary points on scans. If there is no end point, then the line between the start and direction point is used.

CutVec (Cut Vector)
See Cut Plane Vector.

DataPage
DataPage(tm) is a statistical processing software package which links seamlessly with PC-DMIS.

Datum
A datum is an "imaginary" and "perfect" user-defined feature used as a reference point from which to measure other features on a part.

Datum Reference Frame
A datum reference frame is an alignment created from the current set of datums. It is defined by the order of your A, B, C, etc. datums.

DCC
Direct Computer Control.

DCC Mode
This mode puts the Coordinate Measuring Machine into Direct Computer Control (or DCC). With this mode turned on, the computer is in control of many CMM functions.

DCI
Direct CAD Interface

DCT
Direct CAD Translator

DD
Diameter of Datum.

Delimiter
The verb, to delimit, simply means to separate pieces of information. A delimiter then is a symbol that separates distinct pieces of information. In written English for example, the period, question mark, and exclamation mark are delimiters that delimit (or separate) the sentences.

Delta
Used to indicate an option where change or an amount of change is expected to occur.

Dependent curve
A Dependent curve is dependent on the feature set it was created from. This means if the feature set is changed later on, then the constructed curve may also change.

Dependent surface
A Dependent surface is dependent on the feature set it was created from. This means if the feature set is changed later on, then the constructed surface may also change.

Depth
This defines the distance below the surface of a part where the measurement will be taken.

DES
If importing a DES file type, this stands for "Data Exchange Standard". If working with statistical databases, DES stands for "Data Evaluation System".

DF
Diameter of Feature.

DFL

Deflection mode

Diameter
The maximum chord length of a circle, cylinder, or sphere. In the case of PC-DMIS, the chord length will be applied to a best fit feature unless specified otherwise. Imagine a round feature with a line passing through the center of it. The length of this segment is referred to as the diameter. It is sometimes referred to as the thickness or width of the feature.

DIMS
Dimensional Inspection Measurement System file format. This is the format of the PC-DMIS measurement routine files.

Direction Point
The Direction Point of a scan sets the direction of the scan. The scan will continue from the Start Point heading in the direction of the Direction Point until it reaches the End Point.

Disk Tip
Tip shaped as a small disk.

DMO
A DMIS Output file (.dmo). PC-DMIS can save a measurement routine's results to this file in the DMIS output format.

DOF
Degrees of Freedom.

DRF
Datum Reference Frame

DRO
Digital Read Out.

DSL
This is an abbreviation for a Digital Scanning Laser probe assembly.

DSN
Database Source Name. This is the database name for a database created inside ODBC or inside of DataPage+.

DST
This is an abbreviation for a Digital Scanning Tactile probe assembly.

DTT
This is an abbreviation for a Digital Touch Trigger probe assembly.

DXF
Drawing Interchange File.

Element
An element is simply another name for a feature.

ELM1
This abbreviation stands for Element 1.

ELM2
This abbreviation stands for Element 2.

ELOGO.DAT
This data file is used to format the Edit Report's footer. It is only used on the very last page of the Edit Report.

End Ang
Ending Angle.

End effector
An artifact that is placed against the part to hold it stationary in at least one axis. Typically, this is a sphere with a defined diameter. Spheres are used because they will only contact the part at a single location. Other types of end effectors can be pins (for mating holes), cylinders for locating edges, and specialty pieces specifically tailored to the part being fixtured.

End Point
This is the Ending Point of a scan. When the scan execution reaches this point, it stops.

End Touch Vector
The compensation vector for the last point of a scan.

End-of-ram
This term refers to the XYZ coordinates at the end of the arm (or ram) only, not figuring in the XYZ coordinates of the probe tip.

EndVec (End Vector)
See End Touch Vector.

EOF
End of File

Error Map
All CMM's are constructed with inherent inaccuracies. After construction, most CMM manufacturers laser verify their machines to record these inaccuracies. These errors are then stored electronically in a computer file (called abcomp.dat) which can be accessed by PC-DMIS to enhance the accuracy of the CMM. In essence, the computer file is an Error Map of the CMM. See Volumetric Compensation.

Export
The process of converting the drawing information contained in a PC-DMIS measurement routine to a CAD standard output file such as IGES.

Expression
An expression is a user defined condition used with PC-DMIS'S flow control commands. If the condition is met or not, you can determine what action PC-DMIS takes.

Extrude
When a probe is moved from one location to another, geometric volume is created through the move. The term "extrude" is used to define the volume of space that a probe will be in as it moves from one point to the next. The volume is then checked for collision with the part or table.

Faro Arm
This refers to the articulating arm CMM produced by Faro Technologies, Inc.

FBM
Feature Based Measurement

FCF
Feature Control Frame

Feature Height
The distance from the base to the top (center) of the feature.

Feature Length
The measured value along its greatest dimension.

