
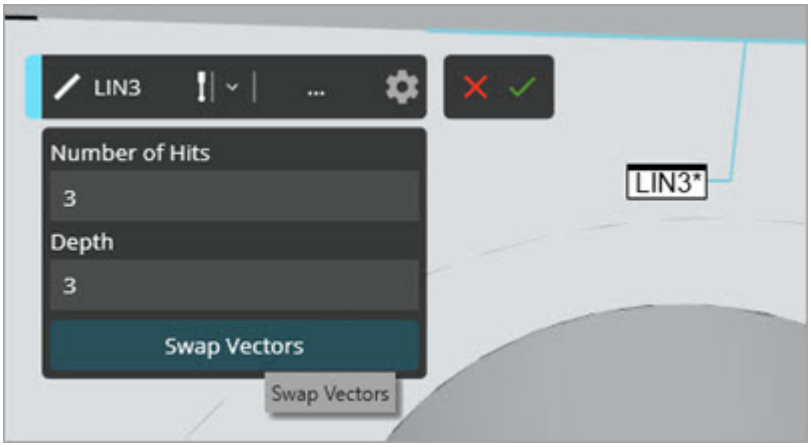
Example of a line feature constructed from two colinear elements.

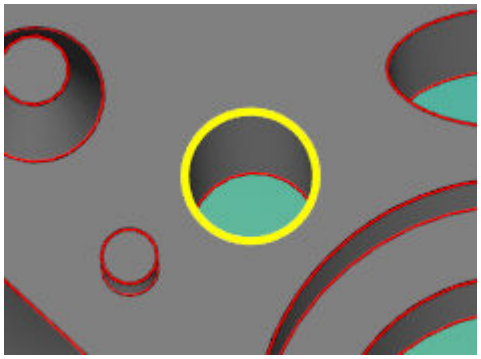
You can use the **Swap Vectors** button on the QuickFeatures Widget to flip the edge vector of the line.



Example of the Swap Vectors button on the QuickFeatures widget.

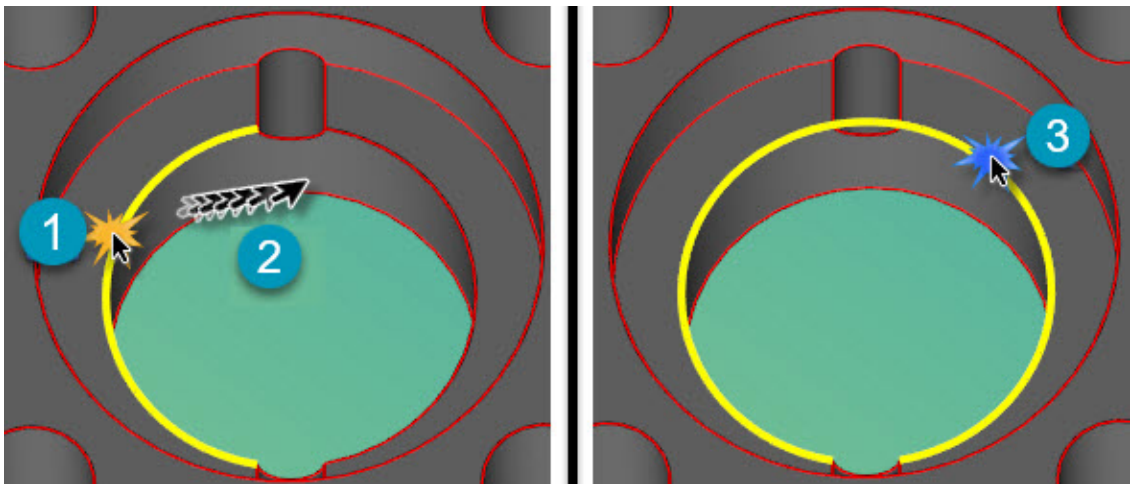
Creating Circle Features

- To create a basic circle feature, press and hold the Shift key, then hover the pointer over the circle's arc. Once it highlights the circle, click the circle to create the feature.



- To create a circle feature from two disjointed arcs:

  1. Press and hold the Shift key, hover the pointer over one arc, and then click to select the arc.
  2. Move the pointer to the other arc to highlight it.
  3. Once the entire circle is highlighted, release the mouse button to create the feature.

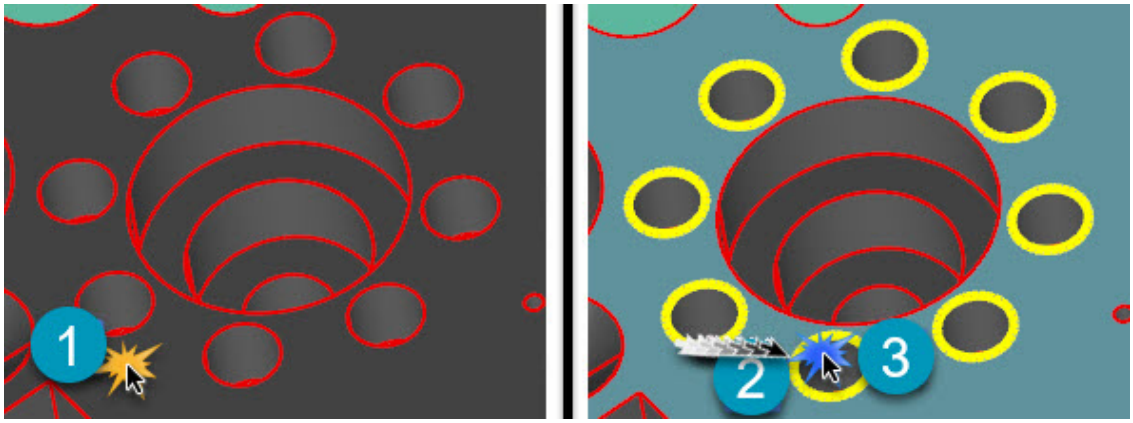


Creating Circular Multi-QuickFeatures

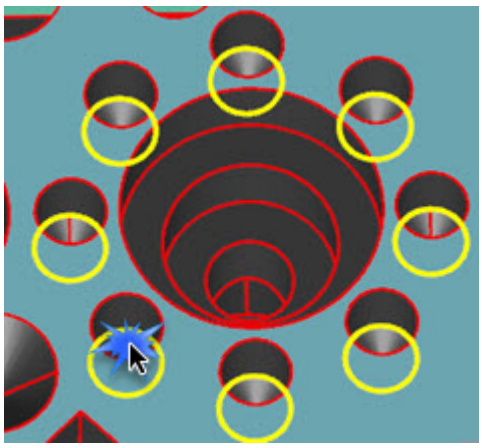
This procedure creates circular features (circles or cylinders) of the same size, such as a bolt hole pattern:

- To create multiple circular features:

  1. Select one or more surfaces, and then press and hold the Shift key.
  2. Hover the pointer over one circular feature to highlight all circular features of that diameter on those surfaces.
  3. Once all the features are highlighted, click the feature to create the highlighted circular features.



- You can also create multiple circular features from countersunk and counterbored holes. To do this, follow the instructions in the preceding paragraph, but select the circular features just below the surface.



The counterbore and countersink algorithm works better with models that natively contain surface topology, such as these model types:

- ACIS
- CATIAv5
- CATIAv6
- Creo
- Inventor
- JT
- NX
- Parasolid
- Solid Edge
- SolidWorks
- STEP

IGES files do not work as well, because they do not contain surface topology.

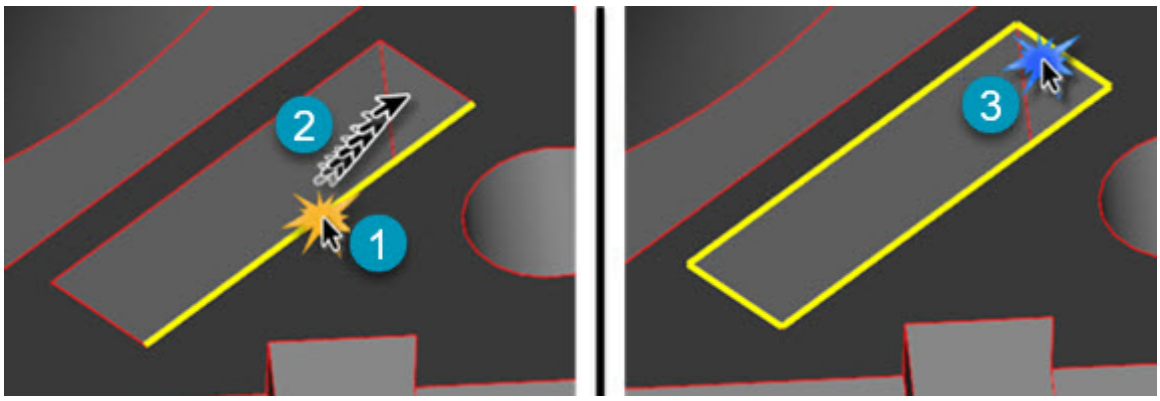
Multi-QuickFeatures work with up to 500 circular features per surface. If you have a surface with more than 500 circular features, Multi_QuickFeatures does nothing. In that case, you need to use the box-select method to create the features. For information, see "Box Selecting to Create Multiple Auto Features".

Creating Square Slot Features

To create a square slot:

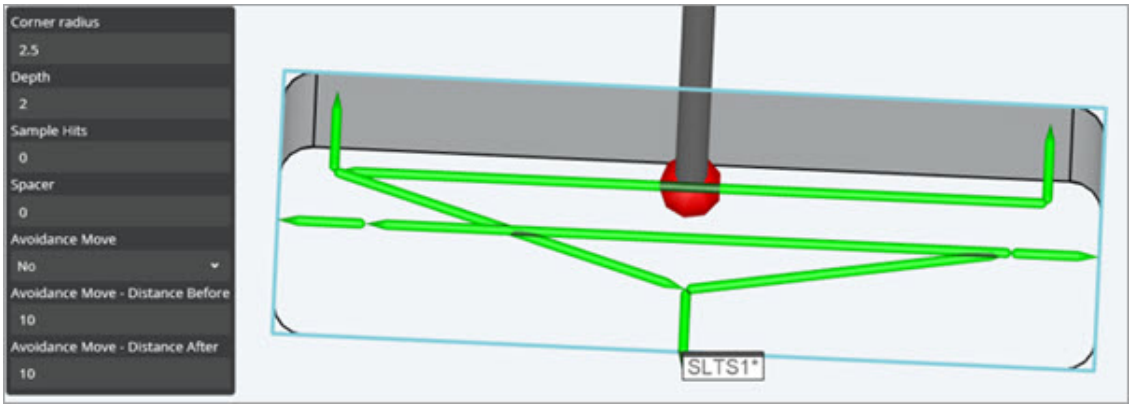
1. Press and hold Shift, and then hover the pointer over one edge of the slot, click and drag the pointer for a short distance along the edge to highlight it.
2. Move the pointer to an adjacent edge.

3. Once the entire slot is highlighted, release the mouse button to create the feature.

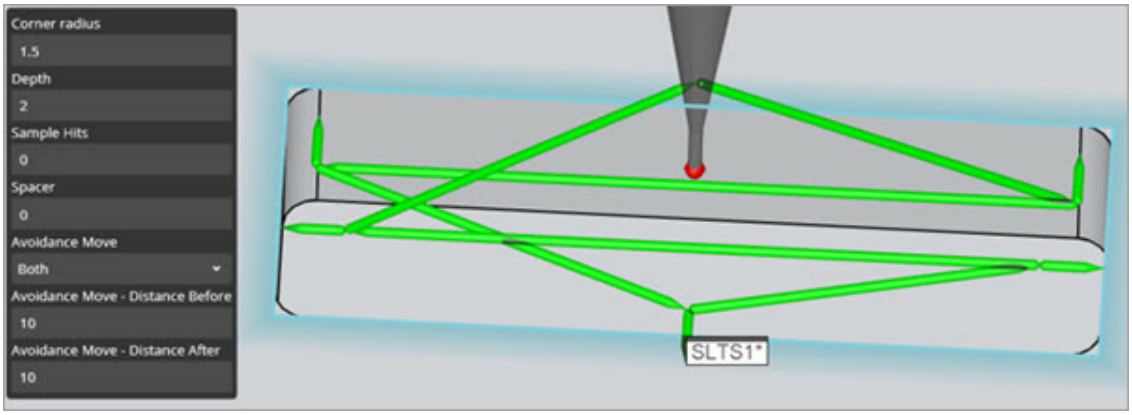


If the slot corner has a radius, PC-DMIS detects it and applies one of these rules:

If the detected blend radius is less than or equal to the currently loaded probe's active tip radius, PC-DMIS sets the auto-slot's corner radius value equal to the active tip radius + 1 mm.



If the detected blend radius is greater than the currently loaded probe's active tip radius, PC-DMIS sets the auto-slot's corner radius equal to the detected blend radius value.



To create square slots that are on a non-planar surface, repeat the above steps but hover the pointer over the planar surface sides of the square slot instead of the edges.

Creating Round Slot Features

- To create a round slot:

  1. Press and hold Shift, and then hover the pointer over one of the circular ends of the slot and click and drag the pointer a short distance along the curve to highlight it.
  2. Move the pointer to a straight side.
  3. Once the entire slot is highlighted, release the mouse button to create the feature.

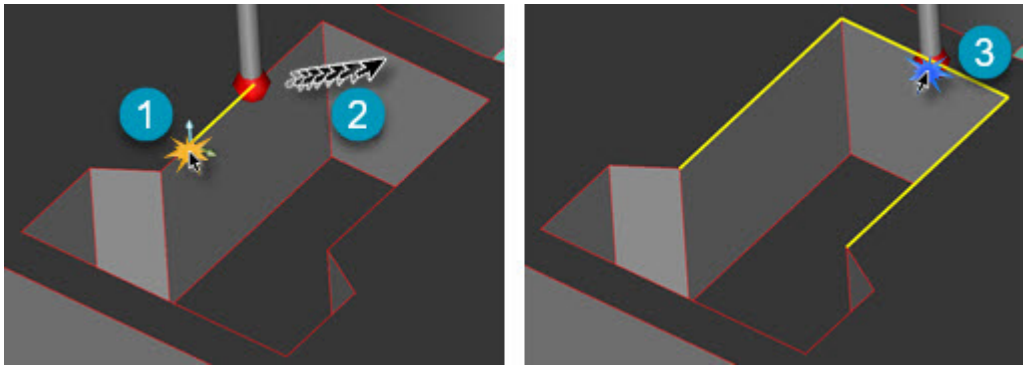
  
  You can also start by hovering over a straight side, click and drag the pointer a short distance to highlight it. Then move the pointer to a circular end. Once the slot is highlighted, release the mouse button to create the feature.

- To create round slots that are on a non-planar surface, repeat the above steps but hover the pointer over a cylindrical end of the round slot instead of a circular edge.

Creating Notch Slot Features

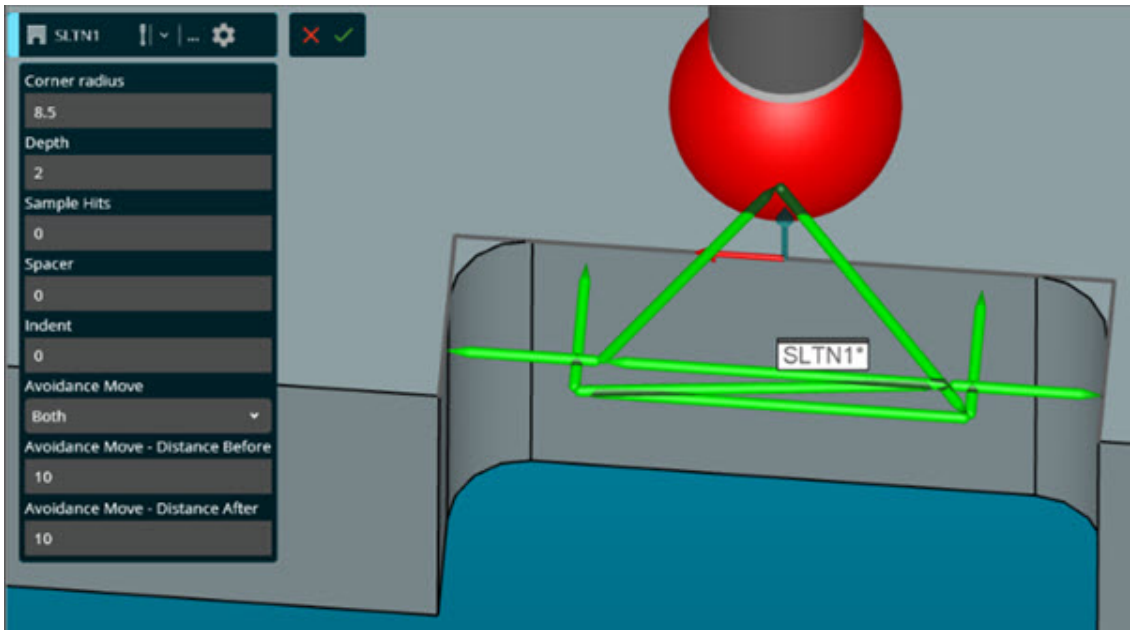
To create a notch slot:

1. Press and hold Shift, and then hover the pointer over one of the legs of the notch.
2. Click and drag the pointer a short distance along the leg to highlight it (1).
3. Move the pointer to an adjacent side (2).
4. Once the entire notch is highlighted, release the mouse button (3).

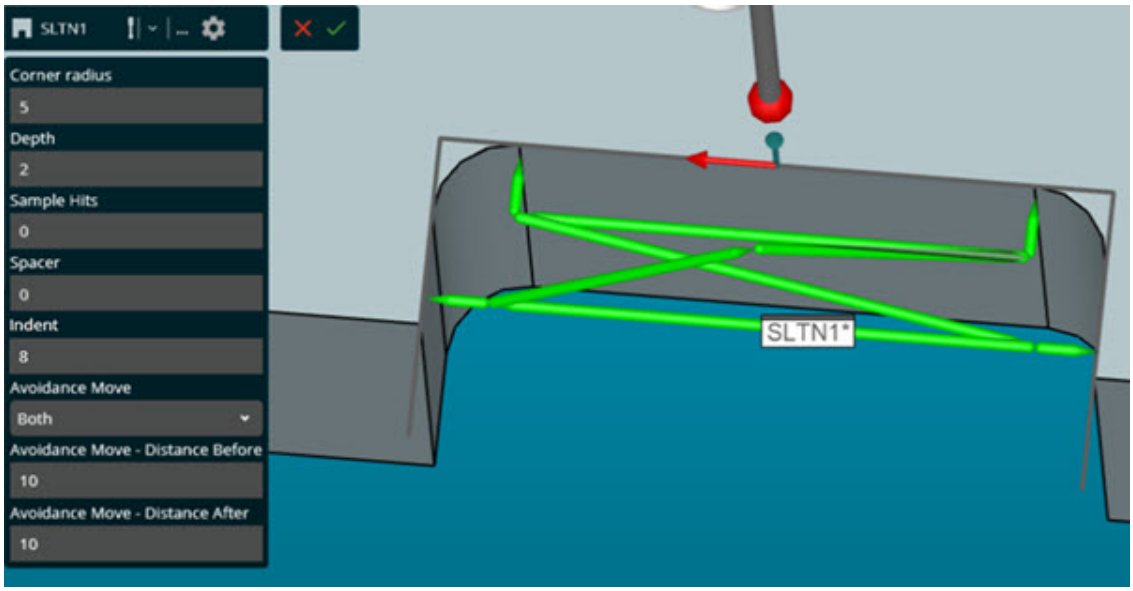


If the notch corner has a radius, PC-DMIS detects it and applies one of these rules:

- If the detected blend radius is less than or equal to the currently loaded probe's active tip radius, PC-DMIS sets the auto-slot's corner radius value equal to the active tip radius + 1 mm.



- If the detected blend radius is greater than the currently loaded probe's active tip radius, PC-DMIS sets the auto-slot's corner radius equal to the detected blend value.



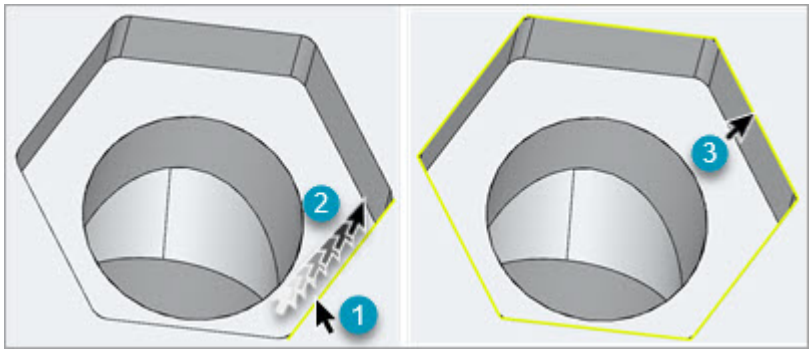
Regardless if the notch has a corner radius or not, the `INDENT` value is always defined to position the hits mid-way along the flat portion of the side walls of the notch.

Creating Polygon Features

To create a polygon feature:

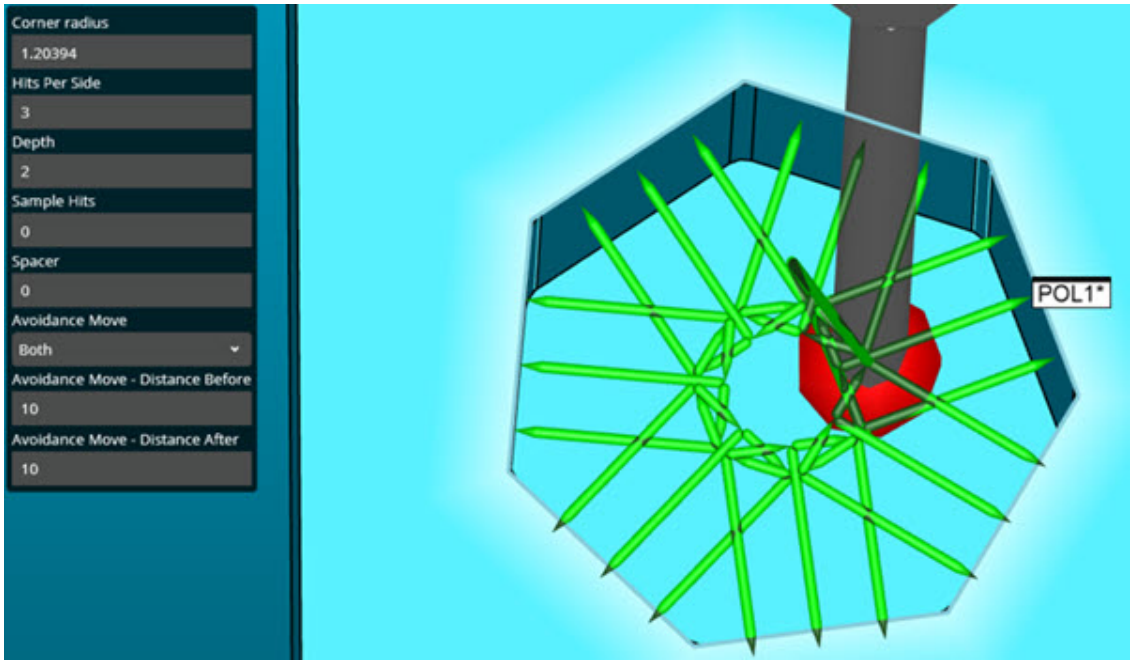
1. Press and hold Shift, and then hover the pointer over one side of the polygon.

2. Click and drag the pointer a short distance along the side to highlight it (1).
3. Move the pointer to an adjacent side (2).
4. Once the entire polygon is highlighted, release the mouse button (3).

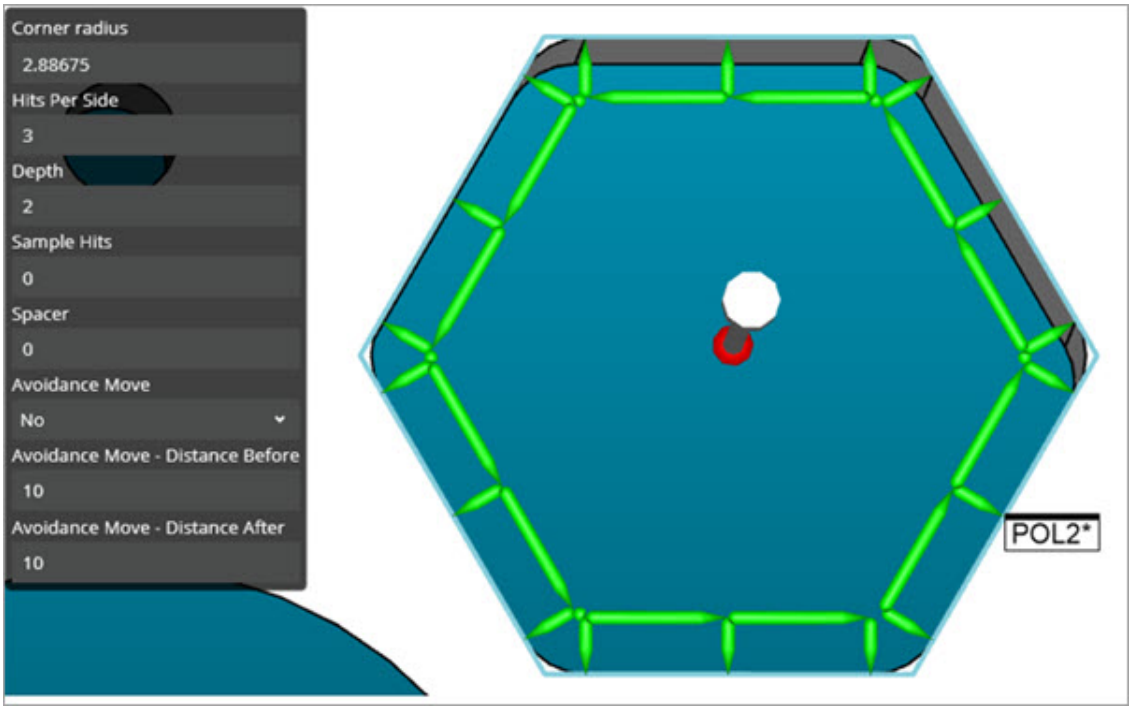


If the polygon corner has a radius, PC-DMIS detects it and applies one of these rules:

- If the detected blend radius is less than or equal to the currently loaded probe's active tip radius, PC-DMIS sets the auto-polygon's corner radius based on a formula which takes the active tip radius, the detected blend radius and the number of sides into account. The probe tip should always clear the corner radius and adjacent wall when taking hits.



- If the detected blend radius is greater than the currently loaded probe's active tip radius, PC-DMIS sets the auto-polygon's corner radius value equal to the tangent point between the detected blend radius and the straight section.



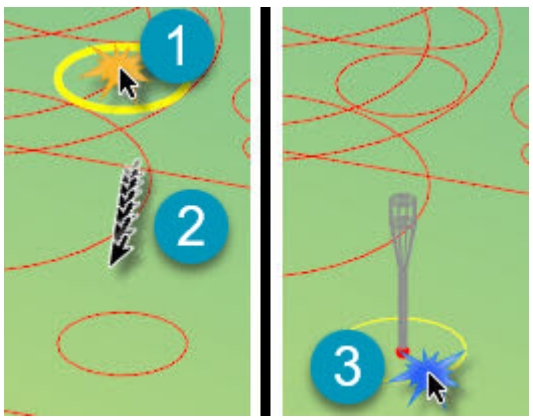
Creating Features from Wireframe Models

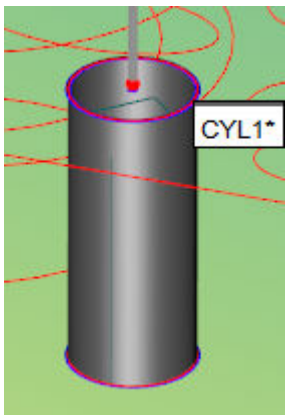
You can create any feature except those mentioned in the "Requirements" heading above.

From the **Graphic Modes** toolbar, select **Curve Mode** and then follow the instructions given in this topic to create the feature as usual.

Cone and cylinder features require two circle elements with coaxial centroids. For cone and cylinder features:

1. Press the Shift key and then hover the pointer over one of the circles making up the feature (1).
2. Click to highlight that circle.
3. Move the pointer to highlight the feature's other circle (2).
4. Once both elements are highlighted, release the mouse button to create the cone or cylinder from the two circles (3).





Example of a cylinder feature created from wireframe elements.

Creating Vector Point Features by Box-Selecting

If your CAD model has a lot of point features, you can quickly create them by box-selecting them. For this to work, the CAD model must already have the points defined as individual CAD elements. Also, the part model must have surface data.

1. From the **Graphic Modes** toolbar, select **Curve Mode** .
2. Press and hold Shift.
3. Click and drag a box around the point features.
4. Release the mouse button to create vector point features from the selected point CAD elements.

Using the Measurement Strategy Widget

The measurement strategy widget lets you change a feature's main parameters for the following items:

- QuickFeatures - For more information on QuickFeatures, see "Creating QuickFeatures" in the previous main topic.
- Features created during GD&T selection of embedded GD&T callouts - For more information on GD&T selection, see "Importing CAD GD&T Callouts" under "Working with CAD GD&T Callouts" in the "Editing the CAD Display: Introduction" chapter.

By default, PC-DMIS shows the widget for CMM configurations. For portable configurations, it hides the widget. For CMM configurations, the measurement strategy widget appears whenever you create one of those features, and there is no other dialog box open. You can change this default behavior from the **Use Measurement Strategy Widget** check box in the **General** tab of the **Setup Option** dialog box. For more information, see "Use Measurement Strategy Widget" in the "Setting Your Preferences" chapter.

When the measurement strategy widget appears, PC-DMIS creates the feature or features in the Edit window. As you make changes to a feature with this widget, PC-DMIS makes the same changes in the Edit window command.

> When the measurement strategy widget is open, you cannot access most other PC-DMIS options, including **Edit | Undo**. If something isn't available in PC-DMIS that you expect to see, check if the measurement strategy widget is open.

The measurement strategy widget has these labeled components:

A. **Grab bar** - The bar on the left is the grab bar. You can reposition the widget with this bar.

B. **[Feature Type]** - This icon and the tooltip text represent the feature type (Circle, Cylinder, and so on). During a GD&T selection import, for some features, you can change the feature type. In that case, a drop-down arrow with additional feature choices appears to the right of the icon.

C. **Feature** - This text shows the feature's name. You can click the text and type a new name.

D. **Sensor** - This is a view-only icon. It represents the type of sensor PC-DMIS needs to measure the feature. A probe icon means PC-DMIS needs to measure the feature with a contact probe sensor.

E. **Strategy** - You can use this list to change the selected measurement strategy.

- If you use a touch-trigger probe, the list contains a strategy named **Touch Trigger User-Defined**. With this strategy, you can click **Properties** and then click on the CAD model to define where PC-DMIS takes the hits.
- If you want to create a custom strategy, you can use the Measurement Strategy Editor. For more information on the Measurement Strategy Editor, see "Using the Measurement Strategy Editor" in the "Setting Your Preferences" chapter.

F. **Options** - This icon shows this menu of options:

- **Save as Default** - This saves your changes as the new default settings for the current feature type. PC-DMIS saves these defaults in the Measurement Strategy Editor.

This is available if you mark the **Use Measurement Strategy** check box from the **General** tab of the **Setup Options** dialog box (F5). For information, see "Using the Measurement Strategy Editor (MSE)" in the "Setting Your Preferences" chapter.

G. **Properties** - Click to display the feature's main properties. You can use the values that appear to change those properties. If you want to change other properties or change what properties appear in the widget, you can use the Measurement Strategy Editor. If you use the **Touch Trigger User-Defined** strategy, the **Properties** shows a **Number of Hits** display. With this display open, you can click on the CAD model to define where PC-DMIS takes the hits.

H. **Cancel** - This closes the widget and removes any features that PC-DMIS created when the widget first opened for the QuickFeature or GD&T callout. It does not remove a feature once you click **Apply** to confirm its creation.

I. **Apply** - This confirms any changes you made to the current feature. If you created only one feature, the widget applies the change and then closes. If you created more than one feature, the widget applies the change to the current feature, and then it shows the next created feature. For QuickFeatures, if you create a new feature and you don't click **Apply** first, the software applies your feature, and the measurement strategy widget shows your next feature. This also works with multi-QuickFeatures.

J. **Apply All** - This confirms any changes you made to all the created features. If you have already used the **Apply** button to modify properties on one or more features, **Apply All** applies the changes to only the *remaining* features.

There's also a grid button that appears on some parameters. The color of the grid button indicates whether the grid is enabled.

- If the button is gray, smart parameters are currently disabled. You can click this button to enable them.
- If the button is green, smart parameters are currently enabled. You can click this button to disable them.

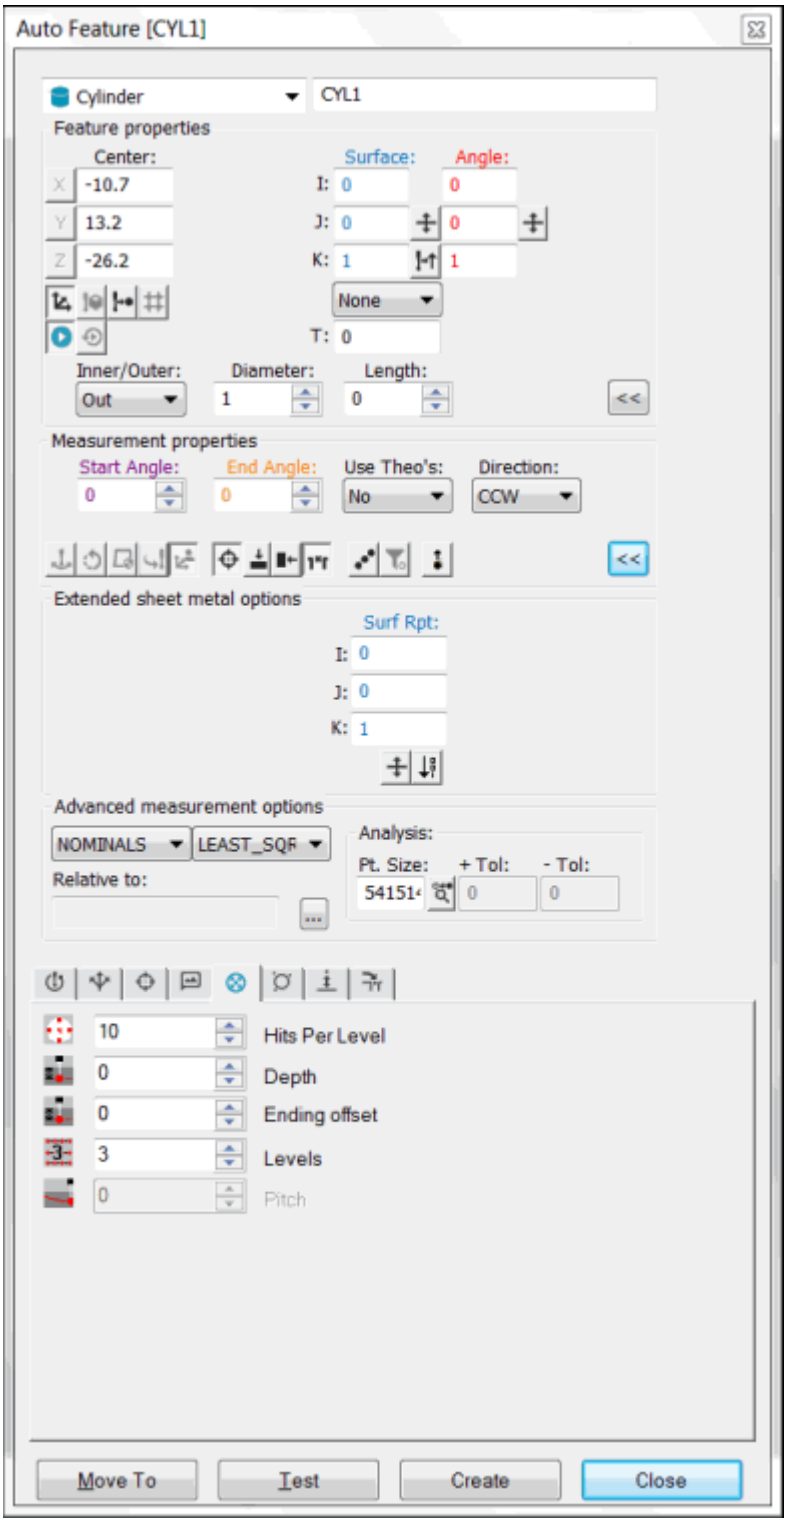
The value of the setting to the left of the grid button shows the value PC-DMIS chooses for the feature. You can click the grid button to switch between the smart parameter value and the default value for the feature you're creating.

If you want to define a custom value, turn off smart parameters and type the value.

For more information on smart parameters, see "Working with Smart Parameters" in the "Setting Your Preferences" chapter.

The Auto Feature Dialog Box

To create an Auto feature, use the **Auto Feature** dialog box. To open the dialog box, select **Insert | Feature | Auto** and then select an item from that menu.



Example of the Auto Feature dialog box for a cylinder feature.

Whenever you open or modify the **Auto Feature** dialog box, PC-DMIS queries the values from and stores them in a JSON file.

For information about the default settings and on how to use the Measurement Strategy Editor to change default settings, see "Using the Measurement Strategy Editor" topic.

Probe Deflection and CAD Click Behavior

If the **Auto Feature** dialog box is open, and PC-DMIS detects a probe hit, it assumes you are trying to learn the currently selected Auto feature type. The software shows a prompt to inform you to measure the remaining hits (if any) to complete the learn process.

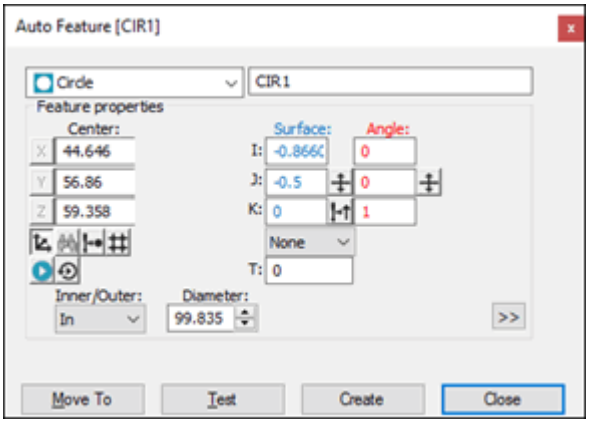
Similarly, if you click on the CAD data while the **Auto Feature** dialog box is open, PC-DMIS assumes that you are trying to learn the currently selected feature type. It populates the dialog box with the information it gathers from the CAD model.

Probe Toolbox

Because PC-DMIS frequently uses the items in the Probe Toolbox when you create Auto features, the Probe Toolbox exists as an embedded portion of the **Auto Feature** dialog box.

Basic or Advanced Configurations

By default, PC-DMIS displays the **Auto Feature** dialog box in a basic configuration where advanced options are hidden from view:



Auto Feature dialog box in its basic configuration.

Click this button in the **Feature properties** area to show this dialog box in an advanced configuration. If the Probe Toolbox is visible before you open the **Auto Feature** dialog box, it is visible, even with the basic configuration. In some configurations of PC-DMIS, such as laser or vision, the Probe Toolbox appears attached to the basic configuration.

Docking or Undocking the Auto Feature Dialog Box

The **Auto Feature** dialog box docks into the left and right sides of the screen by default. If desired, you can change its state to hover over the user interface instead. To do this:

1. Press the Ctrl key, drag the dialog box to a new location, and release the mouse. The dialog box now hovers over the interface.

2. Right-click on the title bar and from the menu, choose **Floating**.

   The next time you open the dialog box, it remains in this floating mode.

3. To return the dialog box to a dockable mode, select **Dockable** from that menu instead.

You can also hold down the Ctrl key while you drag the **Auto Feature** dialog box to prevent it temporarily from docking.

Auto Feature Type List

The **Auto Feature Type** list shows the currently selected Auto feature type. You can also use this list to change to a different Auto feature type. All the supported auto features for your configuration are available from this list. If you change to a different Auto feature type, the **Auto Feature** dialog box changes its contents with items used to create the newly selected feature type.

ID Box

The **ID** box shows the current ID for the Auto feature being created. You can change the ID to something different by modifying this value.

Feature Properties Area

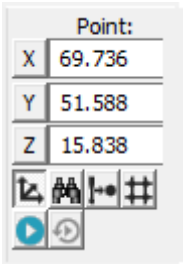
The **Feature Properties** area of the **Auto Feature** dialog box contains some or all of the following items, depending on the Auto feature you are creating.

 XYZ Point boxes	 IJKT Surface boxes Use Thickness	 IJK Edge boxes
 IJK Surface Vector boxes	 IJK Line Vec boxes	 IJK Angle boxes
 XYZ Start Point boxes	 XYZ Start / End boxes	 XYZ Center boxes

An Example:

Auto Line Vectors

XYZ Point Boxes



For a High Point feature, the **XYZ Point** boxes display the X, Y, and Z nominal for the start point.

After the new value is created, PC-DMIS draws the animated probe at the new location. This location indicates the beginning position of the search. After the execution is complete, the XYZ point contains the high point in the current workplane. Subsequent executions however use the original start point for the search.

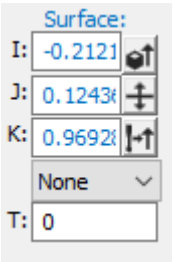
For all other feature types, the **XYZ Point** boxes display the X, Y, and Z nominal for the location of the feature.

After the new value is created, PC-DMIS draws the animated probe at the new location. This location indicates where the probe takes the hit on the part.

For information on the **X**, **Y**, and **Z** axes check boxes, see the "Find Nearest CAD Element" topic.

Icon	Description
	Polar / Cartesian
	Find Nearest CAD Element
	Read Point from Machine
	Snap to Grid
	Measure Now
	Re-Measure

IJKT Surface Boxes



I, J, and K Boxes

These boxes contain the I, J, and K normal vectors that you supply. The I, J, and K should always point away from the surface. After the new value is created, PC-DMIS normalizes the vector, making its length one unit. This vector is used for probe compensation. PC-DMIS displays a corresponding colored arrow showing the surface vector.

If you cannot see the vector arrow or if it appears too small, try changing the value in the **Pt. Size** box in the **Analysis** area. Setting **Pt. Size** to 0 will generally set both the point and the arrow to a desirable size.

For vector point, surface point, and high points: The **IJK Surface** boxes display the approach direction for the hit that was taken to create the Auto feature. For vector points, if you display the feature in **Polar** coordinates, and modify the **A** angle, the surface vector updates automatically. For more information on how to switch between Cartesian and Polar coordinates, see "Polar / Cartesian Toggle".

For high points: After execution, the IJK normal vector will display the approach vector for the high point in the current workplane.

For the circle, cylinder, sphere, and cone features: The **IJK Surface** boxes define the feature centerline. A cone's vector is very important. The normal vector of a cone feature is the direction of the cone from its tip to its base. The height and depth of a cone are always relative to this vector.

For the square slot, round slot, ellipse, and notch features: The **IJK Surface** boxes define the surface normal vector of the plane that the feature lies in (the plane parallel to the feature).

For a plane feature: The **IJK Surface** boxes define the approach direction for the plane's hits.

For a line feature: The **IJK Surface** boxes help define the edge for the auto line hits. Specifically, it defines the surface perpendicular to the surface on which the hits for the line are taken. In other words, it is always perpendicular to the edge vector. See "Example of Auto Line Vectors".

T List and Box

The **T** ("thickness") list and box enable you to select the thickness type (theoretical, actual, or no thickness). For more information, see "Use Thickness".

Icons

Icon	Description
	Find Vectors
	Flip Vector
	Read Vector From Machine

Polar / Cartesian

This icon switches your coordinate system between **Polar** and **Cartesian** modes. This changes the coordinate system PC-DMIS uses to display the point or center values for the Auto feature.

In **Polar** mode, when the icon is raised, the values appear as radius, angle, and height (shown as **R**, **A**, and **H** in the dialog box). The height depends on the workplane currently being used. If the current workplane is ZPLUS, the height is the Z value. In this mode, if you are modifying a Vector Point feature and update the value of the angle in the **A** box, PC-DMIS automatically updates the corresponding surface vector of the feature. This helps you to update the surface vector in measurement routines that don't use CAD. For more information on the surface vector value, see "IJKT Surface Boxes".

Inner/Outer/None list

In **Polar** mode, if you select the Azimuth angle (A) or you select the In or Out option from the list and the proper symmetry is set (Cylindrical or Spherical), the surface vector is correctly defined. If you select None, no change is applied to the surface vector.

The **Inner/Outer/None** is only available when you select the Polar mode option. PC-DMIS applies it when you either:

- Select the Azimuth (A) data value, and validate the data.
- Change the option from In to Out (or Out to In). The software does not apply it when you click on your CAD model in the Graphic Display window. If you select the CAD in the Graphic Display window, you get the surface vector of the exposed CAD.

The **Inner/Outer/None** information for auto vector and auto surface points are not explicitly exposed in the Edit window when it is in Summary Mode, Command Mode, or DMIS Mode.

In **Cartesian** mode, when the icon is depressed, the values appear in XYZ.