Feature Pointer
A Feature Pointer is a variable type that works directly with an existing feature, providing direct access to that feature. For example, the statement ASSIGN/V1 = CIR1 would create a feature pointer to the feature CIR1 and assign it to variable V1. V1 could then be used to access CIR1. CIR1.X would access the measured x component of the centroid of CIR1.

Feature Set
A Feature Set is a collection of previously measured or created elements into one constructed element. The items making up the Feature Set do not necessarily have to be of the same feature type.

Feature Width
The measurement of a feature from side to side. The measured value along a feature's shortest dimension.

FILE I / O
This menu option stands for File Input / Output. Data can be Input (written) to or Output (read) from these files.

FindNoms
Find Nominal Values. When this option is selected from the Nominals option of a scan dialog, PC-DMIS will pierce the closest selected CAD surface in an attempt to gather the theoretical CAD data for each scanned data point. This information will then be used to calculate the deviation of each point.

Fixed Delta
An option for manual scanning with a hard probe where data points will only be gathered at specific, or 'fixed,' increments between each other.

Fixed probe
A fixed probe is synonymous with a "hard probe". It is a probe that doesn't use a touch trigger.

Flat feature type
Flat feature types are planar features. See Flat features.

Flat features
Flat features are defined as points, planes, and lines. See Flat feature type.

Flat Guess
This is a mode of operation utilized when using a hard probe to set order of precedence for the software to guess the type of feature being measured. Flat Guess will attempt to solve for a plane before a circle, cylinder, cone, or sphere. See also Round Guess and Guess Mode.

Floating toolbar
A floating toolbar is a toolbar that is able to be moved out of its set position and allowed to "float" at a desired location on the screen.

Flow Control
This refers to options within the software that allow you to control the direction of the measurement routine.

Fly Mode

This is an option referring to how PC-DMIS will move the probe around the part during the measurement process. To be utilized, the CMM must have a DCC controller capable of Fly Mode operation.

FOV

Field of Vision or Field of View. This refers to what you can see through the eye of a camera, an integral portion of video probes.

Gage

A virtual or physical tool used to perform measurements on a feature.

Gage Diameter

A circle feature that you construct at a given height along a cone. See also "Gage Point".

Gage Point

A point used on a tapered surface or cone where you define a height value (Z) in order to check a point location (X and Y) on the cone; or, where you define a diameter value to check the size of a cone at that diameter; or, where you define a point location (X and Y) to measure the cone's height (Z) at that location. In PC-DMIS, this second definition is accomplished when you construct a Circle feature from a Cone by specifying a height, diameter, or sphere value (for more information, see "Constructing a Circle from a Cone").

Gap & Flush

GAP = Distance (in the same plane) between two mating sheet metal parts. FLUSH = Height difference between two mating sheet metal parts. For example, if you're looking at a top view of an automobile, the distance between a car's fender and hood is the gap (distance between the two parts in one plane). If you look at a side view of the car the flush for the fender and the hood would be the height difference.

Garage

Locations in the probe rack that hold pieces of the probe assembly. Garages are also known as "ports" or "slots".

Gauge

See Gage.

Gaussian Filter

See 95% Confidence factor.

GD&T

Geometric Dimensioning and Tolerancing. This is a standardized, international language that uses a recognized symbology to communicate a part's design specifications.

Geometries

Geometries are features or geometrical shapes such as lines, circles, etc.

Global setting

A global setting is a statement or command that is added to the measurement routine that remains in effect for the remainder of the measurement routine unless it is changed by another modal command.

Gripper

This device, used with flexible fixturing, is placed on the end of the ram. It "grips" (or holds) columns in order to either remove them from their rack and position them on the worktable, or remove them from the worktable and place them back in their rack.

The gripper also uses air injectors (much like air hockey) to lift the column off of the worktable.

Guess Mode
When a fixed probe is used, PC-DMIS can't determine the type of feature that is being measured. Guess Mode allows you to indicate whether the feature is flat or round reducing the possibility of an incorrect guess.

Hard probe
A hard probe is a probe without a touch trigger or removable stylus.

HD
High Definition or High Density.

HEADER.DAT
This data file is used to provide formatting information for the Edit Report's headers. This includes all the pages after the first page.

High Point Feature
A High Point Feature is the type of feature created when using the High Point option of Auto features. (From the main menu Access the Auto features dialog box and then select the High Point tab) The High Point is the point along a specific vector through a surface which has no other point at a higher distance along that vector when compared to the centroid of the surface.

Hit
Contacting the stylus tip with the part. Also known as probing.

Hit Buffer
The hit buffer stores probe hits before you create a feature from those hits. The stored hits can be deleted by pressing the ALT and '-' (minus) key combination.

Hit Retract
This number is a user specified distance which tells the probe at what point to speed up again, after retracting from a probe hit on a part.