Find Nearest CAD Element

When the **Find Nearest CAD Element** button is clicked, PC-DMIS locates the nearest CAD element in the Graphic Display window based on the XYZ location and any selected

axis (or axes). PC-DMIS allows you to either type or surface-select the pertinent information.

Understanding Axes Check Box Selecting

- **For Vector Points or Surface Points** - If you select an **X**, **Y**, or **Z** axis check box, PC-DMIS interprets the selection as the axis that will be modified when you click the **Find Nearest CAD Element** icon.
- **For Edge Points or Angle Points** - If you select an X, Y, or Z axis check box, PC-DMIS interprets the selection of the axis as a selection of the one axis that will NOT be modified when you click the **Find Nearest CAD Element** icon. For example, if you select the **X** check box, PC-DMIS actually select the **Y** and **Z** check boxes signifying that the Y axis and Z axis values will be modified by the Find process.

Understanding the Find Operation without Selecting Axes Check Boxes

- **For Edge Points and Angle Points** - If you click the **Find Nearest CAD Element** icon without an axis selection, PC-DMIS finds the closest CAD edge or angle point.
- **For Vector Points and Surface Points** - If you click the **Find Nearest CAD Element** icon without an axis selection, PC-DMIS finds the closest CAD along the Normal vector specified in the dialog box. PC-DMIS then populates the dialog box with the found vector.

Read Point from Machine

The **Read Point from Machine** icon immediately reads the probe's current position and fills its location into the XYZ of the feature.

Find Vector(s)

The **Find Vector(s)** icon pierces all surfaces along the XYZ point and IJK vector, looking for the closest point. The software then flips this vector based on the current active tip vector.

The surface normal vector is displayed as the `IJK NOM VEC` but the XYZ values do not change.

This icon is available on these Auto features:

- Vector Point
- Surface Point
- Edge Point

- Angle Point
- Corner Point
- High Point
- Auto Line
- Auto Plane

Snap to Grid

The **Snap To Grid** icon snaps a supported auto point feature to the 3D grid display in the Graphic Display window. As long as the **Auto Feature** dialog box is opened to a supported auto point feature, you can use snap to grid even when the 3D grid is not showing.

> To turn on the grid in the Graphic Display window, click the **3D Grid** check box in the **View Setup** dialog box, or click the **Show a 3D Grid in the Graphic Window** icon on the **Graphic View** toolbar.

Supported auto point features include all auto point features except for Corner Point and High Point.

With this icon selected, if you then select a point on a CAD surface, the XYZ value snaps to the grid.

- With the 3D grid turned on, the selected point snaps to the visible grid. For example, if you are looking at the part in a Z+ view, then the X and Y grid lines are used. In general, whichever axis points the most towards you, the other two grid axes are used for the snapping.
- With the 3D grid turned off, the selected point snaps to the invisible grid lines based on the feature normal. For example, if you select a point for a surface point feature, and the surface normal at the selected point is (1,0,0), then the Y and Z grid lines are used for the snapping. In general, whichever axis value of the feature normal is largest, the other two grid axes are used for the snapping.

Measure Now and Re-Measure

Measure Now icon

If you select this icon, the software starts the measurement process for this Auto feature as soon as you click the **Create** button. PC-DMIS measures the part based on the values specified in the Auto Feature dialog box.

Re-Measure icon

This icon is available for these Auto features: Circle, Cylinder, Square Slot, Round Slot, and Notch, both inner and outer.

If you select **Re-Measure**, PC-DMIS automatically re-measures the feature against the measured values obtained the first time the feature is measured.

For all inner and outer features, if you set **Avoidance Move** to a value other than NONE, if avoidance moves are provided, they are used as safe moves in the re-measure path.

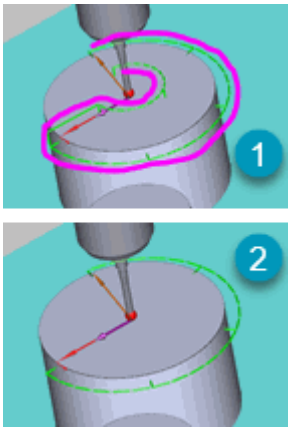
For all inner features, if avoidance moves are not provided (**Avoidance Move** is set to NONE), but **Re-Measure** is set to ON, the safe move is defined to be the center of the feature, with the height equal to the probe diameter.

For all outer features, if avoidance moves are not provided (**Avoidance Move** is set to NONE), but **Re-Measure** is set to ON, the safe moves are defined as the measure path, but REVERSED (see examples below). To use the **Re-Measure** functionality on auto contact outer features, the following conditions must be met:

- The auto contact feature must be an outer feature.
- **Avoidance Move** is set to off.
- The Probe Mode must be set to DCC Mode.
- You must set **Re-Measure** to On.

The following examples describe how the Re-Measure implementation works if the avoidance moves are not provided.

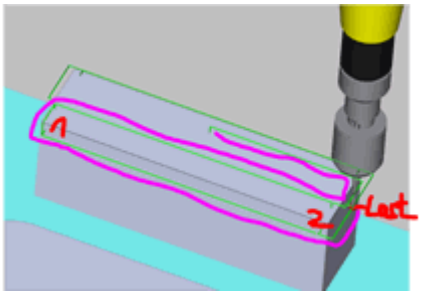
Example 1



When an Outer Circle, Outer Round Slot, or Outer Polygon is being measured, PC-DMIS stores all the collected movements, including the movements to measure the sample hits (1).

When the Re-Measure function is implemented, all movements are sequentially made in reverse to prevent collisions from occurring (2).

Example 2



When an Outer Square Slot auto contact feature is being measured, PC-DMIS stores all the collected movements that include the first and second hits on the first face of the slot, and the last hit on the second face of the slot.

As with example 1, when the Re-Measure function is implemented, all movements are sequentially made in reverse to prevent collisions from occurring.

Flip Vector

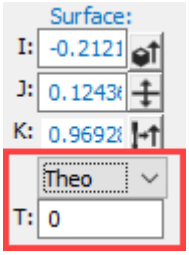
The **Flip Vector** icon allows you to reverse the direction of the surface vectors. Click on **Flip Vector** to reverse the displayed values.

Read Vector From Machine

Clicking this icon tells PC-DMIS to use the currently active tip vector from the machine for the **IJK Surface** boxes used to define the surface vector.

Use Thickness

You can use the **T** ("thickness") list and box in the Feature Properties area of the Auto Feature dialog box to enter the part thickness distance that will be applied to the surface or edge values of a feature depending on the thickness type (theoretical, actual, or no thickness).



When you measure the side of the part that is modeled in PC-DMIS, you should set the part thickness value to zero. You should only use the part thickness option when measuring the side of the part that is not drawn in the CAD data.

Defining a thickness amount is primarily used for thin parts (plastic or sheet metal) where the CAD data only describes one side and you want to measure the other side. Often with thin parts, the CAD engineer will only draw one side of the part, and then specify the material thickness. PC-DMIS will apply this material thickness automatically when using the CAD surface data.

You can use either a positive value or negative value. This thickness will be applied automatically along the surface normal vector each time CAD data is selected. If the feature has more than one normal vector (that is, angle points and corner points), the thickness will be applied along the first normal vector.

From the list, select an option:

Theo - In the **T** box, type the thickness value when the theoretical values need to be adjusted by a thickness, because measurements are being done on opposite side of material. The Edit window command line for this option would read:

```
THEO_THICKNESS = n
```

Where `n` is a numerical value indicating the theoretical thickness of the part.

Actual - In the **T** box, type the thickness value when measurements are being adjusted by the thickness back to the original theoretical XYZ locations. With this option, it will appear that the theoretical and measured values have not been offset

and the target is offset. You still need to modify your target so that PC-DMIS drives to the correct location. The Edit window command line for this option would read:

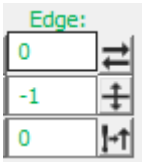
```
ACTL_THICKNESS = n
```

Where `n` is a numerical value indicating the actual thickness of the part.

None - Select this option if you do not need to apply thickness. (You do not need to enter a value in the **T** box.) For most machines, a thickness of 0 or selecting **None** has the same effect. For portable arm machines, however, selecting **None** and specifying a value actually applies the thickness to a shank style measurement. In this type of measurement, you use the cylindrical shank of the probe to measure instead of the probe tip. To do this, you need to first define sample hits. PC-DMIS can then determine the location of the supported feature (circles, ellipses, slots, and notches) using the shank.

When switching between theoretical and actual thickness, the measurement location will not change. When using theoretical thickness, PC-DMIS modifies the theoretical, measured, and target locations to include the (theoretical) thickness. When using actual thickness, PC-DMIS modifies only the target location by adding the (actual) thickness value to the original theoretical location. Later, after feature measurement, PC-DMIS subtracts the (actual) thickness from the measured value. Both methods yield the same measurement location. It is how PC-DMIS reports the feature's theoretical, actual, and target values that changes.

IJK Edge Boxes



These boxes are only available for the Edge Point and Line features.

The **IJK Edge** boxes define the approach direction (vector) for the edge hit or for the points of an auto line. This is a user-supplied I, J, K measured vector. The I, J, K should always point away from the edge and be perpendicular to the edge that is being measured.

After you define a new value, PC-DMIS normalizes the vector, making its length one unit.

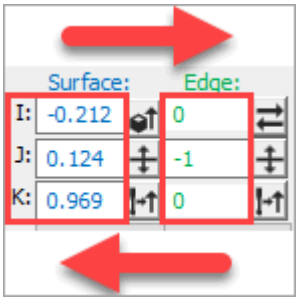
T List and Box

The **T** ("thickness") list and box enable you to select the thickness type (theoretical, actual, or no thickness). For more information, see "Use Thickness".

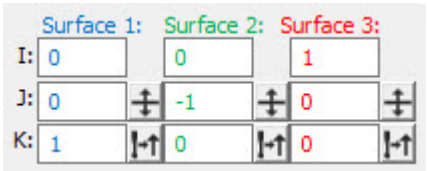
Icon	Description
	Swap Vectors
	Flip Vector
	Read Vector from Machine (for Edge Point)

Swap Vectors

The **Swap Vectors** icon causes the current Edge vector and Surface vector to switch vectors with each other.



IJK Surface 1, 2, and 3 Vector Boxes



Surface 1 and **Surface 2** boxes are only available for Angle Point or Corner Point auto features. **Surface 3** boxes are only available for Corner Point Auto features.

The I, J, K vector should always point away from the measured surface.

- **Surface 1** (blue) - Determines the surface normal vector of the first measured surface.
- **Surface 2** (green) - Determines the surface normal vector of the second measured surface.

- **Surface 3** (red) - Determines the surface normal vector of the third measured surface.

After you define a new value, PC-DMIS normalizes the vector, making its length one unit.

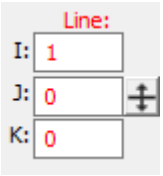
For the three surfaces, PC-DMIS displays corresponding colored arrows showing the surface vectors.

If you can't see the vector arrow or it appears too small, try changing the value in the **Pt. Size** box in the **Analysis** area. If you set **Pt. Size** to 0, it generally sets both the point and the arrow to a desirable size.

Icon	Description
	Flip Vector
	Read Vector from Machine

For more information on surface boxes, see "IJKT Surface boxes".

IJK Line Boxes



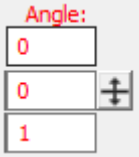
These boxes are only available for the Angle Point and Line features.

The **Line** boxes display the vector of the line on which the angle point or line lies. This is a user-supplied I, J, K normal vector.

After you define a new value, PC-DMIS normalizes the vector, making its length one unit.

Icon	Description
	Flip Vector

IJK Angle Boxes



For Circle, Cylinder, Sphere, and Cone features, the **Angle** boxes define the 0° position about the normal vector. The start and end angles are calculated relative to this vector. If the vectors are not perpendicular, the angle vector is adjusted to the normal vector.

For Square Slot, Round Slot, and Ellipse features, the **Angle** boxes define the feature's secondary vector. This is a user-supplied I, J, K normal vector. The feature centerline and normal vector must be perpendicular to each other.

For a Notch feature, the **Angle** boxes define the notch's secondary vector orientation. This is a user-supplied I, J, K normal vector along the back side of the slot. The notch angle vector and notch normal vector must be perpendicular to each other.

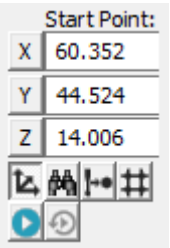
For a Plane feature, the **Angle** boxes define the plane's secondary vector. This helps control the orientation of the plane's path.

For a laser Auto High Point feature, if you select the **Box** method from the **Mode** list in the **Measurement properties** area of the laser **Auto Feature** dialog box, the **Angle** boxes define the vector for the region that PC-DMIS uses to determine the high point.

After a new value is created, PC-DMIS will normalize the vector, making it a length of 1.

Icon	Description
	Flip Vector

XYZ Start Point Boxes



The **XYZ Start Point** boxes define the XYZ location where the search begins for the highest point in the search region. This is used with the Auto High Point feature.

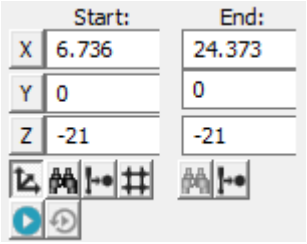
	Read Point from Machine
	Measure Now
	Re-Measure

XYZ Start / End Boxes



The **XYZ Start** and **XYZ End** boxes display the starting and ending points for an Auto Line feature. You can click on the **Read Point from Machine** icons to get the current probe's XYZ location. Or you can simply probe points on the part to show the start and end point values.

Note that the **End** boxes only appear if you select **Yes** from the **Bounded** list from the **Measurement Properties** area.

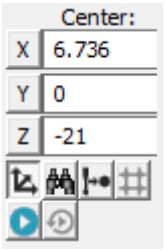
See the "Bounded List" topic.

Icon	Description
	Polar / Cartesian
	Find Nearest CAD Element
	Read Point from Machine
	Measure Now
	Re-Measure

XYZ Center Boxes

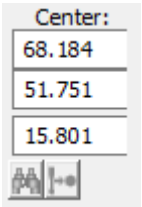
These boxes are only available with these Auto feature types: High Point, Plane, Circle, Ellipse, Round Slot, Square Slot, Notch, Polygon, Cylinder, and Sphere.

For Plane, Circle, Ellipse, Round Slot, Square Slot, Polygon, Cylinder, and Sphere, the **XYZ Center** boxes indicate the nominal center location of the feature.



For a Notch, these boxes indicate the midpoint of the notch along the non-parallel side.

For a High Point, these boxes indicate the center of the search region.



After you define a new value, PC-DMIS normalizes the vector, making its length one unit.

If a cylinder is defined as a hole, the center point must be defined at the top of the cylinder. If the cylinder is defined as a stud, then the center point must be defined at the bottom of the cylinder.

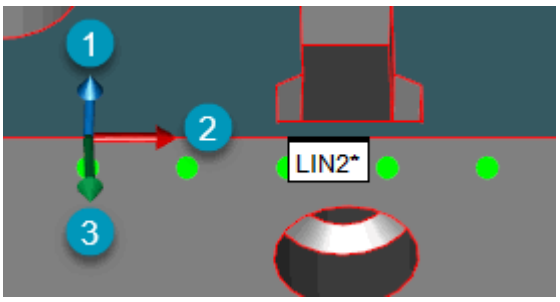
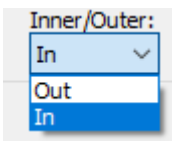
Example of Auto Line Vectors



1. *IJK Surface*
2. *IJK Line Vec*
3. *IJK Edge*

Inner / Outer List



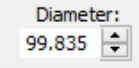
The **Inner / Outer** list tells PC-DMIS to construct the Auto feature as either an internal feature or an external feature.

- If you select **Out**, PC-DMIS constructs the circle as an external feature that protrudes from its surrounding surface.
- If you select **In**, PC-DMIS constructs the feature as an internal feature that sinks into its surrounding surface.

See also:

Exporting Plane Features in IGES

Diameter Box



This box is only available for these Auto features: Circle, Cylinder, Sphere, Cone, Polygon

The **Diameter** box defines the diameter of the feature. In the case of a stud, the diameter box displays the nominal, user supplied value.

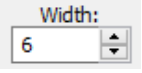
> *For an Auto Cone*, the **Diameter** value in the **Feature properties** area represents the nominal diameter at the location of the cone where you've defined the THEO XYZ location.
>
> *For a polygon*, the diameter is the distance between two opposing sides of even-sided polygons. For other polygons, such as an equilateral triangle, it is twice the radius of the largest circle you can inscribe inside the polygon.

To change the feature's diameter:

1. Select the existing value.
2. Type a new value.

Once the feature is created, PC-DMIS updates the size of the feature in the Graphic Display window.

Width Box

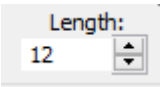


High Point

The **Width** value defines the width of the search region. If you have a value for **Length** but leave the **Width** value 0, then the **Width** value corresponds to the length along the major axis of the current workplane.

Square Slot, Round Slot, Ellipse, or Notch
The **Width** box displays the width of the feature.

Length Box



High Point
The **Length** defines the length of the search region. If you have a value for **Width**, but leave the **Length** value 0, the **Length** value corresponds to the length along the minor axis of the current workplane.

Square Slot, Round Slot, Ellipse, Notch, or Line
The **Length** box displays the length of the feature.

Cone
The **Length** box displays the length of the cone.

> *A positive Length* value indicates that the centroid is toward the cone's tip (the end of the cone feature that has the smaller diameter).
>
> *A negative Length* value indicates that the centroid is toward the cone's base (the end of the cone feature that has the larger diameter).

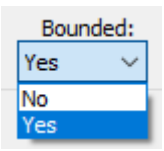
Cylinder
For a hole, the **Length** box defines the nominal length of the feature. If you enter a **Length** value but do not define a depth, PC-DMIS equally divides the **Length** value by the number of rows indicated in the **Levels** box.

The probe then works its way down the cylinder in increments until it reaches the indicated length value.

If a depth value is defined, the actual measured feature becomes the length minus the depth value.

For a stud, if the **Sample Hits** list displays a non-zero value, PC-DMIS will take an extra hit on the top of the stud in the center, as long as the length value is a non-zero positive value. PC-DMIS then will compute the length of the stud.

Bounded List



Bounded list (only for a Line feature)

The **Bounded** list defines whether or not the auto line is bounded by an ending point or an unbounded, open line.

If you select **Yes**, then some **End** boxes will appear in the **Feature Properties** area with the XYZ values for the ending point. PC-DMIS automatically calculates the length of the line based off of the distance between the **Start** and **End** points and displays the line's length in the **Length** box.

If you select **No**, then PC-DMIS expects you to type a value in the **Length** box. It then calculates the line from the starting point, along the line vector for the distance specified in the **Length** box.

See "XYZ Start / End Point Boxes" and "Length box" for additional information.

Num Sides List

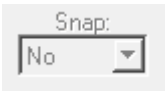
The **Num Sides** list defines the number of sides making up the polygon feature.

Measurement Properties Area

The **Measurement properties** area in the **Auto Feature** dialog box contains some or all of the following items, depending on the Auto feature that you are creating.

Snap List

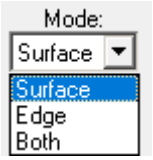
The **Snap** list is automatically enabled in the user interface when working with a Vector Point or a Surface Point feature. For a Circle feature, it is only visible if `EnableCircleDCCSnap` is set to TRUE in the PC-DMIS Settings Editor. In addition, since snap only functions well after a rough alignment, it is disabled until an alignment is established.



The **Snap** list determines whether or not measured values "snap to" the theoretical vector for a Vector Point, a Surface Point, and when enabled, for a Circle feature. This simulates a perfect machine staying exactly on the approach vector, not deviating by as much as a micron when measuring the point. If you set this to **Yes**, then the measured values snap to the theoretical vector with all the deviation along the vector of the point. This is useful for focusing on a deviation along one particular vector.

For example, suppose you want to measure the height (in Z) of a table's top. You don’t really care about your X and Y (secondary and tertiary) axis errors which can occur from machine drift (tunneling error). In this case, with **Snap** set to **Yes**, you will only be reporting the Z value. Any errors in X and Y will be ignored as the measured X and Y values will equal their theoretical counterparts.

Measure Order List



This is only available with the edge point feature.

The **Measure Order** list in the **Measurement Properties** area allows you to choose the order in which the sample points will be taken before the final hit is taken. The choices are: **Surface**, **Edge**, or **Both**.

Surface
Measures the three hits, first on the surface, then on the edge.

Edge
Measures the two hits, first on the edge then the surface.

Both
Measures the surface, then the edge, and then the surface again.

Interior / Exterior List

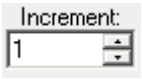
This list is available only on the Angle Point auto feature.

The **Interior / Exterior** list defines the angle as either interior or exterior.

Interior angles have the solid angle of the part less than 180°, while exterior angles are greater than 180°.

It is very important to make sure this option is set correctly because of the differences in measurement sequence for each type.

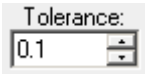
Increment Box



This box is available only on the High Point auto feature.

The **Increment** box allows you to define the increment used for the highest point in the search area. During execution, PC-DMIS begins searching from the start point (or search point) by the amount specified in the **Increment** box.

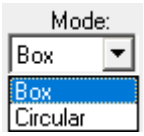
Tolerance Box



This box is available only on the High Point auto feature.

The **Tolerance** box allows you to define a tolerance value that essentially tells PC-DMIS when to stop searching for a high point within a given area. The tolerance value should always be less than the increment value. During the search process, PC-DMIS decreases the increment value until it is less than or equal to the **Tolerance** value supplied, indicating that the highest point in the current workplane has been located.

Box / Circular List



This list is only available for the High Point feature.

The **Box / Circular** list allows you to define the search mode that PC-DMIS will use to return the highest point. You can choose **Box** mode or a **Circular** mode.

Box Mode

Selecting **Box** defines a rectangular search region for the High Point feature. The rectangle is defined by the **Width** and **Length** values. PC-DMIS will report the highest point within that area.

Circular Mode

If you select **Circular**, the **Width** and **Length** boxes change to **Outer Rad** and **Inner Rad** boxes. The search region for the High Point feature becomes a circular search band specified by the **Outer Rad** and **Inner Rad** values.

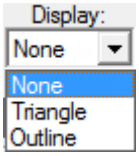
For the Auto Laser High Point feature, PC-DMIS does not display the **Outer Rad** and **Inner Rad** boxes since they are not needed.

- If a complete circular region is desired, set the inner radius to 0.
- If a circular search line is desired, set the inner and outer radii to the same value.

The highest point along the circumference will be reported.

No matter which mode you select, the start point should lie within the defined search region. For the special cases of line searching, the start point will automatically be adjusted to be on the line.

Display List



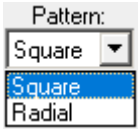
For an Auto Plane feature, the **Display** list determines how the plane will be displayed in the Graphic Display window.

- Selecting **None** will not draw the plane feature even though it's still created in the measurement routine.
- Selecting **Triangle** will cause the plane to appear as a triangle symbol around the region where the plane hits will be taken. The size depends on the hit locations.
- Selecting **Outline** will cause the plane to appear as a square or rectangular outline around the region where the plane hits will be taken. The size depends on the hit locations.

See "Using the Display Area" under the "Constructing a Plane Feature" topic for similar examples of these display types.

When you create an Auto Plane feature, it remembers the last Auto Plane feature and defaults to the last used display state.

Pattern List



For the Auto Plane feature, the **Square** and **Radial** options in the **Pattern** list allow you to determine whether the hits for the plane feature are taken in a square or radial pattern.

If you select **Radial**, PC-DMIS will create the hits in rows coming from the plane center in a circular or radial pattern. PC-DMIS takes 360 degrees and divides it by the value in the **Number of Rings** box to determine the angle between each row. For example, if the

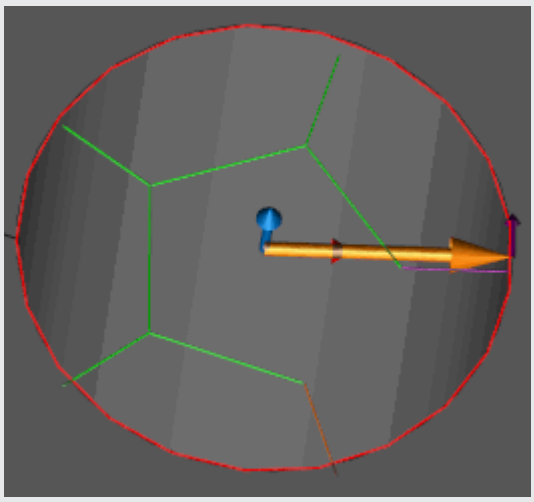
Number of Rings box had 6 and your **Number of Hits** box had 3, PC-DMIS would generate a row of three hits every 60 degrees, for a total of 18 hits.

If you select **Square**, PC-DMIS will create the hits in a grid pattern about the center point of the plane. For example, if the **Number of Rows** box had 3 and the **Number of Hits** box had 4, PC-DMIS would take a total of 12 hits in a grid pattern with the plane center point at the center.

Start and End Angles

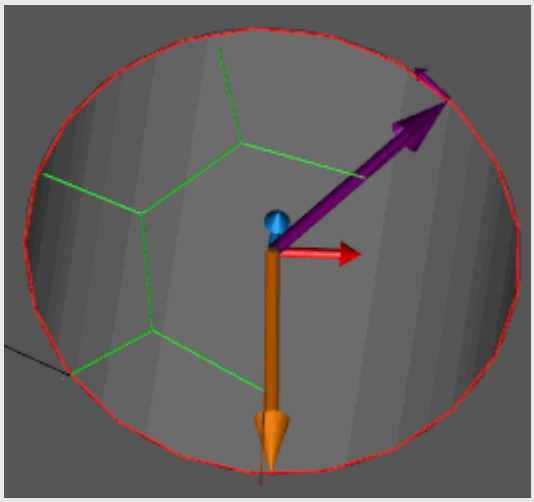
For a circular feature, the different **Start Angle** and **End Angle** boxes define where PC-DMIS probes the feature. For many situations, the default values are sufficient, but there may be times when you need to measure a circular feature that is partially obstructed by another feature or otherwise only partially available for probing. Enter the start and end angles in a counter-clockwise manner.

If you measure a hole with six hits and a **Start Angle** of 0 and an **End Angle** of 360, it looks something like this:



Notice that the **Start Angle** and the **End Angle** are the same: 0 and 360. Also, the six points making up the circle feature are equally distributed between the two angles. In this case, each point is taken at 60 degree intervals with the last point taken at 300 degrees.

However, if you change the **Start Angle** to 45 (purple arrow) and the **End Angle** to 270 (orange arrow), those values limit the hits to a certain portion of the circular feature:

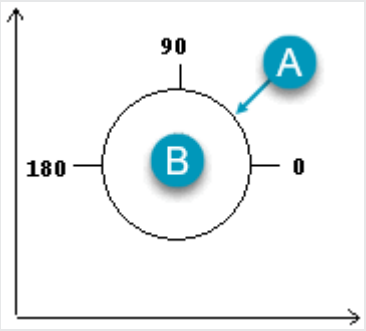


Start and End Angle Boxes

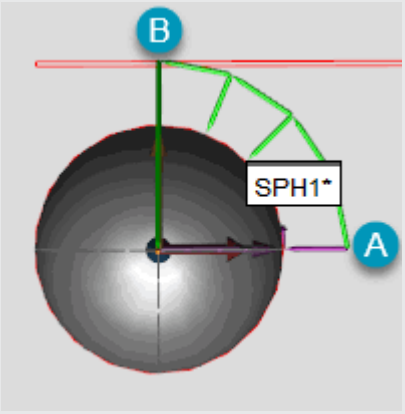
Start Angle and **End Angle** boxes - These boxes let you change the default starting and ending angles on the feature. This is a user-supplied angle in decimal degrees. The starting and ending angles are relative to the values in the **IJK Angle Vector** boxes. If you rotate the view of the feature so that you look down its center, PC-DMIS spaces the desired number of hits beginning at the **Start Angle** in a counterclockwise direction around the centerline until it reaches the **End Angle**.

Consider this example:

Suppose you have a sphere feature with a Start Angle of 0, an end angle of 90, and an IJK Angle Vector of 1,0,0 (along the X+ axis). The starting and ending angles are relative to the angle vector. Measurement proceeds in a counterclockwise manner, equally spaced between 0 and 90 degrees:



(A) - Sphere (B) - Top



Screen capture of an Auto Sphere showing path lines and hit locations from Start Angle of 0 (at A) and End Angle of 90 (at B).

These boxes are only available for Circle, Cylinder, Ellipse, Cone, and Sphere Auto features.

Start Angle 2 and **End Angle 2** boxes - The **Start Angle 2** and **End Angle 2** boxes let you determine the secondary starting and ending angle on a sphere feature. This angle is in decimal degrees. The secondary angle, if looking at a side view of a sphere, starts at the sphere's equator and then moves towards the top pole as the angle increases to 90 degrees and then back down to the equator on the opposite side of the sphere at 180 degrees. These angles allow you to place the hits in an area where the probe can reach them without obstruction.

Consider this example:

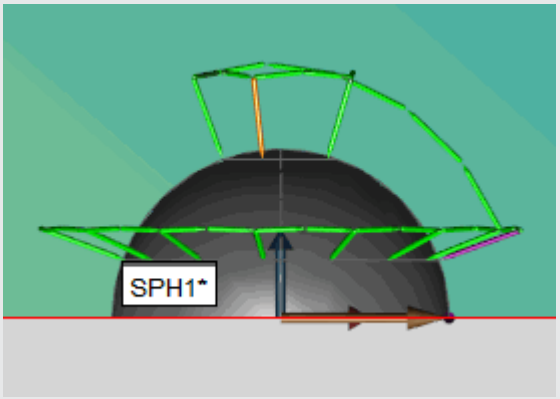
Suppose you have an external sphere that's halfway visible above the surrounding surface. If you use a **Start Angle 2** value of 0 degrees, the probe will collide with the surrounding surface when it attempts to take the hits around the sphere's equator. A slight adjustment in the **Start Angle 2** value resolves this problem.

If you create the sphere with 20 hits, and give it a **Start Angle** of 45, an **End Angle** of 270, a **Start Angle 2** of 20, and an **End Angle 2** to 90, PC-DMIS spaces 19 hits around the sphere 20 degrees up from the equator of the sphere, like this:

	A Top View of the Sphere	*A Side View of the Sphere*

This provides the probe with plenty of room to measure the sphere. The sphere's second level only consists of one hit on top of the sphere.

If you adjusted **End Angle 2** to something like 110 degrees, the second level of hits has 5 hits adjusted 20 degrees down from the top of the sphere:

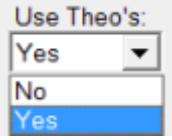


The **Start Angle 2** and **End Angle 2** boxes are only available for Sphere Auto features.

2 Degree Buffer Offset

When you generate an arc using one of the circular Auto features (Circle, Cylinder, Cone, Sphere, or Round Slot), PC-DMIS offsets the start and end angles each by two degrees. This way arcs retrieved from the CAD aren't probed on their starting and ending angles, possibly catching a corner. This shouldn't be an issue in most cases unless you are attempting to generate a small arc of only a few degrees. For example, if you want to generate a four degree arc of an Auto **Circle**, you need to type in an eight degree arc parameter in the **Start Angle** and **End Angle** boxes, knowing that PC-DMIS shortens the arc by two degrees on each angle.

Use Theo's List



This list is only available for the Cylinder feature.

The **Use Theo's** list specifies whether to use the theoretical information displayed in the **Auto Feature** dialog box when calculating the actual feature information from the measured data collected.

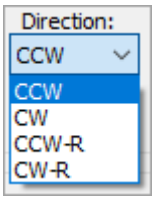
When you select **Yes**, the Best Fit algorithm will use the theoretical values (position, vector, and diameter) as an initial guess for the calculation to ensure the correct convergence of the algorithm to the desired solution. You can select **Yes** when the valid theoretical values and alignment are defined.

Select **No** when no valid alignment or theoretical values are available.

Use Pin List

Setting this list to **Yes**, shows the **IJK Punch** and **IJK Pin** boxes in the **Extended sheet metal options** area for Circle, Square Slot, and Round Slot features. The default value for this for new Auto features is **No**. See the "Extended Sheet Metal Options area" topic for information on enabling that area and using the options it contains.

Direction List



The **Direction** list specifies the direction in which PC-DMIS takes the hits.

The CCW-R and CW-R options are only available for Circle and Cylinder features when you use tactile probes.

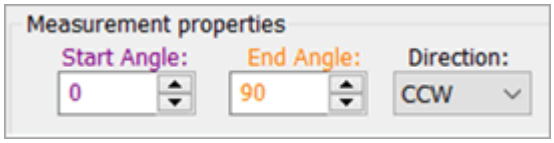
When you select the CCW-R option for example, PC-DMIS:

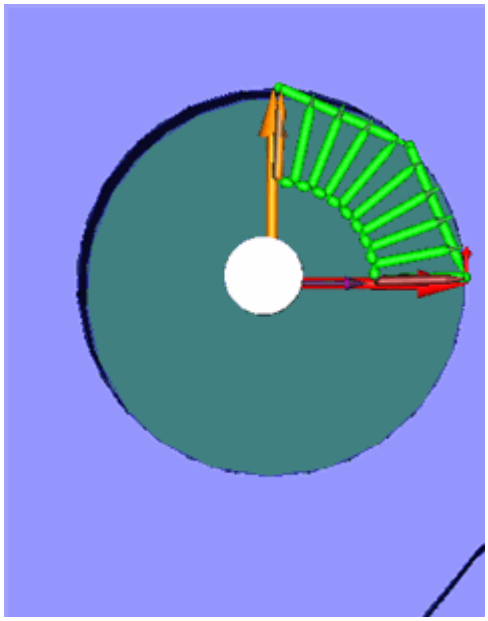
- Automatically reverses the Start and End angles
- Depending on what the original measurement direct was set to, changes the measurement direction
- Updates the feature definition in the Graphic Display window accordingly

The CW-R and CCW-R options are only available from the **Auto Circle** or **Auto Cylinder** feature dialog box. You cannot change the **Direction** option from the Edit window.

CCW Option

CCW - Select this option to change the measurement direction to counterclockwise.

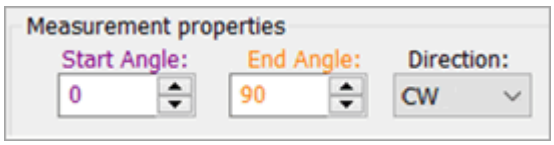


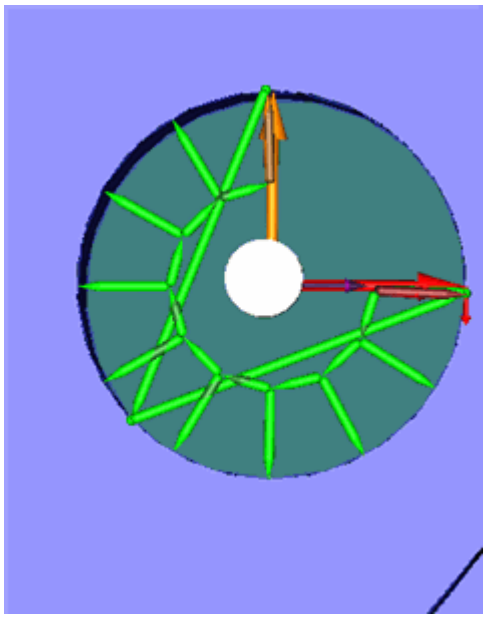


*Example of a circle with **Start Angle** = 0, **End Angle** = 90, and CCW measurement direction.*

CW Option

CW - Select this option to change the measurement direction to clockwise.



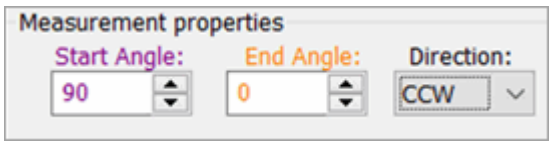


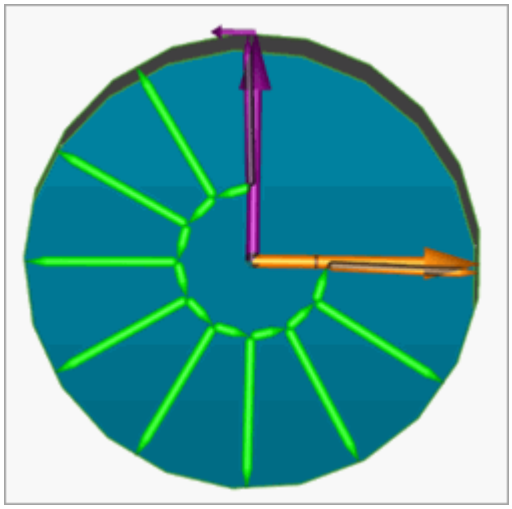
*Example of a circle with **Start Angle** = 0, **End Angle** = 90, and CW measurement direction.*

CCW-R Option

CCW-R - Select this option to reverse the Start and End angle values and to change the measurement direction to counterclockwise. When you select this option, the Graphic Display window immediately refreshes with the new parameters.

For example, if the parameters were originally set as in the **CCW Option** described above and you selected the **CCW-R** option, the result is shown below.





*Example of circle with reversed **Start Angle** = 90, reversed **End Angle** = 0, and CCW measurement direction.*

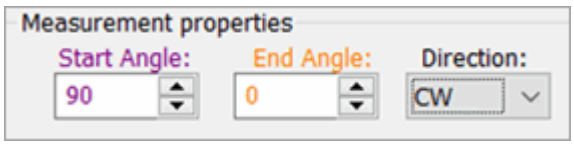
In this case, since the starting measurement direction was CCW and the selected option from the **Direction** list was **CCW-R**, only the **Start angle** and **End angle** values were reversed. The measurement direction remains CCW.

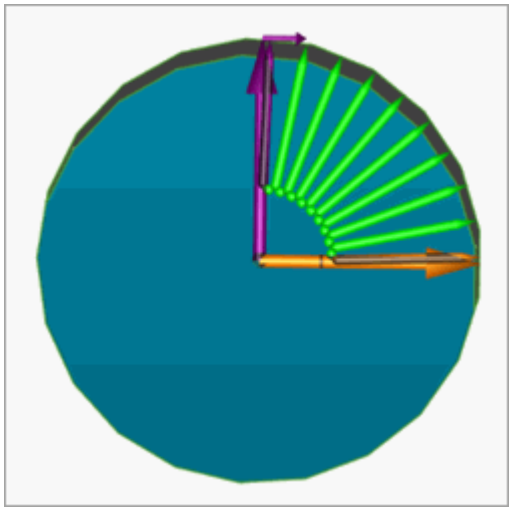
If you instead selected the **CW-R** option from the **Direction** list, PC-DMIS would reverse all three parameters.

CW-R Option

CW-R - Select this option to reverse the Start and End angle values and to change the measurement direction to clockwise. When you select this option, the Graphic Display window immediately refreshes with the new parameters.

For example, if the parameters were originally set as in the **CCW Option** described above and you selected the **CW-R** option, the result is shown below.



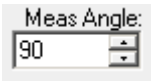


*Example of a circle with reversed **Start Angle** = 90, reversed **End Angle** - 0, and CW measurement direction.*

In this case, since the starting measurement direction was CCW and the selected option from the **Direction** list was **CW-R**, PC-DMIS reversed the **Start angle** and **End angle** values, and the measurement direction changed to CW.

If you instead selected the **CCW-R** option from the **Direction** list, PC-DMIS would only reverse the **Start angle** and **End angle** values.

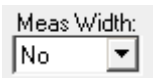
Meas Ang Box



Round slots have two rounded ends, each having up to 180 degrees of measurement radius. The value in the **Meas Ang** box defines how much of the radius to measure. PC-DMIS takes the input value and divides it in two, measuring half on each side of the slot angle vector.

Suppose you type 90 in this box. When creating the Round Slot, PC-DMIS would then measure 45 degrees to the left, and 45 degrees to the right of the angle vector (or vice versa depending on the angle vector).

Meas Width List



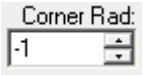
This list is available only on the Square Slot auto feature.

When you select **Yes** from **Meas Width** and then click the **Create** button, PC-DMIS will do the following during measurement:

- Measure two hits on the side of the slot.
- Adjust the angle vector.
- Measure two hits on the opposite side to calculate the width.
- Adjust the position of the last two hits at each end for the width.

Generally, Square Slots only require five hits. With this option, however, taking six hits will yield a better measurement of the width.

Corner Rad (Radius) Box



This box is only available for these feature types: Square Slot Notch, Polygon.

Square Slots, Notches, and Polygons are not always exactly square. They often have radii instead of corners. The **Corner Rad** box holds a value the size of that radius. The radius value controls where the hits take place on these features.

- *For a Square Slot,* it is used to determine the location of each hit during the measurement of the slot to avoid hitting on the radii.
- *For a Notch Slot,* hits along the edge opposite the open side will be adjusted off the radius.
- *For a Polygon*, hits along the polygon edge are adjusted from the corners of the feature adjusted off the radius.

Auto Feature Bar

The **Measurement properties** area in the **Auto Feature** dialog box has a bar with icons. You can use these icons to turn certain functions on or off.

Auto Wrist

Auto Rotary Table Moves

Clearance Plane

Circular Moves

Manual Pre-Position

Show Hit Targets

View Normal

View Perpendicular

Void Detection

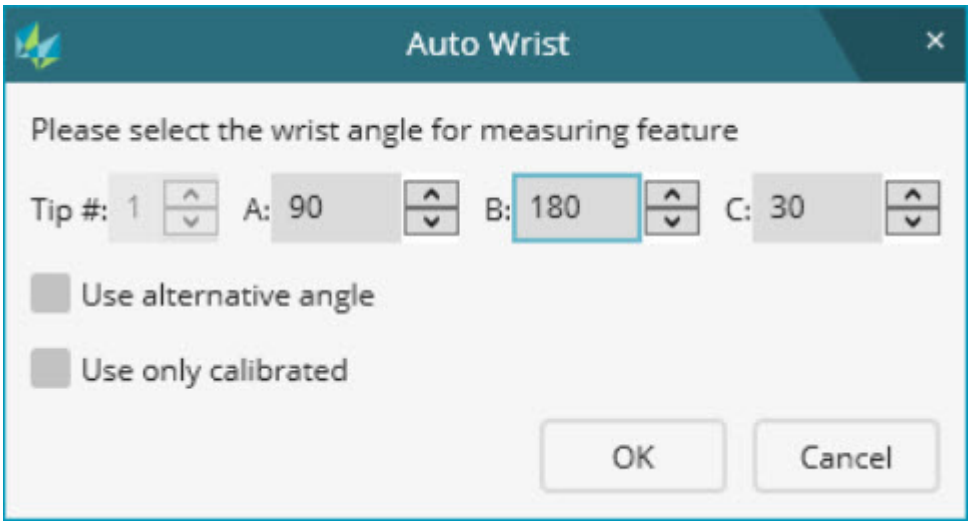
Show Measured Points

Show Filtered Points

To Points

Auto Wrist

When you select the **Auto Wrist** icon on the **Auto Feature** bar, PC-DMIS first checks whether the current active tip can be used to measure the selected feature. If not, it determines the best wrist position (tip) to use when an Auto feature is measured. Upon feature creation, PC-DMIS displays the **Auto Wrist** dialog box in case a new tip is needed:



Auto Wrist Dialog Box

Use the options in the dialog box to specify the wrist angle that best approaches the feature:

- **Tip** # box - This box represents the tip number. Typing or selecting a number in this box inserts the associated TIP command into the measurement routine.

- **A**, **B**, and **C** boxes - These boxes define the A, B, and C angles for the wrist. Click the arrow to the right of each box to increment or decrement the respective angle to the next valid value.
- **Use alternative angle** check box - If you want to avoid a possible collision during the probe rotation, select this check box.
- **Use only calibrated** check box - If you want to only use existing calibrated tips, select this check box.
- **OK** button - To insert the TIP command with the selected angles before the Auto feature, click this button.
- **Cancel** button - To use the current wrist position to measure the feature, click this button.

When you directly measure a Laser Cone or Laser Cylinder with a Tesastar wrist, the best scanning direction may be along the feature's vector or normal to it. This however depends on the ability of the head to rotate to an angle that allows you to scan in a direction normal to the stripe's orientation. For details, see "Auto Cone Paths" or "Auto Cylinder Paths" in the PC-DMIS Laser documentation.

If you select the **Auto Wrist** icon, PC-DMIS chooses a position that most closely approximates the best approach direction:

- For angle point features, the best approach direction is the average of the two surface vectors.
- For corner point features, the best approach direction is the average of the three surface vectors.
- For all other auto types, the best approach direction is the feature surface vector.
- The Vector Point, Surface Point, Angle Point, Corner Point, Line, Edge, and Plane Auto Contact Features use the cone angle of 46 degrees. This is done to prevent a tip change in case the orientation of the current tip lies inside the acceptable cone.
- The tip for the Line and Edge Auto Contact Features has to be inside of a half cone (46 degrees) specified by the edge vector.

If the icon is *not* selected, PC-DMIS uses the current wrist position to measure the feature.

Auto Rotary Table Moves

This is currently non-functional.