Home position
This XYZ position is the 0,0,0 machine location that the probe moves to each time the machine is powered on or off.

I/O
Input/Output

I/O channels
A numbered device in the controller that allows you to set the state to 1 or 0. Compatible devices can then be connected to each channel. One common example is to connect one channel to an air supply for an external device. Setting the channel to 1 turns on the air and setting it to 0 turns it off.

ID
Identification or Identity. Also Label or Feature Name.

IGES
International Graphics Exchange Specification file format.

Import
The process of retrieving a CAD file from a database and processing it into the PC-DMIS measurement routine.

Indent
A value set in from the edge of the feature (to the point location).

Independent curve
An Independent curve no longer depends on the feature set that was used to create it. If the feature set changes, the independent curve will not change.

Independent surface
An Independent surface no longer depends on the feature set that was used to create it. If the feature set changes, the independent surface will not change.

Indexable
The ability of the probe wrist to be positioned at certain predefined (indexed) angles. These positions are mechanically set at regular increments on indexing probe heads. These indexes can vary from 15 to less the 0.1. When a wrist is indexable it means that it has the capability of being moved to different positions within the increments available on that specific wrist.

Indirection
The value of the variable pointed to by the given variable.

Init Sample Hits
The initial sample hits are taken when learning a particular feature. Sample hits are used to determine the surface vector into which the measured feature projects.

Initial Touch Vector
The compensation vector for the start point of a scan.

InitVec (Initial Vector)
See Initial Touch Vector.

INTOF
Intersection of the given feature.

Iterative Alignment
This alignment takes a number of points which approximates the ideal (or nominal). From the points, a mathematical computation repeatedly adjusts or tries to approximate the alignment to the nominal. In a sense, it does a "best fit" computation with the points.

Kinematic Mount
A kinematic mount refers to a set of usually 3 precision tooling balls, receivers for the balls, and a fastening device which is used to provide a highly repeatable connection point for styli, probes, or probe heads. Kinematic mounts are frequently found on devices which may employ an automatic changer and will preclude the need for requalification.

Knot
A knot is a part of the mathematical definition of a spline. They are associated with the control points of a spline and help to define the shape of the spline.

Learn Mode
This term is used to describe the state of PC-DMIS when creating or appending to a measurement routine's instructions in the Edit window.

Learning
This term is often used to describe the process of creating instructions which appear in the PC-DMIS Edit window. This can be done through typing in the actual entries, selecting menu command from the menu bars, or by touching measurement points on a physical part with the CMM and pressing the jog box's DONE button or the keyboard's END key.

LEVEL - 3 +

This means that three or more features are needed to perform the Level command for an iterative alignment.

LEVEL set
This is the set of features needed to perform the Level command for an iterative alignment. See LEVEL -3 +.

Line Distance
The length of a line segment between two features.

Literals
Operands whose symbols literally describe their value. "3" is a literal of type integer. "3" means the number three. It never means the string character â€œ3â€ or â€œthreeâ€. A variable, such as "V1" does not literally denote its value, rather it is a label or holding place for a value. "V1" could hold a value of "2", "3", or "4" or any other number of object type. Literals often have very specific functions and meanings and at times can be used in place of arguments. See also "String Literals".

LK systems
LK systems are CMMs or CMM controllers produced by LK, as opposed to SHARPE models.

LMB
Least Material Boundary

LMC
Least Material Condition.

Logo.dat
This data file contains information that formats a document header for the first page of the Edit Report. It may contain information such as date, time, etc.

Looping
The act of repeating any portion of the measurement routine a predetermined number of times.

Machine Capability
This is the same as the process capability (see Capability Threshold), except standard deviation is calculated in a different way. It this case standard deviation is calculated based on the individual data, not subgroup data. This is essentially the only difference.

Machine Coordinates
The position, expressed as X, Y, and Z values, of a feature or object within the measurement volume of a CMM with respect to the machine's zero reference position.

Manual Probing Point
This refers to the fact that the operator manually moves the machine when taking the hit rather than the machine moving itself in DCC Mode.

Mark Set
This highlights a group of features that will be measured when the measurement routine is executed.

Mark Used
The Mark Used function (selected from the Probe Utilities dialog box) will scan a PC-DMIS measurement routine and mark or highlight the probe angles that are used or referenced by the measurement routine. This will then allow an operator to easily determine which probe angles or tips need to be qualified.

Master Arm Mode

This mode allows one arm, designated by the user as the "Master", on a multi arm CMM, to take precedence over another arm, designated as "Slave", in order to avoid collision of the arms. This is also known as Master / Slave mode.

Material Thickness

Material Thickness is a property which can be associated to CAD files. Many times, especially on parts constructed of sheetmetal, a CAD file will represent only one side of the material. Therefore, in order to accurately measure and dimension on the opposite side of the part, a correction thickness must be applied.

MCR

Module Change Rack

MDI

Multi-Document Interface. This is a program or user interface that allows more than one file open at a time (PC-DMIS for example allows you to have more than one measurement routine open at a time, making it an MDI application).

Measurement Routine

The measurement routine (or part program as it used to be called) is a file with textual commands and descriptions of how to measure or inspect an object. Each measurement routine has a unique name with a .prg file name extension. The measurement routine is created by a CMM programmer and is sometimes executed or ran by someone other than the person who created it. The measurement routine can be, but is not always, associated with a CAD model. If it is associated with a CAD model, the CAD file has the same file name as the measurement routine with a .CAD extension.

Measurement Volume

The measurement volume is the area in the machine that can actually be used for measurement. Although the machine dimensions may be large, the actual space that is available to use for measurement can be much smaller. The measurement volume can increase or decrease depending on the probe configuration (type of wrist, probe body & stylus) being used.

Meta-Character

A meta-character is a character that acts as a wild card for another alpha-numeric character or characters. There are two meta characters available in PC-DMIS: the Asterisk (*) meta-character and the Question mark (?) meta-character.

Microns

A micron is a unit of measurement, one millionth of a meter.

Minus-Lower tolerances

Gives a plus tolerance in the Minus Tolerance field. (i.e. 1.000 + .003 / +.001).

MMB

Maximum Material Boundary

MMC

Maximum Material Condition.

MMIV

This stands for the Micro Measure IV(tm) measurement software package.

MOD

Modular.

Model-space

This is the 3D coordinate space to which surface and curve geometry is mapped.

Modes
Modes are different program states available to PC-DMIS. Each mode offers specific functions. The modes available to PC-DMIS include: Program Mode, Translate Mode, DCC Mode, Manual Mode, and Text Box Mode.

MOHL
Mouse Over Highlighting. You can hover your pointer over CAD elements to highlight them.

Mount point
A defined XYZ location used during certain fixture and probe changer operations. The location is away from the rack, where the machine can move before and after the change cycle. It is a safe point with direct access from all the slots as well as to and from the measurement routine itself. When using multiple racks, the probe would also need to be able to travel from one mount point to the other without colliding with a rack, the part, a clamp, or some other obstruction.

Movement Range
The actual space (volume or area) that can be used on a machine for measurement. It is also known as Measurement Volume.

Moving Average
This is the average value of a set of data points that moves over time. Example: Given a subgroup size of 3 (the number of data points used in calculating a moving average) and the following set of data: [1,2,3,4,3,4,5,4,3,2,3] the first moving average is calculated from the first three points: [1,2,3]. Its value is 2. The second moving average is calculated by moving over one step to the right within the data, giving the following data: [2,3,4]. Its value is 3. The next 3 points are: [3,4,3]. Its average is 3.33. The next 3 are: [4,3,4]. This is done up to the end of the data.

Mrad
This is an abbreviation for milliradians. A milliradian is an angular distance of one thousandth of a radian.

MSE
Measurement Strategy Editor. This editor allows you to save groups of settings for each Auto feature.

Nested subroutines
These are subroutines which are called from (or nested within) another subroutine.

Newtons
A "newton" is a unit of force. One newton is the force needed to accelerate a mass of 1 kilogram to a speed of 1 meter per second per second.

Normal To
The phrase "normal to" a certain feature or geometrical element, simply means "perpendicular to" or at a 90 angle to some other feature.

Notch
A feature type which is similar to one-half of a square ended slot.

OCR
Optical Character Recognition

ODBC
Open Database Connectivity

Offset Feature

PC-DMIS allows three types of Offset Features, Offset Points, Offset Lines and Offset Planes. An Offset Feature is constructed from one or more other features. Each feature comprising the Offset Feature may then have an offset or correction value associated with it. Thereby, each feature contained in the offset feature may or may not actually coincide with the new constructed feature.

OLE

This stands for Object Linking and Embedding.

On Error

On Error is a function of some CMM controllers where if an electronic probe contacts or doesn't contact a part unexpectedly, the PC-DMIS measurement routine will branch to a separate set of instructions to be executed. This function may be called from the main menu by selecting the On Error menu item.

Open GL

Open Graphics Library. This refers to a library of graphic routines used to aid in the display of graphical information.

Operand

The part of an equation that is being operated on by an operator. In the equation "2+3", the numbers 2 and 3 are operands and the plus sign (+) is the operator.

Optical Probe

An Optical probe is a probe that uses optics to determine its location. For example, a laser probe would be considered an Optical Probe.

ORIGIN set

This is the set of features needed to perform the Set Origin command for an iterative alignment. See SET ORIGIN - 1.

Outliers

Outliers are "wild points" and usually result from glitches in the measuring process rather than representing actual material. You may find it useful to identify and ignore such points.