Clearance Plane

This icon lets you determine whether or not PC-DMIS inserts an automatic `MOVE/CLEARPLANE` command before measuring the first automatic hit of any Auto features created after selecting the toggle icon.

In order to enable the **Clearance Plane** function in the **Auto Feature** dialog box, a clearance plane command needs to be in the measurement routine (press the F10 key on your keyboard and then click the **Clearance Plane** tab): `CLEARP/ZPLUS,0,ZPLUS,0,OFF` or `CLEARP/ZPLUS,0,ZPLUS,0,ON`)

The OFF/ON at the end of this command acts as the default for the **Clearance Plane** function, each time you open a new **Auto Feature** dialog box to create a new feature. This means that each time a new **Auto Feature** dialog box is opened, the default is the OFF/ON you have on the last `CLEARP/ZPLUS,0,ZPLUS` command. If you want to create an Auto feature WITHOUT the **Auto Feature** dialog box open (using the **QuickFeature** mode for example, with hovering – Shift + hover), the value of the next QuickFeature is the last value you set it to in the dialog box. This is why with QuickFeatures you don't have control over this, while you can control it if you open the **Auto Feature** dialog box.

- If selected, PC-DMIS automatically inserts a `MOVE/CLEARPLANE` command (relative to the current coordinate system and part origin) into the Edit window before the first automatic hit of the feature. This causes the probe to move to the defined clearance plane before measuring the feature. After the last hit on the feature is measured, the probe will stay at probe depth until called to the next feature.
- If not selected, PC-DMIS creates Auto features normally without inserting any `MOVE/CLEARPLANE` commands.

Using clearance planes reduces programming time because the need to define intermediate moves is reduced. It can also help protect your hardware from an inadvertent collision with the part. For additional information on Clearance Planes, see "Parameter Settings: Clear Plane tab" in the "Setting your Preferences" chapter.

When measuring studs, be sure to set the spacer value to a distance that allows the probe to move around the stud.

Move Clearance Plane Active

The default for the **Clearance Plane** function for all Auto features is defined by the Clearance Plane Active option (if defined) and is recalled whenever the **Auto Feature** dialog box opens to create new features.

Circular Moves

This icon determines whether or not the probe will move along an arc as opposed to usually moving in a straight line when moving from one hit to the next. This option is particularly helpful when working with ring grooves.

> This icon is available for these Auto features: Circle, Cylinder, Cone, Sphere, and Plane. For a Plane feature, it becomes available if you are using a radial pattern for the feature's hits.

For information on how to insert circular moves into the Edit window, see "Inserting a Move Circular Command" in the "Inserting Moves" chapter.

Manual Pre-Position

> This icon only functions if you have PC-DMIS Vision enabled on your PC-DMIS license.

If selected, this icon prompts the user to move the camera to the position that is over the target before continuing. For additional information, see the PC-DMIS Vision documentation.

Show Hit Targets

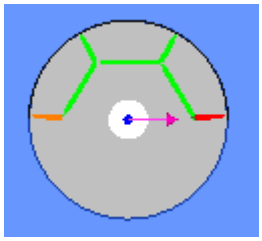
Click this icon to show the path lines and hit locations for the current feature. If the Probe Toolbox is visible, it also displays the toolbox's **Hit Targets** tab. Deselecting it hides this information.

The path lines appear as green lines on the CAD model. The red line indicates the starting hit, and the orange line indicates the ending hit. You can also modify hit locations by simply selecting and dragging the lines with your mouse.

You can also right-click on any path line or hit and use a shortcut menu to perform a variety of functions. See the "Auto Feature Path Lines Shortcut Menu" topic in the "Using Shortcut Keys and Shortcut Menus" chapter for more information.

The following example uses an auto circle feature to explain this functionality.

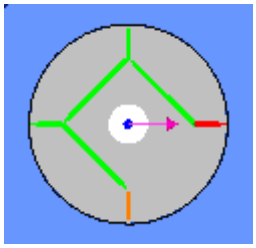
In this example, the starting and ending angles are set to measure only 180 degrees of the circle with four hits.



If you edit the starting or ending angle boxes, the hits display changes as well.

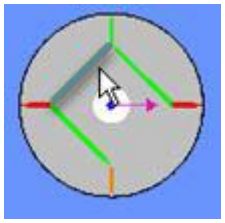
For example, if you change the ending angle from 180 to 360, PC-DMIS would then show the hits around the entire circle.

Alternately, with supported Auto features, *you can click on a hit target and drag it to a new location*. The software updates the start or end angle in the dialog box accordingly.



You can click on a path line and drag any hit to a new location.

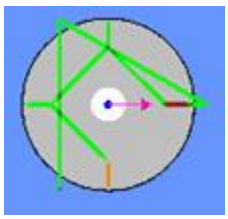
To modify a path line, move the mouse over the path line until PC-DMIS highlights the line, then click and drag the hit to a new location.



Suppose your auto circle uses three sample hits to locate the surface around the circle. PC-DMIS shows these lines as well.

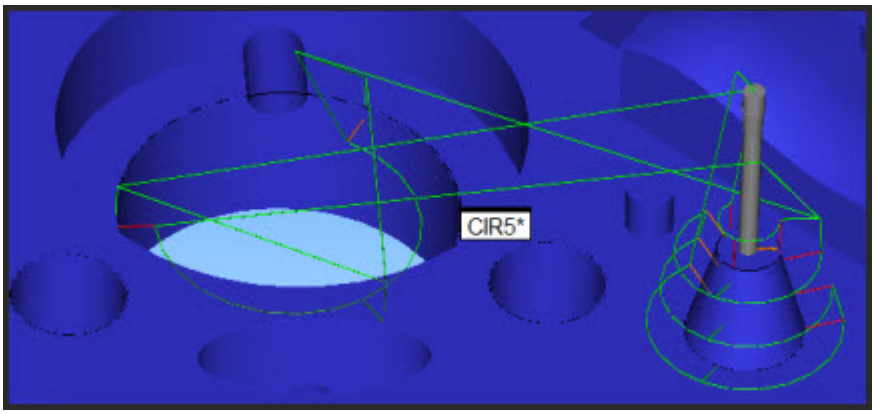
To modify sample hit path lines, click on and drag these lines to a new location.

- If you don't have user-defined hits, PC-DMIS dynamically updates the **Spacer** value as well as the feature hits.
- If you already have user-defined hits, PC-DMIS will modify only that one sample hit's location.



Show Path Lines from Previous Auto feature

With the **Show Hit Targets** icon selected, you can also show temporary path lines from the previous Auto feature to the one you're currently creating. To do this, select the **Operation | Graphic Display Window | Clearance Moves | With Feature Creation** menu item before you access the **Auto Feature** dialog box.



Example showing temporary path lines between auto features.

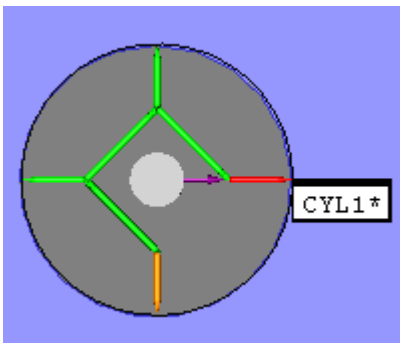
Clicking **Create** from the **Auto Feature** dialog box when doing this action creates the Auto feature as usual, and it also inserts a preceding `MOVE/POINT` command into the measurement routine.

To expand this functionality to test for collision detection between the two features, select the **Operation | Graphic Display Window | Clearance Moves | With Collision Detection** menu item. See "Inserting Clearance Moves with Collision Detection" in the "Inserting Move Commands" chapter.

View Normal

> This icon is unavailable for selection if your measurement routine is in Manual Mode.

Clicking this icon orients the CAD so that you look down on the feature. Deselecting it returns the CAD to the previous view. You can also select this by right-clicking on the path and selecting **View Normal** from the resulting menu.

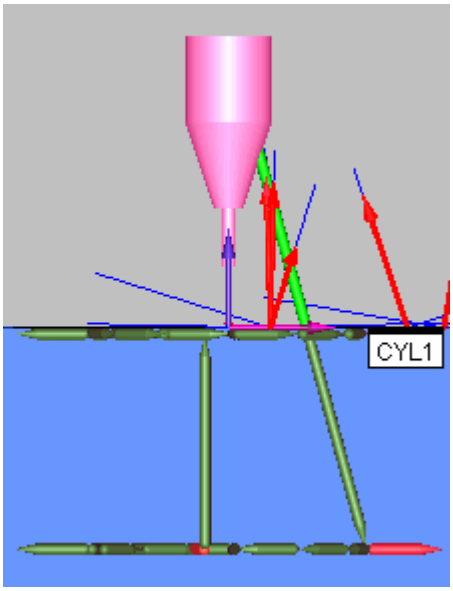


Example of a cylinder feature with the View Normal option selected.

View Perpendicular

> This icon is grayed out and unavailable for selection if your measurement routine is in Manual Mode.

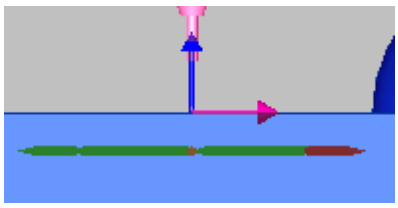
Clicking this icon orients the CAD so that you look at the side of the feature. This is ideal for defining a feature's depth or adding additional rows of hits for features that support additional levels, such as cones or cylinders. To set additional rows, right-click and select **Add Row** from the resulting menu.



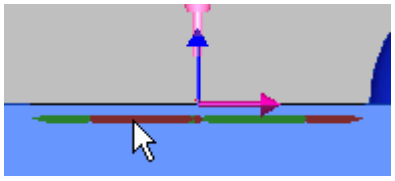
Example of a cylinder feature with the View Perpendicular option selected.

Deselecting **View Perpendicular** returns the CAD to the previous view. You can also set the view to perpendicular, by right-clicking on the path and selecting **View Perpendicular** from the resulting menu.

> With **Show Path** and **View Perpendicular** selected, you can view the feature in its perpendicular view and see at what depth PC-DMIS will take the hits.



To modify the depth, highlight the green line of hits in this view, and then click and drag either up or down to set the new depth.

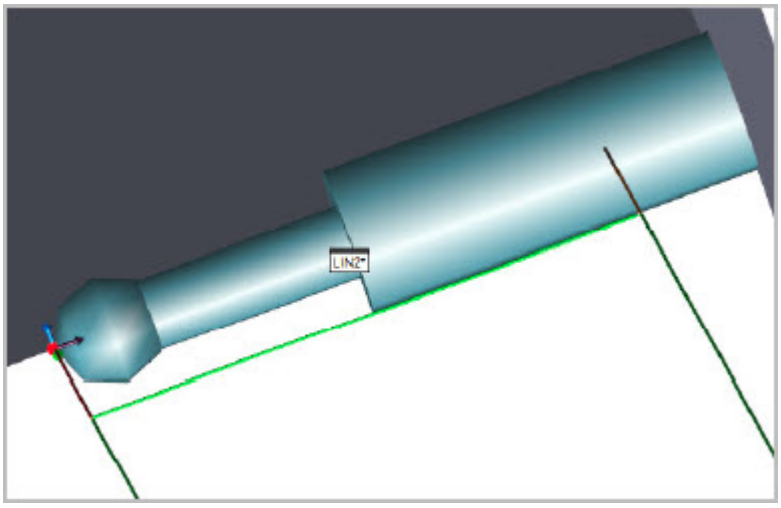


Void Detection

This icon only functions if you are working with one of these supported features: Surface Point, Edge Point, Line, Plane, Circle, Cylinder, and Round Slot.

If selected, PC-DMIS detects hit targets that would normally occur in voids (empty spaces) on the CAD model and repositions them to a safe location, usually near the edge of the void.

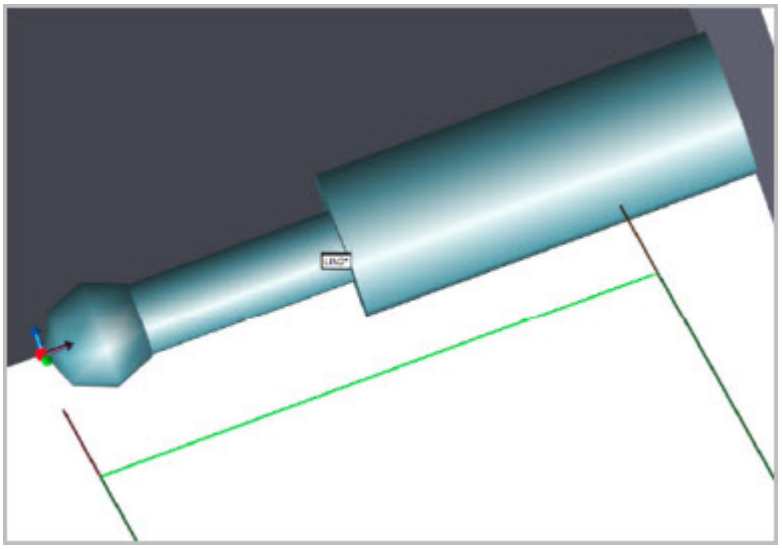
As an example, the first image shows the behavior of a line created right on the edge of two different surfaces with no Depth or Void Detection enabled.



Example of a line feature generated with Void Detection option disabled.

In this case, PC-DMIS places the hits for the line just on the edge. If you enable Depth Detection without Void Detection enabled, the hits are as far from the edge as the depth parameter.

The next image shows the behavior when Void Detection is enabled on the same line and Depth Detection is set to 0 (zero).



Example of a line feature generated with Void Detection option enabled.

The Void Detection algorithm is designed to add some intelligence to the hits distribution. Due to the instability of calculating a line on or very near to an edge, a "security distance" is determined. PC-DMIS then uses this to place the hits for the feature. The "security distance" is based on a multiple of the probe's radius.

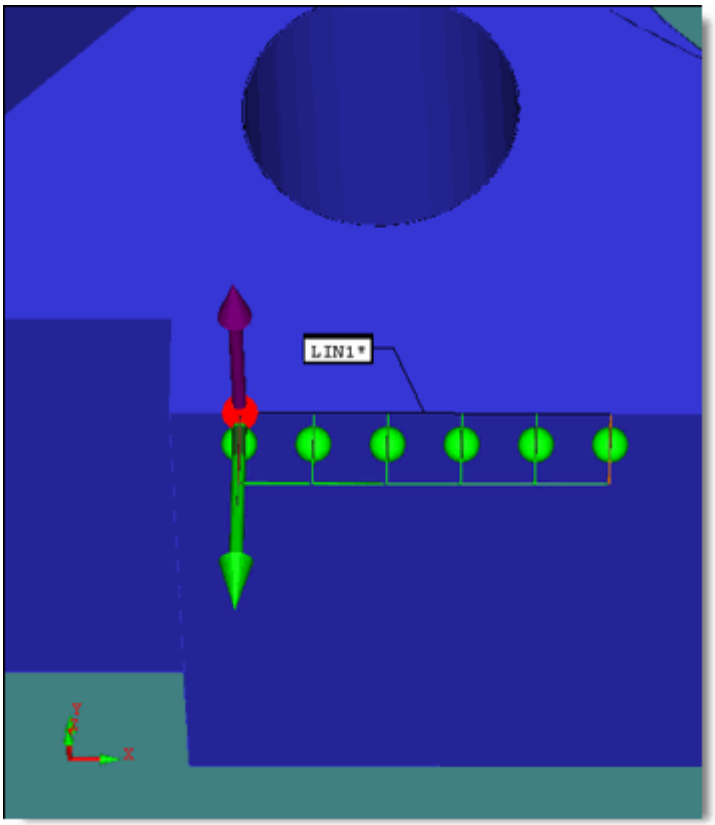
In QuickFeature mode, you can select multiple colinear or coplanar entities. Void Detection creates a hit pattern that considers all selected entities. For details on how to turn this function On and Off, see the "VoidDetectionNewAlgorithm" topic in the Settings Editor documentation.

You can also drag-select hits to determine an edge. Note that when you drag-select hits with **Void Detection** set to **On**, the Void Detection algorithm is still used to calculate the starting point of the drag operation. Once dragging starts, however, the **Void Detection** option is automatically set to **Off**, and the remaining hits are detected manually. The Void Detection algorithm is used to intelligently define the path while drag-selecting manually determines the path.

Show Measured Points

This icon only functions with features that are already measured. Until a feature is measured, either with the **Test** button on the **Auto Feature** dialog box or with the actual measurement routine execution, the icon remains unavailable for selection.

Select this icon to show, in the Graphic Display window, a visual depiction of the data points used to measure the feature.



Example showing the measured points of an auto line feature.

Show Filtered Points

> This icon only functions if you have PC-DMIS Vision enabled on your PC-DMIS license. You also need to have a feature with outlier filtering enabled and some filtered points.

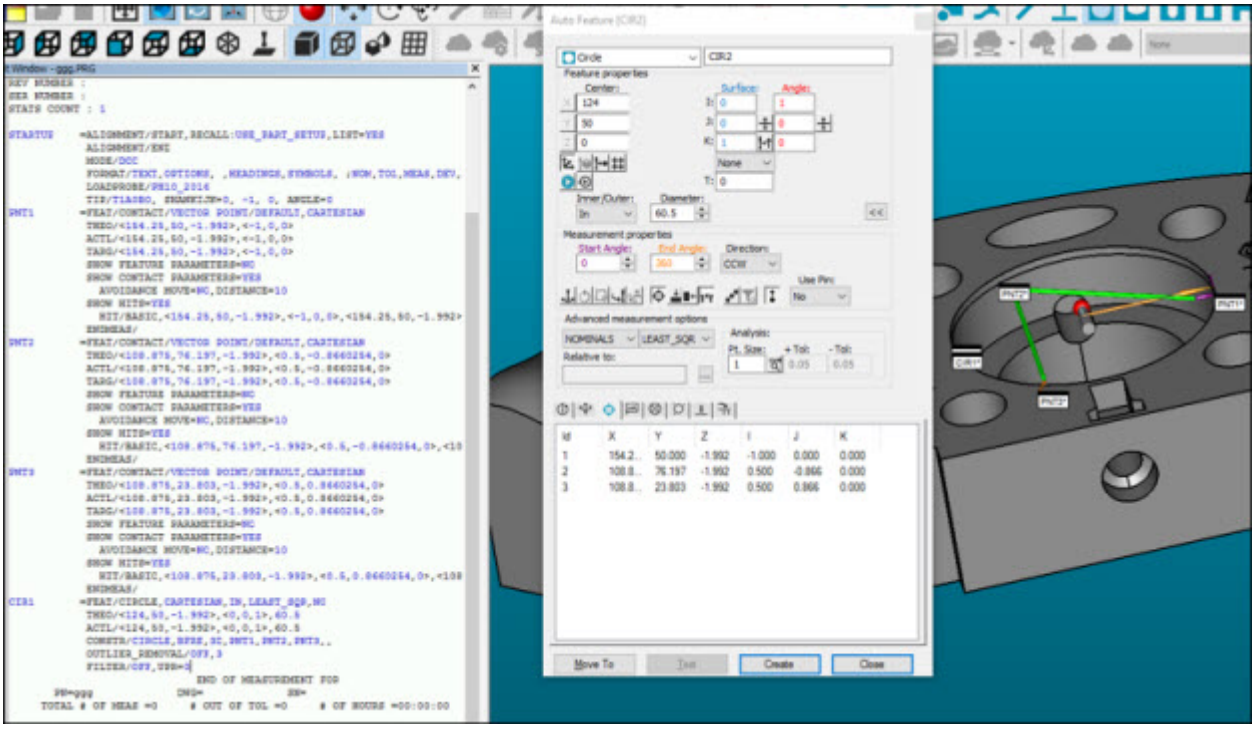
Select this icon to show on the Live and CAD Views image processing data points that were acquired and then discarded by the current filter settings. For additional information, see the PC-DMIS Vision documentation.

To Points

> The **To Points** function is available for auto contact features of type Plane, Circle, and Cylinder.

If you select the **To Points** icon on the Auto feature bar, PC-DMIS creates the feature as individual Vector Points with the associated shape constructions. PC-DMIS uses the hits of the Auto feature to obtain the Vector Points.

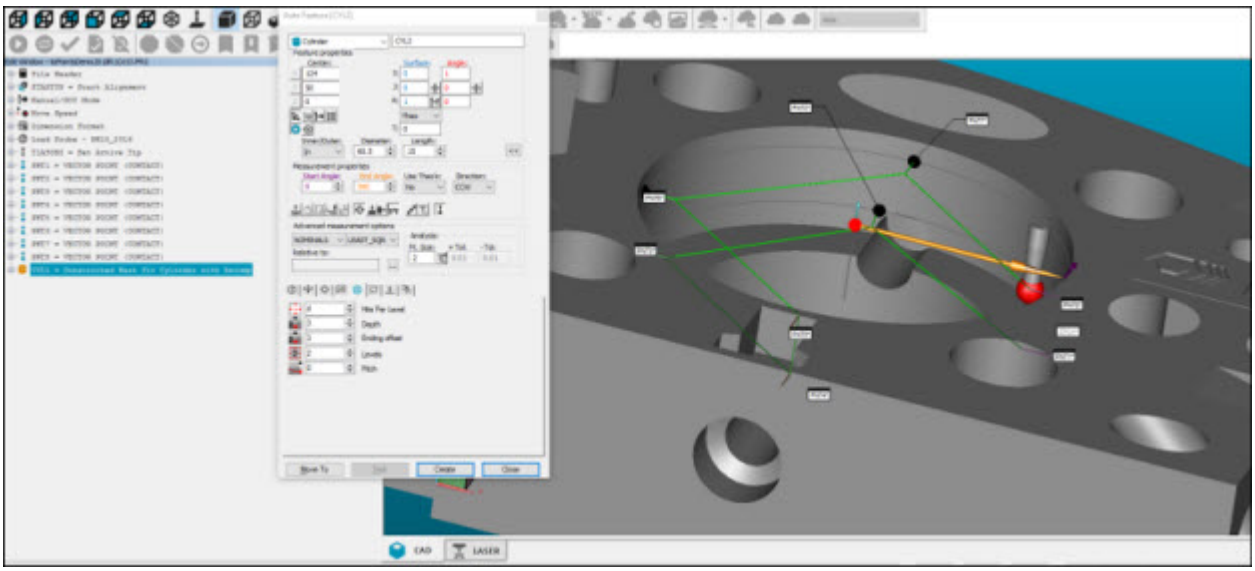
PC-DMIS applies the Best Fit Recompensate algorithm to the Vector Points to compute the constructed feature. Following is an example for a Circle feature:



Example of a circle feature generated with the To Points option enabled.

For more information about the Best Fit Recompensate algorithm, see the "Constructing a Best Fit or Best Fit Recompensate Circle" topic.

If the **Void Detection** function is enabled for the Auto feature, or if you drag the hits (user-defined hits), the resulting Vector Points will take care of it. For example:



Example of a cylinder feature generated with the Void Detection and To Points options enabled.

The **To Points** function also works with QuickFeatures. It is feature-type dependent. For example, you can enable the icon for circle features and disable it for cylinder and plane features.

After you create the measurement routine, the "optimize path" task can be used to assign the probe head orientation and to re-order the vector points. This feature enables PC-DMIS to measure all of the points with the same tip in one step even if they belong to different features. For more information about path optimization, see the "Optimizing the Path" topic.

PC-DMIS ignores some Auto feature measurement options (such as auto wrist, circular moves, clearance plane, and sample hits).

PC-DMIS moves some of the measurement options from the original Auto feature to the resulting Vector Points (such as the coordinate types and the thickness).

The **Test** button is unavailable if the **To Points** option is enabled.

Extended Sheet Metal Options Area

The **Extended sheet metal options** area of the **Auto Feature** dialog box contains some of the less frequently-used sheet metal options for supported Auto features.

Showing Extended Sheet Metal Options

The **Extended sheet metal options** area is hidden until the following conditions are met:

- You must select the **Show Extended Sheet Metal Options** check box on the **General** tab in the **Setup Options** dialog box (select **Edit | Preferences | Setup** or press the F5 key to access this dialog box.
- The type of Auto feature must support the extended options.

> Except for Corner Point and High Point, all other Contact and laser Auto features support the **Extended Sheet Metal Options** area.

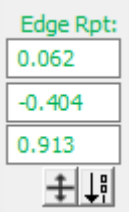
- You must select the **>>** button in the **Auto Feature** dialog box for Show Advanced Sheet Metal Options.
- You must select the **>>** button in the **Auto Feature** dialog box for Show Extended Sheet Metal Options. This button appears only for supported features.

This displays the **Auto Feature** dialog box with all of the available options visible.

Extended Sheet Metal Options

Depending on the feature you selected, the following items appear in the **Extended sheet metal options** area.

IJK Edge Report boxes



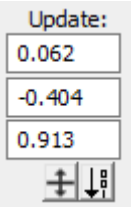
These boxes display the vector used for reporting deviation. This is a user-supplied I, J, K vector.

For the Line and Edge Point features, these boxes display the vector for the **RT** computation.

The Location Dimension option **RT** displays the deviation calculated along this vector. After the new value is created, PC-DMIS will normalize the vector, making its length one unit.

Supported Auto features: **Line, Edge Point**

IJK Update boxes

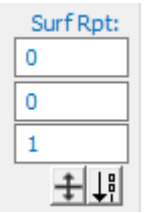


These boxes display the updated vector that PC-DMIS uses to pierce the CAD surface, if the option is active by setting the SET NOM AX mode. This is a user-supplied I, J, K normal vector.

The I, J, K should always point away from the surface. After the new value is created, PC-DMIS will normalize the vector, making its length one unit.

Supported Auto features: **Vector Point**

IJK Surf Rpt boxes



These boxes display the vector used for reporting deviation. This is a user-supplied I, J, K vector.

- For the Line and Edge Point features, these boxes display the vector for the **RS** computation.
- For the Angle Point feature, these boxes display the vector for the **RT** computation. You can use these boxes to deviate from the S and T deviations on the dimension for an Angle Point feature.
- For features that display only the **IJK Surf Rpt** boxes (they do not display the **IJK Edge Report** boxes), these boxes display the vector for the **RT** computation.

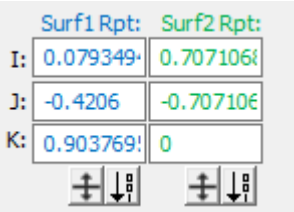
After the new value is created and you exit the dialog box, PC-DMIS will normalize the vector, making its length one unit.

The Location dimension's **RS** check box displays the deviation calculated along this vector.

The Location dimension's **RT** check box displays the measured deviation in the surface vector direction along this defined report vector.

Supported Auto features: **All features, except Corner Point, High Point, and Sphere**

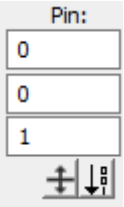
IJK Surf1 Rpt and Surf2 Rpt boxes



These boxes display the surface vectors for the **RS** (deviation along surface report) computation. You can use these boxes to deviate from the S and T deviations on the dimension for an Angle Point feature.

Supported Auto features: **Angle Point**

IJK Pin boxes

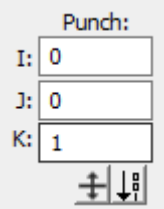


These boxes define the vector of the stud through the hole formed by the punch.

When pins are created on a sheet metal surface, they are not always perpendicular to the surface. This naturally creates an elliptical shape at the surface of the metal, even though a round pin may have been used. The **Pin** vector then allows for more accurate measurement and data analysis in this situation.

Supported Auto features: **Circle, Square Slot, Round Slot**

IJK Punch boxes



These boxes define the vector of the punch through the sheet metal. This vector is positioned at the XYZ center, plus half the thickness along the surface normal vector.

The punches used to place holes in sheet metal are not always perpendicular to the surface. This naturally creates an elliptical shape at the surface of the metal, even though a round punch may have been used. The **Punch** vector then allows for more accurate measurement and data analysis in this situation.

For the Circle feature, the diameter of the feature is also along this vector.

Supported Auto features: **Circle, Square Slot, Round Slot**

For more information on these vector boxes, see "Extended Sheet Metal Vector Diagrams".

Icon	Description
	Flip Vector
	Reset Vector to Surface Vector

Reset Vector to Surface Vector

The **Reset Vector to Surface Vector** icon will set the vector to match the normal Surface vector values.

Extended Sheet Metal Vector Diagrams

This topic contains various diagrams illustrating the vectors that you can use when you choose the show extended sheet metal feature options:

Normal Vector: The normal vector is the vector perpendicular to the surface at a point feature's location. See the diagram below:

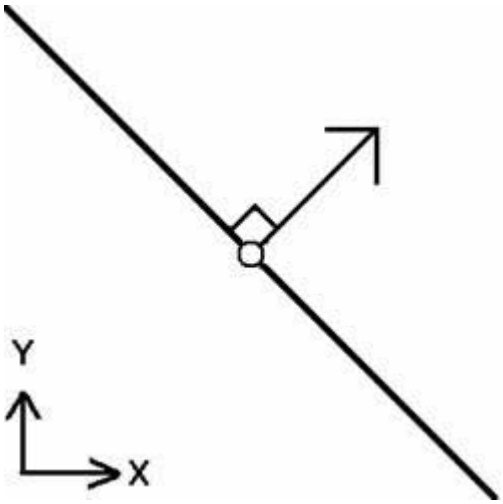


Diagram of a Normal Vector

	= Normal Vector
	= Surface
	= Point Location

Update Vector: The update vector is the vector used to determine the direction to follow when updating a point to a new surface. This update vector is derived from the reference line used in the initial creation of the feature. See the diagram below:

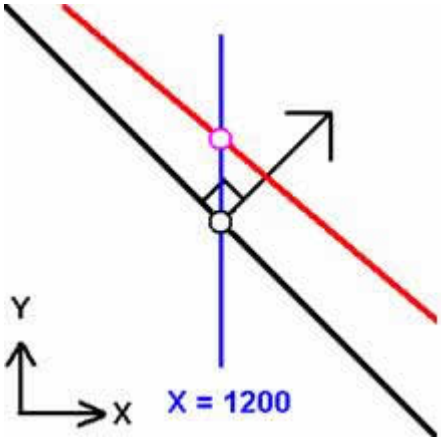

Diagram of an Update Vector

	= Updated or new surface
	= Original or old surface
	= Original point location
	= Updated point location
	= Reference line used to generate point location. Also known as the update vector.

Report Vector: The report vector lets you control the direction of the deviation by allowing you to define a vector onto which the deviation along the surface vector is then projected. The report vector may differ from the surface normal, such as along a specified axis (shown below as either Yr or Xr). See the diagrams below:

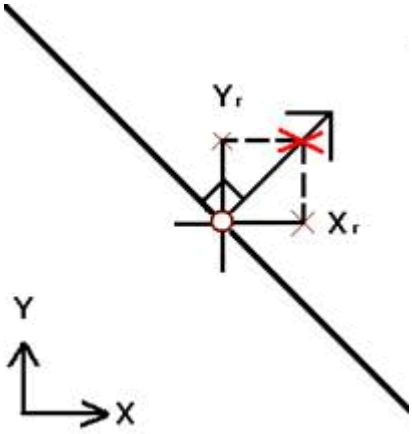

Diagram of a Report Vector

———	**= Theoretical surface**
o	**= Nominal point location**
×	**= Actual point location**
X_r	**= Deviation in X axis**
Y_r	**= Deviation in Y axis**

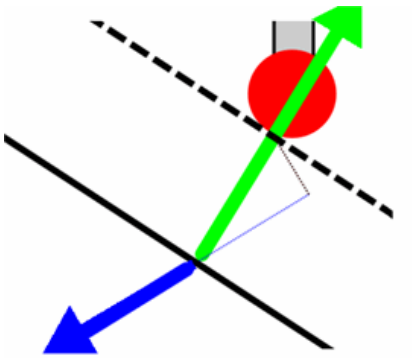

Diagram depicting a surface vector deviation projected onto the report vector

	= Theoretical surface
	=Actual surface
	=Surface vector
	=Report vector
	=Surface vector deviation projected to the report vector
	=Probe tip contacting actual surface

Pin Vector: Applied to slots and holes, the pin vector specifies the vector of the pin as it locates the product. See the diagram below:

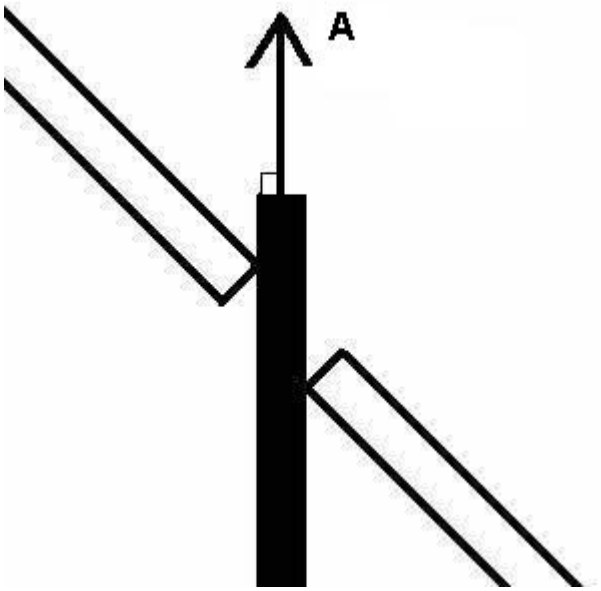

Diagram of a Pin Vector
***A** = Pin Vector*

Punch Vector: Applied to slots and holes, the punch vector specifies the direction of the punch used to create the feature. This vector is usually close to the surface normal within a few degrees. See the diagram below:

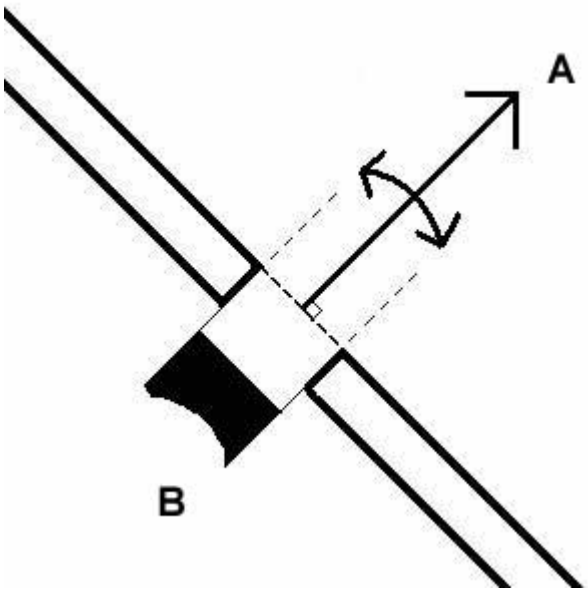

Diagram of a Punch Vector
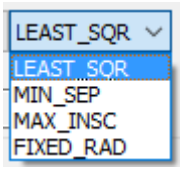
***A** = Punch Vector. Close to the surface normal within +/- 5 degrees*
***B** = The Punch*

Advanced Measurement Options Area

The **Measurement Properties** area of the **Auto Feature** dialog box contains some or all of the following items, depending on the Auto feature you selected.

Calculation List



You can use the **Calculation** list in the **Advanced measurement options** area to specify how you would like the feature calculated from the measured hits. This list is available for the Circle, Cylinder, and Plane Auto features.

PC-DMIS dynamically filters the available options. The list of options depend on the type of feature that you select and whether the feature is an Inner (hole) or Outer (stud) feature type.

The available options for Circle and Cylinder features are:

LEAST_SQR, MIN_SEP, MAX_INSC, MIN_CIRCSC, and FIXED_RAD

The available options for the Plane feature are:

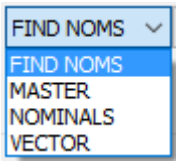
LEAST_SQR and MIN_SEP

For legacy Form dimensions (Circularity, Cylindricity, Flatness, and Straightness), as well as a Location dimension's RN Line, PC-DMIS uses the feature solution to compute the dimension. By default, this is Least Squares. However, you can choose to solve the feature using Minimum Separation, Maximum Inscribed, Minimum Circumscribed, or Fixed Radius regression algorithms.

PC-DMIS computes Geometric Tolerance Form commands, on the other hand, using the Chebyshev algorithm (Min/Max) as required by the Y14.5 standard. Because of the change in calculation, PC-DMIS generally computes Geometric Tolerance Form dimension commands to a slightly smaller value than their legacy counterparts.

These calculation types are already discussed in detail in the "Best Fit Type" topic in the "Constructing New Features from Existing Features" chapter.

Nominals Mode List



The **Mode** list in the **Advanced Measurement Options** area determines how PC-DMIS computes the nominals for a given point. PC-DMIS allows you to choose between FIND NOMS, MASTER, NOMINALS, VECTOR, and SET NOM AX.

- If `MODE = FIND NOMS` is active, PC-DMIS pierces the CAD model to find the closest location on a CAD edge (or surface) to the measured point and sets the nominals to that location on the CAD element.
- If `MODE = MASTER` is active, PC-DMIS uses the measured feature as the nominal, but PC-DMIS does not update the X, Y, Z and diameter data in the dialog box.
- If `MODE = NOMINALS` is active, PC-DMIS compares the measured feature with the theoretical data in the dialog box. It uses the measured data for calculations.
- If `MODE = VECTOR` is active, PC-DMIS uses your first three hits to calculate the appropriate vector to use for the feature. PC-DMIS does not adjust the location of the feature. You must take the hits with the **Auto Features** dialog box active.
- If `MODE = SET NOM AX` , PC-DMIS updates the nominal point location and the nominal approach direction before each execution.

For each mode, see the more detailed description in the table below if you need more information.

If a nominal value is not known, select **FIND NOMS** from the list. While this option is active, every time you select a value to change, PC-DMIS prompts you to take the appropriate measurements on the part to obtain the values needed.

FIND NOMS
When you select **FIND NOMS** from the **Mode** list, PC-DMIS pierces the CAD model to find the closest location on a CAD edge (or surface) to the measured point, and sets the nominals to that location on the CAD element.

To find the nominals using CAD data:

1. Verify that PC-DMIS is set to **Curve** mode or **Surface** mode (available from the Graphic Modes toolbar), as is appropriate for the particular measurement routine.
2. Click on the desired CAD element in the Graphic Display window. PC-DMIS pierces the CAD element to obtain the location, but does not create a feature. Once the desired elements have been selected, PC-DMIS automatically fills in the X, Y, Z and I, J, K values.
3. If the values are satisfactory, select the **Create** command button.

If you select the **Measure** check box, PC-DMIS measures the feature during creation. If you have not added clearance moves, this may cause a probe collision with the part.

If you take a hit on the part while in **FIND NOMS** mode, PC-DMIS searches through the CAD elements and finds the nominal CAD information that is closest to the measured point. If necessary, PC-DMIS prompts you to take any additional hits on the part.

The next time you measure the part, PC-DMIS sets the nominal data to the nearest CAD element it can find. The mode switch is then reset to **NOMINALS**.

Using Find Noms with Fixed Probes

A Faro or Romer arm using a fixed probe doesn't generate good approach vectors. Because of this, PC-DMIS cannot easily determine where to look for the surfaces.

To improve vectors from fixed probes:

1. Place the fixed probe on the part.
2. Press the **Hit** button.

3. Move the probe away from the part along the approximate surface vector.
4. Press the **End** button.

PC-DMIS calculates and then uses the vector between the hit and the probe tip's position.

Also, because the default vector from a Faro arm uses the axis of the fixed probe, the more you position the vector normal to the surface, the more useful the vector is for Find Noms operations.

MASTER
If you create a point when the **Mode** list is set to **MASTER**, then the next time you measure the part, PC-DMIS sets the nominal data equal to the measured data. The **Mode** list is then reset to **NOMINALS**.

NOMINALS
The **NOMINALS** option also requires that you have nominal data before you start the measurement routine. PC-DMIS compares the measured feature with the theoretical data in the dialog box. It uses the measured feature for any necessary calculations.

VECTOR
The **VECTOR** option allows you to update only the feature's vector during learn mode; it does not update the nominal XYZ values.

This option is *only* available for the Vector Point and Surface Point Auto features.

This option helps you to set a feature's vector that you may not be able to obtain otherwise. With the dialog box open, take three hits on the feature. This determines its vector.

You can use this mode as long as the dialog box remains open. Once you close the dialog box, the option is not available for the feature in the Edit window.

Supported Features: Vector Point, Surface Point, Corner Point, Line, Plane, Circle, Ellipse, Round Slot, Square Slot, Notch Slot, Polygon, Cylinder, Cone, Sphere

SET NOM AX
The **SET NOM AX** option updates (or "sets") the nominal point location and the nominal approach direction before each execution. If you select an axis check box from the **Location** area, PC-DMIS pierces the CAD surfaces along that axis. Otherwise, PC-DMIS uses the updated vector.

This option is *only* available for the Vector Point and Surface Point Auto features.

The axis (or vector) selected tells PC-DMIS along which axis (or vector) to pierce the CAD surface to find a new theo and target.

To select the **SET NOM AX** option:

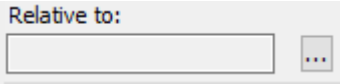
1. Make sure the **Show Extended Sheet Metal Option** check box is selected. See "Show Extended Sheet Metal Options" in the "Setting Your Preferences" chapter.
2. If desired, select one of the axis check boxes from the **Location** area.
3. Click **SET NOM AX** from the **Mode** list in the dialog box.
4. When you are done defining the rest of the Auto feature, click the **Create** button. The FIND NOM AXIS is then set to either the axis or the vector selected.

The Edit window for this option reads: FIND NOM AXIS = TOG

TOG represents the axis or vector to which FIND NOM AXIS is set. Available options for TOG include XAXIS, YAXIS, ZAXIS, VEC, and NONE.

If you don't select any axis, then the result reads FIND NOM AXIS = VEC by default.

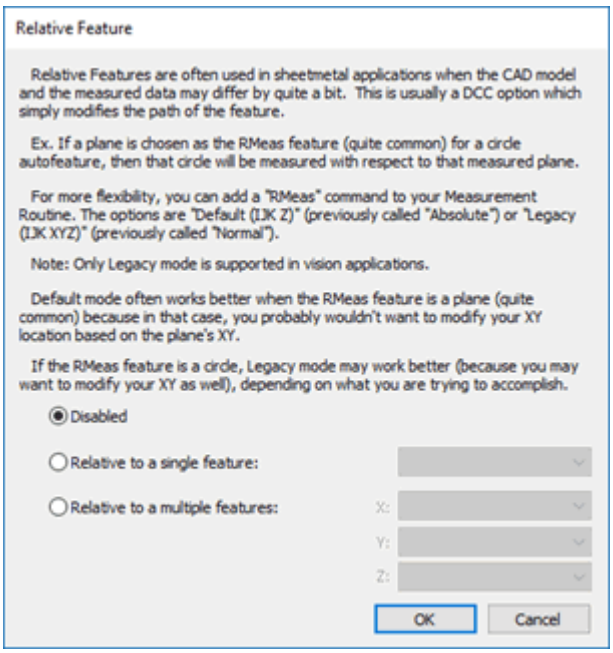
Relative To



Using the **Relative to** portion of the **Auto Feature** dialog box, you can keep the relative position and orientation between a chosen feature or features and the current auto feature. Before selecting a relative feature, make sure you choose a relative measure mode. For information on how to set up the relative measure mode, see "Setting Up Relative Measure".

The relative feature or features you choose must already exist in the measurement routine.

You can click the **…** button to display a **Relative Feature** dialog box and choose the relative feature (or features):



Relative Feature Dialog Box

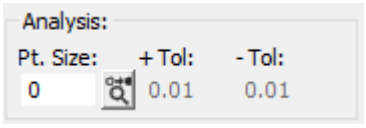
From this dialog box, you can choose to select either:

- A single feature from the list to the right
- Multiple features (one for each axis) from the lists to the right

After you select the relative feature or features and click **OK**, the **Relative To** box displays what you chose.

This option supports the DMIS V3.0 RMEAS formats 1, 3, and 6.

Analysis Area



The **Analysis** area allows you to determine how each measured hit/point is displayed.

This functionality was originally created for PC-DMIS Vision. For in-depth information on its usage, see the **Analysis area** section of the "Advanced Measurement Options Area" topic in the PC-DMIS Vision documentation.

A Note on Point and Arrow Vector Size

If your vector arrows for your Auto Point features seem too small, increasing the **Pt. Size** value increases both the size of the point in the Graphic Display window and the corresponding size of the vector arrow. Since Auto features are used on widely differing

machines, no one default size works for everyone. However, you can decide what size works best for you. PC-DMIS then defaults to your last entered value.

If your point appears like a large blob on your screen, set the **Pt. Size** value to 0. This generally produces a good-looking point size and vector arrow.

Auto Feature Command Buttons

Move To button

This moves the field of view in the Graphic Display window and centers it on the current feature's XYZ location.

In some cases, such as a Vector Point, the XYZ location is actually offset along the normal vector by the pre-hit value. This prevents the probe from crashing into the part.

If a feature is composed of more than one point (such as a line), then clicking this button switches between the points making up the feature.

Test button

This tests a feature's creation and previews its dimensional data before it's actually created. It performs a measurement using the current parameters.

WARNING: When you do this, the machine moves. To avoid injury, stay clear of the machine. To avoid hardware damage, run the machine at a slower speed.

You can change parameters and click **Test** repeatedly until you have an acceptable measurement. Then when you click **Create,** the software converts the temporary feature into a normal feature in the measurement routine.