PA

This abbreviation stands for Polar Angle. Also seen as PANG. The Polar Angle is used in cylindrical coordinates and is used with Polar Radius. See PR.

Pang

This abbreviation stands for Polar Angle. Also seen as PA. The Polar Angle is used in cylindrical coordinates and is used with Polar Radius. See Prad.

Parameter-space

This is the 2D coordinate space of a surface's parametric domain. For example, one corner of a surface is defined at parameter position (0,0) and the opposite corner is at (1,1). Varying this parameter between these two positions defines the entire surface. Given the geometric definition of surface, a parameter-space position can be mapped to a model-space point.

Parent

A 'parent' is a command (or information from a command) used in another command.

Part Coordinates

The position, expressed as X, Y, and Z values, of a feature on a physical part with respect to an origin location.

Part Program

The old name for a measurement routine. See Measurement Routine.

PC-DMIS
The term "PC-DMIS" is derived from the acronym "DMIS", which stands for Dimensional Measuring Interface Standard.

Perm
Abbreviation for permanent. See Perm Sample Hits.

Perm Sample Hits
The number of sample hits which will be used in measuring a particular feature during execution of a measurement routine.

PH9
This is the model number of a particular Renishaw probe head. The abbreviation stands for Probe Head 9. This term is also used to refer generically to articulating motorized wrist type probe heads.

Pierce Point
An intersection point found on a CAD surface using the measured hit coordinates and approach vector. It is equivalent to a ray that uses the approach vector and starts from the hit's XYZ location and then, using the approach vector, pierces the surface at an appropriate point.

Pins
Pins are removable features that stick out of a part (as opposed to holes which go into the part). Pins are similar to "studs".

Pitch
Pitch is the distance moved along the axis of the feature in one revolution.

PlaneVec (Plane Vector)
See Boundary Plane Vector.

PMI
This is an abbreviation for the term "Product Manufacturing Information" and relates to design, manufacturing, quality or any other information that is included with 3D CAD model files.

PMM
This is a CMM brand manufactured by Leitz.

PNT TOL
This abbreviation for vector point tolerance is used in the Edit window (as PNT TOL = n) to specify the vector point tolerance for manual touches in an iterative alignment.

POI
Point of Interest

Point to Point Digitizing
Point to Point Digitizing is a process of gathering the data about the surface of a part for reverse engineering purposes. Data is gathered by scanning the part with a machine and software capable of generating discrete measurement points. Once a sufficient number of points are gathered, they are taken as a group and processed to generate the electronic surfaces of a part which can be used by CAD software to complete a design.

POLAR
Refers to a Polar (also seen in the Edit window as POLR) coordinate system containing U and V coordinates. U represents the polar radius and V represents the polar angle or vector.

POLR
An abbreviation for Polar.

Polyline
In computer graphics, a polyline is a continuous line made up of one or more line segments. A polyline is sometimes treated as a single object, or it may be divided into its component segments.

Port
Locations in the probe rack that hold pieces of the probe assembly. Ports are also known as "slots" or "garages".

Portlock
A hardware lock that connects to a USB or your printer port that is programmed to allow PC-DMIS and specific purchased options to run. PC-DMIS will not run on your computer unless you have a valid portlock attached.

Pose
The combined position and orientation of a rigid body or coordinate system: three translations and three rotations.

Potentiometers
These are instruments that measure electromotive forces.

PPAP
PPAP (Production Part Approval Process) defines requirements for production part approval.

PR
Stands for Polar Radius. Also seen as Prad. The Polar Radius is used in cylindrical coordinates with Polar Angle. See PA.

Prad
Stands for Polar Radius. Also seen as PR. The Polar Radius is used in cylindrical coordinates with Polar Angle. See PA.

Precedence
Precedence in algebraic expressions or assignment operations refers to the order in which operations occur. For example, multiplication has a higher precedence than addition therefore, the expression "2 + 3 X 6" evaluates to 20 since 2 is added to the result of 3 X 6. Not following precedence might result in the errant result of 30.

Pre-Hit
This is number which determines at what distance a probe will reduce speeds while approaching a part to take a hit.

Probe
The sensing unit that is attached either to the Ram of the CMM or the indexable wrist. The probe requires a stylus be mounted to it in order to gather measurement data (except in the case of a hard probe).

Probe Changer
A rack placed in the measurement volume of the CMM. The probe changer secures multiple probe types for use in a single measurement routine. The CMM can switch between probe types without the need of operator assistance.

Probe Depth
The Probe Depth is the location of the probe along the Z axis, normal to the CMM's table.

Probe Extension
A Probe extension is a cylindrical piece that is inserted between the probe head and the probe itself.

Probe Shanking
This is the accidental contact of the probe's shank with the part or a feature on the part.

Probing Cycle
This is the cycle of operation an analog probe/controller goes through to take a point.

PROE
ProEngineer CAD file format.

Profile
"A profile is the outline of an object in a given plane (two-dimensional figure). Profiles are formed by projecting a three-dimensional figure onto a plane or by taking cross sections through the figure."-ASME Y14.5M-1994 Dimensioning and Tolerancing. Often on CAD drawings, when you look at a surface in different views, it won't look like a surface, but a curve, line, or a collection of individual points. These are the result of this projection of a three-dimensional figure onto a plane or by taking cross sections through the figure.

Profile Error
This is the deviation of the actual or measured profile from the theoretical or nominal profile

Program Mode
This mode allows you to create your measurement routine in the Edit window. It also shows the image of the probe in the Graphical Display window.

Pt
Abbreviation for Point.

Qualification Tools
See Calibration Tool.

Qualify
To qualify also means to calibrate, or determine the position (of a probe tip, for example).

Question Mark (?) Meta-Character
The question mark meta-character (?) acts in the same way as the asterisk (*), except that the question mark meta-character will match only 1 alpha-numeric character.

Radian
A radian is a unit of angle measurement such that an angle of one radian has an arc length along the edge of the circle equal in length to the radius.

Ram
This refers to the end of the arm to which the probe is attached. On a horizontal machine, the Ram is the horizontal beam on the machine and usually moves in the X or Y axis of the machine. On a vertical machine (commonly called a "bridge" machine) the ram is mounted vertically and moves in the Z axis of the machine.

Read POS
Read Position. This function will get the current XYZ coordinates from the CMM controller.

RECT

Rectangular. Used where the referenced coordinate system should be expressed in rectangular (XY) or Cartesian (XYZ) form.

References
An expression syntax that refers to the value of data. All of the syntax used to access different data elements of the measurement routine. "CIR1.X" is a reference to the measured x value of the centroid of the feature called CIR1. "LINE.LENGTH" is a reference to the length of LINE. "C1.INPUT" is a reference to the input of the comment named C1.

Relearn Mode
This is a scan option for execution of a scan. If the Execute option is selected to RELEARN, then every time a scan is re-executed the compensation vectors for each scan point are recalculated.

RFS
Regardless of Feature Size.

RLE
RLE stands for Run Length Encoding and is a way of compressing bitmap files.

RMB
Regardless of Material Boundary

Rmeas
Relative Measurement. Can be used to create a new Auto feature at coordinates which are derived from the actual measured coordinates of a previously measured feature.

ROI
This is a computerized box displayed on the computer screen for the NC-100 video probe. Measurement of the feature must be within the box.

ROTATE - 2 +
This means that two or more features are needed to perform the Rotate command for an iterative alignment.

ROTATE set
This is the set of features needed to perform the Rotate command in an iterative alignment. See ROTATE - 2 +.

Round feature type
A round feature type is a circular or curved feature. See Round features.

Round features
Round features are defined as circles, spheres, cones, and cylinders. See Round feature type.

Round Guess
This is a mode of operation utilized when using a hard probe to set order of precedence for the software to guess the type of feature being measured. Round Guess will attempt to Solve for a circle, cylinder, cone, or sphere before a plane. See also Guess Mode.

RTF
Rich Text File.

Scan Point Density
The Scan Point density determines the number of hits that the CMM returns for each millimeter.

Scripting
See Basic Scripting.

Section lines
Section Lines are CAD entities that can be superimposed on a CAD drawing. Though they contain no dimensional or drawing information, they can be referenced by a Section scan to provide a linear scan across one particular section of a part. These are reference lines used by engineers when specifying locations of part features.

SET ORIGIN - 1
This means that one feature is needed to perform the Set Origin command for an iterative alignment.

Setting Gage
This is a piece of hardware used to calibrate the ACR3 Probe Rack. The setting gage is inserted into the specified port on the probe changer. You would then use the setting gage to take hits on the port without having to use the probe body.

Setting Gauge
See Setting Gage.

SFT
Soft probing cycle

Shank
This is the shaft portion of the stylus that extends from the measuring tip to the stylus mounting joint. In the case of a shank tip, there is no precision tip (see shank tip). The shaft which supports the qualification tool is also referred to as a shank.

Shank Qual
Shank Qualification is utilized with sheetmetal styli to provide the axis direction of the shank as well as the center point of the spherical tip end.

Shank Tip
Tip shaped like a straight shaft.

Shanking
A term used when the probe is triggered by contacting the part with the shank of the stylus as opposed to the tip of the stylus. When this occurs, erroneous data is gathered.

Sheet Bodies
This is Unigraphic's modeling engine's terminology for surfaces.

Sheetmetal Stylus
A sheetmetal stylus is designed for measuring very thin part. The sheetmetal stylus will have semi-spherical ball on its end with a short section of shank which is coaxial and concentric to the center of the ball.

Sheetmetal Thickness
See Material Thickness.

SHSP
Stylus Holder Setting Piece

Sigma
The Greek letter often used to represent standard deviation.