Create button

This inserts the defined Auto feature into the Edit Window at the current position.

Close button

This closes the **Auto Feature** dialog box.

Show Advanced Measurement Options button

This extends the **Auto Feature** dialog box and displays any available advanced measurement options. The button then changes to the **Hide Advanced Measurement Options** button.

Hide Advanced Measurement Options button

This shortens the **Auto Feature** dialog box and only shows the basic options for that Auto feature. The button then changes to the **Show Advanced Measurement Options** button.

Show Extended Sheet Metal Measurement Options button

For supported features, this displays the **Extended Sheet Metal Options** area. The button then changes to **Hide Extended Sheet Metal Measurement Options** button.

Hide Extended Sheet Metal Measurement Options button

This hides the **Extended Sheet Metal Options** area. The button then changes to the **Show Extended Sheet Metal Measurement Options** button.

Inserting Auto Features

The PC-DMIS configurations that support Auto features differ in which Auto features they support as well as how those features are created. Because of this, information on creating and inserting Auto Features into your measurement routine is not covered here. Instead, consult the documentation set for your PC-DMIS configuration from the list below:

Contact (PC-DMIS CMM)	Vision (PC-DMIS Vision)	Laser (PC-DMIS Laser)
Auto Vector Point		
Auto Surface Point	Auto Surface Point	Auto Surface Point
Auto Edge Point	Auto Edge Point	Auto Edge Point
Auto Angle Point		
Auto Corner Point		
Auto High Point		Auto High Point
Auto Line	Auto Line	
Auto Plane		Auto Plane
Auto Circle	Auto Circle	Auto Circle
Auto Ellipse	Auto Ellipse	
Auto Square Slot	Auto Square Slot	Auto Square Slot
Auto Round Slot	Auto Round Slot	Auto Round Slot
Auto Notch Slot	Auto Notch Slot	
Auto Polygon	Auto Polygon	Auto Polygon

Auto Cylinder		Auto Cylinder
Auto Cone		Auto Cone
Auto Sphere		Auto Sphere
		Auto Flush and Gap
Probe Toolbox Information		
Contact Probe Toolbox	Vision Probe Toolbox	Laser Probe Toolbox

Once an Auto feature is created, its command appears inside the Edit window (see "Auto Feature Field Definitions"). You can then mark the command and have PC-DMIS execute it like any other command or feature.

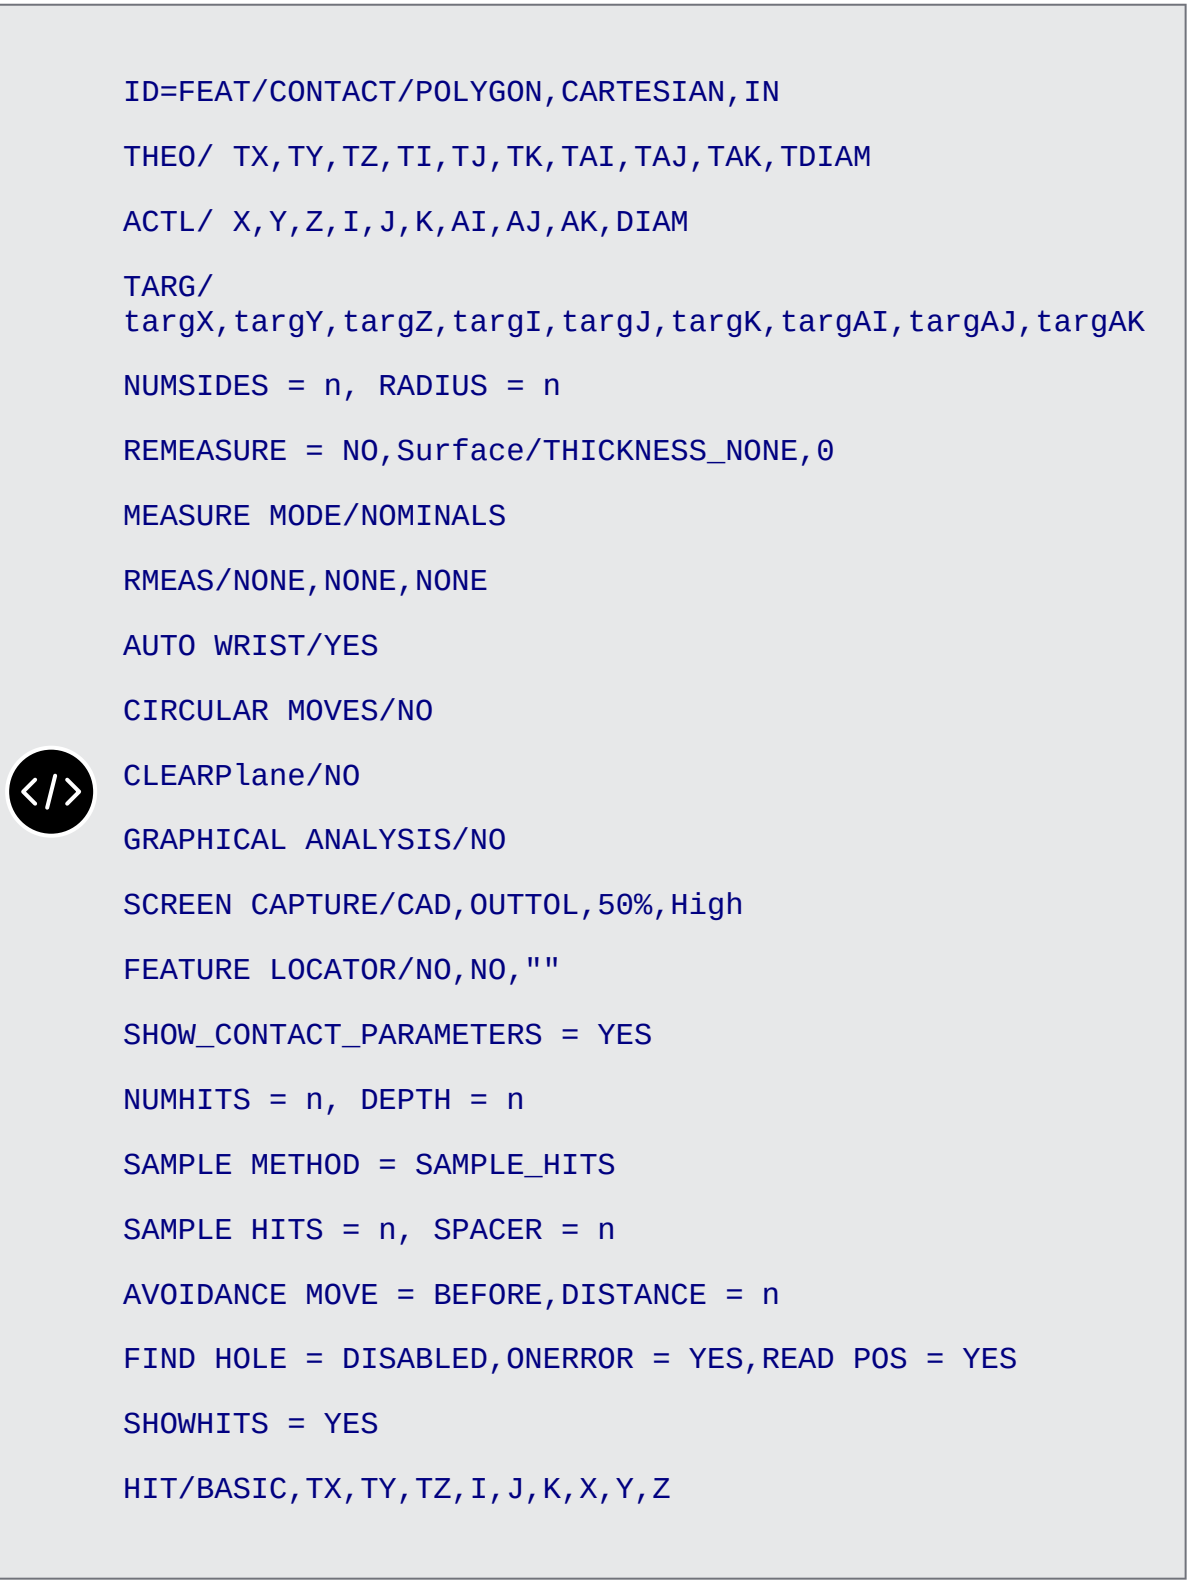
Auto Feature Field Definitions

When you create an Auto feature, PC-DMIS inserts the command for that feature into the Edit window. This topic documents the different fields that may appear in the Command mode of the Edit window for the different features.

In the table below, locate the field or command line used in your Auto Feature to see what it does.

Auto Polygon Field Definitions

The Edit window command line for an Auto Polygon feature would read:



```
ID=FEAT/CONTACT/POLYGON,CARTESIAN,IN
THEO/ TX,TY,TZ,TI,TJ,TK,TAI,TAJ,TAK,TDIAM
ACTL/ X,Y,Z,I,J,K,AI,AJ,AK,DIAM

Fields or commands in this documentation that are marked with ● relate to Extended Fields ⓘ.

A red bullet (●) in the documentation below indicates that this field only appears in the Edit window if you have enabled the **Show Extended Sheet Metal Options** check box found on the **General** tab of the **Setup Options** dialog box (**Edit | Preferences | Setup** or press F5 to access the dialog box). For more information, see "Show Extended Sheet Metal Options".

ID
This field shows the feature's identification label. See "ID box".

FEAT/CONTACT
This command displays the type of probing and the Auto feature type. See "Auto feature Type list".

POLAR or CARTESIAN
This field switches between POLAR and CARTESIAN and displays the X, Y, Z, I, J, K values in the selected coordinate system. See "Polar / Cartesian Toggle".

TRIANGLE or OUTLINE
For a Plane feature, this field switches between TRIANGLE or OUTLINE. It determines how PC-DMIS displays the plane in the Graphic Display window. See "Display list".

Used only on the **Plane** feature.

IN or **OUT**
This field switches between IN and OUT. It determines whether or not the feature is an internal feature (such as a hole) or an external feature (such as a stud). See "Inner / Outer".

Used only on these features: **Circle**, **Ellipse**, **Round Slot**, **Square Slot**, **Cylinder**, **Cone**, **Sphere**, **Polygon**

LEAST_SQR
This field determines the calculation routine used to create the feature from the measured hits. It can toggle between LEAST_SQR, MIN_SEP, MAX_INSC, MIN_CIRCSC, and FIXED_RAD. See "Calculation list".

The Plane feature can toggle between LEAST_SQR and MIN_SEP only.

Used only on these features: **Circle**, **Cylinder**, **Plane**, **Sphere**

THEO/
This stands for "theoretical".

TX, TY, TZ, TI, TJ, TK represent the theoretical (or nominal) hit location and vector.
TLI, TLJ, TLK represent the theoretical line vector.
TEI, TEJ, TEK represent the theoretical edge vector.
TSI, TSJ, TSK represent the surface theoretical vector.
TS2I,TS2J,TS2K represent the theoretical vector for the second surface.
TLENGTH represents the feature's theoretical length.
TDIAM represents the feature's theoretical diameter. For ellipses, this is the major diameter.
TDIAM2 is an ellipse's minor diameter. TANG1 represents the feature's theoretical starting angle. TANG2 represents the feature's theoretical ending angle.

TAI,TAJ,TAK represents the theoretical angle vector.
TWIDTH and TLENGTH represent the theoretical width and length of the feature.
TAngle represents the feature's angle.

ACTL/
This stands for "actual".

X, Y, Z, I, J, K represent the actual measured hit location and vector.
SI, SJ, SK, represent the measured vector for the surface.
LI, LJ, LK represent the measured line vector.
EI, EJ, EK represent the measured edge vector.
LENGTH represents the feature's measured length.
DIAM represents the feature's measured diameter. ANG1 represents the feature's actual starting angle. ANG2 represents the feature's actual ending angle.
AI, AJ, AK represents the measured angle vector.
WIDTH and LENGTH represent the measured width and length of the feature.
Angle represents the feature's angle.

TARG/
This stands for "target".

The fields targX, targY, targZ, targI, targJ, targK allow you to control the measurement location and vector approach direction for execution while having the ability to have a completely different THEO value.

The fields targAI, targAJ, targAK let you modify the target's angle IJK vector.

MEAS/
This stands for "measured".

The fields X, Y, Z, I, J, K represent the actual measured hit location and vector.

SI, SJ, SK represent the measured vector for the surface. S2I, S2J, S2K represent the measured vector for the second surface.

NUMSIDES
This editable value must be an integer of three or higher. It defines how many sides are in the polygon. See "Num Sides list".

Used only on the **Polygon** feature.

RADIUS
This editable value defines a radius for each corner in the polygon or square slot. When taking hits, PC-DMIS moves in along the side by that amount before taking hits. This helps to avoid taking hits directly in the corner. See "Corner Rad box".

Used only on these features: **Polygon**, **Square Slot**

NUMSIDES
Used only on the **Polygon** feature.

START ANG
This field defines the feature's starting angle. See "Start and End Angles".

Used only on these features: **Ellipse**, **Cone**, **Cylinder**

START ANG1
This field defines the feature's starting angle horizontally, around the equator of a sphere. See "Start and End Angles".

Used only on the **Sphere** feature.

START ANG2
This field defines the feature's starting angle vertically, around the poles of a sphere. See "Start and End Angles".

Used only on the **Sphere** feature.

END ANG
This field defines the feature's ending angle. See "Start and End Angles".

Used only on these features: **Ellipse**, **Cone**, **Cylinder**

END ANG1
This field defines the feature's ending angle horizontally, around the equator of a sphere. See "Start and End Angles".

Used only on the **Sphere** feature

END ANG2
This field defines the feature's ending angle vertically, around the poles of a sphere. See "Start and End Angles".

Used only on the **Sphere** feature.

MEAS Angle
This field defines an angle value determining how much of the arc making up the rounded edges of the Round Slot to measure. See "Meas Angle box".

Used only on the **Round Slot** feature

INCREMENT
This field defines the increment distance away from the start point that the probe moves when following its search pattern. See "Increment box".

Used only on the **High Point** feature.

TOL
This defines the tolerance value to use during the search process. See "Tolerance box".

Used only on the **High Point** feature.

CIRCULAR or **BOX**
This field switches between CIRCULAR or BOX. It defines the search region. See "Box / Circular list".

Used only on the **High Point** feature.

OUTER RADIUS
For a CIRCULAR search region, this field defines the search region's outer radius. See "Inner/Outer list".

Used only on the **High Point** feature.

INNER RADIUS
For a CIRCULAR search region, this field defines the search region's inner radius. See "Inner/Outer list".

Used only on the **High Point** feature.

WIDTH
For a BOX search region, this field defines the width of the rectangular search region. See "Width box".

Used only on the **High Point** feature.

LENGTH
For a BOX search region, this field defines the length of the rectangular search region. See "Length box".

Used only on the **High Point** feature.

BOUNDED or **UNBOUNDED**
This field appears for Line features. It determines the type of Line feature. It switches between BOUNDED and UNBOUNDED. See "Bounded list".

Used only on the **Line** feature.

EXTERIOR or **INTERIOR**
This field switches between EXTERIOR and INTERIOR; it describes the type of angle. See "Interior / Exterior list".

Used only on these features: **Angle Point**, **Corner Point**

REPORT VEC -
This command indicates the vector used for reporting deviation. See "Extended Sheet Metal Options area".

Used only on these features: **Line**, **Surface Point**, **Vector Point**

UPDATE VEC -
This command indicates the update vector that is used to pierce the CAD surface. See "Extended Sheet Metal Options area".

Used only on the **Vector Point** feature,

Angle VEC
This defines the angle vector for the feature. See "IJK Angle boxes".

REMEASURE
This field, if set to YES, re-measures the feature against the feature's measured values. See "Measure Now and Re-Measure Toggle".

Used only on these features: **Circle**, **Notch Slot**, **Square Slot**, **Round Slot**, **Cylinder**, **Polygon**

PUNCH -
This field indicates the direction of the punch through the sheet metal. It is an editable value. See "Extended Sheet Metal Options area".

Used only on these features: **Circle**, **Square Slot**, **Round Slot**

PIN -
This field indicates the direction of the point through the hole formed by the punch. See "Extended Sheet Metal Options area".

Used only on these features: **Circle**, **Square Slot**, **Round Slot**

REPORT -
This field indicates the vector used for reporting deviation. See "Extended Sheet Metal Options area".

Used only on the **Edge Point** feature.

Surface_REPORT -
This field indicates the vector used for reporting deviation. See "Extended Sheet Metal Options area".

Used only on the **Edge Point** feature.

MEASURE ORDER
This toggle field displays the order of measuring the sample hits. The available choices are Surface, Edge, or BOTH. See "Measure Order list".

Used only on the **Edge Point** feature.

Square or **RADIAL**
For a Plane feature, this field switches between Square and RADIAL. It defines the hit pattern for hits making up the feature. See "Pattern list".

Used only on the **Plane** feature.

Surface/, **Surface2/**, **Surface3/**
Any of these command lines switches between either THEO_THICKNESS, ACTL_THICKNESS, or THICKNESS_NONE. If the latter, then no thickness is used.

Otherwise, this displays the thickness of the part for the positive or negative values can be used. See "Use Thickness".

Edge/
For a Line feature, this command determines the edge thickness of the line. See "Use Thickness".

Used only on the **Line** feature.

MEASURE MODE
This command switches between these measuring modes: FINDNOMS, Vector, NOMINAL, MASTER, and SET NOM AX. See "Nominals Mode list".

RMEAS/
This command has three fields separated by commas. If you have a single RMEAS feature (relative feature), it occupies all three fields. If you have an RMEAS feature, one for each axis, they occupy the three fields left to right: X axis RMEAS feature, Y axis RMEAS feature, and Z axis RMEAS feature. See "Setting Up Relative Measure (RMEAS)".

The relative feature or features in this command must already exist in the measurement routine.

DIRECTION
This command defines the direction in which hits are taken. It switches between CCW (counterclockwise) and CW (clockwise). See "Direction List".

Used only on these features: **Circle**, **Cylinder**

CIRCULAR MOVES/
This command has a single YES/NO toggle field. If set to yes, then PC-DMIS moves the probe in a circular motion. See "Circular Moves".

Used only on these features: **Circle**, **Ellipse**, **Round Slot**, **Square Slot**, **Notch Slot**, **Cylinder**, **Cone**, **Sphere**, **Polygon**

AUTO WRIST/
This command has a single YES/NO toggle field. If set to YES, then during feature creation PC-DMIS automatically chooses the best probe angle to use for measuring the feature and inserts the appropriate TIP/ command before the feature. See "Auto Wrist".

CLEARPlane/
This command has a single YES/NO toggle field. If set to YES, then during feature creation PC-DMIS automatically inserts a `MOVE/CLEARPlane` command (relative to the current coordinate system and part origin) before the feature. See "Clearance Plane".

GRAPHICAL ANALYSIS/
This command has a YES/NO toggle field. If set to YES, then PC-DMIS displays a graphical analysis of the feature in the Graphic Display window. Three other fields become

enabled. These three fields, from left to right, allow you to determine the Graphical Analysis Point Size, the Plus Tolerance, and the Minus Tolerance. See "Analysis area".

FEATURE LOCATOR/
Initially, this command looks like this: `FEATURE LOCATOR/NO,NO,"<text instructions>"`

The left-most YES/NO toggle field indicates whether or not the **Feature Locator** tab displays a bitmap image. If you set this to YES, an additional field bounded by quotation marks becomes enabled, allowing you to type the full pathway to the bitmap image to display:

```
FEATURE LOCATOR/YES,"<pathway to bitmap file>",NO,"<text instructions>"
```

The next YES/NO toggle field indicates whether or not the **Feature Locator** tab plays an audio file (.wav). If you set this to YES, an additional field bounded by quotation marks becomes enabled, allowing you to type the full pathway to the audio file to play:

```
FEATURE LOCATOR/YES,"<pathway to bitmap file>",YES,"pathway to audio file","<text instructions>"
```

The final field, "<text instructions>", lets you display textual instructions in the **Feature Locator** tab. See "Feature Locator Tab" topic in the PC-DMIS Vision documentation.

SHOW_CONTACT_PARAMETERS
This YES/NO toggle field determines whether or not PC-DMIS displays additional contact parameters used with the Auto feature in the Edit window. Setting this to YES displays the following fields if applicable to the Auto feature: NUMHITS, NUMROWS, PITCH, DEPTH, STARTING DEPTH, ENDING DEPTH, SAMPLE HITS, SPACER, INDENT, AVOIDANCE MOVE, FIND HOLE, ON ERROR, READ POS.

SAMPLE METHOD
This toggle field determines whether surface sampling is done by using the hits from an existing feature or by sample hits.

- If SAMPLE METHOD = SAMPLE_HITS then the SAMPLE HITS and SPACER fields appear in the command block.
- If SAMPLE METHOD = SAMPLE_FEATURE then the SAMPLE FEATURE field appears in the command block, and the SAMPLE HITS and SPACER fields are hidden.

For details, see the "Working with Contact Sample Hits Properties" topic in the PC-DMIS CMM documentation.

Used only on these features: **Circle**, **Cone**, **Cylinder**, **Ellipse**, **Polygon**, **Notch**, **Round Slot**, **Square Slot**, **Surface Point**, **Line**

SAMPLE FEATURE
If the SAMPLE METHOD = SAMPLE_FEATURE, this field appears. It determines the feature to use for surface sampling.

For details, see the "Working with Contact Sample Hits Properties" topic in the PC-DMIS CMM documentation.

Used only on these features: **Circle**, **Cone**, **Cylinder**, **Ellipse**, **Polygon**, **Notch**, **Round Slot**, **Square Slot**, **Surface Point**, **Line**

SAMPLE HITS
For features that support sample hits, this value defines the number of sample hits to take during feature measurement. Acceptable values depend on the type of feature.

A single sample hit adjusts only the location (offset) where PC-DMIS measures the feature. Three or more sample hits also adjust the feature's vector (orientation).

For details, see the "Working with Contact Sample Hits Properties" topic in the PC-DMIS CMM documentation.

Used only on these features: **Angle Point**, **Circle**, **Cone**, **Corner Point**, **Cylinder**, **Edge Point**, **Ellipse**, **Line**, **Notch Slot**, **Polygon**, **Round Slot**, **Sphere**, **Square Slot**, **Surface Point**

SPACER
This field defines the distance from the nominal point location (or locations) that PC-DMIS uses to measure a sample plane if sample hits are specified.

For details, see the "Working with Contact Sample Hits Properties" topic in the PC-DMIS CMM documentation.

Used only on these features: **Surface Point**, **Edge Point**, **Angle Point**, **Corner Point**, **Plane**, **Circle**, **Ellipse**, **Round Slot**, **Square Slot**, **Notch Slot**, **Cylinder**, **Cone**, **Polygon**, **Line**

INDENT1, **INDENT2**, **INDENT3**
For all but Line, this defines offset distance from the feature's point or center location to the first sample hit.

For the Line feature, INDENT2 defines the offset distance from the line's end points to the sample hits for points two and three when three sample hits are used. INDENT1 defines the offset distance for point 1 when one or three sample hits are used.

For details, see the "Working with Contact Sample Hits Properties" topic in the PC-DMIS CMM documentation.

Used only on these features: **Edge Point**, **Angle Point**, **Corner Point**, **Notch Slot**, **Line**

NUMHITS
This field determines the number of hits to take when measuring the feature. For more information, see "Working with Contact Path Properties" in the PC-DMIS CMM documentation.

Used only on these features: **Line**, **Plane**, **Circle**, **Ellipse**, **Round Slot**, **Cylinder**, **Cone**, **Sphere**, **Polygon**

NUMROWS
This field determines how many rows of hits to use when measuring the feature. For more information, see "Working with Contact Path Properties" in the PC-DMIS CMM documentation.

Used only on the **Plane** feature.

NUMLEVELS
This field determines how many levels of hits to use when measuring features with multiple levels. For more information, see "Working with Contact Path Properties" in the PC-DMIS CMM documentation.

Used only on these features: **Cone**, **Cylinder**

DEPTH
This field determines the offset distance either below a surface or up from the bottom of a feature where PC-DMIS measures the feature. For more information, see "Working with Contact Path Properties" in the PC-DMIS CMM documentation.

Used only on these features: **Edge Point**, **Line**, **Circle**, **Ellipse**, **Round Slot**, **Square Slot**, **Notch Slot**, **Polygon**

STARTING DEPTH
This field defines the starting depth of the first level of hits for features with multiple levels. This depth is offset from the top of the feature. For more information, see "Working with Contact Path Properties" in the PC-DMIS CMM documentation.

Used only on these features: **Cone**, **Cylinder**

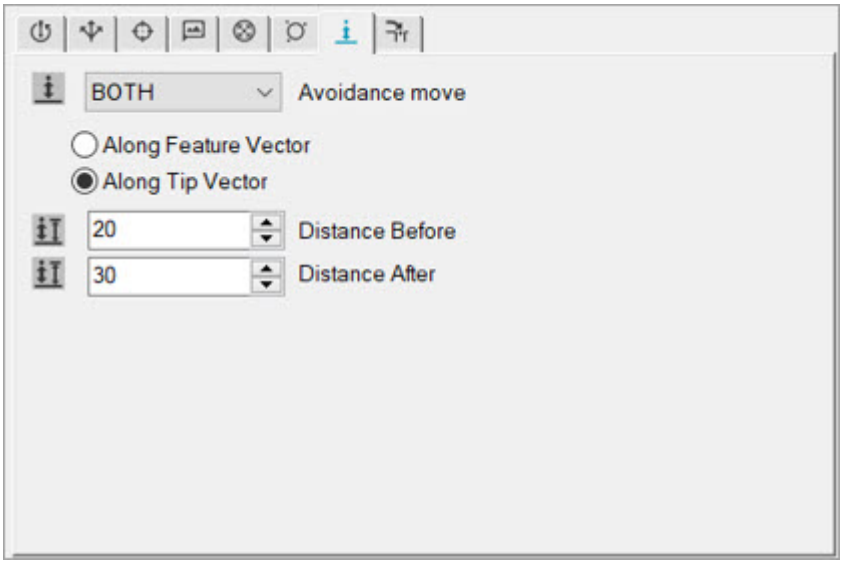
ENDING DEPTH
This field defines the ending depth of the last level of hits for features with multiple levels. This depth is offset from the top of the feature. For more information, see "Working with Contact Path Properties" in the PC-DMIS CMM documentation.

Used only on these features: **Cone**, **Cylinder**

PITCH
This field determines the distance between threads along the axis of the feature. For more information, see "Working with Contact Path Properties" in the PC-DMIS CMM documentation.

Used only on these features: **Circle**, **Cylinder**

AVOIDANCE MOVE/
You define the `AVOIDANCE MOVE` command from the **Contact Auto Move Properties** tab of the **Probe Toolbox**. From this tab you define the type of avoidance move from the **Avoidance move** list, the approach you want the tip to take and the amount to move before and after you create the Auto feature.



Probe Toolbox - Contact Auto Move Properties Tab

This tab becomes visible when you have the **Auto Feature** dialog box open and you enable a contact probe.

The **Avoidance move** list contains these options:

NO - PC-DMIS does not perform any avoidance move. This sets the `PTP_AvoidMove` setting entry to 0 (zero).

BOTH - PC-DMIS performs both the **Distance Before** and **Distance After** moves. This sets the `PTP_AvoidMove` setting entry to 1.

- The probe moves to a distance defined by the value set by the `PTP_AutoMoveDistance` setting entry above the centroid *before* it takes the first hit of the feature being created.
- The probe moves to the distance defined by the value set by the `PTP_AutoMoveDistance2` setting entry *after* it takes the last hit of the feature being created.

BEFORE - PC-DMIS only performs the **Distance Before** move where the probe moves to a distance defined by the `PTP_AutoMoveDistance` entry above the centroid *before* it takes the first hit of the feature being created. This sets the `PTP_AvoidMove` setting entry to 2.

AFTER - PC-DMIS only performs the **Distance After** move where the probe moves to the distance defined by the `PTP_AutoMoveDistance2` entry *after* it takes the last hit of the feature being created. This sets the `PTP_AvoidMove` setting entry to 3.

You must verify any measurement routine that uses the **Distance Before** and **Distance After** settings for collision detection if you intend on running it on an earlier version of PC-DMIS that only supports the **Distance Before** option. PC-DMIS uses the smaller of the two values for versions that only support the **Distance Before** option, which may result in a hardware crash.

For details on the Auto Move settings in the Settings Editor application, see "`PTP_AutoMove`" in the PC-DMIS Settings Editor documentation.

Select the tip's approach:

Along Feature Vector - PC-DMIS applies the avoidance move along the feature's vector.

Along Tip Vector - PC-DMIS applies the avoidance move along the tip's vector.

Depending on the option you select from the **Avoidance move** list, you can type the **Distance Before** and/or **Distance After** values. These let you define the avoidance move's distance before and after you create the Auto feature. For more information, see "Working with Contact Auto Move Properties" in the PC-DMIS CMM documentation.

USE BOUNDARY OFFSET
This YES/NO toggle field appears if VOID DETECTION=YES and if the current Auto feature is a plane. It determines whether or not a user-defined boundary offset distance is used for void detection. If this is set to YES, then the OFFSET field appears defining the minimum distance. If it is set to NO, then the OFFSET field is hidden, and the software uses a default distance of the radius of the current tip. For more information, see "Working with Contact Auto Move Properties" in the PC-DMIS CMM documentation.

Used only on these features: **Circle**, **Cylinder**, **Round Slot**, **Square Slot**, **Notch Slot**, **Polygon**

FIND HOLE
This toggle field determines the method PC-DMIS uses to find hole features. Available options include: DISABLED, CENTER, SINGLE HIT, or NOCENTER. For more information, see "Working with Contact Find Hole Properties" in the PC-DMIS CMM documentation.

Used only on these features: **Circle**, **Cylinder**, **Polygon**

ONERROR
This YES/NO field determines whether or not PC-DMIS uses improved error checking when it detects an unexpected or missed hit.

If set to YES and a machine error (such as an unexpected hit) occurs, then PC-DMIS displays the **Read Position** dialog box. You can then use your jog box to move the machine to the feature's location and attempt to re-measure it.

If set to NO, the usual "Movement Interrupted" message appears instead.

For more information, see "Working with Contact Find Hole Properties" in the PC-DMIS CMM documentation.

Used only on these features: **Angle Point**, **Circle**, **Edge Point**, **Corner Point**, **Ellipse**, **Round Slot**, **Square Slot**, **Notch Slot**, **Cylinder**, **Cone**, **Polygon**

READ POS
This YES/NO field determines whether or not PC-DMIS pauses execution above the surface feature displaying a message, asking if you want to use the current data. For more information, see "Working with Contact Find Hole Properties" in the PC-DMIS CMM documentation.

Used only on these features: **Circle**, **Ellipse**, **Round Slot**, **Square Slot**, **Notch Slot**, **Cylinder**, **Cone**, **Polygon**

SHOWHITS
This YES/NO toggle field determines whether or not PC-DMIS displays all the hits making up the feature. If set to YES, then PC-DMIS displays a HIT/BASIC command line for each hit.

If you want to see the hits in the Graphic Display window, see "Show Hit Targets".

HIT/BASIC
This command line displays the theoretical XYZ, the theoretical IJK, and the measured XYZ values for the hit.

Setting Up Relative Measure (RMEAS)

To set the relative measurement mode for Auto features, select **Insert | Parameter Change | Auto Relative Measure**. When you select this menu option, PC-DMIS inserts an `RMEAS` command into the Edit window. By default, PC-DMIS sets the mode to use the Default (I,J,K, T) mode. This mode (previously called Absolute mode) uses the RMEAS feature’s measured position and vector. It applies any positional offsets along that vector. For more information about this mode, see the "Default (I,J,K, T) RMEAS Mode" topic.

You can change the mode to the Legacy (I,J,K, X,Y,Z) mode if desired. This mode (previously called Normal mode) uses the deviation of the RMEAS feature’s position and orientation. To change the mode, select **Insert | Parameter Change | Auto Relative Measure**. For more information about this mode, see the "Legacy (I,J,K, X,Y,Z) RMEAS Mode" topic.

The **Insert | Parameter Change | Auto Relative Measure** menu option toggles between Default (I,J,K, T) mode and Legacy (I,J,K, X,Y,Z) mode.

Before you use RMEAS, ensure that the `RMEAS_modeDefaultForPlane` entry is correctly set. For details, see the "RMEAS_modeDefaultForPlane" topic in the "USER_AutoFeatures" section of the PC-DMIS Settings Editor documentation.

Also, if you are using a dual-arm machine, remember to also check the same setting in the USER_AutoFeatures_CMM2 section.

For information on how to use PC-DMIS Settings Editor, see the "Modifying Setting Entries" appendix.

You should insert the RMEAS command into the measurement routine before you use the **Relative to** option in the **Advanced measurement options** area in the **Auto Feature** dialog box. If no RMEAS command appears in the measurement routine, PC-DMIS uses the default RMEAS algorithm to compute the RMEAS. For more information, see the "Relative To" topic.

Default (I,J,K, T) RMEAS Mode

When an Auto feature has a relative planar measure feature associated with it (see "Relative To"), PC-DMIS measures the Auto feature in a location that is adjusted according to the following rules:

- The measuring orientation of the Auto feature is corrected by the rotation offset that exists between the orientation of the nominal and the actual RMEAS feature.
- The measuring location of the Auto feature is corrected by the positional offset that exists between the location of the nominal and the actual RMEAS feature.

The Edit window command for this option is:

```
RMEAS/DEFAULT (I,J,K, T)
```

Math Process of the Default (I,J,K, T) RMEAS Mode

The Default (I,J,K T) RMEAS mode controls I, J, K, T, and therefore works well with RMEAS features such as planes.

Using the numerical values taken from the example features in the table below, follow these steps to understand how RMEAS/DEFAULT (I,J,K, T) functions when the RMEAS feature is "plane reducible".

A "reducible" feature is a feature that also contains information to be used as another feature. For example, a circle feature is point reducible because a point feature can be automatically extracted from the circle's centroid. It is also line reducible because a line can be drawn along the vector and through the centroid. It is plane reducible because a plane can be drawn intersecting all of the circle's hits.

1. Create a coordinate system (roto-translation matrix) given the nominal RMEAS feature XYZ IJK and the intersection vector between the nominal and the actual RMEAS feature.
2. Move the nominal Auto feature XYZ and IJK into the RMEAS coordinate system.
3. Zero-out the T value and rotate the nominal Auto feature XYZ on the plane of the actual RMEAS feature.
4. Offset the transformed Auto feature XYZ back to the original T offset plus the distance between the actual and the nominal RMEAS feature.
5. Move the transformed Auto feature XYZ and IJK back into the PART coordinate system.
6. Use the new nominal XYZ and IJK to measure the Auto feature.

Example Feature	XYZ	IJK
Nominal RMEAS Feature	0, 0, 2	0, 0, 1
Actual RMEAS Feature	-1, 0, 1	-0.7071, 0, 0.7071
Nominal Auto Feature	2, 1, 0	0.7071, 0, 0.7071
New Nominal Auto Feature	1.4142, 1, 0.4142	0, 0, 1

Example with Translation only	XYZ	IJK
Nominal RMEAS Feature	124, 50, 0	0, 0, 1
Actual RMEAS Feature	123, 50, -1	0, 0, 1
Nominal Auto Feature	93.5, 19.5, 0	0, 0, 1
New Nominal Auto Feature	93.5, 19.5, -1	0, 0, 1

Legacy (I,J,K, X,Y,Z) RMEAS Mode

The Legacy (I,J,K, X,Y,Z) RMEAS mode takes the position and the orientation of the reference feature into account.

To understand this mode, examine an Auto Circle with three sample hits. PC-DMIS first takes three hits on the surface around the circle and then measures the circle based on the plane's location and the surface normal vector's orientation. Therefore, if the plane is at a 45-degree angle, PC-DMIS also measures the Auto Circle at a 45-degree angle.

Similarly, if the relative measure feature is rotated from its original orientation, then the associated feature is also measured with the same rotational offset.

Before you use Legacy RMEAS mode, ensure that the `RMEAS_modeDefaultForPlane` entry is correctly set. For details, see the "RMEAS_modeDefaultForPlane" topic in the "USER_AutoFeatures" section of the PC-DMIS Settings Editor documentation.

For information on how to use PC-DMIS Settings Editor, see the "Modifying Setting Entries" appendix.

This process makes Legacy mode slightly smarter than Default mode, because when it looks at the reference feature, it only offsets the main feature by valid axes for the reference feature type. For example, it makes more sense to shift in a plane's normal vector instead of in all directions, which Legacy mode now does.

The Edit window command line for this option is:

```
RMEAS/LEGACY (I,J,K, X,Y,Z)
```

Math Process of the Legacy (I,J,K, X,Y,Z) RMEAS Mode

The Legacy (I,J,K, X,Y,Z) RMEAS mode controls I, J, K, X,Y, Z (T) and therefore works well with 3D RMEAS features, such as circles with sample hits.

Use the numerical values from the example features in the table below, and follow these steps to understand how RMEAS/LEGACY (I,J,K, X,Y,Z) functions.

1. Create a coordinate system (roto-translation matrix) given the nominal RMEAS feature XYZ IJK.
2. Move the nominal Auto feature XYZ and IJK into the RMEAS coordinate system.
3. Create a new coordinate system given the actual RMEAS feature XYZ IJK.
4. Now, move the roto-translated Auto feature XYZ and IJK back into the PART coordinate system using the new RMEAS coordinate system.
5. Use the new nominal XYZ and IJK to measure the Auto feature.

Example Feature	XYZ	IJK
Nominal RMEAS Feature	0, 0, 2	0, 0, 1
Actual RMEAS Feature	-1, 0, 1	-0.7071, 0, 0.7071
Nominal Auto Feature	2, 1, 0	0.7071, 0, 0.7071
New Nominal Auto Feature	1.8284, 1, 1	0, 0, 1

Example with Translation Only	XYZ	IJK
Nominal RMEAS Feature	124, 50, 0	0, 0, 1
Actual RMEAS Feature	123, 50, -1	0, 0, 1
Nominal Auto Feature	93.5, 19.5, 0	0, 0, 1
New Nominal Auto Feature	92.5, 19.5, -1	0, 0, 1

Creating Measured Features

Creating Measured Features: Introduction

Whenever you take hits on a part, PC-DMIS interprets those hits into different features depending on the number of the hits, their vectors, and so forth. PC-DMIS creates measured features from these hits. PC-DMIS supports the following measured features:

- Measured Point
- Measured Line
- Measured Plane
- Measured Circle
- Measured Sphere
- Measured Torus
- Measured Cone
- Measured Cylinder
- Measured Round Slot
- Measured Square Slot

These features are described in detail in the "Understanding the Command Format" topic.

The following major topics are covered in this chapter.

- Understanding the Command Format
- Inserting a Measured Feature
- Editing a Measured Feature
- Overriding a Guessed Measured Feature
- Creating Measured Feature Sets

You can also use insert measured features into your measurement routine by using the **Quick Start** toolbar. For information, see the "Quick Start: Measure Toolbar" topic in the "Using Toolbars" chapter.

Understanding the Command Format

All measured features are displayed in the following format in the Command Mode of the Edit window. There will be slight variations that are explained more thoroughly in the following sections. The actual Edit report will be displayed using all CAPS.

For example:

```
feature_name=FEAT/FEATURE_TYPE,TOG1,TOG4
THEO/TX,TY,TZ,TI,TJ,TK,TD,TMD,TL
ACTL/X,Y,Z,I,J,K,D,MD,L
MEAS/TOG2,TOG3,
   HIT/TOG5,TX,TY,YZ,TI,TJ,TK,X,Y,Z,USE_THEO=TOG6
ENDMEAS/
```

feature_name - This displays the name of the feature. This is a user editable field.

FEATURE_TYPE - This denotes the type of feature and is the same as TOG2 but is non-editable and cannot be toggled.

..... - This indicates that what follows is unique to each feature.

TOG1 - This field is present in all features and can be toggled between RECT / POLR. If you set this to RECT, PC-DMIS displays all the points in the Cartesian system (x, y, z). If you set this to POLR, PC-DMIS displays all the points in the Polar system (x_radius, y_angle, z_height). Vectors do not change.

***TOG2* -** This field is present in all measured features and can be switched between:

> **CIRCLE / CONE / CURVE / CYLINDER / LINE / PLANE / POINT / SET / SLOT / SPHERE / TORUS**
>
> POINT is the default feature type when the measured command line is opened for the first time in a measurement routine. The default feature type then becomes the last measured feature type.

TOG3 - This field represents the number of hits to take, according to the type of feature displayed in *TOG2*. The HIT line is varied, based on the number of hits you define. For example, 1 hit = 1 HIT/BASIC line, 3 hits = 3 HIT/BASIC lines. The required minimum number is indicated as the default.

***TOG4* -** This field also takes unique values according to the type of feature represented in TOG2. Linear features allow you to toggle between BOUND/ UNBOUND. Circular features allow you to switch between IN/OUT. Angular features allow you to switch between LENGTH/ANGLE.

TOG5 - This field represents the type of hit that is to be taken:

BASIC

TOG6 - This field allows you to determine whether or not to use the theoretical vector as the approach vector for the hit. This defaults to YES. If set to NO, PC-DMIS calculates the approach vector by subtracting the theoretical hit point (X,Y,Z) from the current probe position.

TX,TY,TZ,TI,TJ,TK - These numbers (TX,TY,TZ) represent the theoretical target vector and the theoretical approach vector (TI,TJ,TK) and you can edit them.

TD - For circular features, this number is the theoretical diameter.

TMD - For a torus feature, this number is the theoretical minor diameter.

X,Y,Z,I,J,K - These numbers are non-editable and represent the measured point and measured approach vector.

D - For circular features, this number is the measured diameter.

MD - For a torus feature, this number is the minor diameter.

TL - This is the theoretical length of features that have a length.

L - This is the measured length of features that have a length.

Basic Measurement Format for a Point

A single hit is required for a point.

```
Feature_name=FEAT/POINT,TOG1
THEO/TX,TY,TZ,TI,TJ,TK
ACTL/X,Y,Z,I,J,K
MEAS/POINT,TOG3
   HIT/…
ENDMEAS/
```

TOG1 - This field can be toggled between RECT / POLR.

TOG3 - This list the number of hits that PC-DMIS should take to measure this feature. Since a point can only have one point, you cannot edit this value for this feature.

... - A single hit is entered at the ellipsis.

Basic Measurement Format for a Line

The minimum number of hits for a line is two.

```
Feature_name=FEAT/LINE,TOG1,TOG4
THEO/TX,TY,TZ,TI,TJ,TK
ACTL/X,Y,Z,I,J,K
MEAS/LINE,TOG3,TOG7
   ...
ENDMEAS/
```

TOG1 - This field can be toggled between RECT / POLR.

TOG3 - This value is user-editable and is determined by the feature being measured. The HIT line is varied, based on the number of hits set up by the user. For example, 2 hits = 2 HIT/BASIC lines, 3 hits = 3 HIT/BASIC lines.

TOG4 - This field can be toggled between BND / UNBND. If set to BND, the THEO and ACTL fields, no longer display the vector information, but instead show the XYZ values for the second point along with the first.. See "Line Definition Format" later in this chapter.

TOG7 - This field switches between the various reference types. These include FEATURE, 3D, WORKPLANE, XPLUS, YPLUS, ZPLUS, XMINUS, YMINUS, ZMINUS.

... - As many hits as are necessary are entered at the ellipsis.

Measured Lines and Workplanes

When creating a measured line, PC-DMIS expects the hits for the line to be taken at a vector perpendicular to the current workplane.

For example, if your current workplane is ZPLUS (with a vector 0,0,1), and you have a block-like part, the hits for the measured line must be on a vertical face of that part, such as the front or side.

If you then wanted to measure a line feature on the top surface of the part, you would need to switch the workplane to XPLUS, XMINUS, YPLUS, or YMINUS, depending on the direction of the line.

Basic Measurement Format for a Plane

The minimum number of hits for a plane is three.

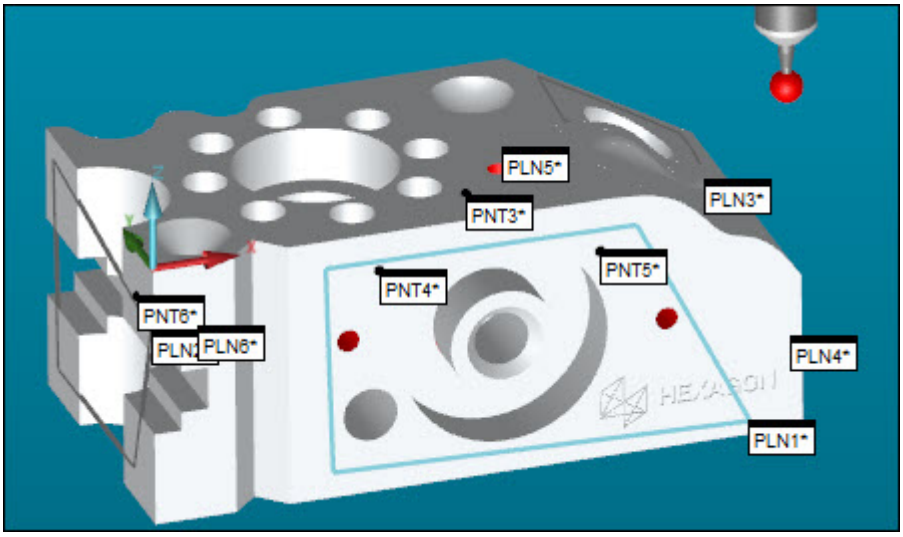
```
Feature_name=FEAT/PLANE,TOG1
THEO/TX,TY,TZ,TI,TJ,TK
ACTL/X,Y,Z,I,J,K
MEAS/PLANE,TOG3
   ...
ENDMEAS/
```

TOG1 - This field can be toggled between RECT / POLR.

TOG3 - This value is user editable and is determined by the feature being measured. The HIT line is varied, based on the number of hits set up by the user. For example, 3 hits = 3 HIT/BASIC lines, 8 hits = 8 HIT/BASIC lines.

... - As many hits as are necessary are entered at the ellipsis.

When you create a plane feature, PC-DMIS shows the outline of the plane from the plane's hits in the Graphic Display window:



Sample plane from four hits taken on the Y- face

Basic Measurement Format for a Circle

The minimum number of hits for a circle is three.