Slot
Locations in the probe rack that hold pieces of the probe assembly. Slots are also known as "ports" or "garages".

SNSDEF
This statement is a DMIS major word used to defined sensors in the DMIS language.

Soft Probing
Soft Probing (or SFT) is Leitz terminology for a frequently used probing mode used to measure soft materials.

Solid Bodies
This Unigraphic's modeling engine's terminology for solids.

Spacer
A user defined value indicating the offset distance between the edge of a feature and a sample point.

SPC
This stands for Statistical Process Control. In PC-DMIS SPC charts can be created and updated from a defined database.

Spline
A spline is a specific type of curve or surface. Splines are used in modeling because of their mathematical properties which make them easier to use in a wide variety of ways. Splines can be used in both curves and surfaces.

Square-up
"Square-up" means to align (or rotate) the part in the Graphical Display window until that part lines up and is parallel to an edge of the screen.

Standard Deviation
This is the root mean square of the deviation from the mean. In equation form it is this: sqrt((sum((xi-m)^2))/n-1) where: m = the mean value n = the number of data points xi = the ith data point.

Start Ang
Starting Angle.

Start point
The Start Point in a scan is the beginning point of the scan's execution.

State Mode
The four states of operation are Translate Mode, 2D Rotate Mode, 3D Rotate Mode, and Program Mode. These four options can be individually selected from PC-DMIS'S toolbar icons.

Statistical Output File
This file contains printable stats for a measurement routine. Information is saved in the file named "xtats11.tmp" usually in the PCDMIS directory or the location that you chose to install PC-DMIS.

STEP AP203 & AP214
STEP stands for Standard for the Exchange of Product Model Data. STEP was forwarded to the international community in 1988. It is a standard for the computer-interpretable representation and exchange of product data. The objective of STEP is to provide a neutral medium capable of describing a product throughout its life cycle.

Step Mode
Step Mode is a variation in execution of a measurement routine in which the CMM will execute only one block of commands at a time. User intervention is required for the program to continue. In effect, this is 'stepping' through the measurement routine.

Stitch Type Scan

This is the type of scanning performed on DCC CMMs which have Touch Trigger Probes. During the scan, the CMM will contact the part, move away the retract distance, move to the next prehit point, then move in and contact the part. This process continues to repeat until the scan is complete. The term Stitch Type comes from this process which is similar to the functioning of a sewing machine.

STL

Stereolithography format. An ASCII or binary file used in manufacturing, provides a list of the triangular facets that describe a computer generated solid model.

Studs

Studs are non-removable features that stick out of a part (as opposed to holes which go into the part). Pins are similar to "studs".

Stylus

Also referred to as "Probe Stylus" is a cylindrical shaft (shank) with a high precision tip. The stylus screws into the probe body and is usually interchangeable with other Styli (plural for stylus).

Stylus Changer

See Probe Changer.

Stylus Extension

A Stylus extension is a cylindrical piece that attaches to the probe body and to the stylus. It is used to extend the length of the measuring tip. Multiple extensions can be used at one time.

Stylus Holder

The Stylus Holder is a part of the probe assembly that the software drops off or picks up from a probe changer. It is the component that the system exchanges within the probe changer. There are many places in the probe changer calibration process where the software prompts to make sure the stylus holders are removed from the probe changer ports before PC-DMIS proceeds with the measurement of the probe changer. This is necessary in situations where the ports need to be empty so the system can reach them during the measurement process.

Subroutine

A subroutine is a sub-program within the measurement routine. These sub-programs contain commands from the current file or an external file and that are able to be used repeatedly.

Surface of Revolution

This is a surface which may be generated by rotating a curve plane about an axis in its plane.

System Calibration

This is the process of checking the accuracy of a CMM and making adjustments mechanically to the CMM or electronically to the VolComp file to reduce the inaccuracy.

TAPER TIP

Tip that has been tapered to a conical shape which gets smaller toward the end.

TARG

This stands for target. It is the size or location information at which the CMM will try to measure.

Tessellation

The act of breaking up a surface into a group of polygons in order to shade a graphical image.

THEO
This stands for theoretical. It is the nominal size or location information.

Thread
The portion of the tip that is screwed into another part is referenced by the size of thread. The tread is the corkscrewed band that holds the parts together.

Time Delta
This user specified value is used to weed out hits taken with manual scans using a hard probe that come in faster than the specified time increment. The increments are in seconds.

Tip
This is the portion of the stylus that comes into contact with the part being inspected/measured. Styli may have several types of tips. The tip can be a ball, disc, or a pointer.

Tip Changer
See Probe Changer.

TKJ Pin
This refers to the Tesa Kinematic Joint pin. A wrist that has the TKJ connection has a nub that the TKJ locks onto. The "nub" is the TKJ Pin.

TOG
TOG is a "toggle" field in the Edit window. To toggle through the available options within the Edit window, place the cursor over toggle field and press F7.

Tool Changer
See Probe Changer.

Touch Trigger Probe
This type of probe automatically triggers a hit when it touches the part.

TP
Acronym for the old "True Position" term. Now known as "Position" in the software.

Tracefield
This two field command is used in PC-DMIS's Edit window. The first field represents the name or title of the tracefield. The second field displays the current value of the tracefield (such as "Temperature : 75" or "Shift : afternoon"). Tracefield data is often included with measurement data when a measurement run (or transaction) is sent to a database.

Translate Mode
This places PC-DMIS into a program state which allows you to move the part on the screen as well as change the part's display size in the Graphic Display window, etc.

Trihedron
A graphical representation of the planes meeting and forming a point. Also termed a trihedral.

TTP
See Touch Trigger Probe.

T-Value

The distance of the measured hit from the nominal point along the nominal CAD surface vector. In technical terms, it is the combination of the difference in the 3 axes for the hit, essentially the square root of the sums of the squares.

UG

UniGraphics CAD file type.

UPR

This stands for Undulations Per Revolution.

Variable

An object used to hold a value. A variable has a name and a value. The name is used to access the value of the variable. The name is constant, the value can be changed. For example, the statement ASSIGN/V1 = 2 creates a variable with a name of V1 and a value of 2. ASSIGN/V2 = V1 + 2 accesses the value of V1. If V1 still had a value of 2 when this assign statement was executed, V2 would then have a value of 4. A variable is a value that refers to integer, real, string or point operands.

Variable Delta

Variable Delta is a type of scan that can be accomplished only with a hard probe. During a Variable Delta scan, data points are read only when the requirements of a specific minimum time increment, and a minimum distance increment are achieved.

VDAF

VDAF stands for VDA Surface Data Interface format. VDAFS was published as a German national standard in 1986. It is used by the German Motor Manufacturers Association (VDA) to exchange 3D CAD model data.

VDAFS

See VDAF.

View ID

View ID is a user defined name for a view that the user has saved in memory.

VolComp File

The "comp.dat" file. For a CMM to measure accurately, this file must be located in the PC-DMIS operating directory of the computer used to operate CMM's which are Volumetrically Compensated. See Volumetric Compensation (VolComp).

Volumetric Compensation (VolComp)

Volumetric Compensation is the process of accessing a CMM's Error Map and applying the error as a correction factor to measurements in order to enhance the accuracy of the CMM. This is accomplished automatically by PC-DMIS once a CMM has been properly initialized. (See also Error Map.)

Weight

A value calculated from a tolerance used when calculating a best fit. The smaller the tolerance the less room there is for error. A smaller tolerance, then, carries a greater "weight" or importance in a best fit calculation.

Wild Cards

Wild Cards are made up of two meta-characters, the asterisk (*) and the question mark (?). The asterisk meta-character (*) will match, or take the place, of any character or characters in a search. The question mark meta-character (?) acts in the same way as the asterisk (*), except that the question mark meta-character will match only 1 alpha-numeric character.

Wire Bodies

This is Unigraphic's modeling engine's terminology for wireframe features (wire, lines, curves, etc.).

Workplane

The Active and Pass Through Planes define the workplane. PC-DMIS allows you to indicate the specific plane into which a feature is projected when it is measured. The term "work" is the same as "current" or "active" when referring to the workplane.

Wrist Map

See Error Map and Volumetric Compensation.

Wrist Warning Delta

This option can be found on the Part/Cmm tab of the Setup Options dialog box. If a CAD selected feature to be measured does not have a vector which agrees with the active probe angle within the Wrist Warning Delta limit, a warning is generated.

X, Y, and Z Center

These values show the location of the center of the ball tip.

XBarR

XBar is a way of writing out the statistical symbol X which is the mean or average. Thus, the XBar chart is a mean or average of a process. This is usually calculated over time and the chart is set up such that the X axis of the chart is time and the Y axis of the chart is the mean value. XBarR is an abbreviation for "XBar and R". This is essentially an XBar chart with additional information. The "R" represents the range of data in any given sample. A sample is defined as a predetermined number of measurements. The range of a sample is calculated by subtracting the Min from the Max of the sample. This is then plotted at the same time position on the chart as the mean of the sample giving two data points for the sample at that time.

XBarS

XBar is a way of writing out the statistical symbol X which is the mean or average. Thus, the XBar chart is a mean or average of a process. This is usually calculated over time and the chart is set up such that the X axis of the chart is time and the Y axis of the chart is the mean value. XBarS is an abbreviation for "XBar and S". This is essentially an XBar chart with additional information. The "S" represents the Standard Deviation of the sample. There is a mathematical equation to determine the standard deviation of a sample.

Z rail

The Z rail is the vertical arm of the CMM.