```
Feature_name=FEAT/CIRCLE,TOG1,TOG4,TOG6
THEO/TX,TY,TZ,TI,TJ,TK,TD
ACTL/X,Y,Z,I,J,K,D
MEAS/CIRCLE,TOG3,TOG7
   ...
ENDMEAS/
```

TOG1 - This field can be toggled between RECT / POLR.

TOG3 - This value is user editable and is determined by the feature being measured. The HIT line is varied, based on the number of hits set up by the user. For example, 3 hits = 3 HIT/BASIC lines, 5 hits = 5 HIT/BASIC lines.

TOG4 - This field can be toggled between IN / OUT.

TOG6 - This field switches between the various Best Fit types available. These include: LEAST_SQR, MIN_SEP, MAX_INSC, MIN_CIRCSC, FIXED_RAD

TOG7 - This field switches between the various reference types. These include FEATURE, 3D, WORKPLANE, XPLUS, YPLUS, ZPLUS, XMINUS, YMINUS, ZMINUS.

... - As many hits as are necessary are entered at the ellipsis.

Basic Measurement Format for a Sphere

The minimum number of hits for a sphere is four.

```
Feature_name=FEAT/SPHERE,TOG1,TOG4
THEO/TX,TY,TZ,TI,TJ,TK,TD
ACTL/X,Y,Z,I,J,K,D
MEAS/SPHERE,TOG3
   ...
ENDMEAS/
```

TOG1 - This field can be toggled between RECT / POLR.

TOG3 - This value is user editable and is determined by the feature being measured. The HIT line is varied, based on the number of hits set up by the user. For example, 4 hits = 4 HIT/BASIC lines, 7 hits = 7 HIT/BASIC lines.

TOG4 - This field can be toggled between IN / OUT.

... - As many hits as are necessary are entered at the ellipsis.

Basic Measurement Format for a Torus

The minimum number of hits for a torus is seven.

```
Feature_name=FEAT/TORUS,TOG1,TOG4
THEO/TX,TY,TZ,TI,TJ,TK,TD,TMD
ACTL/X,Y,Z,I,J,K,D,MD
MEAS/TORUS,TOG3
   ...
ENDMEAS/
```

TOG1 - This field can be toggled between RECT / POLR.

TOG3 - This value is user editable and is determined by the feature being measured. The HIT line is varied, based on the number of hits set up by the user. For example, 7 hits = 7 HIT/BASIC lines, 9 hits = 9 HIT/BASIC lines.

TOG4 - This field can be toggled between IN / OUT.

... - As many hits as are necessary are entered at the ellipsis.

Basic Measurement Format for a Cone

The minimum number of hits for a cone is six.

```
Feature_name=FEAT/CONE,TOG1,TOG4,TOG5
THEO/TX,TY,TZ,TI,TJ,TK,TL,TD1,TD2
ACTL/X,Y,Z,I,J,K,L,D1,D2
MEAS/CONE,TOG3
   ...
ENDMEAS/
```

TOG1 - This field can be toggled between RECT / POLR.

TOG3 - This value is user editable and is determined by the feature being measured. The HIT line is varied, based on the number of hits set up by the user. For example, 6 hits = 6 HIT/BASIC lines, 11 hits = 11 HIT/BASIC lines.

TOG4 - This field can be toggled between IN / OUT.

TOG5 - This field can be toggled between LENGTH / ANGLE.

... - As many hits as are necessary are entered at the ellipsis.

TD1,TD2 - These are the cone's two theoretical diameters.

D1,D2 - These are the actual measured values for the cone's two diameters.

Basic Measurement Format for a Cylinder

The minimum number of hits for a cylinder is six.

```
Feature_name=FEAT/CYLINDER,TOG1,TOG4,TOG6
THEO/TX,TY,TZ,TI,TJ,TK,TD,TL
ACTL/X,Y,Z,I,J,K,D,L
MEAS/CYLINDER,TOG3
   ...
ENDMEAS/
```

TOG1 - This field can be toggled between RECT / POLR.

TOG3 - This value is user editable and is determined by the feature being measured. The HIT line is varied, based on the number of hits set up by the user. For example, 6 hits = 6 HIT/BASIC lines, 11 hits = 11 HIT/BASIC lines.

TOG4 - This field can be toggled between IN / OUT.

TOG6 - This field switches between the various Best Fit types available. These include: LEAST_SQR, MIN_SEP, MAX_INSC, MIN_CIRCSC, FIXED_RAD

... - As many hits as are necessary are entered at the ellipsis.

If you create a measured cylinder with more than two rows, and later change the **Number of Hits** in the **Measured Cylinder** dialog box (**Insert | Feature | Measured Feature**), PC-DMIS will keep the number of rows the same.

Basic Measurement Format for a Round Slot

The minimum number of hits for a round slot is six.

```
Feature_name=FEAT/SLOT,TOG1,TOG2
THEO/TX,TY,TZ,TI,TJ,TK,SI,SJ,SK,TW,TL
ACTL/X,Y,Z,I,J,K,MI,MJ,MK,W,L
MEAS/SLOT,TOG3,TOG4
   ...
ENDMEAS/
```

TOG1 - This field can be toggled between RECT / POLR.

TOG2 - This field can be toggled between IN / OUT.

TX,TY,TZ - Theoretical XYZ

TI,TJ,TK - Theoretical IJK vector

SI,SJ,SK - Theoretical IJK slot vector

TW - Theoretical width

TL - Theoretical length

X,Y,Z - Actual measured XYZ

I,J,K - Actual measured IJK

MI, MJ,MK - Measured IJK slot vector

W - Actual measured width

L - Actual measured length

TOG3 - This value is user editable and is determined by the feature being measured. The HIT line is varied, based on the number of hits set up by the user. For example, 6 hits = 6 HIT/BASIC lines, 8 hits = 8 HIT/BASIC lines.

TOG4 - *This value lets you choose the reference type for the slot.*

... - As many hits as are necessary are entered at the ellipsis.

Basic Measurement Format for a Square Slot

The minimum number of hits for a square slot is five.

```
Feature_name=FEAT/SLOT,TOG1,TOG2
THEO/TX,TY,TZ,TI,TJ,TK,SI,SJ,SK,TW,TL
ACTL/X,Y,Z,I,J,K,MI,MJ,MK,W,L
MEAS/SLOT,TOG3,TOG4
   ...
ENDMEAS/
```

TOG1 - This field can be toggled between RECT / POLR.

TOG2 - This field can be toggled between IN / OUT.

TX,TY,TZ - Theoretical XYZ

TI,TJ,TK - Theoretical IJK vector

SI,SJ,SK - Theoretical IJK slot vector

TW - Theoretical width

TL - Theoretical length

X,Y,Z - Actual measured XYZ

I,J,K - Actual measured IJK

MI, MJ,MK - Measured IJK slot vector

W - Actual measured width

L - Actual measured length

TOG3 - This value is user editable and is determined by the feature being measured. The HIT line is varied, based on the number of hits set up by the user. For example, 5 hits = 5 HIT/BASIC lines.

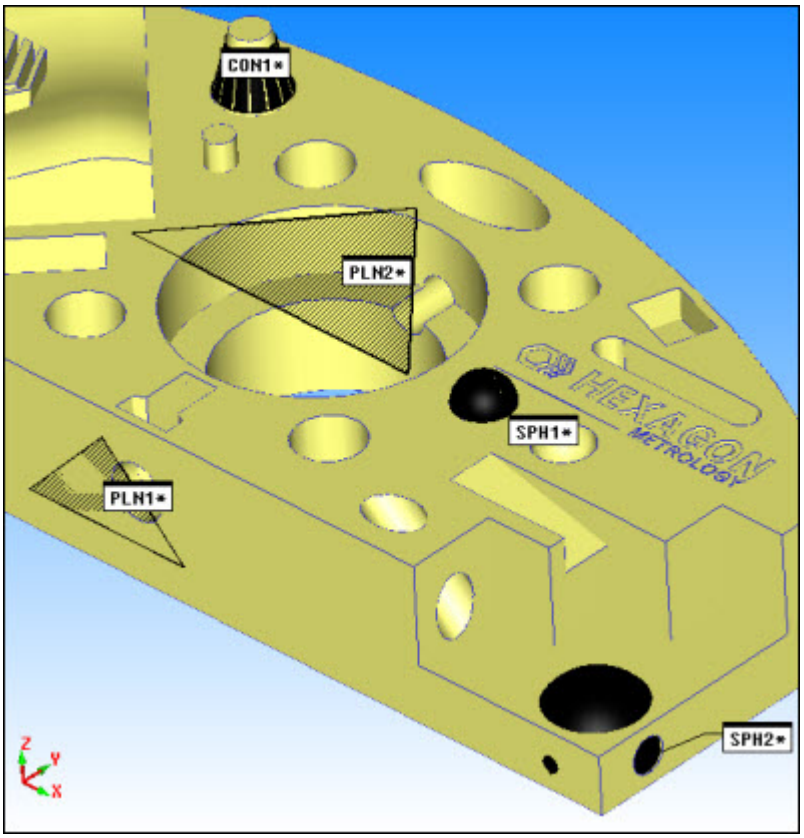
TOG4 - This value lets you choose the reference type for the slot.

... - As many hits as are necessary are entered at the ellipsis.

Inserting a Measured Feature

PC-DMIS allows you to insert measured features into your measurement routine by interpreting your probe hits and guessing the correct feature type. If PC-DMIS guesses incorrectly, you can force PC-DMIS to choose the correct feature type as long as you have taken the minimum number of hits for the desired feature.

As hits are taken and once the feature is created, PC-DMIS draws the measured feature on the screen. For 3D measured features (Torus, Cylinder, Sphere, Cone) and for the 2D Plane feature, PC-DMIS will draw the feature with a shaded surface.



Example showing the measured features displayed with shaded surfaces.

Hiding Shaded Plane Features

You can hide shaded planes by setting the **None** option in the **Display** area of the **Measured Plane** dialog box (**Insert | Feature | Measured Feature**). You can also globally hide all drawn shaded planes for future plane features by marking the **Do Not Display Plane** check box in the **Setup Options** dialog box.

Changing Feature Color

If desired, you can modify the feature color used during feature creation by using the **ID Setup** tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**). See the **Color** check box that appears after choosing **Features** under the **Labels for** item.

For information on creating the different feature types, consult the documentation set for your PC-DMIS configuration:

- PC-DMIS CMM
- PC-DMIS Portable

The procedures given in the following topic assume that you are working in Offline mode.

To Force the Insertion of a Certain Measured Feature Type

If PC-DMIS guesses the wrong measured feature type, you can cause it to insert the desired type by selecting the correct measured feature from the **Measured Features** toolbar or submenu *prior to pressing the END key*. Once you press the END key, PC-DMIS will insert the selected feature type into the Edit window.

Guessing a Measured Feature Type

If the **Measured Features** toolbar is set to **Measured Guess** ( ), then PC-DMIS is in Guess Mode. The following table shows the minimum number of hits PC-DMIS needs to guess a particular measured feature and that feature's dimension type.

Minimum # of Hits	Feature	Dimension
1	Point	1D
2	Line	2D
3	Plane	2D
3	Circle	2D
6	Cylinder	3D
6	Cone	3D
4	Sphere	3D
7	Torus	3D
6	Round Slot	2D
5	Square Slot	2D

Measured Point - Rules:

- Probe compensation is in the nearest axis (X, Y, or Z). This is determined based on the direction of machine motion at the time the hit is taken. Always approach normal to the surface.
- Only measure points on surfaces perpendicular to the X, Y, or Z axis to ensure accurate probe compensation. Use Vector or Surface points for other surfaces (Auto feature).
- Measured points are 1D; therefore, dimensional information is only valid in one axis (X, Y, or Z).

Measured Line - Rules:

- Measured lines are 2D; therefore, they are dependent on the active workplane for calculation purposes. You must activate the appropriate workplane before you measure a line.
- You control the direction of the measured line. The direction will go from the first hit towards the second hit.
- The dimensional information in the X, Y, or Z axis is from the centroid of the line.

Measured Circle - Rules:

- Measured circles are 2D; therefore, they are dependent on the active workplane for calculation purposes. You must activate the appropriate workplane before you measure a circle.
- A minimum arc of 90 degrees is required to accurately calculate a measured circle.
- The dimensional information in the X, Y, or Z axis is from the centroid of the circle, and the diameter is the average diameter by default (least squares).

Measured Plane - Rules:

- Measured planes are 3D; therefore, they are not dependent on the active workplane for calculation purposes.
- The IJK vector for the plane is perpendicular to the plane, and its direction points away from the material of the part.
- The dimensional information in the X, Y, or Z axis is from the centroid of the plane.

Measured Cylinder - Rules:

- Measured cylinders are 3D; therefore, they are not dependent on the active workplane for calculation purposes.
- You control the direction of the IJK vector for the cylinder. It goes from the first circular cross-section toward the second circular cross-section. When possible, take three circular cross-sections to increase the hit data used to calculate the cylinder.

- The dimensional information in the X, Y, or Z axis is from the centroid of the cylinder, and the diameter is the average by default (least squares).

Measured Cone - Rules:

- Measured cones are 3D; therefore, they are not dependent on the active workplane for calculation purposes.
- You do not control the direction of the IJK vector for the cone. The IJK vector always points away from the vertex of the cone. When possible, take three circular cross-sections to increase the hit data used to calculate the cone.
- The dimensional information in the X, Y, or Z axis is from the centroid of the cone.

Measured Sphere - Rules:

- Measured spheres are 3D; therefore, they are not dependent on the active workplane for calculation purposes.
- In some cases, it is not possible to take a hit on top of the sphere. In these cases, take three circular cross-sections. The IJK vector direction will go from the first toward the last cross-section.
- The dimensional information in the X, Y, or Z axis is from the centroid of the sphere, and the diameter is the average.

Measured Torus - Rules:

- Measured tori are 3D; therefore, they are not dependent on the active workplane for calculation purposes.
- The first three hits must be taken in a plane around the torus that is perpendicular to the center circle.
- The dimensional information in the X, Y, or Z axis is from the centroid of the torus.

Measured Round Slot - Rules:

- Six hits are required.
    - Option 1: Two points on each straight side and one point on each curve.
    - Option 2: Three points on each curve.

Measured Square Slot - Rules:

- Five hits are required: Two points on one of the long sides and one hit on each of the three remaining sides.
- The hits must be taken in a strictly clockwise or counterclockwise direction.

Using Guess Mode

1. Access the Edit window, and place it in either Command Mode or Summary Mode.
2. Place PC-DMIS into Program Mode, and set the appropriate probe depth.

3. Access the **Measured Features** toolbar and then click the **Guess Mode** icon .
4. Click on the model of the part at the location where you want to insert the feature.
    - *If you're using an imported wireframe CAD model*, PC-DMIS automatically uses the nearest wire as the basis for the feature you selected.
    - *If you're using an imported solid CAD model*, PC-DMIS counts each mouse click as an individual hit.
5. Press the End key. PC-DMIS interprets your hits and places the guessed feature into the Edit window.

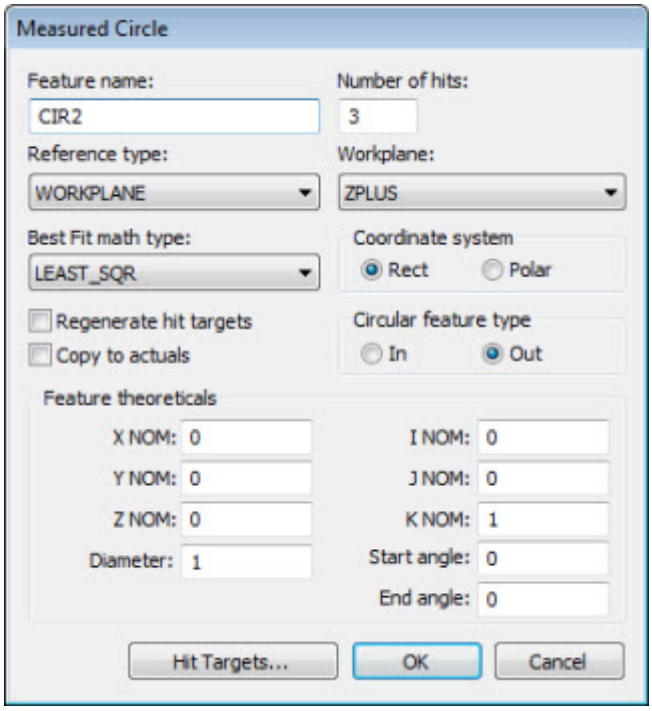
For information about the **Guess Mode** icon and the **Measured Features** toolbar, see "Measured Features Toolbar" in the "Using Toolbars" chapter.

Editing a Measured Feature

PC-DMIS will allow you to select the desired measured feature in the Edit window and make any corrections directly to the Edit window. The **Measured Feature** dialog box was created to offer a user friendly alternative to editing the Edit window.

To open a **Measured Feature** dialog box, follow these steps:

1. Place the cursor within the first four lines of the desired measured feature.
2. Press the **F9** key.



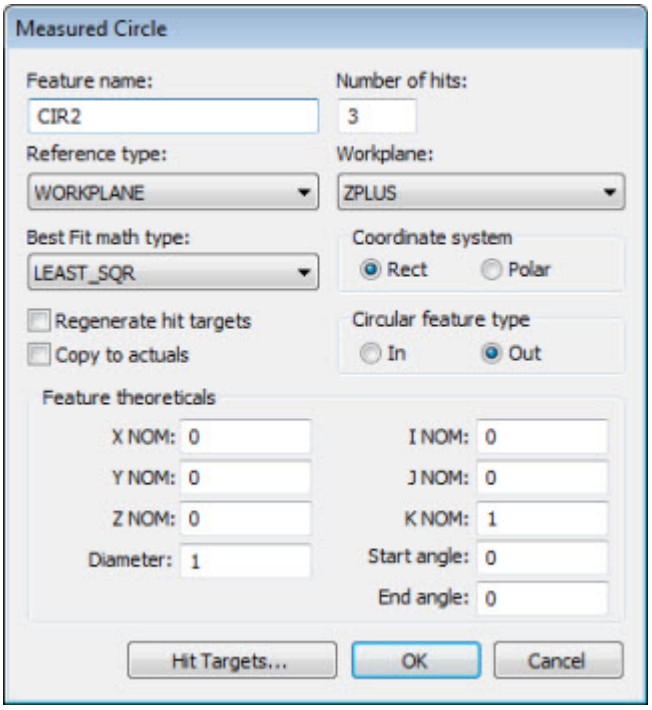
Measured Circle Dialog Box

Generally a **Measured Feature** dialog box opens based on the feature type. However, if you place the cursor on a listed hit (such as HIT/BASIC) within the measured feature and you press the **F9** key, PC-DMIS instead displays the **Measured Hits** dialog box for the selected hit.

Measured Feature Dialog Box Description

Measured features can be created or edited using the **Measured Feature** dialog box.

Select **Insert | Feature | Measured Feature** and then selecting an item from that menu to create your feature. Once created, place the cursor within the first four lines of the measured feature and press the F9 key on your keyboard to display the **Measured Feature** dialog box.



Measured Circle Dialog Box

The following topics describe the different elements of the **Measured Feature** dialog box. Some elements of the dialog box may only appear for certain feature types.

Feature Name

The **Feature Name** box allows you to change the name of the displayed feature.

You can also change the name in the Edit window. To do that, highlight the feature ID in the Edit window, type in a new identification and press the Enter key.

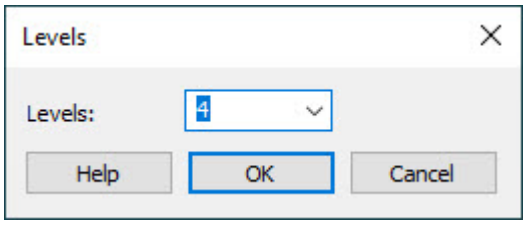
Number of Hits

The **Number of hits** box allows you to change the number of hits for a specified feature.

Suppose there are four hits in the edit box. If you delete a hit, the software removes the last hit (#4) in the feature list. If you delete two hits, the software removes the last two hits (#4 and #3). PC-DMIS renumbers the remaining hits based on its current numbering assignment.

If you add a hit, PC-DMIS increases the **Hit Targets** list by one, displaying an extra hit at the end of the hit list. This hit does not indicate any x, y, z, i, j, k values until the measurement routine is executed. At that time, PC-DMIS prompts you to take the additional hit. PC-DMIS asks if the hits are to be equally spaced.

- If you click **Yes**, PC-DMIS takes the hits in equally spaced intervals. For a cone, sphere, cylinder, or torus feature, PC-DMIS displays a **Levels** dialog box.



Levels Dialog Box

You can use this dialog box to specify the number of levels PC-DMIS uses to equally space the hits. The default is two.

- If you click **No**, PC-DMIS displays the hit values as 0, 0, 0, 0, 0, 1. You then need to manually enter the hit values.

Reference Type

Some measured features (circles, ellipses, lines, polygons, and slots) can be projected relative to a reference plane.

The **Reference Type** list controls whether or not the measured feature is 3D (not projected), projected relative to the current workplane, or projected relative to another specified plane. This affects mathematically how the final characteristics of the feature are derived.

For a detailed explanation on reference types, see the description of the **Reference Feature** area in the "Reference Feature" portion of "Using the Quick Start Dialog Box" topic in the "Using Other Windows, Editors, and Tools" chapter.

Best Fit Math Type

This **Best Fit Math Type** list indicates the type of math algorithm that will be used to measure the feature. LEAST_SQR is the standard Best Fit method.

For legacy Form dimensions (Circularity, Cylindricity, Flatness, and Straightness), as well as a Location dimension's RN Line, PC-DMIS uses the feature solution to compute the dimension. By default, this is Least Squares. However, you can choose to solve the feature using Minimum Separation, Maximum Inscribed, Minimum Circumscribed, or Fixed Radius regression algorithms.

PC-DMIS computes Geometric Tolerance Form commands, on the other hand, using the Chebyshev algorithm (Min/Max) as required by the Y14.5 standard. Because of the change in calculation, PC-DMIS generally computes Geometric Tolerance Form dimension commands to a slightly smaller value than their legacy counterparts.

See "Calculation List" in the "Creating Auto Features" chapter for a discussion on these types.

Regenerate Hit Targets

The **Regenerate Hit Targets** check box regenerates this feature's `HIT/BASIC` commands so that they are updated with changed data from the **Feature** Theoreticals area.

Copy to Actuals

The **Copy to Actuals** check box copies any changes made to the **Feature Theoreticals** area of the **Measured Feature** dialog box (**Insert | Feature | Measured Feature**) and applies the same changes to the actual measured data.

Coordinate System

The **Coordinate System** area allows you to choose between rectangle and polar coordinates. If the Rect option is selected, all points are represented in Cartesian system (x, y, z). If Polar is selected, all points are displayed in polar system (x_radius, y_angle, z_height). Vectors do not change.

Angular Definition Format

If an angular feature is displayed, you can choose between LENGTH and ANGLE.

- *The length option* displays the diameters of two circles. It also displays the length between the two circles.
- *The angle option* will display the nominal (x, y, z) and vector (i, j, k) of the point. It also displays the angle value.

Circular Feature Type

If a circular feature is displayed, PC-DMIS allows you to choose between IN and OUT.

Line Definition Format

If a linear feature is displayed, PC-DMIS will allow you to choose between the Bound and Unbound options in the **Linear Definition Format** area.

Selecting **Bound** causes PC-DMIS to display the two end points that make up the line in the **Feature Theoreticals** area, like this:

X, Y, Z

and

X2 Nom, Y2 Nom, and **Z2**

For Bounded lines, the **Length** value is grayed out and unavailable for modification.

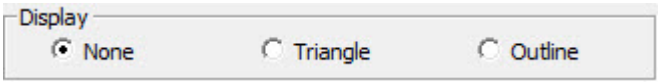
Selecting **Unbound** causes PC-DMIS to display the line's nominal information in the Feature Theoreticals area, like this:

X, Y, Z, and **length**

and

I Nom, J Nom, and **K**

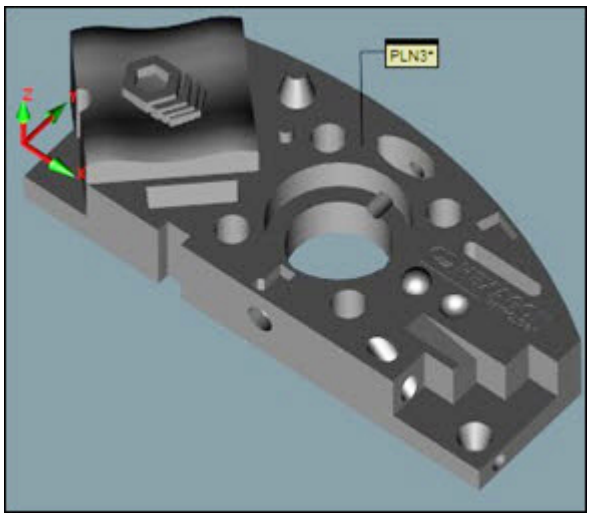
Using the Display Area



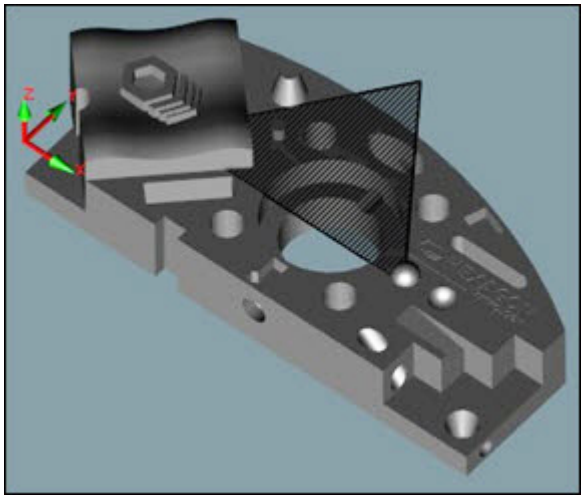
Display Area

This area defines how the plane feature draws in the Graphic Display window. It contains these options:

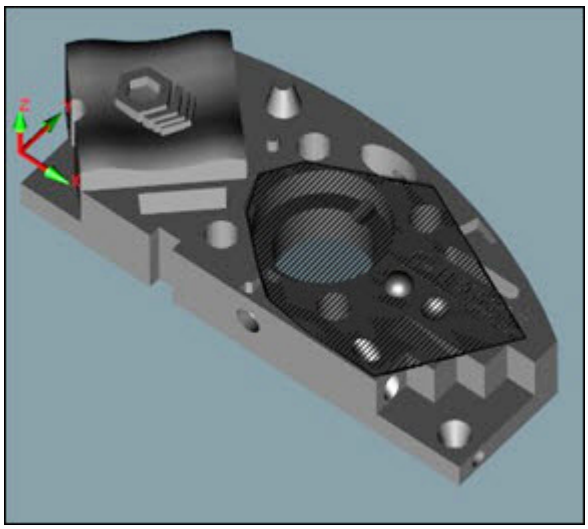
None - PC-DMIS only displays the ID of the constructed plane in the Graphic Display window. It does not display a drawing or outline of the constructed plane.



Triangle - PC-DMIS draws the constructed plane as a shaded triangle. The size of the constructed plane depends on the number of hits that make up the plane.



Outline - PC-DMIS draws the constructed plane as an outline from all the hits. The size depends on the number of hits that make up the constructed plane.



The Display Outline of Plane or Do Not Display Plane options on the **General** tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**) define the default display state for future measured or constructed planes. They do not affect the display state of existing planes.

Feature Theoreticals

This area contains the theoretical data for the feature. You can update this data by making changes and clicking **OK**. Note that this will only update the theoretical data. If you want to affect the hits and the actual measured data, select the **Regenerate Hits** and **Copy to Actuals** check boxes described above.

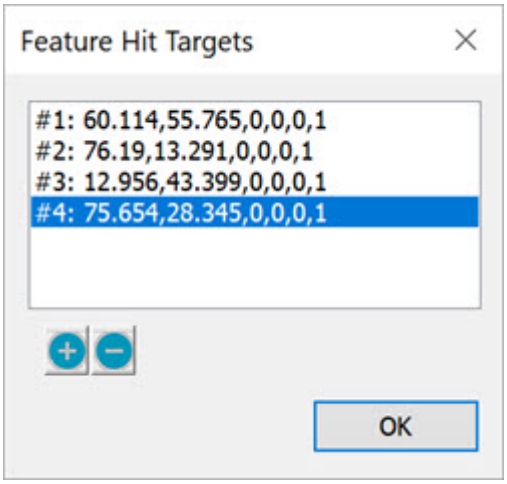
Hit Targets

Supported features:

- Measured Circle
- Measured Cylinder
- Measured Point
- Measured Plane
- Measured Sphere
- Measured Line
- Measured Cone

For supported measured features, the **Hit Targets** button allows you to view or change hit data for the feature.

Clicking the **Hit Targets** button opens the **Feature Hit Targets** dialog box.

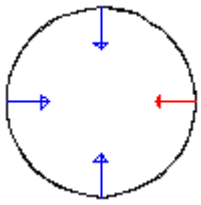


Feature Hit Targets Dialog Box

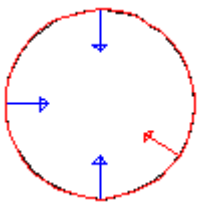
This dialog box lists the hit data by rows. The numbers to the left of the rows indicates the order of the hits. You can change the hit data by double-clicking on a row and editing its values in the resulting **Measured Hits** dialog box.

The **Feature Hits Targets** dialog box also lets you view and edit hit data from the Graphic Display window. As long as the **Feature Hit Targets** dialog box remains open, you can do the following:

- *View individual hits with red colored arrows.* Click any of the rows with hit data listed in the **Feature Hit Targets** dialog box and the associated arrow in the Graphic Display area turns red.



- *Click to move a hit to a new location.* To move a hit to a new location on the CAD, from the **Feature Hit Targets** dialog box, select one of the hits in the list. PC-DMIS changes the color of the vector for the selected hit to red in the Graphic Display window. Click a new location on the CAD in the **Graphic Display** window. The vector relocates to the new position and PC-DMIS recalculates the data and updates the values in the **Feature Hit Targets** dialog box for the selected hit.

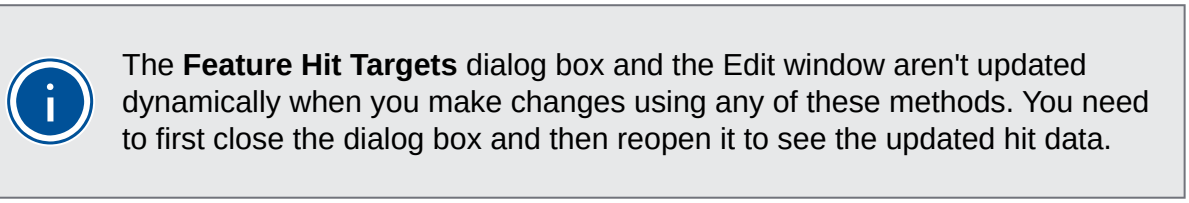


- *Insert new hits.* You can also insert new hits into an existing feature. To do this:

1. From the **Feature Hit Targets** dialog box, select a hit from the list.
2. Click the **+** button to generate a new hit. PC-DMIS generates a new hit at the same location as the selected hit.
3. Click a different location on the CAD in the Graphic Display window to relocate the new hit.
4. Click the **OK** button on the **Feature Hit Targets** dialog box.
5. Click the **OK** button on the **Measured Feature** dialog box. Once you click the **OK** button, PC-DMIS asks if you want to update the feature theoretical values.

   If you select **Yes**, PC-DMIS inserts the new hits you added for the current feature and also updates the feature's theoretical values with the new hits.

   If you select **No**, PC-DMIS inserts the new hits you added for the current feature but does not update the feature's theoretical values with the new hits.

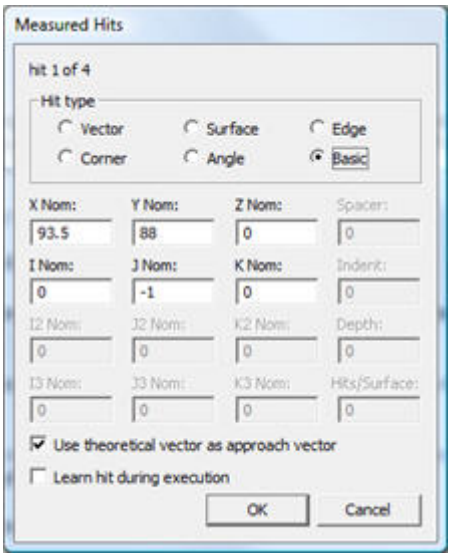


The **Feature Hit Targets** dialog box and the Edit window aren't updated dynamically when you make changes using any of these methods. You need to first close the dialog box and then reopen it to see the updated hit data.

- *Remove hits.* You can remove hits from an existing feature. To do this:

  1. From the **Feature Hit Targets** dialog box, select a hit from the list.
  2. Click the **-** button. PC-DMIS immediately deletes the selected hit.
  3. You can continue selecting and deleting hits for the selected feature this way. PC-DMIS, however, requires that a minimum number of hits remain for the feature type. So, for example, you can delete hits for a plane up until there are three hits remaining. The software will not allow you to delete any more hits for this feature type since a plane requires a minimum number of three hits to define it.

Measured Hits Dialog Box Description



Measured Hits Dialog Box

The **Measured Hits** dialog box allows you to edit individual hits of a measured feature. To access this dialog box, select one of the BASIC hits inside the Edit window and press F9. You can edit the following items:

- Hit Type
- X, Y, and Z position.
- Various vectors
- Spacer
- Indent
- Depth
- Hits per Surface

Some items are unavailable unless you select a specific hit type. To update hit data for the selected measured feature, edit the values in this dialog box, and click **OK**.

Editing Basic Hits by Probing:

You can also update Basic hits by probing the part in Online mode or clicking on the CAD in Offline mode with the **Measured Hits** dialog box open. PC-DMIS automatically updates the dialog box with the new results.

For Basic hits, these check boxes appear:

Use Theoretical Vector As Approach Vector
This check box allows you to specify whether or not the theoretical vector should be used as the approach vector. If deselected, PC-DMIS calculates the approach vector by subtracting the theoretical hit point (X,Y,Z) from the current probe position.

Learn Hit During Execution
This check box allows you to specify whether or not PC-DMIS should relearn the basic hit during measurement routine execution.

Overriding a Guessed Measured Feature

For information, see "Overriding Guessed Features" in the "Editing a Measurement Routine" chapter.

Creating Measured Feature Sets

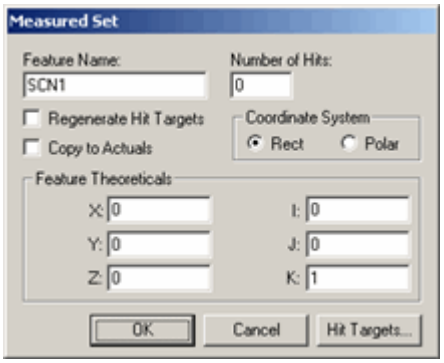
You can measure a single point multiple times as a measured feature set (also called a Point Set). The **Insert | Feature | Measured | Feature Set** menu item inserts a `FEAT/SET` command into the Edit window. This measured feature command creates a scan of a single point that measures the same point a defined number of times to obtain an averaged (and hopefully more accurate) representation of the point measurement.

Point Sets are most often used as inputs when performing Leapfrog alignment operations with a manual arm machine. See "Performing a Leapfrog Operation" in the "Creating and Using Alignments" chapter for more information.

In Command Mode, the Measured Feature Set looks like this:

```
SCN1=FEAT/SET,RECT
   THEO/0,0,0,0,0,1
   ACTL/0,0,0,0,0,1
   MEAS/SET,0
   ENDMEAS/
```

You can press F9 while your cursor is in the command to display the **Measured Set** dialog box to edit this command:



Measured Set Dialog Box

For information on this dialog box, see the "Editing a Measured Feature" topic above. The **Measured Feature** dialog box contains many of the same items that are already discussed in that topic.

To Create a Measured Feature Set (Point Set):

1. Select **Insert | Feature | Measured | Feature Set** to insert a measured feature set command.
2. Press F9 on the inserted measure feature set command.
3. In the dialog box, in the **Feature Theoretics** area, type in the point's theoretical XYZ location and IJK vector.
4. In the **Number of Hits** box, specify the number of measurements you want PC-DMIS to take on this point. The higher the number, the better the average you will receive.
5. Select other options in the dialog box as desired.
6. Click **OK**. PC-DMIS updates the command in the Edit window.

   For example, a finished point set scan with 5 iterations might look like this:

```
SCN1       =FEAT/SET,RECT
            THEO/107,11,21,0,0,1
            ACTL/0,0,0,0,0,1
            MEAS/SET,5
            HIT/BASIC,NORMAL,107,11,21,0,0,1,0,0,0,USE
THEO = YES
            HIT/BASIC,NORMAL,107,11,21,0,0,1,0,0,0,USE
THEO = YES
            HIT/BASIC,NORMAL,107,11,21,0,0,1,0,0,0,USE
THEO = YES
            HIT/BASIC,NORMAL,107,11,21,0,0,1,0,0,0,USE
THEO = YES
            HIT/BASIC,NORMAL,107,11,21,0,0,1,0,0,0,USE
THEO = YES
            ENDMEAS/
```

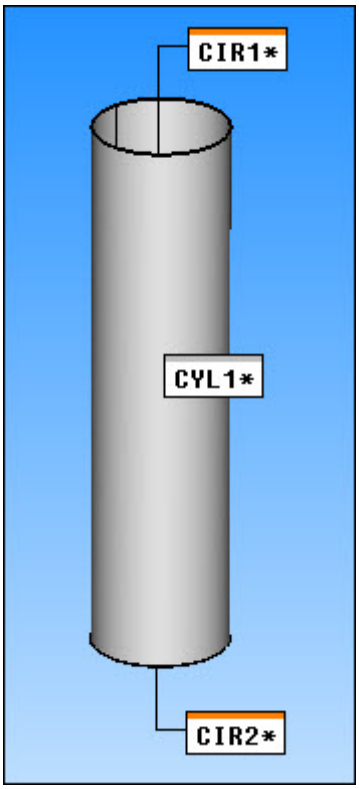
Constructing New Features from Existing Features

Constructing New Features from Existing Features: Introduction

Use the **Insert | Feature | Constructed** submenu to construct features when probing on a required element is not possible (for example, the intersection point of two edges).

The items on this menu enable you to create features (points, lines, circles, and other features) from existing features (ones already probed or constructed). The "Navigating the User Interface" chapter describes the several ways to specify input features. See the "Selecting Features Using the Graphic Display Window" topic in the "Editing the CAD Display" chapter for a description of the several ways to specify input features.

Once you construct the feature, PC-DMIS draws the new feature on the screen. For 3D features (Cylinder, Sphere, and Cone) and for a 2D plane, PC-DMIS draws the feature with a shaded surface.



Example of a cylinder feature (CYL1) drawn with shaded surfaces and constructed from two circles (CIR1 and CIR2).

You can use Hit arrays to define the inputs for constructed features. For details, see the "Using Hit Arrays to Define Constructed Feature Inputs" section of the "Hit Arrays" help topic in the "Using Expressions and Variables" chapter of the PC-DMIS Core documentation.

Hiding Shaded Plane Features

To hide shaded planes, set the **None** option in the **Display** area of the **Construct Plane** dialog box (**Insert | Feature | Constructed | Plane**). To globally hide all drawn shaded planes for future plane features, select the **Do Not Display Plane** check box in the **Setup Options** dialog box.

Changing the Feature Color

If desired, you can use the **ID Setup** tab in the **Setup Options** dialog box to modify the feature color used during feature creation. See the **Color** check box that appears after you choose **Features** under the **Labels For** item.

You can construct a feature by selecting features in the dialog boxes or the Edit window (see "To Construct a Feature from the Edit Window" and "To Construct a Feature Using the Construction Dialog Boxes:" below). You can find specific rules to construct a feature from other features from the topics below. These rules apply to either method of construction.

The default method to construct a feature is **Auto**. In this case, PC-DMIS automatically determines the best construction type based on the input feature or features. The order of selection (unless noted otherwise) is usually not important. It is only necessary that you choose the correct feature type or types. For example, to construct an intersect point between a line and a slot, simply select the necessary line and slot. PC-DMIS creates a point where the line intersects the slot.

It is important to note that the documented conventions are just tools that allow you to become familiar with the rules that govern the Edit window. The actual Edit report displays in all capital letters.

Here are two command line examples that show a constructed point in the Edit window:

```
CONSTR/POINT, INTOF, line_id, slot_id
```

or

```
CONSTR/POINT, INTOF, slot_id, line_id
```

The main topics in this chapter include:

- Understanding the General Command Format
- Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions
- Specifying Feature Theoreticals
- Constructing a Point Feature

- Constructing a Line Feature
- Constructing a Plane Feature
- Constructing a Circle Feature
- Constructing an Ellipse Feature
- Constructing a Round Slot Feature
- Constructing a Square Slot Feature
- Constructing a Curve
- Constructing a Cylinder Feature
- Constructing a Cone Feature
- Constructing a Sphere Feature
- Constructing a Surface
- Constructing a Set of Features
- Constructing a Filter Set
- Constructing an Adjusted Filter
- Constructing a Width Feature

To Construct a Feature from the Edit Window

1. Access the Edit window (**View | Edit Window**).
2. Place the cursor where you want to construct the feature in the Edit window.
3. Type the command `CONST` , and press the Tab key.
4. In the Edit window, locate the `CONSTR/` line.
5. Click on that line, and press the Tab key until you highlight the feature type on the right side of the slash.
6. Press F7 and F8, and choose the type of feature to construct. (For an example of the command line for a constructed point, see "Constructing New Features from Existing Features: Introduction" above).

To Construct a Feature Using the Construction Dialog Boxes

1. Select the **Insert | Feature | Constructed** menu.

2. From the **Constructed** menu, select the type of feature to construct.
3. From the dialog box, select the input features.

You can also use the Graphical Hit Selection method to select inputs to your construction. For details, see "Graphical Hit Selection Method".

4. From the dialog box, choose other options as needed. For information on the available options, see the specific constructed feature type.
5. Click the **Create** button.

PC-DMIS constructs the feature and then displays it on the screen. It also displays the feature's center point in the Edit window. PC-DMIS constructs the requested feature, leaves the dialog box open, and adds the newly-constructed feature into the dialog box. This allows you to construct multiple features based on newly-constructed features.

Understanding the General Command Format

In the Edit window, all constructed features display in the following format. There are slight variations that are explained more thoroughly in the following sections.

The actual Edit report displays in all capital letters.

For example:

```
Feature_name=FEAT/TYPE OF FEATURE,TOG1,.....
THEO /x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,......
ACTL /x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,......
CONSTR/TOG2,TOG3,......
```

feature_name - The name of the feature. This is an editable field.

TYPE OF FEATURE - This field denotes the feature type. This feature type is the same as TOG2 but it is not editable, and it is not a toggle field.

..... : This indicates that what follows is unique to each feature. This is explained more thoroughly as needed in the appropriate topics.

TOG1 - This field is present in all features and can be switched between RECT / POLR. If this feature is RECT, all points are represented in the Cartesian system (x, y, z). If the field is POLR, all points display in the polar system (x_radius, y_angle, z_height). Vectors do not change.

TOG2 - This field is present in all features and can be switched between the different types of features through the following values:

> CIRCLE / CONE / CYLINDER / LINE / PLANE / POINT / SPHERE / CURVE / SURFACE / SET /
>
> POINT is the default feature type when the construct command line is opened for the first time in a measurement routine. The default feature type then becomes the last constructed feature type.

TOG3 - This field is also present in all features, but it takes unique values according to the type of feature. (See the specific feature type for additional information.)

Accessing the Construct [Feature] Dialog Box from a Constructed Feature

To access the corresponding construction dialog box from which an Edit window's feature was created:

1. Make sure the Edit window is open.
2. In the Edit window, click the mouse on the feature's name.
3. Press the F9 key to open the construction dialog box.

Use this dialog box to make any changes. When you click the **Create** button, the updated changes are made to the Edit window.

Decimal Placement Conventions

The following statements refer to metric measurements where the maximum number of decimal places is 6. For standard measurement (inches), the maximum number of decimal places is seven.

Please note the following information about decimal place conventions for constructed features:

- All vectors (i_vect, j_vect, k_vect) are represented by a maximum of six places to the right of the decimal.
- All lengths and distances (x_cord, y_cord, z_cord, diam, height, length, etc.) are represented by a maximum of six places to the right of the decimal.
- All angles are represented by a maximum of six places to the right of the decimal.
- If the decimal place is zero, then the number is represented as an integer.

You can change the decimal places through the **Dimension** tab (F5) in the **Setup Options** dialog box (**Edit | Preferences | Setup**). If you set the decimal place limit, PC-DMIS inserts a `DISPLAYPRECISION` command in the Edit window. All features that follow this command conform to the specified number of decimal places.

Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions

Best Fit Recompensate (BFRE) is only accurate when you construct a feature using actual surface data.

If the inputs for the construction are a mixture of features that have surface data and features that do not, you should use the Best Fit (BF) calculation method.

If none of the inputs for the construction have surface data and you choose BFRE, PC-DMIS uses the Best Fit calculation method internally, instead.

The table below shows a list of feature types that have actual surface data (left), and the feature types that don't have surface data (right).

Features That Contain Actual Surface Data	Features That Do Not Contain Surface Data
Measured Points	Generic Features (All Types)
Directly Referenced Hits of Measured Lines	Auto Vector Points – Self Centring Point Strategy
Directly Referenced Hits of Measured Planes	Auto Edge Points (All Sensor Types)
Directly Referenced Hits of Measured Circles	Auto Angle Points (All Sensor Types)
Directly Referenced Hits of Measured Cylinders	Auto Corner Points (All Sensor Types)
Directly Referenced Hits of Measured Cones	Auto High Points (All Sensor Types)
Directly Referenced Hits of Measured Spheres	Laser/Vision Auto Surface Points
Directly Referenced Hits of Measured Toruses	Vision Auto Lines
Directly Referenced Hits of Measured Sets	Laser Auto Planes
Probed Auto Vector Points	Laser/Vision Auto Circles
Probed Auto Surface Points	Laser Auto Cylinders
Directly Referenced Hits of probed Auto Lines (All Strategies)	Laser Auto Cones

Directly Referenced Hits of probed Auto Planes (All Strategies)	Laser Auto Spheres
Directly Referenced Hits of probed Auto Circles (All Strategies)	Laser/Vision Auto Ellipses
Directly Referenced Hits of probed Auto Round Slots	Laser/Vision Auto Polygons
Directly Referenced Hits of probed Auto Square Slots	Laser/Vision Auto Round Slots
Directly Referenced Hits of probed Auto Notch Slots	Laser/Vision Auto Square Slots
Directly Referenced Hits of probed Auto Cylinders (All Strategies)	Laser/Vision Auto Notch Slots
Directly Referenced Hits of probed Auto Spheres	Laser Auto Flush & Gaps
Directly Referenced Hits of probed Auto Ellipses	Vision Auto 2D Profiles
Directly Referenced Hits of probed Auto Polygons	Laser Pointcloud data
Directly Referenced Hits of probed Scans (except Basic Center scans)	Laser Mesh data
	Gages (all types)
	Constructed Features (all types)
	Basic Center Scans

	Uni-Scans
	Scans performed with a laser sensor

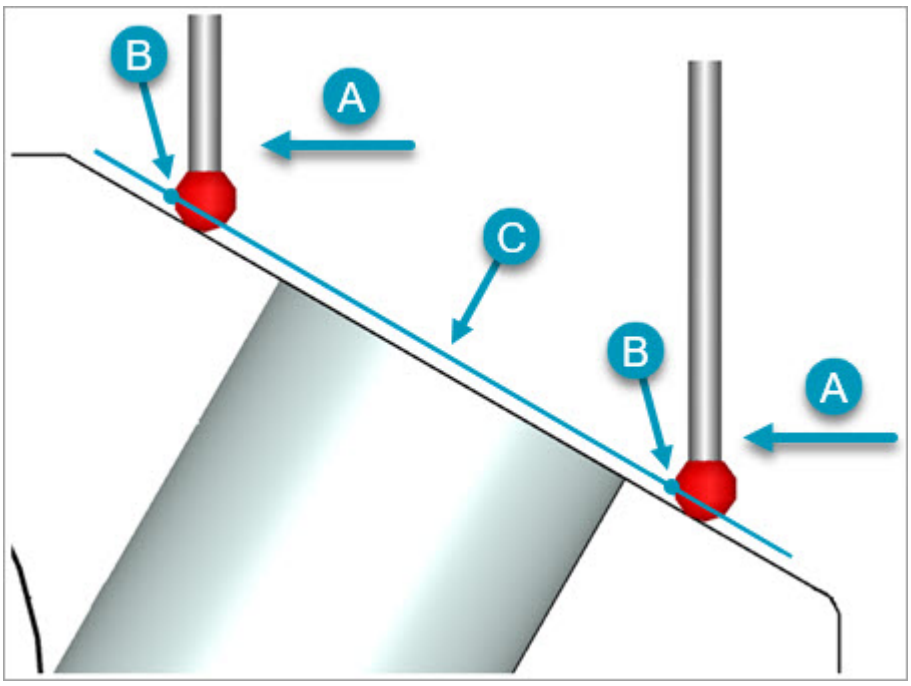
The Best Fit construction method takes the actual measured points in their pre-compensated state. The Best Fit Recompensate method takes the ball's center and applies further re-compensation after fitting the feature. In both cases, the average squared error is minimized in the Least Squares method and the maximal error is minimized in the Min/Max method. You can also choose to remove outliers or apply a Gaussian filter to the constructed Line, Plane or Circle.

- The Best Fit option uses the ball center data shifted one tip radius in the direction of the negated hit vector to perform the compensation prior to fitting.
- The Best Fit Recompensate option uses the ball center data and the tip compensation as part of the fitting process.

Consider the following example where the probe is not approaching normal to the surface. The resultant hits are compensated in the direction of travel (**A**), resulting in some amount of measurement error.

> This example is an extreme case, deliberately chosen for illustration purposes only.

If you construct a BF line from the points, it will also be in error because it passes through the pre-compensated hit locations.



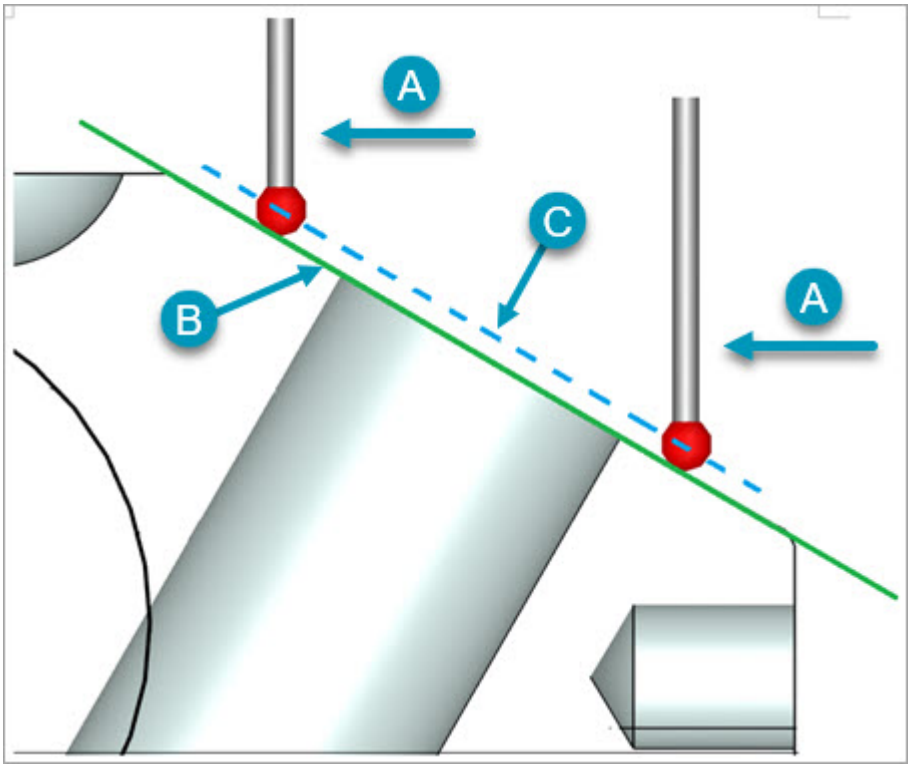
Example of probe not approaching normal to the surface using the BF method

A. *Probe direction*

B. *Compensated points*

C. *Constructed Best Fit Line passing through both pre-compensated points*

However, if you construct a BFRE line, it corrects for this error because PC-DMIS applies the radius compensation to the line ***AFTER*** it first fits it through the ball centers.



Example showing probe not approaching normal to the surface using the BFRE method

A. *Probe direction*

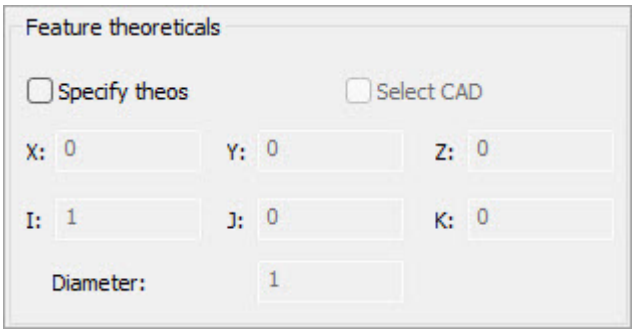
B. *BFRE Line, compensation applied normal to the line*

C. *Initial line fitted through the ball centers*

Specifying Feature Theoreticals

PC-DMIS provides the ability to specify theoretical information for most of the available constructed feature types. Traditionally, PC-DMIS uses theoretical values from the input features to calculate a theoretical value for the constructed feature. In some circumstances, however, you may not want this result. To make constructed features more flexible, you can override the traditional behavior and specify your own theoretical values for the feature.

The **Feature theoreticals** area is at the bottom-right of the constructed feature's dialog box (**Insert | Feature | Constructed**). This area is unavailable for selection until you select the **Specify theos** check box. This enables the other items in the area, which you can use to override the calculated theoretical values from the input features with the specified theoretical values.



Example of the Feature Theoreticals area for a constructed circle feature.

The items that appear in the **Feature theoreticals** area change, depending on the feature you are constructing. Each feature displays at least the **X**, **Y**, and **Z** boxes (the location) and the **I**, **J**, and **K** boxes (the orientation). For features with characteristic sizes, such as circles, slots, and cones, additional items appear in this area.

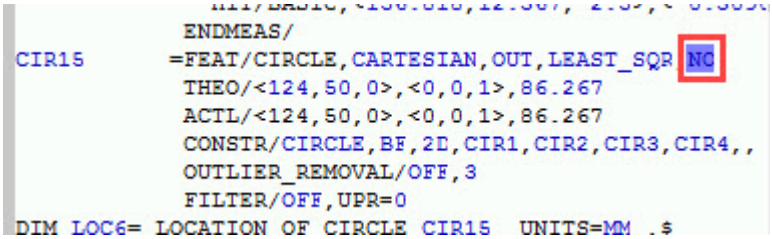
Overriding Feature Theoreticals

To change an existing feature from the traditional method to the new theoretical override:

1. From the Edit window, press **F9** to see the dialog box for that constructed feature.
2. Select the **Specify theos** check box to enable the **Feature theoretical** area.
3. Change the theoretical values by:
    - Manually editing the available items.
    - Select the **Select CAD** check box and then click the corresponding element on the CAD model.

4. Click the **Create** button when finished.

Alternately, you can edit the feature from the Edit window. To do this, in Command mode, set the last field on the first line of the feature to **YES** and then manually type the values in the `THEO` line.



Sample Constructed Feature in Command Mode

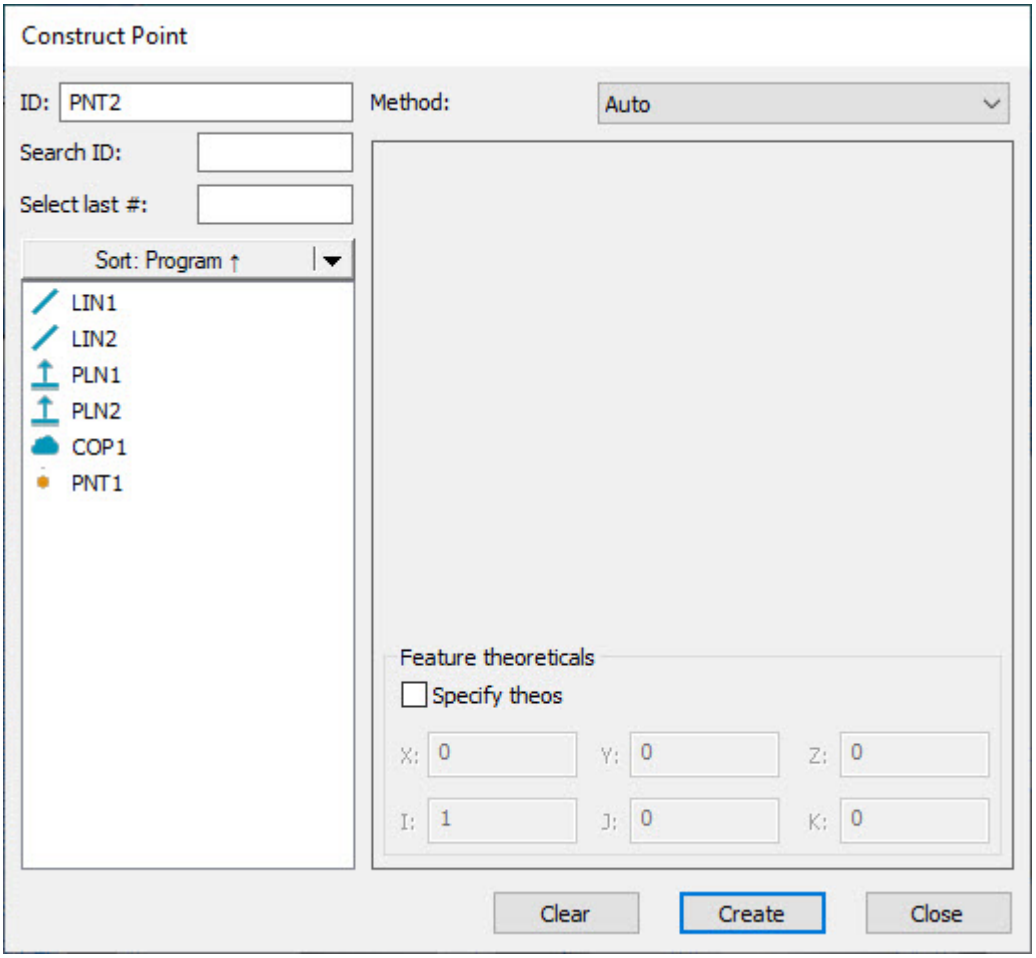
To have PC-DMIS automatically calculate the feature information based on the input features (the traditional method), clear the **Specify theos** check box in the dialog box or change the appropriate value in the Edit window. The features update accordingly.

Because you are editing feature theoretical values, PC-DMIS asks if you want to update your measured values and the theoretical values of any associated dimensions. This is standard PC-DMIS behavior.

All constructed features have this capability except for:

Specify Theos	Select CAD
Adjust Filter	Adjust Filter
Curve	Curve
Filter	Filter
Set	Line
Surface	Point
	Set
	Surface
	Width

Constructing a Point Feature



Construct Point Dialog Box

There are a number of ways to use PC-DMIS to construct a point. The following table lists the various types of constructed points along with their necessary inputs. Some features may require no inputs while others may require three inputs or more. In the table, the term "Any" indicates that the construction can take *any* type of feature as input for construction. PC-DMIS allows the features to be selected in any order.

Construct Feature Type	Edit Window Symbol	Number of Required Input Features	Primary Feature	Secondary Feature	Tertiary Feature	Comments
Auto Point	-	-	-	-	-	See "Auto Point Construction".
Intersect Point	INTOF	2	See topic below for valid features.	See topic below for valid features.	-	Constructs a point at the intersection of the linear attribute of two features.
Origin Point	ORIGIN	0	-	-	-	Constructs a point at the alignment origin.
Drop Point	DROP	2	Any	Cone, Cylinder, Line, Slot	-	First feature is dropped onto the second line feature.
Cast Point	CAST	1	Any	-	-	Constructs a point at the centroid of the input feature.
Mid Point	MID	2	Any	Any	-	Constructs a mid point between the centroids of the inputs.
Corner Point	CORNER	3	Plane	Plane	Plane	Constructs a point at the intersection of three planes.
Project Point	PROJ	1 or 2	Any	Plane	-	One input feature will project the point to the workplane.

Pierce Point	PIERCE	2	See topic below for valid features.	See topic below for valid features.	-	Constructs a point where one feature pierces the surface of another feature.
Vector Distance Point	VECT_DIST	2	Any	Any	-	Constructs a point at a distance from the second feature along the line from the two input features.
Offset Point	OFFSET	1	Any	-	-	Requires three offsets corresponding to X,Y, and Z.
Tertiary Datum Point	TERTIARY_DATUM	1	Point, Plane, Line, Set of Points	(Additional Point features if first feature is a point)	(Additional Point features if first feature is a point)	Constructs a point which simulates a tertiary datum that is external to material.
Extracted Edge Point	EXTRACTED_EDGE_POINT	1	COP or Mesh	-	-	Extracts and constructs a point from the selected COP or Mesh command.
Extracted Surface Point	EXTRACTED_SURFACE_POINT	1	COP or Mesh	-	-	Extracts and constructs a surface point from the selected COP or Mesh command.

If you select inappropriate feature types, PC-DMIS displays this message on the Status bar:

"Cannot construct [feature]. Combination of input features not accepted."

To construct a point, do the following:

1. Open the **Construct Point** dialog box (**Insert | Feature | Constructed | Point**).
2. From the **Method** list, select the feature type to construct.
3. From the **Feature Selection** list, select the features to use to create the constructed point. If the feature type requires you to select more than one feature, select the features in the order you want PC-DMIS to process them in: Primary, Secondary and Tertiary.
4. In the **Parameters** area, select and enter the values you want to apply to the selected method. The available parameters are dependent on the selected method. For example, if you choose **Auto** from the **Method** list, you can select the **Specify theos** check box in the **Feature theoreticals** area and then enter the **X**, **Y**, **Z**, **I**, **J**, and **K** values.
5. Click the **Create** button.

The Edit window command line for a sample point construction would read:

```
feature_name=FEAT/POINT,TOG1
THEO/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec
ACTL/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec
CONSTR/TOG2,TOG3,......
```

The actual Edit report displays in all capital letters.

TOG1 = POLR or RECT

TOG2 = POINT

TOG3 = CAST / CORNER / DROP / INTOF / MID / OFFSET / ORIG / PIERCE / PROJ / TERTIARY_DATUM

The first three lines that display in the Edit window are the same for all constructed points. The fourth line is slightly different according to the type of feature you are constructing. To switch between the different types of points, place the cursor on TOG3 and press F7 or F8. (See "Command Mode Keyboard Functions" in the "Using the Edit Window" chapter.)

When two or more features are involved, PC-DMIS automatically determines the necessary order of the input features. This improves the accuracy of the measurement process.

AUTO is the default method of construction. This option automatically determines the best way to construct a point using the input feature or features. See "Auto Point Construction".

The following topics describe the options for constructing a point.

Auto Point Construction

The list below indicates the type of point that the software constructs when you select certain inputs along with the **Auto** option. The order of the selected features is not important. If you select an incorrect input feature or features, PC-DMIS displays an error message and does not automatically construct the indicated feature type.

To allow PC-DMIS to automatically determine the best method of construction:

1. Access the **Construct Point** dialog box (**Insert | Feature | Constructed | Point**).
2. Select the **Auto** option from the **Method** list.
3. Select the desired feature or features based on the information below.
4. To change the feature theoreticals values, click the **Specify theos** check box in the **Feature Theoreticals** section and update the **X**, **Y**, **Z**, **I**, **J**, and **K** values as necessary.
5. Click the **Create** button.

Input Feature List

Along with the table below, the following lists each input feature and what it can construct:

- 3 Points = Corner Point
- Any one feature = Cast Point

<table>
<tr><th></th><th>Circle</th><th>Cone</th><th>Cylinder</th><th>Ellipse</th><th>Line</th><th>Plane</th><th>Point</th><th>Set</th><th>Slot</th><th>Sphere</th></tr>
<tr><td>Circle</td><td>Mid Point</td><td colspan="2">Drop Point</td><td>Mid Point</td><td>Pierce Point</td><td>Project Point</td><td colspan="4">Mid Point</td></tr>
<tr><td>Cone</td><td rowspan="2">Drop Point</td><td colspan="2" rowspan="2">Intersection Point</td><td rowspan="2">Drop Point</td><td rowspan="2">Intersection Point</td><td rowspan="2">Pierce Point</td><td colspan="2" rowspan="2">Drop Point</td><td rowspan="2">Intersection Point</td><td rowspan="2">Drop Point</td></tr>
<tr><td>Cylinder</td></tr>
<tr><td>Ellipse</td><td>Mid Point</td><td colspan="2">Drop Point</td><td>Mid Point</td><td>Drop Point</td><td>Project Point</td><td colspan="4">Mid Point</td></tr>
<tr><td>Line</td><td>Pierce Point</td><td colspan="2">Intersection Point</td><td>Drop Point</td><td>Intersection Point</td><td>Pierce Point</td><td colspan="2">Drop Point</td><td>Intersection Point</td><td>Drop Point</td></tr>
<tr><td>Plane</td><td>Project Point</td><td colspan="2">Pierce Point</td><td>Project Point</td><td>Pierce Point</td><td colspan="5">Project Point</td></tr>
<tr><td>Point</td><td rowspan="3">Mid Point</td><td colspan="2" rowspan="2">Drop Point</td><td rowspan="3">Mid Point</td><td rowspan="2">Drop Point</td><td rowspan="3">Project Point</td><td colspan="4" rowspan="2">Mid Point</td></tr>
<tr><td>Set</td></tr>
<tr><td>Slot</td><td colspan="2">Intersection Point</td><td>Intersection Point</td><td colspan="2">Mid Point</td><td>Intersection Point</td><td>Mid Point</td></tr>
<tr><td>Sphere</td><td colspan="2">Drop Point</td><td>Drop Point</td><td colspan="4">Mid Point</td></tr>
</table>

Mesh and Pointcloud Feature List

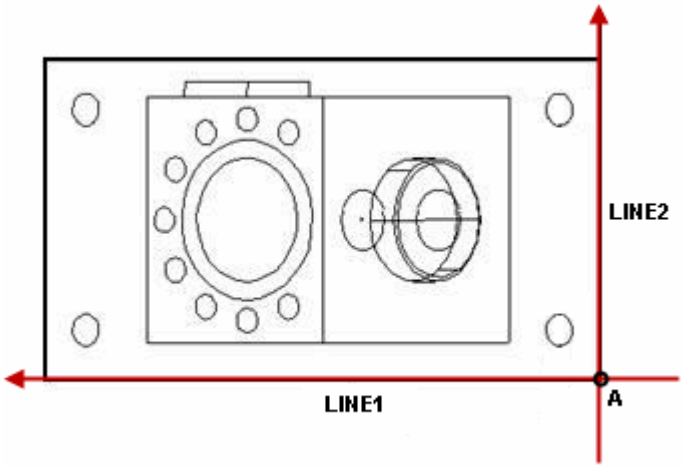
- You can extract and construct an Edge Point from a COP or Mesh command. For details, see "Constructing an Extracted Edge Point" in this document.
- You can extract and construct a Surface Point from a COP or Mesh command. For details, see "Constructing an Extracted Surface Point" in this document.

Constructing an Intersection Point

You can construct a point between two valid features:

First Valid Feature	Second Valid Feature
Plane	Line, Cylinder, Cone, or Curve
Line	Plane, Sphere, Cone, Cylinder, Curve, Line, Circle, or Slot
Cylinder	Plane, Line, Cone, Cylinder, Circle, or Slot
Cone	Plane, Line, Cone, Cylinder, Circle, or Slot
Curve	Plane, Line
Sphere	Line
Circle	Line, Cone, Cylinder, Circle, or Slot

The point is created where the lines (centerlines) of the two features intersect or where a linear feature pierces a planar feature.



Constructing an intersection point from two lines
***A** - Point constructed from two lines (LINE1 and LINE2)*

If you want to intersect or pierce a circle with a line, see "Constructing a Pierce Point".

To construct an Intersect Point:

1. Select **Insert | Feature | Constructed | Point** to display the **Construct Point** dialog box.
2. Select the **Intersection** option from the **Method** list.
3. Use the table above to select the first and second valid features types.

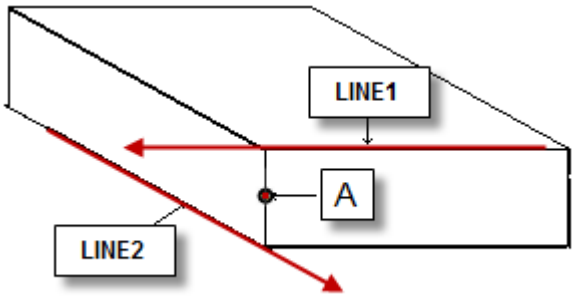
4. To change the feature theoreticals values, click the **Specify theos** check box in the **Feature Theoreticals** section and update the **X**, **Y**, **Z**, **I**, **J**, and **K** values as necessary.
5. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/POINT,INTOF,feat_1,feat_2
```

If the two features do not intersect, the point is constructed midway between the two features at the apparent intersection. In other words, the intersect point is the mid-point of the shortest line connecting the two input features.

In this example, **A** indicates where the intersect point is constructed between LINE1 and LINE2:



Example of an Intersection Point constructed from two non-intersecting lines.

You can intersect two circle features and as long as they have the same (or very similar) vectors, PC-DMIS generates a constructed point feature at one of the intersection points. If you switch the order of the selected input features in the **Construct Point** dialog box, PC-DMIS constructs a point at the other intersection point.

You can intersect a line feature with a constructed curve. The line and curve are first projected onto the current workplane, where the intersection is computed. If there is no intersection, an error message appears. Even though there may be many intersection points, PC-DMIS only reports the one closest to the start of the curve. To get the other intersection points, it may be possible to subdivide the curve and compute intersections on the sub curves.

If you select a slot as one of your input features, PC-DMIS uses the slot centerline vector when constructing this point instead of the slot normal vector. If you want to use the older slot normal vector, you need to modify the value for the `UseLegacySlotVector` entry in PC-DMIS Settings Editor. For information on how to modify the value, see the "Modifying Setting Entries" topic in the PC-DMIS Core documentation.

Constructing a Point at the Origin

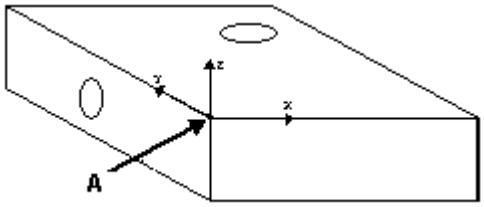
You can construct a point at the current alignment origin.

To construct an origin point:

1. Access the **Construct Point** dialog box (**Insert | Feature | Constructed | Point**).
2. Select the **At Origin** option.
3. Do *not* select any input features.
4. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/POINT,ORIG
```



Example of a point feature constructed at the origin.

***A** - Point constructed at the origin (0,0,0)*

Constructing a Drop Point

You can construct a point from any feature and a line (cone, cylinder, or slot). PC-DMIS drops the centroid of the first feature onto the second feature. The "dropped" point is dropped on a line that is perpendicular to the line, centerline, or plane. If two line features are selected, PC-DMIS drops the centroid of the first line feature onto the second line feature.

For this construction method, you must select feature types in the correct order.

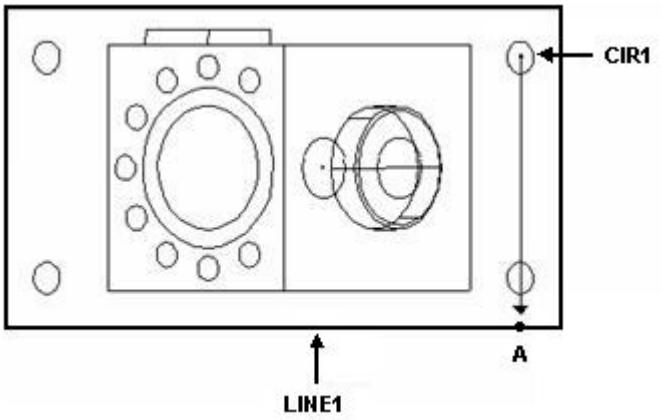
To construct a drop point:

1. Select **Insert | Feature | Constructed | Point** to display the **Construct Point** dialog box.
2. Select the **Drop Point** option from the list of options.
3. Select the first feature. It may be of any type.
4. Select the second feature. It must be cone, cylinder, line, or slot.

5. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/POINT,DROP,feat_1,feat_2
```



A - Point is constructed by normally projecting circle, CIR1 (the designated point) to line, LINE1
Example showing a drop point constructed from a circle and a line.

If you select a slot as one of your input features, PC-DMIS uses the slot centerline vector when it constructs this point instead of the slot normal vector. If you want to use the older slot normal vector, you need to modify the value for the `UseLegacySlotVector` entry in PC-DMIS Settings Editor. For information on how to do this, see "Modifying Setting Entries".

Constructing a Cast Point

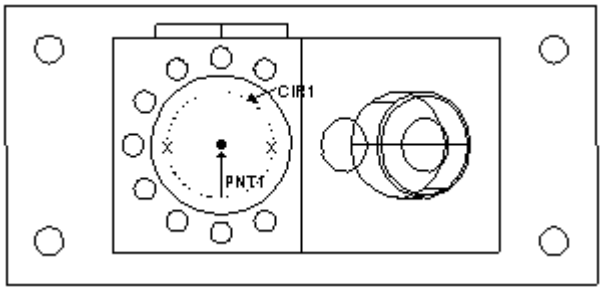
You can construct a point by changing any given feature into the point. PC-DMIS constructs the point at the centroid of the input feature.

To construct a cast point:

1. Access the **Construct Point** dialog box (**Insert | Feature | Constructed | Point**).
2. Select the **Cast** option from the list of options.
3. Select any feature.
4. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/POINT,CAST,feat_1
```



Constructing a cast point from a circle.

Constructing a Mid Point

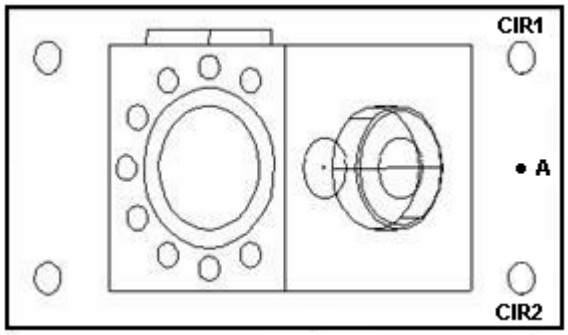
You can construct a point from any two features without direction. PC-DMIS creates a mid point between the centroids of the two input features.

To construct a mid point:

1. Access the **Construct Point** dialog box (**Insert | Feature | Constructed | Point**).
2. Select the **Mid Point** option from the list of options.
3. Select any two features.
4. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/POINT,MID,feat_1,feat_2
```



Example showing a mid point constructed from two circles.

***A** - Point constructed midway between two circles, CIR1 and CIR2*

Constructing a Corner Point

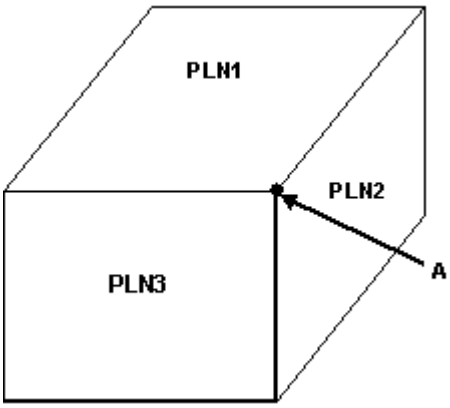
You can construct a point from three planes. PC-DMIS creates a point at their intersection. The vector of the constructed corner point is the cross product of the second input vector into the third input vector.

To construct a corner point:

1. Access the **Construct Point** dialog box (**Insert | Feature | Constructed | Point**).
2. Select the **Corner Point** option from the list of options.
3. Select three different planes.
4. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/POINT,CORNER,feat_1,feat_2,feat_3
```



A - Point constructed at the intersection of three planes (PLN1, PLN2, and PLN3)
Constructing a corner point from three planes

Constructing a Projected Point

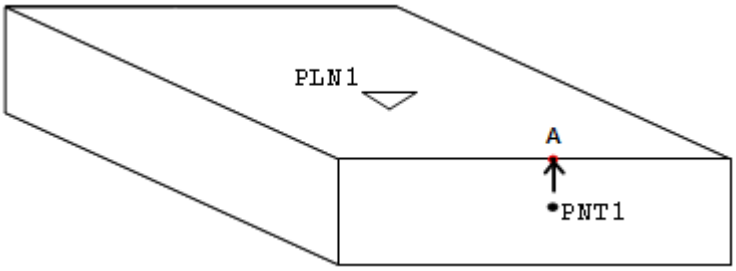
You can construct a point from any feature and a plane. PC-DMIS projects the point where the plane intersects the point. If there is only one input feature, the projection will be to the workplane.

To construct a projected point:

1. Access the **Construct Point** dialog box (**Insert | Feature | Constructed | Point**).
2. Select the **Projection** option from the list of options.
3. Select a feature from which to create the projected point.
4. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/POINT,PROJ,feat_1,(feat_2)
```



Example of a project point constructed from a point and a plane.

***A** - Projected point constructed from a point, PNT1, and a plane, PLN1*

Constructing a Pierce Point

You can construct a point where one feature pierces the surface of another feature:

First Valid Feature	Second Valid Feature
Line	Plane, Sphere, Cylinder, Circle, Cone, or Ellipse
Slot	Plane, Sphere, Cylinder, Circle, Cone, or Ellipse
Cone	Plane, Sphere, Cylinder, Circle, Cone, Ellipse, Line, or Slot
Cylinder	Plane, Sphere, Cylinder, Circle, Cone, Ellipse, Line, or Slot
Circle	Plane, Sphere, Cylinder, Circle, Cone, Ellipse, Line, or Slot
Ellipse	Plane, Sphere, Cylinder, Circle, Cone, Ellipse, Line, or Slot
Plane	Line, Slot, Cone, or Cylinder
Sphere	Line, Slot, Cone, or Cylinder

Normally, the first feature selected would be the surface to pierce, with these exceptions:

- If one of the inputs is a Plane, Sphere, Circle, or Ellipse, no matter what the input order is, this feature becomes the pierced surface.
- If the second feature is a cylinder and the first input is not a cylinder, circle, cone, or line (these are all line-reducible features), then the cylinder becomes the line-reducible feature, and the first feature becomes the pierced surface.

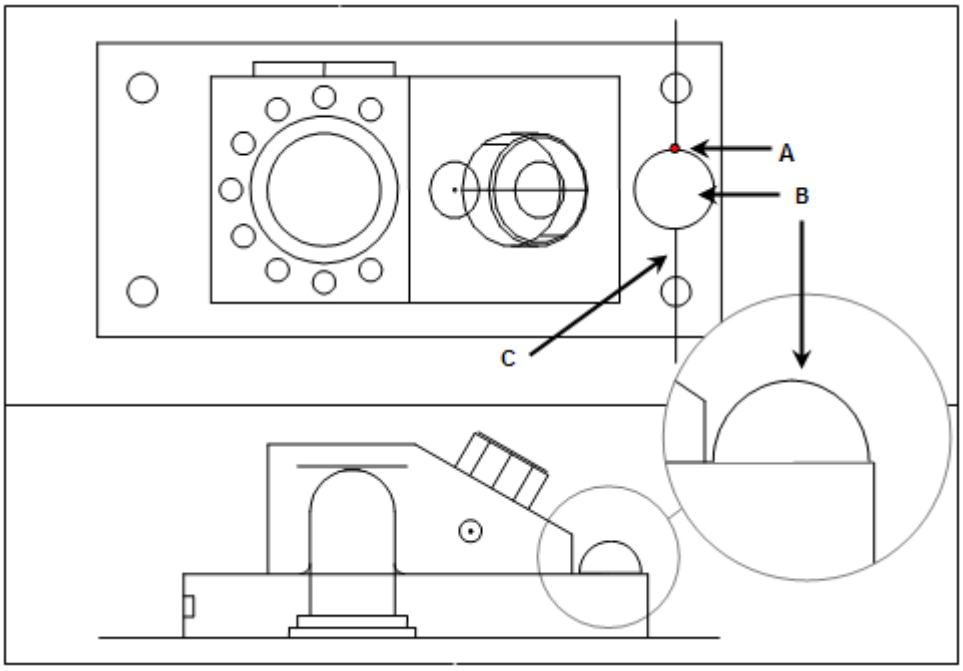
- If the second feature is a cone and the first feature is not a cylinder, circle, cone, line, or slot, then the cone becomes the line-reducible feature and pierces the surface of the first input.

To construct a pierce point:

1. Access the **Construct Point** dialog box (**Insert | Feature | Constructed | Point**).
2. Select the **Pierce** option from the list of options.
3. Select a first valid feature.
4. Select a second valid feature.
5. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/POINT,PIERCE,feat_1,feat_2
```



Constructing a pierce point from a Line and a Sphere
A *- Point constructed at the intersection of a line and sphere*
B *- Sphere feature*
C *- Line (please note the direction)*

Additional notes:

- If the pierced feature is a circle or an ellipse, PC-DMIS creates a cylindrical circumference about the centerline, and constructs the pierce point. If two similar features (two cylinders, for example) are provided, PC-DMIS pierces the second feature with the first feature.

- If the pierced feature is a sphere, circle, cone, or cylinder, the pierce point is constructed where the piercing input feature first intersects the surface of the pierced element. The first intersection point is determined by the direction of the line. It is important to know the direction in which the line was defined. If the wrong point is constructed, create a new, flipped line (see "Changing the Direction of a Line"), and use it to construct the point.

Constructing a Vector Distance Point

You can construct a point at a specified distance along an imaginary line created from two input features. PC-DMIS constructs the point along the line from the first input to the second input at a specified distance from the second input.

For example, if your two input features were in order, PNT1 and PNT2, and you defined a distance of 10 mm, PC-DMIS would construct the point (PNT3) like this:

Example of a constructed vector distance point (PNT3) created from input features (PNT1 and PNT2).

To construct a vector distance point:

1. Access the **Construct Point** dialog box (**Insert | Feature | Constructed | Point**).
2. Select the **Vector Distance** option from the **Method** list.
3. Select the first feature.
4. Select the second feature.
5. Specify a distance in the **Distance** box. You can type a negative value to construct the point *between* the two input features.
6. To change the feature theoreticals values, click the **Specify theos** check box in the **Feature Theoreticals** section and update the **X**, **Y**, **Z**, **I**, **J**, and **K** values as necessary.
7. Click the **Create** button. PC-DMIS constructs a point at the specified distance from the second input feature along the line from the first feature to the second feature.

The Edit window command line for this option would read:

```
CONSTR/POINT,VECT_DIST,feat_1,feat_2,distance
```

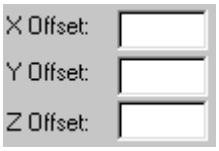
Constructing an Offset Point

You can construct a point a specified distance from any input feature.

To construct an offset point:

1. Access the **Construct Point** dialog box (**Insert | Feature | Constructed | Point**).
2. Select the **Offset Point** option from the **Method** list.
3. Select a feature from which to create the offset point.
4. Enter the offset values in the **X offset**, **Y offset**, and **Z offset** boxes as necessary to create an offset from the origin. To create an offset point relative to a particular feature, select the desired feature and type the values in the **X offset**, **Y offset**, and **Z offset** boxes.
5. To change the feature theoreticals values, click the **Specify theos** check box in the **Feature Theoreticals** section and update the **X**, **Y**, **Z**, **I**, **J**, and **K** values as necessary.
6. Click the **Create** button.

XYZ Offset



These fields allow you to enter in offset distances for the X, Y, and Z, axes. These options remain unavailable until you select the **Offset Point** option from the **Method** list.

The Edit window command line for this option would read:

```
CONSTR/POINT,OFFSET,feat_1,dx,dy,dz
```

Constructing a Tertiary Datum Point

You can construct a Tertiary Datum Point from a plane, line, or set of points. The set of points can be multiple selected points, a constructed set of points, or a scan feature that contains multiple points.

The tertiary datum construction uses the points within the input feature (or features), as well as with the specified primary and secondary datums to create an "orientation constrained" and "external to material" point. You can use this point in alignments to simulate a tertiary datum.

- "Orientation constrained" means that the resulting point feature is solved with a nominal orientation, with respect to the specified primary and secondary datum.
- "External to material" means that the resulting point feature lies on the highest point on the input feature (or features), subject to the orientation constraint.

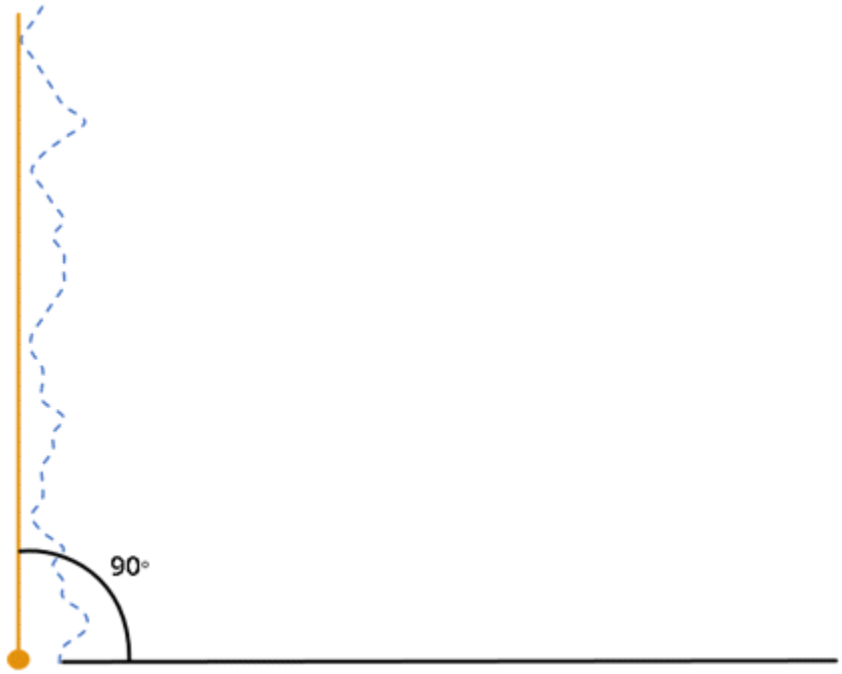
PC-DMIS constructs the tertiary datum point at the highest point along a vector that is oriented perpendicular to the specified primary datum, and at the keyed-in angle from the specified secondary datum. PC-DMIS places the point on the secondary datum line in the primary datum plane to simplify use in the alignment command.

Examples

The examples below showcase two different angles. The first angle is orthogonal, and the second angle is non-orthogonal:

Case 1 : 90 Degrees (Orthogonal)

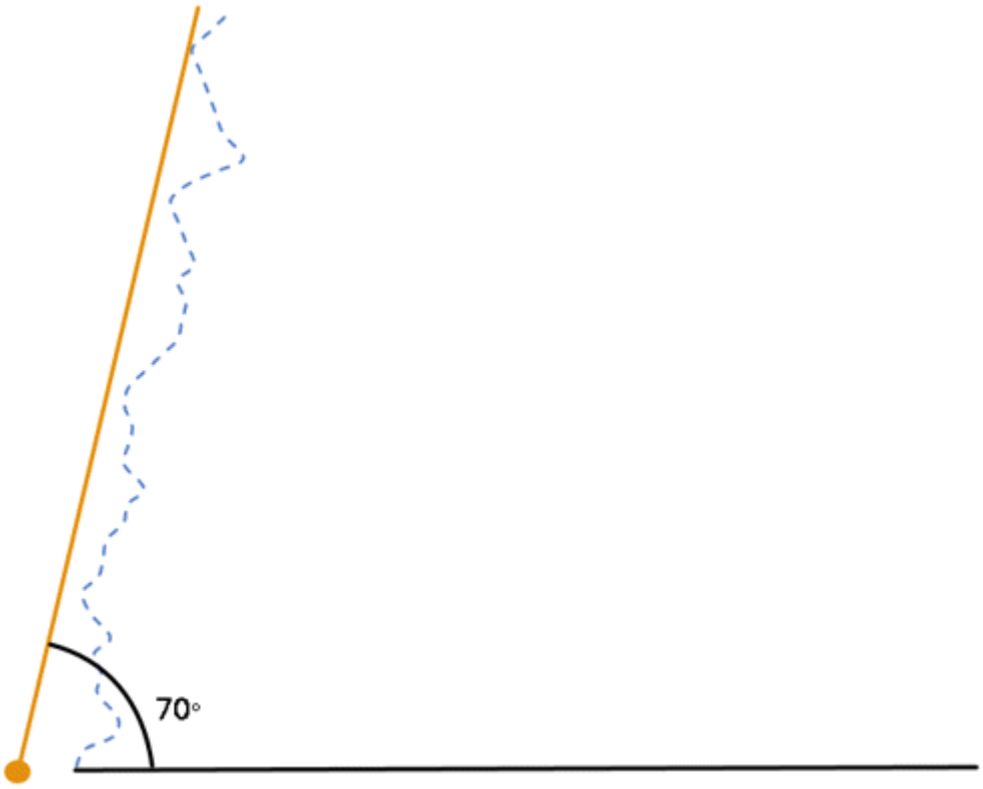
The yellow tertiary datum point below is constructed from the highest input point (where the yellow line contacts the blue dotted line) that is relative to the basic angle (90 degrees) from the specified secondary datum line in the primary datum plane's workplane.



Constructed Tertiary Datum Point feature from a 90-degree basic angle

Case 2 : 70 Degrees (Non-Orthogonal)

Similar to Case 1, the yellow tertiary datum point is again constructed from the highest input point relative to the specified datums. This example shows how a non-orthogonal tertiary datum is created.



Constructed Tertiary Datum Point feature from a 70-degree basic angle

How to Construct a Tertiary Datum Point

1. Access the **Construct Point** dialog box (**Insert | Feature | Constructed | Point**).
2. Select the **Tertiary Datum** option from the **Method** list.
3. From the list of features, select the input feature (or features). For valid input feature types, see the table in the "Constructing a Point Feature" topic. The selected features determine the initial **Secondary-tertiary basic angle** value.
4. From the **Primary datum** list, select the primary datum. The feature must either be a plane or workplane relative to the alignment.
5. From the **Secondary datum** list, select the secondary datum. The feature must be a line.
6. From the **Compensation type** area, from the second drop-down list, select a probe compensation option. The available options are **BF** for Best Fit or **BFRE** for Best Fit REcompensate.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

7. If you need a different basic angle, type it in the **Secondary-tertiary basic angle** box.
8. To change the feature theoreticals values, click the **Specify theos** check box in the **Feature Theoreticals** section and update the **X**, **Y**, **Z**, **I**, **J**, and **K** values as necessary.
9. Click the **Create** button to insert the constructed point feature into your measurement routine.

The Edit window command line for this option is:

```
CONSTR/POINT,TERTIARY_DATUM,feat_1,feat_2, …
MATH_TYPE/BFRE
PRIMARY DATUM PLANE/FEATURE,PLN1
SECONDARY DATUM PLANE/FEATURE,LIN1
SECONDARY TERTIARY BASIC ANGLE/<angle>
```

<angle> = This is the basic angle between the secondary and tertiary datums.

Constructing an Extracted Edge Point

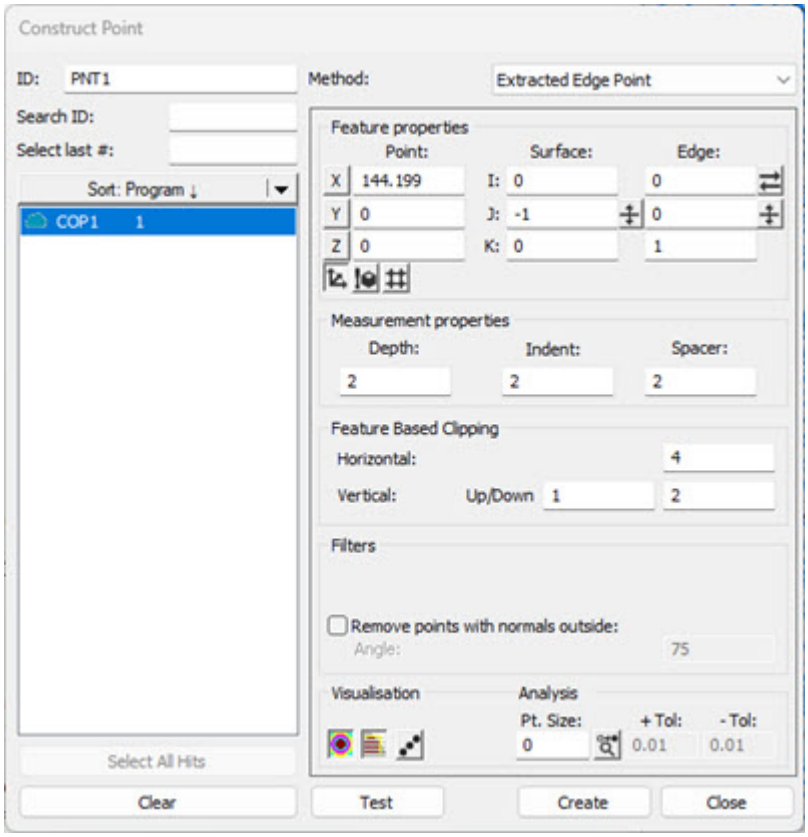
For details on extracting Auto features from a Mesh, see the "Extracting Auto Features from a Mesh" topic in the PC-DMIS Laser documentation.

For details on extracting Auto features from a Pointcloud (COP), see the "Extracting Auto Features from Pointclouds" topic in the PC-DMIS Laser documentation.

You can construct an edge point that is extracted from a scanned pointcloud (COP) or mesh.

To do this, follow these steps:

1. Ensure that your measurement routine has a Pointcloud (COP) or Mesh command.
2. Access the **Construct Point** dialog box (**Insert | Feature | Constructed | Point**).



Construct Point Dialog Box - Extracted Edge Point Option

3. Select the **Extracted Edge Point** option from the **Method** list. This changes the **Construct Point** dialog box to show the options to create the extracted point.
4. From the **Reference** area, select the COP or Mesh.
5. Click on the CAD model or data to define the nominal (or from the **Feature properties** area, in the **X**, **Y**, and **Z** boxes, type the nominal location). A black line shows the current edge vector. The center of this line is the nominal location.

   PC-DMIS draws the extraction zone and centers it around the XYZ location point. This box defines the extraction zone that PC-DMIS uses for the edge point extraction. The yellow rectangle is the horizontal zone and the green rectangle is the vertical. The orange points are the candidate points that the extraction considers.
6. In the **I**, **J**, and **K** boxes, define the **Surface** and **Edge** vectors. The black line, the edge vector, needs to be in the same direction as your part's edge.

   You can use these controls to perform the associated functions:

Flip Vectors

Polar/Cartesian

Find Nearest CAD element

Snap to Grid

For details on these controls, see the appropriate topic in the "Feature Properties Area" section of the "Creating Auto Features" chapter of the PC-DMIS Core documentation."

7. From the **Measurement properties** area, define the **Depth** at which you want to evaluate. Use the **Indent**, and **Spacer** values to determine the plane and the edge. For information on these properties, see the "The Dialog Box Options" sub-topic below.

8. From the **Feature Based Clipping** area, define the **Horizontal**, **Vertical Up/Down**, and **Vertical** values. This sets the dimensions for the green extraction zone region. Consider part variability when you define the extraction zone.

9. If you want to filter out any points that are outside of a maximum incidence angle, from the **Filters** area, select the **Remove points with normals outside** check box and type the value in the **Angle** (Max Incidence Angle) box.

The Max Incidence Angle filter was initially designed to compare the incidence direction of the laser (which is roughly the laser sensor orientation) to the estimated normal of the segregated points. For 3D laser features (Laser Auto Cone, Cylinder, Plane, Sphere, Surface Point and Constructed Extracted Cone, Cylinder, Plane, Sphere, Surface Point), the filter now compares the estimated normal of the pointcloud point to the nominal normal of the feature, which greatly improves the results. 2D laser features remain unchanged, using the legacy incidence angle filter method.

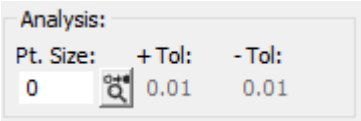
For details on the **Filters** area, see the "Filters" topic in the PC-DMIS Laser documentation.

10. In the **Visualisation** section, PC-DMIS provides these options to perform the described function:

Visualisation Tools On/Off - This button toggles the display of the colored visualisation tools. For more information, see "Understanding the Visualisation Tools".

Show/Hide segregated points - This button toggles the display of the points that the software passes to the feature extractor engine based on the current settings.

Show/Hide measured points - This button toggles the display of the measured points. It remains greyed out until you click **Test** or **Create**. For more information, see the "Show Measured Points" topic in the PC-DMIS Core documentation.



- The **Analysis** area allows you to determine how each measured hit/point is displayed. For more information, see the "Analysis Area" topic in the PC-DMIS Core documentation.

11. Click the **Test** button to test a feature's creation and preview its dimensional data before you create it. PC-DMIS performs a measurement using the current parameters. You can change the parameters and click **Test** repeatedly until you have an acceptable measurement. Then, when you click **Create**, the software converts the temporary feature into a normal feature in the measurement routine.

12. Click the **Create** button. Based on the parameters that you specified in the dialog box, PC-DMIS does an analysis of the candidate points and returns (or extracts) each measured point and projects them to the surface.

    PC-DMIS creates the command in the Edit window:

```
PNT1 =FEAT/POINT,CARTESIAN
   THEO/location,edge_vec,surf_vec
   ACTL/location2,edge_vec2,surf_vec2
   DEPTH=n1,INDENT=n2,SPACER=n3,
   HORIZONTAL CLIPPING=n4,VERTICAL CLIPPING=n5,
   REMOVE POINTS WITH NORMALS OUTSIDE=tog1,n6
   CONSTR/POINT,EXTRACTED_EDGE_POINT,ref_1
```

    location - This stands for the XYZ nominal location.

    edge_vec - This stands for the I, J, K edge vector.

    surf_vec - This stands for the I,J,K surface vector.

    location2, edge_vec2, surf_vec2 - These are the same as the items above but contain the actual measured values.

    n1 through **n6** - These numbers stand for the values for the different properties. **n6** is visible only when **tog1** is YES.

tog1 - This is either YES or NO based on the check box state.

ref_1 - This is the reference to the cloud of points (i.e. COP1).

For an example command, see the example below.

The Dialog Box Options

ID - Defines the extracted point feature's label.

Reference - Select the Pointcloud or Mesh object(s) from this list that PC-DMIS will use in the extraction.

Feature properties - This area defines the location for the point and the surface and edge vectors.

Point 1 - The **X**, **Y**, and **Z** boxes define the location of the point. PC-DMIS draws a black line for the edge vector in the Graphic Display window. The center of the black line is the point's location.

Surface - The **I**, **J**, and **K** boxes define the surface vector. PC-DMIS uses this vector along with the spacer value to calculate the surface. PC-DMIS draws the surface as a yellow plane in the Graphic Display window. When PC-DMIS creates the extracted point, it projects it to this surface.

Edge - The **I**, **J**, **K** boxes define the edge vector. PC-DMIS draws the edge vector as a black line in the Graphic Display window.

Measurement properties - This area defines properties that PC-DMIS uses to extract the point.

Depth - This defines the depth. PC-DMIS extracts the point from the considered points at this depth up to the edge. It then calculates the best point and projects it onto the plane. PC-DMIS shows an upside-down blue T to indicate the depth. One blue line extends down from the reference plane. Another blue line is drawn parallel to the black line at that depth. The **Depth** value must be within the **Vertical** value of the **Feature Based Clipping** area.

Indent - This defines how far from the edge to draw the center of the spacer. PC-DMIS shows a red line to indicate the indent distance.

Spacer - This defines the size of the circular area (a radius) that PC-DMIS uses to calculate the surface. PC-DMIS draws a purple circle to indicate the spacer.

Feature Based Clipping - This area defines the boundaries of the extraction zone. Consider part variability when you define the extraction zone.

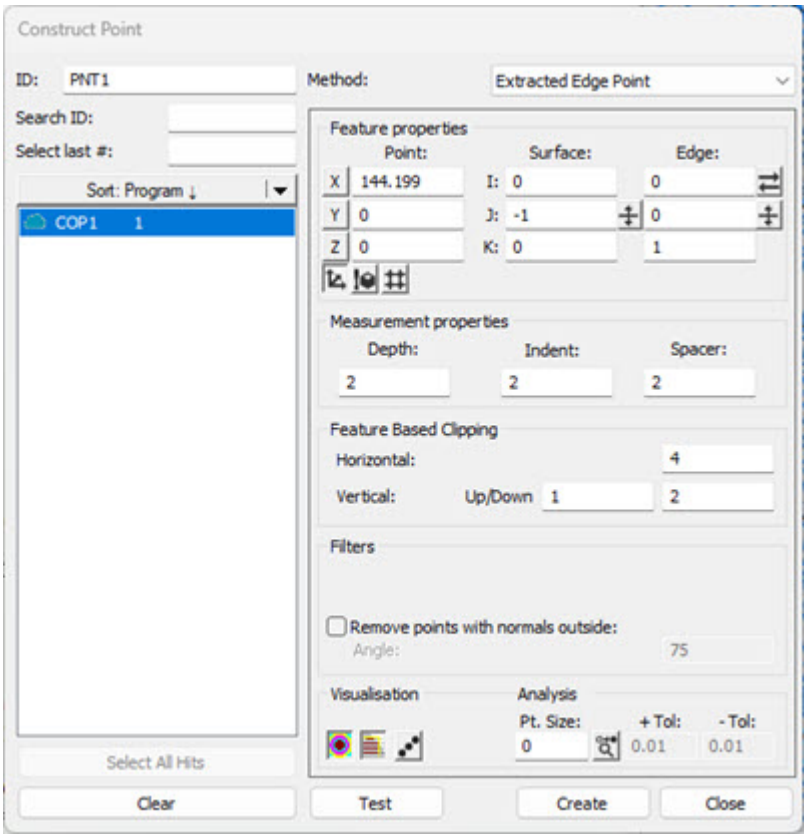
Horizontal - This defines the width of the extraction zone (yellow rectangle).

Vertical - This defines the height of the extraction zone (green rectangle). If you type a **Depth** value larger than this value, PC-DMIS increases this value to match the depth.

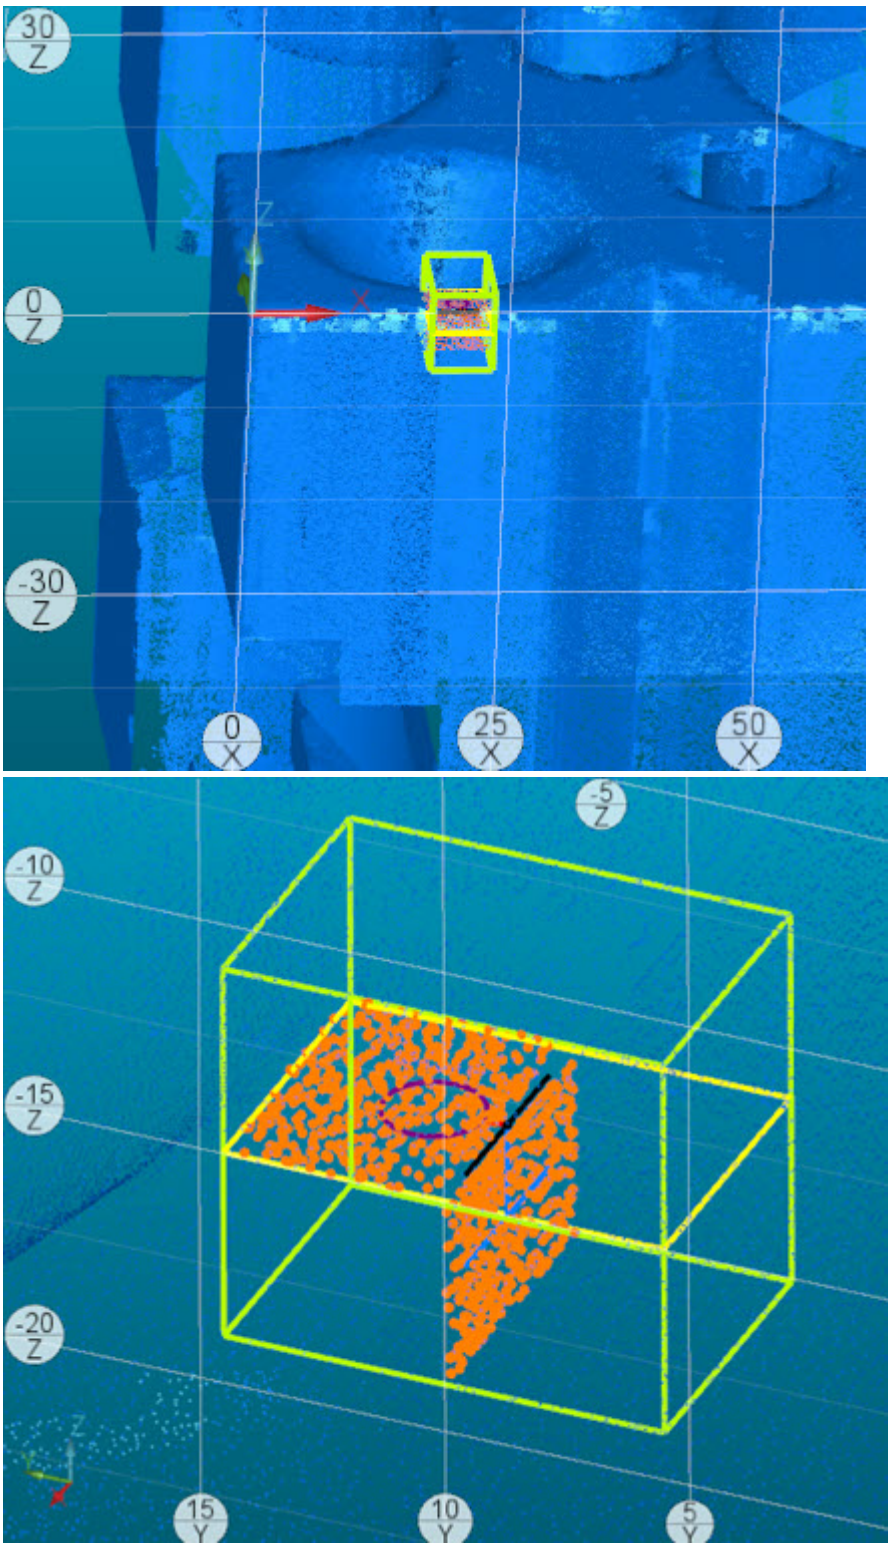
Filters - This area provides a check box and an angle box to filter out points beyond a defined incidence angle. This is useful if you have thin parts, like sheet a metal part, and the extraction zone may include scan data on both sides of the part. You can use the **Max incidence angle** box to define an angle. If you mark the check box, PC-DMIS compares the estimated normal of each scanned point to the feature theoretical normal. Points that are beyond that angle are removed from consideration.

An Example

Suppose that you have a pointcloud scan of the Hexagon demo block named COP1, and you have these values in the **Construct Point** dialog box:

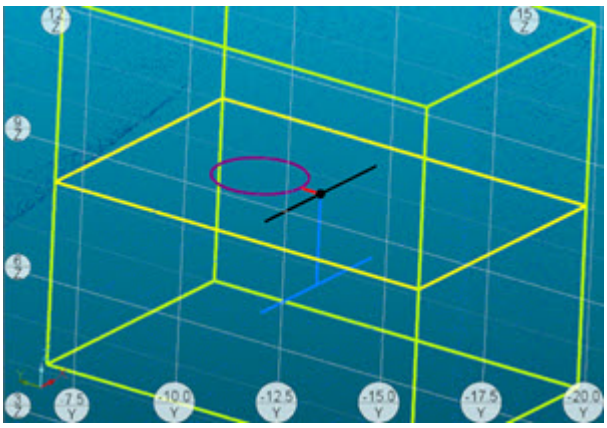


The result in the Graphic Display window while the dialog box is open, is this:



Example of a constructed edge point shown in a zoomed-out view (left) and a zoomed-in, rotated view (right).

Here's a view without the orange candidate points to provide a more visible example:



- The green box defines the extraction zone. The yellow plane defines the surface.
- The black line matches the edge vector.
- The center of the black line, the black dot, indicates the center location of the cube. This dot appears once you create the point. This is defined from the XYZ location.
- The red line shows the indent. In the above picture, you can see that it extends from the edge in the Y plus direction. This defines the spacer's distance from the edge.
- The purple ellipse shows the spacer.
- The blue line shows the depth.

When you click **Create**, PC-DMIS adds this point in the Edit window:

```
PNT1=FEAT/POINT,CARTESIAN
    THEO/<20,0,0>,<0,-1,0>,<0,0,1>
    ACTL/
<20,-0.064,0.054>,<0.0000197,-1,0.0002969>,<0.0042823,0.0002
97,0.9999908>
    DEPTH=2,INDENT=1.5,SPACER=1,
    HORIZONTAL
CLIPPING=2,VERTICAL CLIPPING=4,
    REMOVE POINTS
WITH NORMALS OUTSIDE=YES,0
            CONSTR/POINT,EXTRACTED_EDGE_POINT,COP1
```

Constructing an Extracted Surface Point

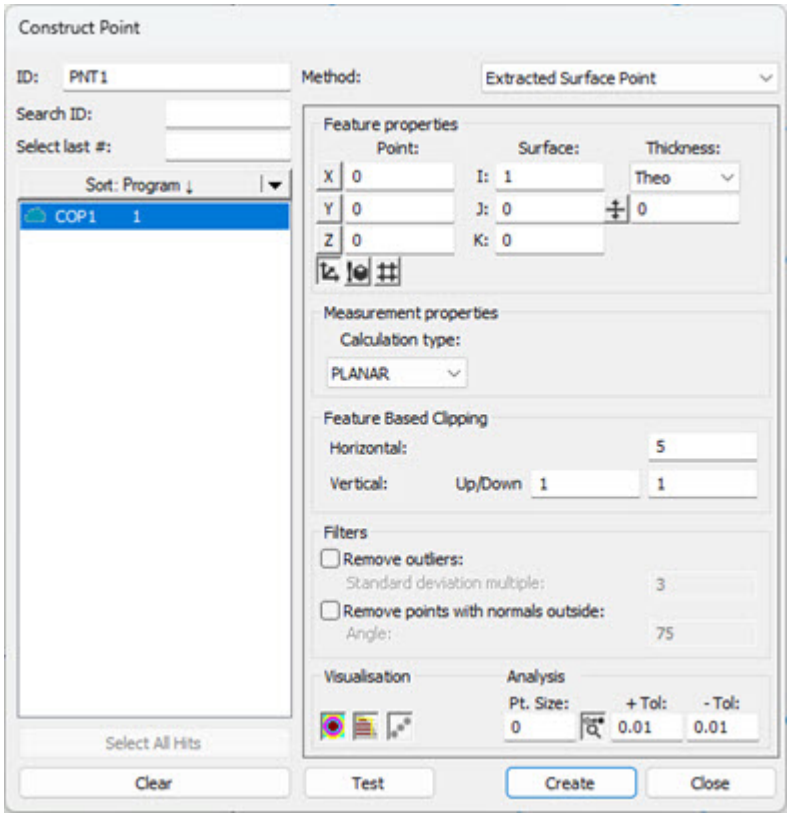
For details on extracting Auto features from a Mesh, see the "Extracting Auto Features from a Mesh" topic in the PC-DMIS Laser documentation.

For details on extracting Auto features from a Pointcloud (COP), see the "Extracting Auto Features from Pointclouds" topic in the PC-DMIS Laser documentation.

You can construct a surface point that is extracted from a scanned pointcloud (COP) or mesh.

To do this, follow these steps:

1. Ensure that your measurement routine has a Pointcloud (COP) or Mesh command.
2. Access the **Construct Point** dialog box (**Insert | Feature | Constructed | Point**).



Construct Point Dialog Box - Extracted Surface Point Option

3. Select the **Extracted Surface Point** option from the **Method** list. This changes the **Construct Point** dialog box to show the options to create the extracted point.
4. From the **Reference** area, select the COP or Mesh.

5. Click on the CAD model or data to define the nominal (or from the **Feature properties** area, in the **X**, **Y**, and **Z** boxes, type the nominal location).

   PC-DMIS draws the extraction zone and centers it around the XYZ location point. This box defines the cylinder zone that PC-DMIS uses for the surface point extraction. The yellow cylinder is the surface. The yellow cylinder is also the horizontal zone and the green cylinder is the vertical zone. The orange points are the candidate points that the extraction considers.

   
   Example showing a constructed surface point with mesh displaying the candidate points.

   You can use these controls to perform the associated functions:

   Flip Vectors

   Polar/Cartesian

   Find Nearest CAD element

   Snap to Grid

   For details on these controls, see the appropriate topic in the "Feature Properties Area" section of the "Creating Auto Features" chapter of the PC-DMIS Core documentation."

6. From the **Measurement Properties** area, select the appropriate measurement method from the **Calculation type** list.

   The options are:

   - **PLANAR**
   - **SPHERICAL**

- **EXTENDED**

7. From the **Feature Based Clipping** area, define the **Horizontal**, **Vertical Up/Down**, and **Vertical** values. This sets the dimensions for the green extraction zone region. Consider part variability when you define the extraction zone.

8. If you want to filter out any points that are outside of a maximum incidence angle, from the **Filters** area, select the **Remove points with normals outside** check box and type the value in the **Angle** (Max Incidence Angle) box.

The Max Incidence Angle filter was initially designed to compare the incidence direction of the laser (which is roughly the laser sensor orientation) to the estimated normal of the segregated points. For 3D laser features (Laser Auto Cone, Cylinder, Plane, Sphere, Surface Point and Constructed Extracted Cone, Cylinder, Plane, Sphere, Surface Point), the filter now compares the estimated normal of the pointcloud point to the nominal normal of the feature, which greatly improves the results. 2D laser features remain unchanged, using the legacy incidence angle filter method.

For details on the **Filters** area, see the "Filters" topic in the PC-DMIS Laser documentation.

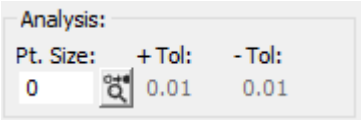
9. If you want to filter out any outlier points, from the **Filters** area, select the **Remove outliers** check box and define the **Standard deviation multiple** to determine which points PC-DMIS excludes as outliers.

10. In the **Visualisation** section, PC-DMIS provides these options to perform the described function:

Visualisation Tools On/Off - This button toggles the display of the colored visualisation tools. For more information, see "Understanding the Visualisation Tools".

Show/Hide segregated points - This button toggles the display of the points that the software passes to the feature extractor engine based on the current settings.

Show/Hide measured points - This button toggles the display of the measured points. It remains greyed out until you click **Test** or **Create**. For more information, see the "Show Measured Points" topic in the PC-DMIS Core documentation.



- The **Analysis** area allows you to determine how each measured hit/point is displayed. For more information, see the "Analysis Area" topic in the PC-DMIS Core documentation.

11. Click the **Test** button to test a feature's creation and preview its dimensional data before you create it. PC-DMIS performs a measurement using the current parameters. You can change the parameters and click **Test** repeatedly until you have an acceptable measurement. Then, when you click **Create**, the software converts the temporary feature into a normal feature in the measurement routine.

12. Click the **Create** button. Based on the parameters that you specified in the dialog box, PC-DMIS does an analysis of the candidate points and returns (or extracts) each measured point and projects them to the surface.

    PC-DMIS creates the command in the Edit window:

```
PNT1 =FEAT/POINT,CARTESIAN,PLANAR
   THEO/<78.752,27.187,0>,<0,0,1>
   ACTL/
<78.752,27.187,0>,<-0.002493,-0.0020317,0.9999948>
   THEO_THICKNESS,0,
   HORIZONTAL CLIPPING=1,VERTICAL CLIPPING=2,
   USE OUTLIER REMOVAL=YES,0.1,
   REMOVE POINTS WITH NORMALS OUTSIDE=YES,5,
   CONSTR/POINT,EXTRACTED_SURFACE_POINT,REF=COP1
```

Constructing an Extreme Point

For details on extracting Auto features from a Mesh, see the "Extracting Auto Features from a Mesh" topic in the PC-DMIS Laser documentation.

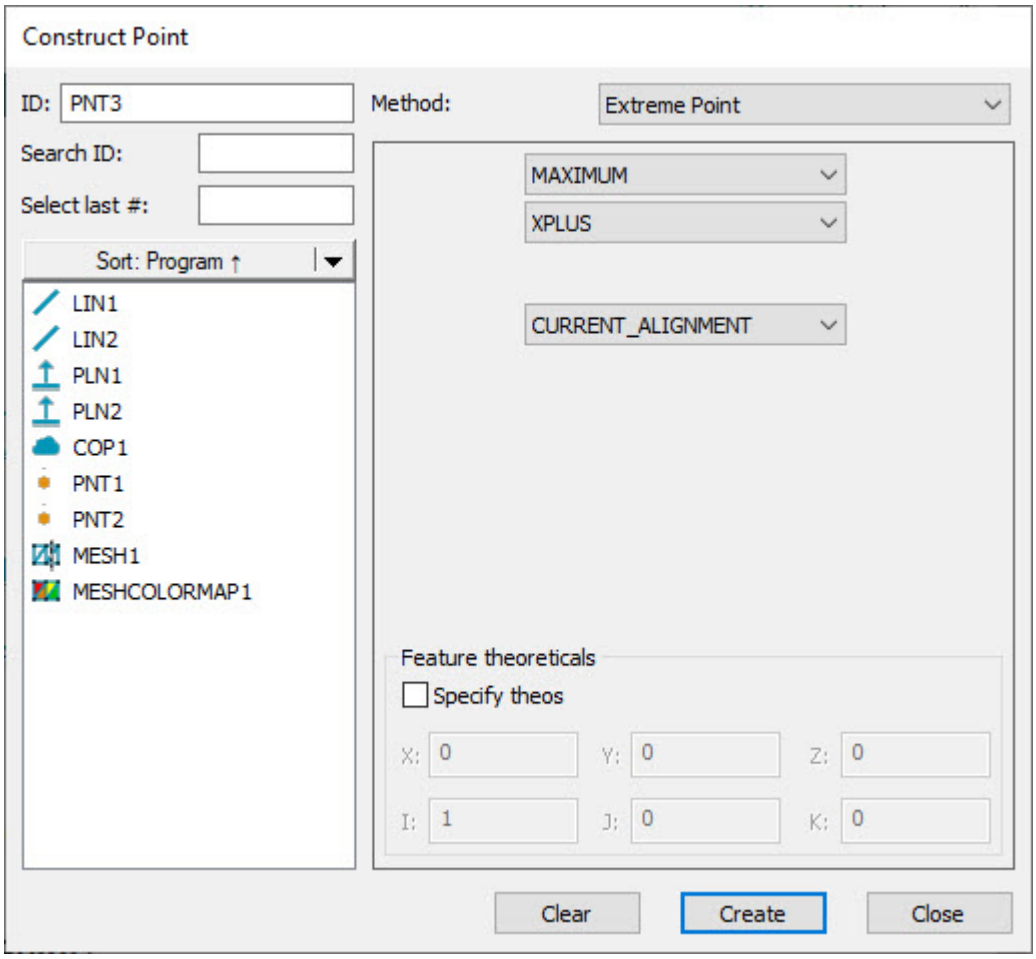
For details on extracting Auto features from a Pointcloud (COP), see the "Extracting Auto Features from Pointclouds" topic in the PC-DMIS Laser documentation.

You can construct an extreme point from a measured feature, scanned object, or from a scanned cloud of points (COP) or MESH.

To do this:

1. Ensure that your measurement routine has a measured feature, scanned object, or a Pointcloud (COP) or Mesh command.

2. Access the **Constructed Point** dialog box (**Insert | Feature | Constructed | Point**).



Construct Point Dialog Box - Extreme Point Option

3. Select the **Extreme Point** option from the **Method** list. This changes the **Constructed Point** dialog box to show the options to create an extreme point.

4. From the **Feature List** area, select the desired feature.

5. The **Options** area consists of three combo-boxes and the Feature theoreticals area. From the first combo-box, select either **MAXIMUM** or **MINIMUM**.

6. From the second combo-box, select the direction (**XPLUS**, **XMINUS**, **YPLUS**, **YMINUS**, **ZPLUS**, or **ZMINUS**) for the extreme point calculation. This is the direction that PC-DMIS uses to find the extreme point.

    - If you selected **MAXIMUM** in step 5, PC-DMIS defines the extreme point as:

        - If you selected **XPLUS**, **XMINUS**, **YPLUS**, **YMINUS**, **ZPLUS**, or **ZMINUS**, the largest value from the origin along the selected axis relative to the start point.

    - If you selected **2D_PR** or **3D_PR**, the longest polar radius from the origin relative to the start point.

- If you selected **MINIMUM** in step 5, PC-DMIS defines the extreme point as:

    - If you selected **XPLUS**, **XMINUS**, **YPLUS**, **YMINUS**, **ZPLUS**, or **ZMINUS**, the smallest value from the origin along the selected axis relative to the start point.

    - If you selected **2D_PR** or **3D_PR**, the shortest polar radius from the origin relative to the start point.

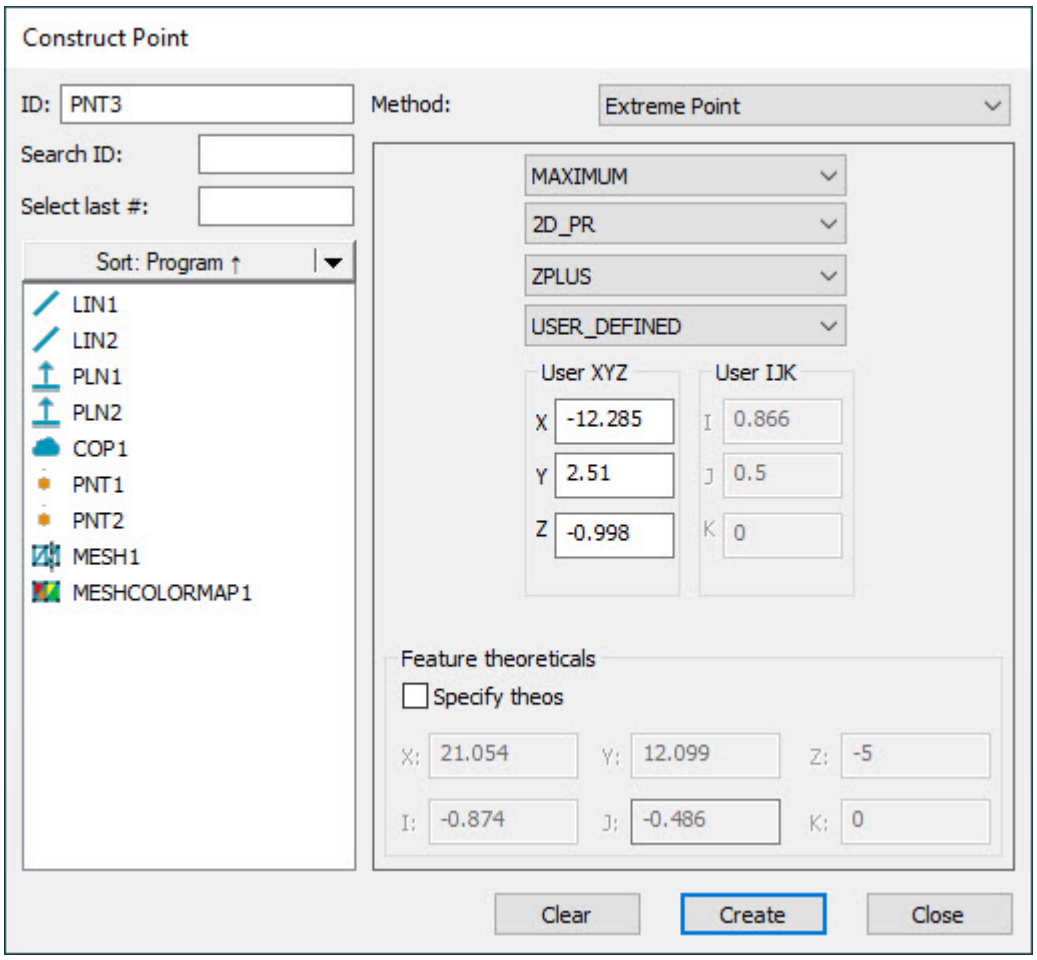
  If you select the **2D_PR** (2D-Polar Radius) option, PC-DMIS enables another combo-box just below the second combo-box. Use this to select the workplane (**ZPLUS**, **XPLUS**, **YPLUS**, **ZMINUS**, **XMINUS**, or **YMINUS**) in which to apply the 2D-Polar Radius.

  Select the **3D_PR** (3D-Polar Radius) option to define a 3D polar radius direction.

7. Use the third combo-box to define the start point that PC-DMIS uses to calculate the extreme point.

    - **CURRENT_ALIGNMENT** - Select this option to specify the origin (0, 0, 0) and orientation of the currently active alignment.

    - **USER_DEFINED** - Select this option to specify a new centroid starting point and starting axis vector. If you choose one of the polar radius calculations from the second combo-box (**2D_PR** or **3D_PR**), you can only specify the new centroid starting point.



When you select the **USER_DEFINED** option from the third combo-box, PC-DMIS creates a local alignment using the supplied X, Y, and Z values as the origin, the current workplane as the axis, and then rotates the primary axis using the supplied I, J, and K values. You can type the values into the **X**, **Y**, and **Z** boxes or click inside one of the boxes and then click a feature to use its centroid. Similarly, you can type the values into the **I**, **J**, and **K** boxes or click inside one of the boxes and then Alt + click a feature to use its direction.

8. From the **Feature theoreticals** area, you can select the **Specify theos** check box. Here you can set the theoretical **X**, **Y**, **Z** and **I**, **J**, **K** values for the constructed extreme point.

9. Click the **Create** button. Based on the parameters that you specified in the dialog box, PC-DMIS returns the calculated extreme point.

PC-DMIS created the command in the Edit window:

```
PNT1=FEAT/POINT,CARTESIAN,tog1
   THEO/<theoXyz>,<theoIjk>
   ACTL/<actXyz>,<actIjk>
   CONSTR/
POINT,EXTREME,feat1,tog2,tog3,optTog,tog4,udXyz,udIjk
```

Where:

tog1 – This is either `YES` or `NO` based on the values entered for the **Specify theos** option.

feat1 – This is the input feature selected in step 4 that PC-DMIS uses to find the extreme point.

tog2 – This is either **MAXIMUM** or **MINIMUM** selected in step 5.

tog3 – This is either **XPLUS**, **XMINUS**, **YPLUS**, **YMINUS**, **ZPLUS**, **ZMINUS**, **2D_PR** (2D-Polar Radius), or **3D_PR** (3D-Polar Radius). This specifies the direction to search for the extreme point.

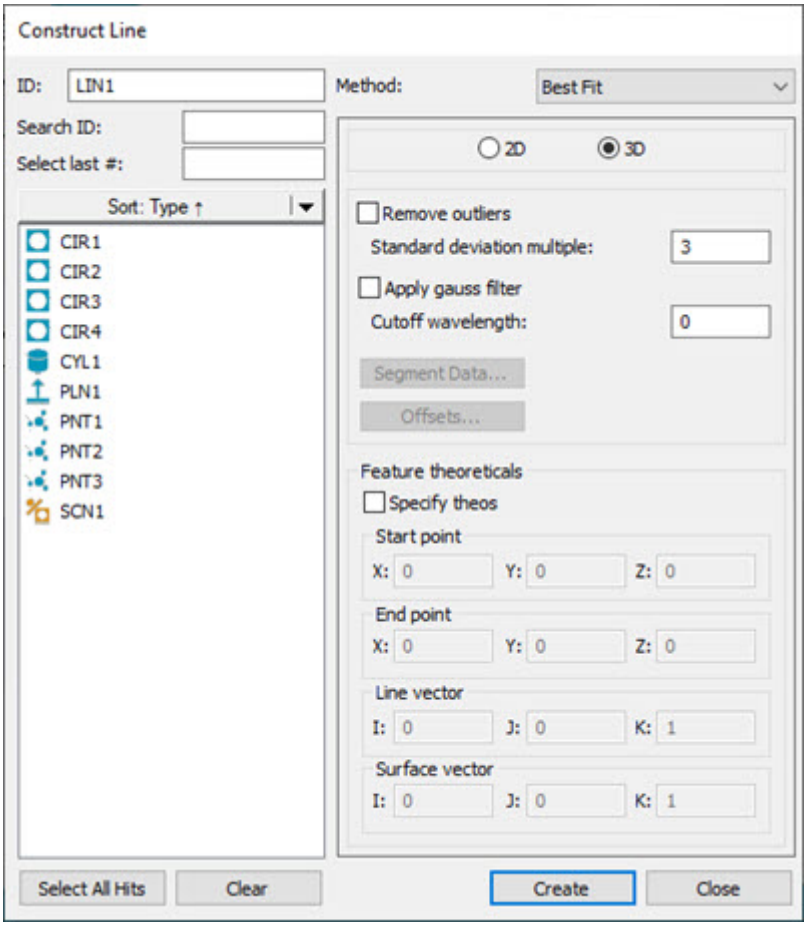
optTog – This is only available when **tog3** = **2D_PR**. This can be **ZPLUS**, **XPLUS**, **YPLUS**, **ZMINUS**, **XMINUS**, or **YMINUS**.

tog4 – This is either **CURRENT_ALIGNMENT** or **USER_DEFINED**. When you select **CURRENT_ALIGNMENT**, PC-DMIS calculates all extreme points from the origin (0, 0, 0). If you select **USER_DEFINED**, you can specify a new starting point and direction to calculate from. This is a way of creating a temporary alignment for the extreme point calculation.

udXyz – This is the user-defined X, Y, Z point that PC-DMIS uses to calculate the extreme point from.

udIjk – This is the user-defined I, J, K direction vector. This allows you to specify a new starting direction axis.

Constructing a Line Feature



Construct Line Dialog Box

There are many methods PC-DMIS uses to construct a line. The following table lists the various types of constructed lines along with their necessary inputs. Some features may require no inputs while others may require three or more inputs. In the table, the term "Any" indicates that the construction can take any type of feature as input for construction. PC-DMIS allows you to select the features in any order.

CONSTRUCT FEATURE TYPE	SYMBOL IN EDIT WINDOW	# OF INPUT FEATURES REQUIRED	FEATURE #1:	FEATURE #2:	COMMENTS
Auto Line	-	-	-	-	See "Auto Line Construction".
Alignment Line	ALIGN	0	-	-	Constructs a line through the alignment origin.
Best Fit Line	BF	At least 2 inputs are needed.	-	-	Constructs a best fit line using the inputs.
Best Fit with Recomp Line	BFRE	At least 2 inputs are needed. (1 must be a point)	-	-	Constructs a best fit line using the inputs.
Cast Line	CAST	1	Any	-	Constructs a line at the centroid of the input feature.
Intersect Line	INTOF	2	Plane	Plane	Constructs a line at the intersection of two planes.
Mid Line	MID	2	Line, Cone, Cylinder, Slot, Plane	Line, Cone, Cylinder, Slot, Plane	Constructs a mid line between the input features.
Offset Line	OFFSET	At least 2 inputs are needed.	Any	Any	Builds a line through the first feature and the offset from the second feature by a specified amount.

Parallel Line	PLTO	2	Any	Any	Constructs a line parallel to the first feature and passing through the second feature.
Perpendicular Line	PRTO	2	Any	Any	Constructs a line perpendicular to the first feature and passing through the second feature.
Project Line	PROJ	1 or 2	Any	Plane	Using one input feature will project the line to the workplane.
Reverse Line	REV	1	Line	-	Constructs a line passing through the input with a reversed vector.
Scan Segment Line	SCAN_SEGMENT	1	Scan	-	Constructs a line from a part of a Linear Open or Linear Close scan.
Secondary Datum Line	SECONDARY_DATUM	1	Point, Plane, Line, Set of Points	(Additional Point features if first feature is a point)	Constructs a line which simulates a secondary datum that is external to material.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

If you select inappropriate feature types, PC-DMIS displays this message on the Status bar:

"Cannot construct [feature]. Combination of input features not accepted."

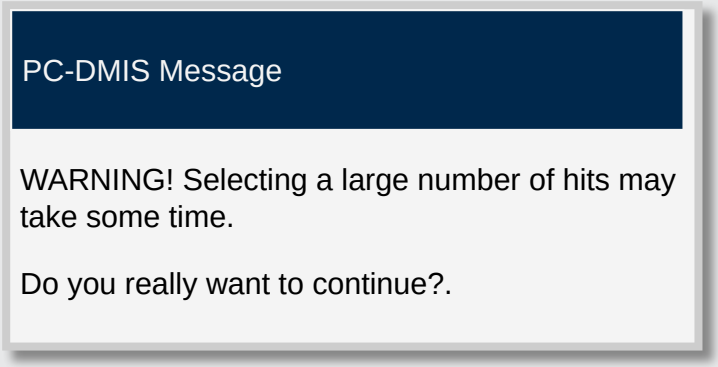
To construct a line:

1. Open the **Construct Line** dialog box (**Insert | Feature | Constructed | Line**).
2. Select the desired features from the **Feature** list.
3. From the **Method** list, select the method of the constructed line. The available options are:
    - Auto
    - Alignment
    - Best Fit
    - BF Recomp
    - Cast
    - Intersection
    - Mid
    - Parallel
    - Perpendicular
    - Projection
    - Reverse

- Scan Segment
- Offset
- Secondary Datum

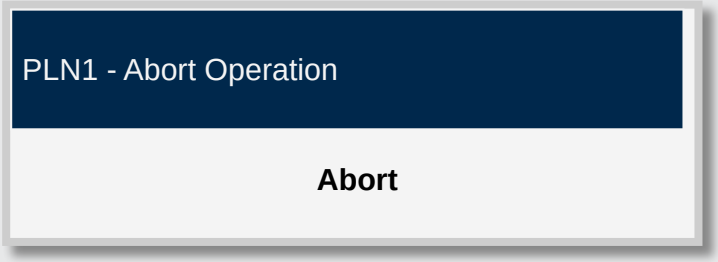
If you select the **Best Fit** or the **BF Recomp** (Best Fit Recomp) method for this feature, PC-DMIS allows you to click the **Select All Hits** button to create the construction from the individual hits of the input features instead of their centroids.

If there are a large number of points involved (about 10,000 or more), PC-DMIS shows a message asking if you are sure you want to proceed as this may take some time to complete.



Click **Yes** to proceed, click **No** to abort the process. You can select the **Don't ask me again** check box to prevent this message from recurring.

If you click **Yes**, another message is shown similar to the one shown below to let you know that PC-DMIS is generating the features from the hit points.

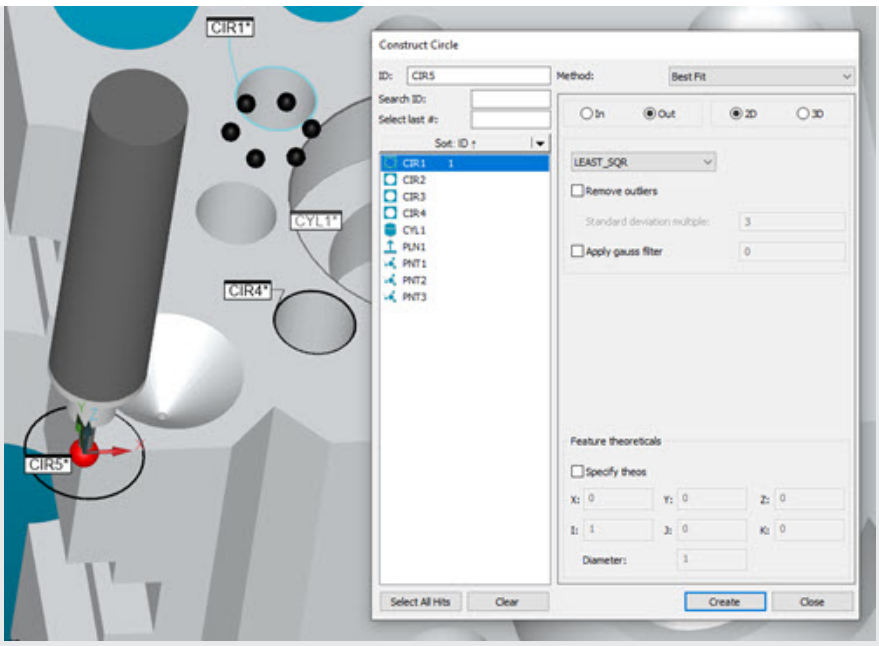


Once all the constructed features are created, the message disappears.

You can click the **Abort** button at any time to stop the process. Any features created up to this point are listed in the **Feature list** area of the dialog box.

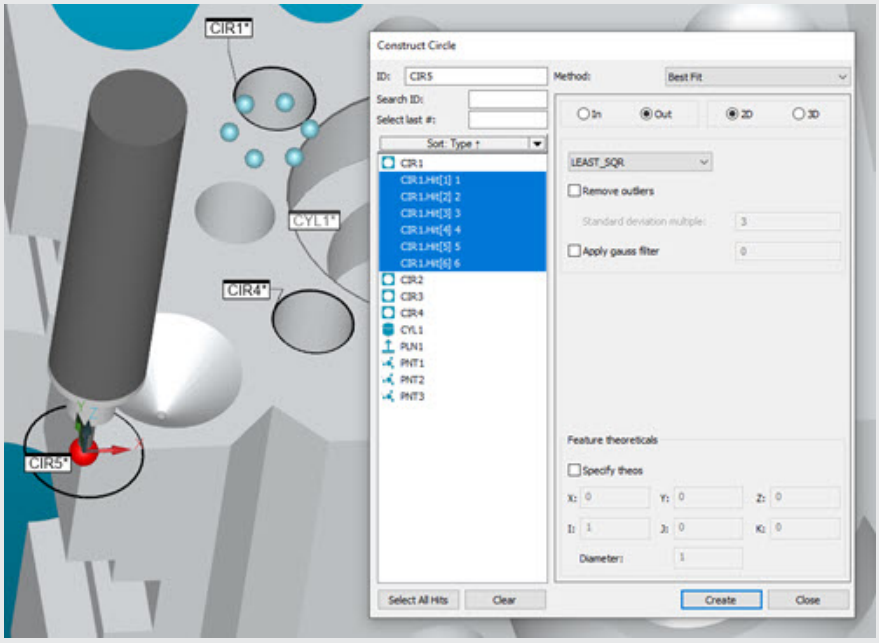
To create constructed features from the individual hits of the input features, do this:

1. From the **Feature list**, select the feature or features that you want to use to create the constructed feature.



Example showing a selected feature prior to clicking the Select All Hits button.

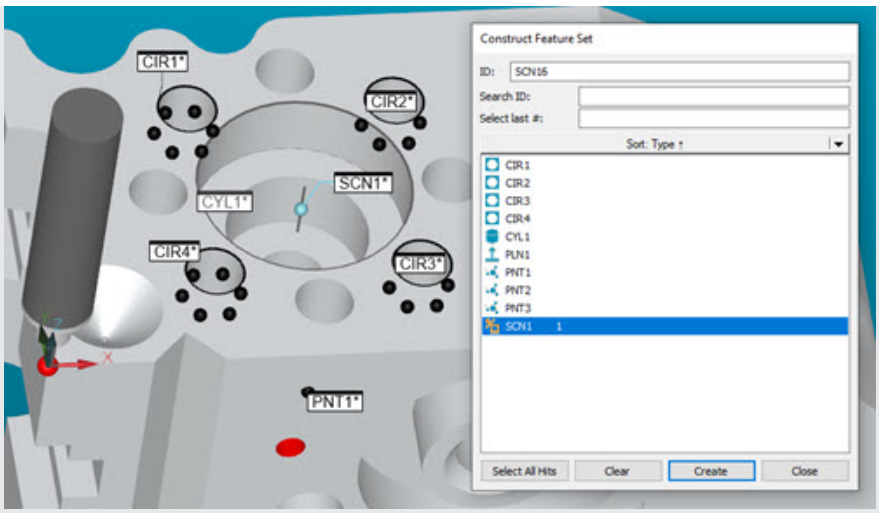
2. Click the **Select All Hits** button to display all the components that comprise the selected feature or features.



Display of items that make up the selected feature are highlighted in the dialog box and in the Graphic Display window.

PC-DMIS displays and highlights all the components of the selected feature (or features) in the **Feature list** are of the dialog box. You can select or de-select any of the features or feature components shown in the list to include or exclude them.

3. Click the **Create** button to create the Constructed feature based on the final features and feature components that you selected.



Constructed feature created based on the selected items from the Feature list.

4. From the **Feature** list, use the table above to select the features based on the selected method.
5. Select either the **2D** or **3D** option.
6. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
7. Click the **Create** button.

The Edit window command line for this option would read:

```
feature_name=FEAT/LINE,TOG1,TOG4
THEO/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,length
ACTL/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,length
CONSTR/TOG2,TOG3,...
```

If TOG2 = LINE and TOG3 = BF or BFRE then the command has the following format:

```
feature_name=FEAT/LINE,TOG1,TOG4
THEO/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,length
ACTL/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,length
CONSTR/LINE,TOG3
OUTLIER_REMOVAL/TOG5, stdDevMultiplier
FILTER/TOG5, WAVELENGTH=cutoffWavelength
```

The actual Edit report displays in all capital letters.

TOG1 = POLR or RECT

TOG2 = LINE

TOG3 = ALIGN / BF / BFRE / CAST / INTOF / MID / OFFSET / PLTO / PROJ / PRTO / REV / SCAN_SEGMENT / SECONDARY DATUM

TOG4 = BND / UNBND

TOG5 = OFF / ON

Length = This value represents the theoretical or actual length of the line.

stdDevMultiplier = This multiplier value determines whether or not a measured point is an outlier. If the point from the line is further than the standard deviation multiplied by this value, then it is an outlier and is removed if you selected the **Remove Outlier** option.

cutoffWavelength = This value controls the amount of data smoothing. The longer the wavelength, the more smoothing there is.

The first three lines that display in the Edit window are the same for constructed lines. The fourth line is slightly different, according to the type of feature you are constructing. To switch between the different types of lines, place the cursor on TOG3 and press F7 or F8. (See "Command Mode Keyboard Functions" in the "Using the Edit Window" chapter.)

When two or more features are involved, PC-DMIS automatically determines the necessary order of the input features. This improves the accuracy of the measurement process.

AUTO is the default method of construction. See "Auto Line Construction"

The following topics describe the available options for constructing a line:

Auto Line Construction

The list below indicates the type of line that the software constructs when you select certain input features along with the **Auto** option. The order of the selected features is not important. If you select an incorrect input feature or features, PC-DMIS shows an error message and will not construct the indicated feature type.

To allow PC-DMIS to automatically determine the best method of construction:

1. Open the **Construct Line** dialog box (**Insert | Feature | Constructed | Line**).
2. From the **Method** list, select the **Auto** option.
3. From the **Feature** list, select the desired feature or features based on the "Input Feature List" table below.
4. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
5. Click the **Create** button.

Input Feature List

Input Feature(s)	Constructs
Three or more features	Best Fit Line
Any one feature (except line/set)	Cast Line
Any one set	Best Fit Line
Any two features + offset value	Offset Line
Circle + Circle	Best Fit Line
Circle + Ellipse	Best Fit Line
Circle + Point	Best Fit Line
Circle + Set	Best Fit Line
Circle + Slot	Best Fit Line

Circle + Sphere	Best Fit Line
Cone + Circle	Parallel to Line
Cone + Cone	Mid Line
Cone + Cylinder	Mid Line
Cone + Ellipse	Parallel to line
Cone + Point	Parallel to Line
Cone + Set	Parallel to Line
Cone + Sphere	Parallel to Line
Cylinder + Circle	Parallel to Line
Cylinder + Cylinder	Mid Line
Cylinder + Ellipse	Parallel to Line
Cylinder + Point	Parallel to Line
Cylinder + Set	Parallel to Line
Cylinder + Sphere	Parallel to Line
Ellipse + Ellipse	Best Fit Line
Ellipse + Set	Best Fit Line
Ellipse + Sphere	Best Fit Line
Line	Reverse Line
Line + Circle	Parallel to Line

Line + Cone	Mid Line
Line + Cylinder	Mid Line
Line + Ellipse	Parallel to Line
Line + Line	Mid Line
Line + Point	Parallel to Line
Line + Set	Parallel to Line
Line + Slot	Mid Line
Line + Sphere	Parallel to Line
Point + Ellipse	Best Fit Line
Point + Point	Best Fit Line
Point + Sphere	Best Fit Line
Point + Slot	Best Fit Line
Point + Set	Best Fit Line
Plane + any feature (except plane)	Project Line
Plane + Plane	Intersect Line
Slot + Cone	Mid Line
Slot + Cylinder	Mid Line
Slot + Ellipse	Parallel to Line
Slot + Slot	Best Fit Line

Constructing an Alignment Line

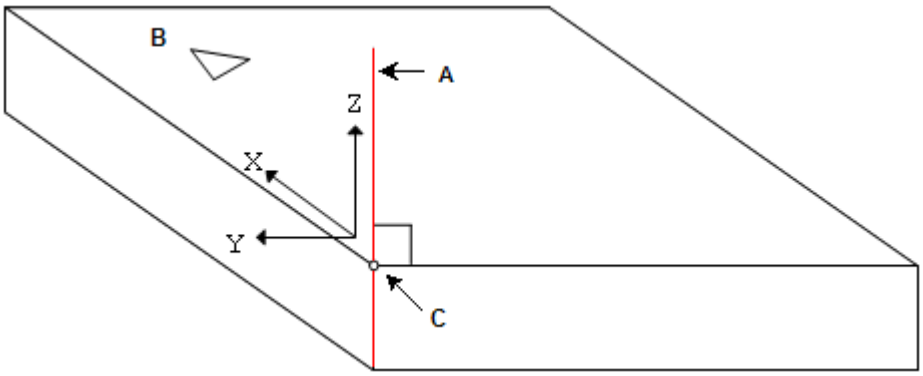
You can construct a line through the current origin, normal to the current workplane. (Input features do not need to be provided.)

To construct an alignment line:

1. Open the **Construct Line** dialog box (**Insert | Feature | Constructed | Line**).
2. From the **Method** list, select the **Alignment** option.
3. Do *not* select any features.
4. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
5. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/LINE,ALIGN,length
```



Constructing a Line Normal to the Workplane

A. *Line through the current origin normal to the current workplane*

B. *Current workplane*

C. *Origin*

Constructing a Best Fit or Best Fit Recompensate Line

Best Fit Recompensate is only accurate when you use points to construct a line.

You can construct a "best fit" two or three-dimensional line from two or more features. The average squared error is minimized in the least squares method and the maximal error is minimized in the min/max method. You can also choose to remove outliers or apply a Gaussian filter to the constructed line.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

- The **Best fit** option compensates prior to fitting by using the ball center data shifted one tip radius in the direction of the negated hit vector.
- The **BF Recomp** option uses the ball center data and the tip compensation is part of the fitting process.

To construct a best fit or best fit recompensate line:

1. Open the **Construct Line** dialog box (**Insert | Feature | Constructed | Line**).
2. From the **Method** list, select either the **Best Fit** or **BF Recomp** option.
3. From the **Feature** list, select at least two features.
4. Select either the **2D** or **3D** option.
5. If desired, click the **Remove outliers** check box and specify a value in the **Standard deviation multiple** box.
6. If desired, click the **Apply gauss filter** check box and specify a value in the **Cuttoff wavelength** box.
7. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
8. Click the **Create** button.

The Edit window command line for the **Best Fit** method would read:

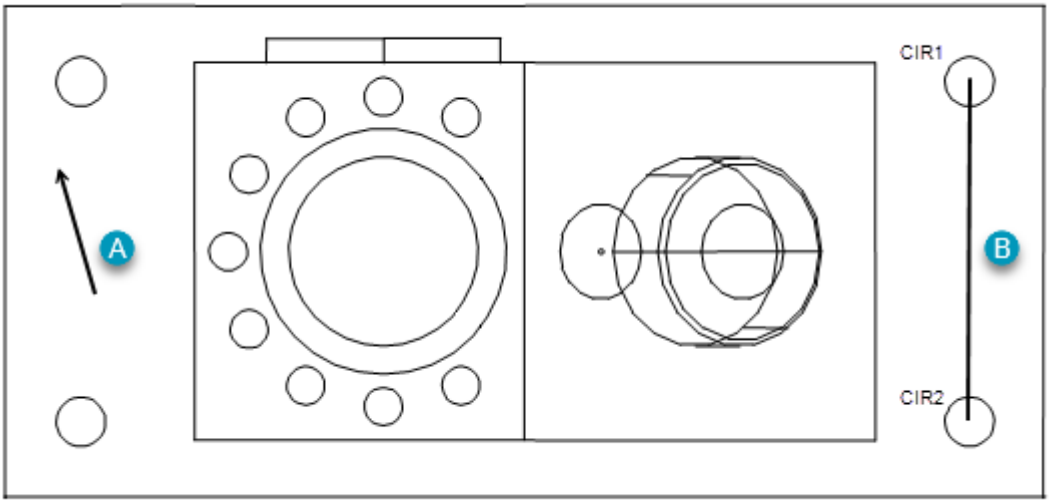
```
CONSTR/LINE,BF, feat_1,feat_2, …
OUTLIER_REMOVAL/(ON | OFF), stdDevMultiple
FILTER/(ON | OFF),WAVELENGTH=ctfoffWavelength
```

(This method uses the actual measured points for construction.)

The Edit window command line for the **Best Fit Recompensate** method would read:

```
CONSTR/LINE,BFRE,feat_1,feat_2, …
OUTLIER_REMOVAL/(ON | OFF), stdDevMultiple
FILTER/(ON | OFF),WAVELENGTH=cutoffWavelength
```

(This method uses the center of the probe for the measurement, and then recompensating after measuring the features.)



A *- Level*
B *- Line*
Constructing a Line from Two or More Features

Remove Outliers / Standard Deviation Multiple

For a best fit (BF) or best fit recompensate (BFRE) line, you can choose to remove outliers based on the distance from the best fit feature. This allows the removal of anomalies that arise in the measurement process.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

PC-DMIS first fits a line to the data and then determines which points are outliers based on the value in the **Standard Deviation Multiple** box. It then does the following:

- Recalculates the best fit line with those outliers removed.
- Checks for outliers again.
- Recalculates the best fit line.
- Continues to repeat this process until no more outliers exist or until PC-DMIS cannot compute the line. (PC-DMIS can't compute the line if there are fewer than three data points.)

For 2D lines, the deviation is calculated in a plane parallel to the workplane.

For 3D lines, the deviation is computed as the distance from the measured point to the nearest point along the line.

Apply Gauss Filter / Cutoff Wavelength

The Best Fit (BF) and Best Fit Recompensate (BFRE) constructed lines have the option of filtering the deviations of the measured data points from the best fit line computed from the measured data.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

Apply Gauss Filter - If you select this check box, PC-DMIS applies a Gaussian filter which controls the smoothing by the cutoff wavelength. Generally, a longer cutoff wavelength produces smoother filtered data.

Remove Outliers - If you select this check box and you are filtering the data, it removes the outlier data prior to filtering.

For 2D lines, PC-DMIS filters the deviations in a plane parallel to the workplane.

For 3D lines, PC-DMIS filters the deviations in two planes perpendicular to each other, both planes containing the line. PC-DMIS filters these deviations in 3D.

Constructing a Cast Line

You can construct a line by changing any given feature into a line. PC-DMIS constructs the line at the centroid of the input feature.

You can modify the length of the line; this changes the line from DEPENDENT to INDEPENDENT. This means that when the line is executed, the length does not change based on the input feature, but is independent of the input feature, while the position and vector remain dependent on the input feature. This allows you to have control over the line length in cases where the input feature doesn’t really have a length, such as a point. The DEPENDENT/INDEPENDENT field is a toggle field that you may change.

To change the length of a line:

1. Open the Edit window.
2. Click on the line feature.
3. Press the Tab key until the length field is selected.
4. Type in a new length.
5. Press the Tab key. PC-DMIS updates the length.

PC-DMIS uses this length value for all calculations instead of a default length.

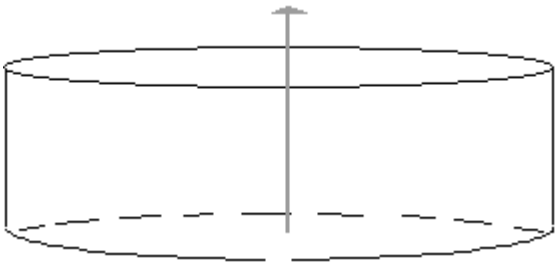
To construct a cast line:

1. Open the **Construct Line** dialog box (**Insert | Feature | Constructed | Line**).
2. From the **Method** list, select the **Cast** option.
3. From the **Feature** list, select one feature of any type.
4. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.

5. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/LINE,CAST,feat_1,length,(DEPENDENT | INDEPENDENT)
```



Constructing a Line from a Cylinder

Constructing an Intersect Line

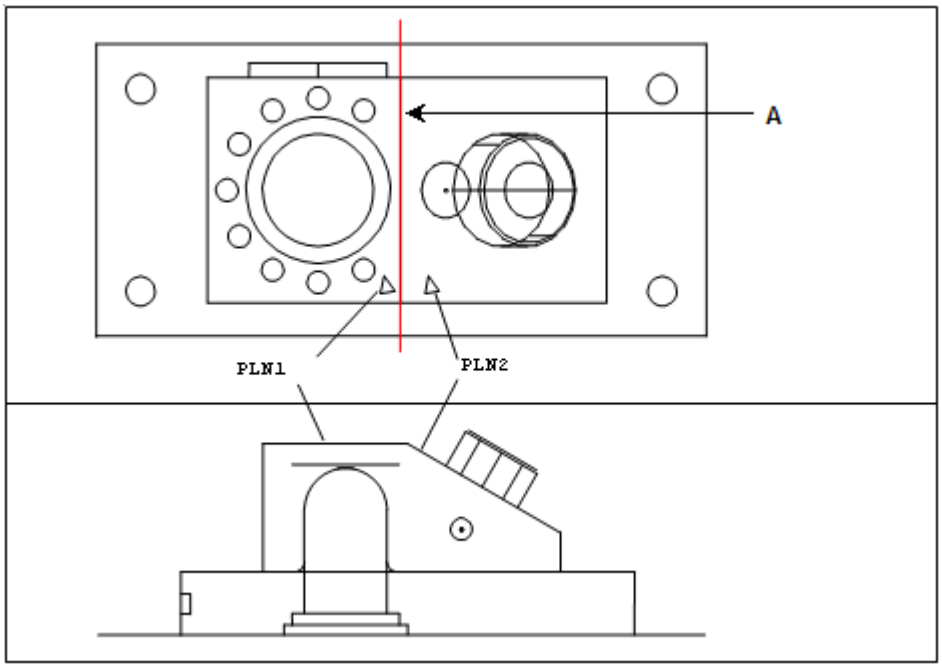
You can construct a line at the intersection of two planes.

To construct an intersect line:

1. Open the **Construct Line** dialog box (**Insert | Feature | Constructed | Line**).
2. From the **Method** list, select the **Intersection** option.
3. From the **Feature** list, select the first feature. It must be a plane.
4. From the **Feature** list, select the second feature. It must be a plane.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/LINE,INTOF,feat_1,feat_2,length
```



Constructing a Line from Two Planes

***A** - Line constructed at the intersection of two planes (PLN1 and PLN2)*

Constructing a Mid Line

You can construct a mid line between a line (cone, slot, cylinder, or plane) and a line (cone, slot, cylinder, or plane). PC-DMIS creates a line (mid line) such that each of its points is the same distance from both input lines. You can construct mid lines from lines that are parallel as well as lines with any angle between them. The lines do not have to intersect.

The mid line centroid is a point on the line segment between the centroids of the input lines that is the same distance from both lines (it is not necessarily the midpoint of the line segment).

The direction of the mid line vector depends on the location of the mid line centroid and on the two input vectors, with the sense of the mid line vector determined by the first line vector. Expressed mathematically, if the first line vector is V1 and the second line vector is V2 then the direction of the mid line vector is generally either V1 + V2 or V1 - V2.

To construct a mid line:

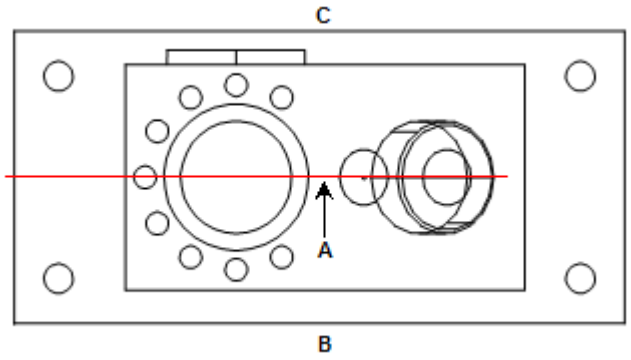
1. Open the **Construct Line** dialog box (**Insert | Feature | Constructed | Line**).
2. From the **Method** list, select the **Mid** option.
3. From the **Feature** list, select the first feature. It must be either a line, cone, cylinder, or slot.
4. From the **Feature** list, select the second feature. It must be either a line, cone, cylinder, or slot.

5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.

6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/LINE,MID,feat_1,feat_2,length
```



A - Constructed line (a mid line) equally spaced between two lines (FRONT and BACK)
B - FRONT
C - BACK
Constructing a Mid Line from Two Lines

Constructing a Parallel Line

You can construct a line parallel to any two features. PC-DMIS creates a line parallel to the first input feature and passing through the center of the second input feature.

To construct a parallel line:

1. Open the **Construct Line** dialog box (**Insert | Feature | Constructed | Line**).

2. From the **Method** list, select the **Parallel** option.

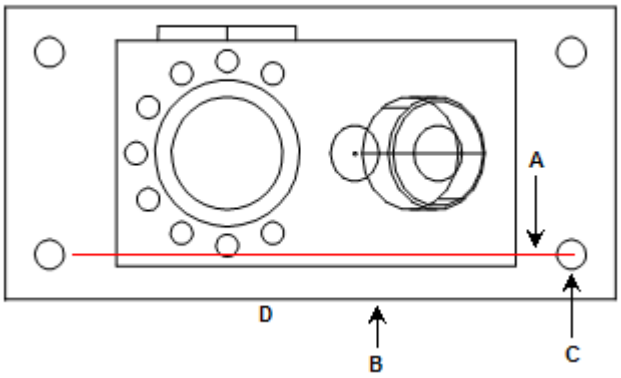
3. From the **Feature** list, select two features of any type.

4. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.

5. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/LINE,PLTO,feat_1,feat_2,length
```



Constructing a Parallel Line

***A** - Line constructed parallel to the first feature and through the second feature*
***B** - First feature*
***C** - Second feature*
***D** - FRONT*

Constructing a Perpendicular Line

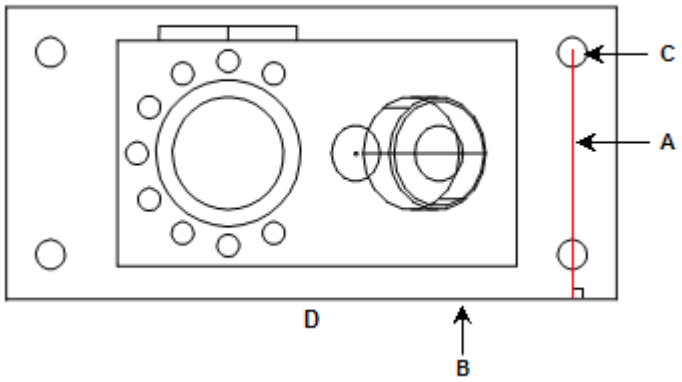
You can construct a line perpendicular to the first input feature and passing through the centroid of the second input feature.

To construct a perpendicular line:

1. Open the **Construct Line** dialog box (**Insert | Feature | Constructed | Line**).
2. From the **Method** list, select the **Perpendicular** option.
3. From the **Feature** list, select two features of any type.
4. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
5. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/LINE,PRTO,feat_1,feat_2,length
```



Constructing a Perpendicular Line

***A** - Line constructed perpendicular to the first feature and through the center of the second feature*
***B** - First feature*
***C** - Second feature*
***D** - FRONT*

Constructing a Projected Line

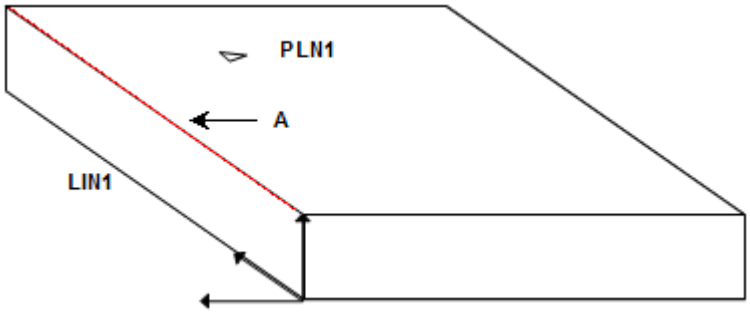
You can construct a line from any feature and a plane. PC-DMIS projects the line where the plane intersects the line. If there is only one input feature, the projection is to the workplane.

To construct a projected line:

1. Open the **Construct Line** dialog box (**Insert | Feature | Constructed | Line**).
2. From the **Method** list, select the **Projection** option.
3. From the **Feature** list, select either one or two features. The first feature may be of any type. If you select two features, the second feature *must* be a plane.
4. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
5. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/LINE,PROJ,feat_1,(feat_2),length
```



Example of a Line feature constructed from a Line and a Plane.
***A** - Constructed line projected from a line feature (LIN1) onto a plane feature (PLN1)*

Changing the Direction of a Line

You can construct a line with a reversed vector.

To construct a reverse line:

1. Open the **Construct Line** dialog box (**Insert | Feature | Constructed | Line**).
2. From the **Method** list, select the **Reverse** option.
3. From the **Feature** list, select one feature. It *must* be a line or an axial feature.
4. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
5. Click the **Create** button. PC-DMIS reverses the vector of the line and also flips the start and end points.

The Edit window command line for this option would read:

```
CONSTR/LINE,REV,feat_1,length
```

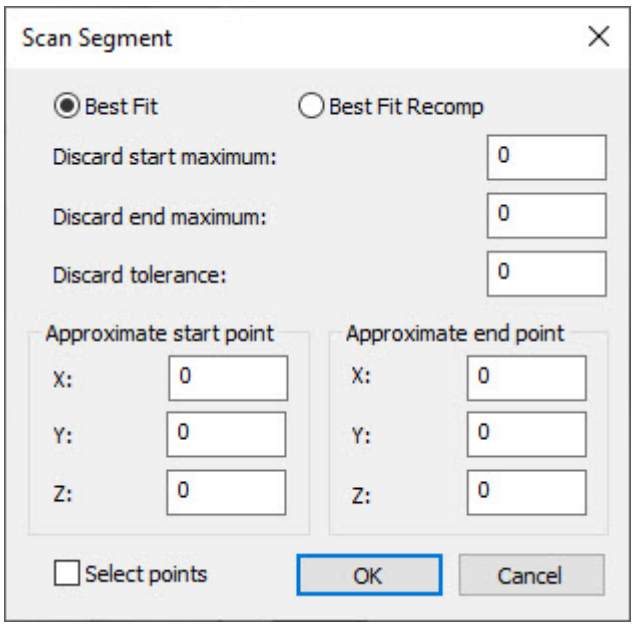
Constructing a Line from Part of a Scan

You can construct a line from a segment of a Linear Open or Linear Close scan. PC-DMIS creates a line from part of the scan. The details of the construction are included in this topic.

To construct a scan segment line:

1. Open the **Construct Line** dialog box (**Insert | Feature | Constructed | Line**).
2. Select the **Scan Segment** option.
3. Select a previously created Linear Open or Linear Close scan.

4. Click the **Segment Data** button to open the **Scan Segment** dialog box.



Scan Segment Dialog Box

5. Select either the **Best Fit** or **Best Fit Recomp** option.

6. Select the portion of the scan used in the construction from this dialog box.

7. Type the number of points to potentially discard by entering values in the **Discard start maximum** and **Discard end maximum** boxes.

8. Type a distance from the best fit line into the **Discard tolerance** box. This tolerance is a form tolerance; it allows you to control what end points are accepted as part of the line. If the distance from the scan point to the best fit line is greater than this tolerance value, then the end point is discarded.

9. Enter the X, Y, and Z values in the **Approximate start point** and **Approximate end point** areas. To do this, select the **Select points** check box and then click in the Graphic Display window to complete the **X**, **Y**, and **Z** boxes. You can click anywhere in the Graphic Display window; however, PC-DMIS places the point on the scan nearest to where you clicked. You can also type in the values.

10. Click **OK** to accept the data and close the **Scan Segment** dialog box.

11. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.

12. Click **Create** to construct the line from the scan.

The Edit window command line for this option reads:

```
 CONSTR/
LINE,SCAN_SEGMENT,fit_type,feat_1,start_x,start_y,start_z,end_x,end_y,end_z,
```

If you want more than one arc or line from a given scan, then you need to add another command for a different section of the scan.

Determining the Data Used to Construct the Line

The data used to construct the line is determined as follows:

- First, a segment of the scan is determined using a starting point and an ending point within the scan. The starting and ending points are chosen as the point in the scan nearest `[start_x, start_y, start_z]` and the point nearest `[end_x, end_y, end_z]` , respectively.
- Points are then discarded from the start and end points of the scan. The number of points discarded is `discard_start` and `discard_end` from the start and end, respectively. A line is then fitted to this set of points.
- Finally, the starting and ending points are added back in if they are within the tolerance defined. The line is then refitted once more to the new set of points.

The value of `fit_type` may be `BF` (Best Fit) or `BFRE` (Best Fit Recompensate). This determines whether a best fit or best fit with recompensation is done when calculating the line. For a description of Best Fit and Best Fit Recompensate, see "Constructing a Best Fit or Best Fit Recompensate Line".

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

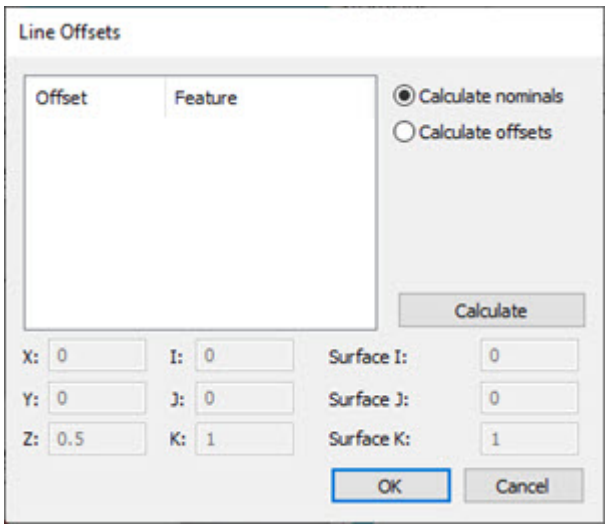
Constructing an Offset Line

You can construct an offset line between the input features and then offset by specified distances from the input features.

To construct an offset line:

1. Open the **Construct Line** dialog box (**Insert | Feature | Constructed | Line**).
2. From the **Method** list, select the **Offset** option.
3. From the **Feature** list, select *at least* two features from which to create the offset line. They can be of any type.

4. Click the **Offsets** button to open the **Line Offsets** dialog box.



Line Offsets Dialog Box

5. Choose either to calculate the nominals from the offsets or calculate the offset value from the specified nominal values.

   - To calculate the nominals from the offset values, select the **Calculate nominals** option. In the **Offset** field, type the offset values for the desired features and then click **Calculate**.
   - To calculate the offsets from specified values, select the **Calculate offsets** option, modify the nominal values, and then click **Calculate**. For more information, see the procedures below.

6. Click the **OK** button to close the **Line Offsets** dialog box.
7. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
8. Click the **Create** button to create the constructed offset line based on your values.

If the offset values exceed the distance between the input features, PC-DMIS cannot solve the offset line. Instead, it constructs a line without any offsets between the first and last feature.

The Edit window command line for this option would read:

```
CONSTR/LINE,OFFSET     SURFACE
NORMAL = i_vec, j_vec, k_vec, TOG1     ID = id1, id2, …
   OFFSET = val1, val2, …
```

TOG1 = changes between MULTI POINT and TWO POINT. For new constructions, you should use MULTI POINT.

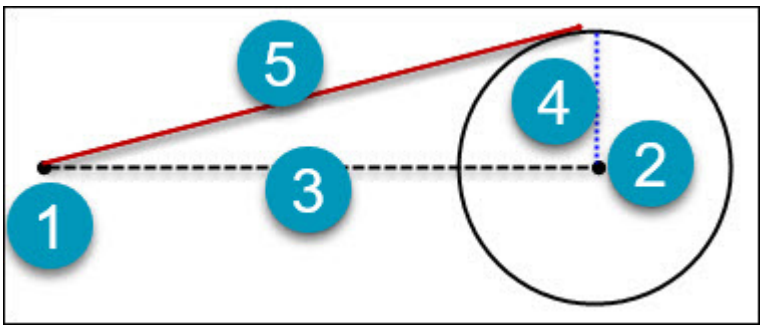
- **MULTI POINT** - This newer algorithm is the default algorithm used whenever you construct a new offset line. It constructs the offset line between the selected input features. You can specify offset values from any of the features.
- **TWO POINT** - This older algorithm is retained to support measurement routines from old PC-DMIS versions. It constructs the offset line between two input features. The offset value for the first feature must always be zero. Also, the way the positive or negative signs function is opposite how it works for MULTI POINT.

How It Works

Consider these statements along with the pictures below:

- PC-DMIS makes all offsets in a direction perpendicular to the given surface normal direction.
- PC-DMIS attempts to construct the line starting at the first input feature and ending at the last input feature.
- An offset value basically results in an imaginary circle drawn around each input feature's centroid by that value.
- PC-DMIS attempts to construct a line tangent to the imaginary circle around each input feature's offset radius. A tangent line touches the circle at only one point.
- In cases where more than two input features are used and they have varying offset values, PC-DMIS cannot construct a line tangent to all the offsets; instead, it tries to accommodate the offsets as best it can with a best fit line.
- PC-DMIS constructs a line so that the shortest distance from each input feature to the line is the corresponding offset amount.
- The offsets signs are determined by the direction of the line.

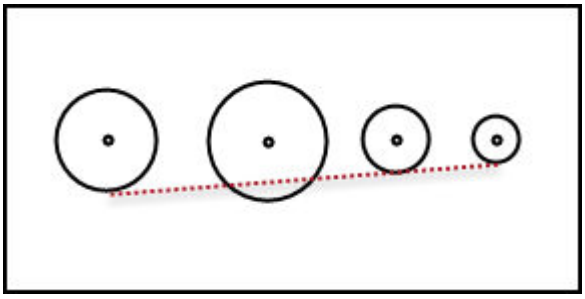
Suppose you have two points as input features, and the second point has an offset value:



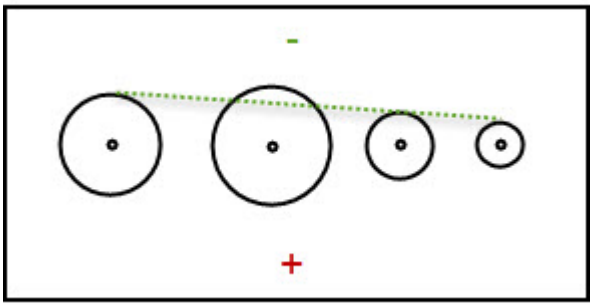
1. First point
2. Second point

3. Resulting line if no offset is defined
4. Offset distance (radius) from the feature's center that results in an imaginary circle around the feature
5. Constructed line from starting feature tangent to the imaginary circle

For example, suppose you have four points as your input features, and each point has a different offset value, as indicated by their circles. PC-DMIS constructs a best fit line that is tangent to those circles, as indicated in this diagram:



A positive or negative value on the offset determines on what side of the circle the line is constructed. For example, suppose you reverse the signs on all the offsets, from positive to negative, you might end up with something similar to this:

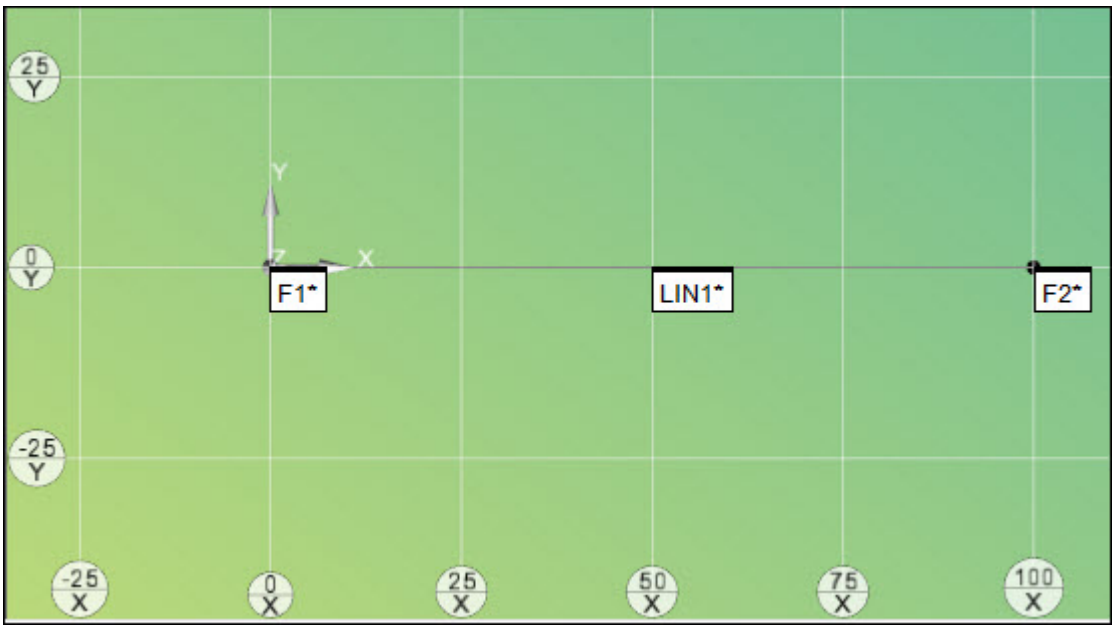


If you get a line opposite from what you expected, cancel the feature and reconstruct it, and try reversing the sign of the offsets values.

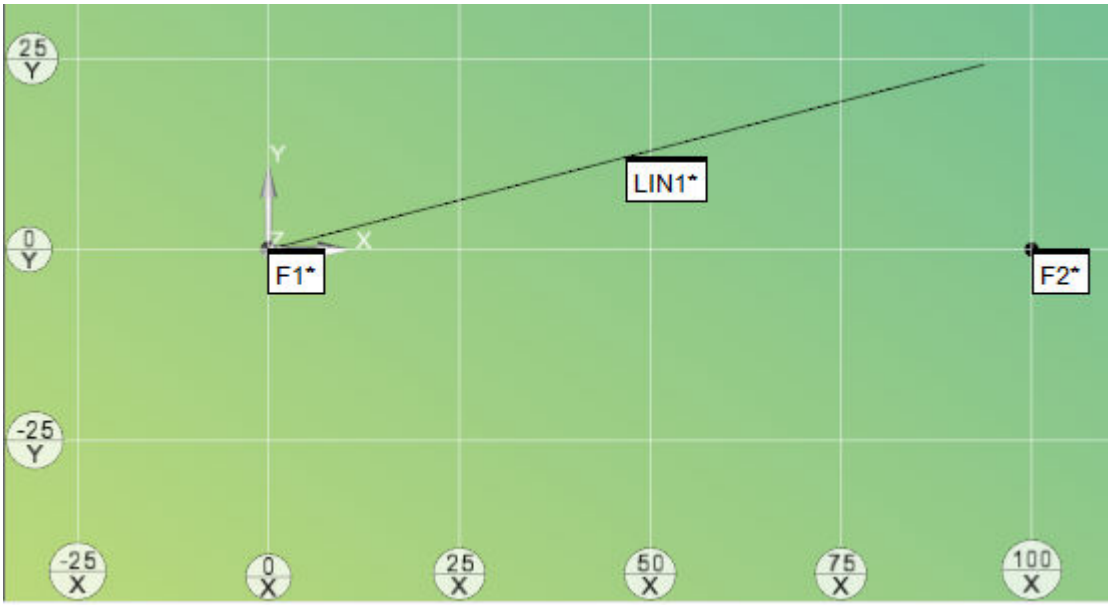
Examples

Here are some examples:

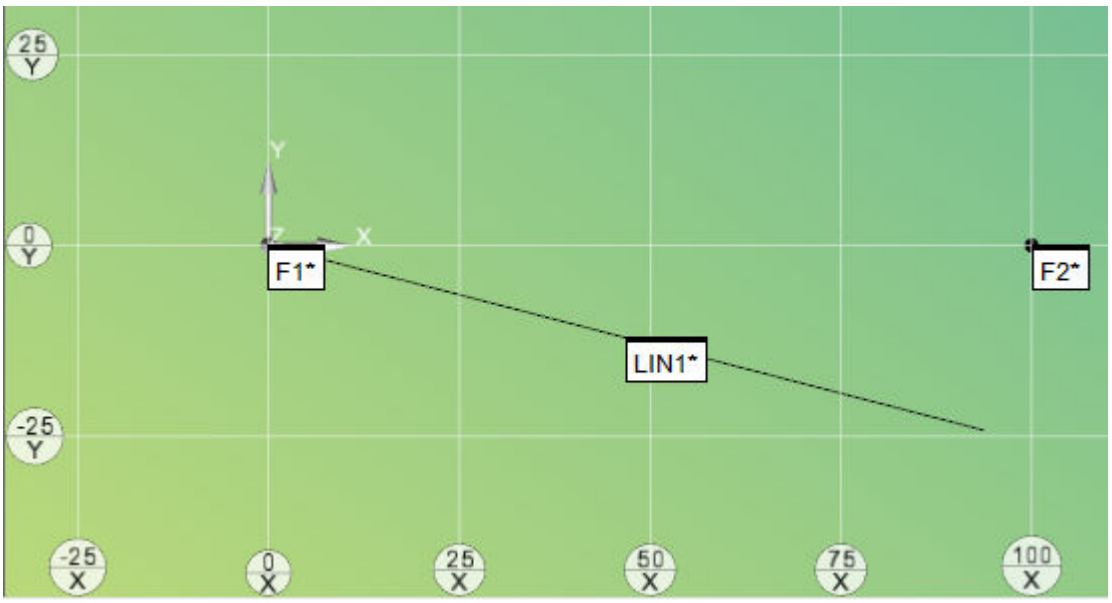
Example 1 - F1 and F2 are the inputs. Both have offsets that are set to zero:



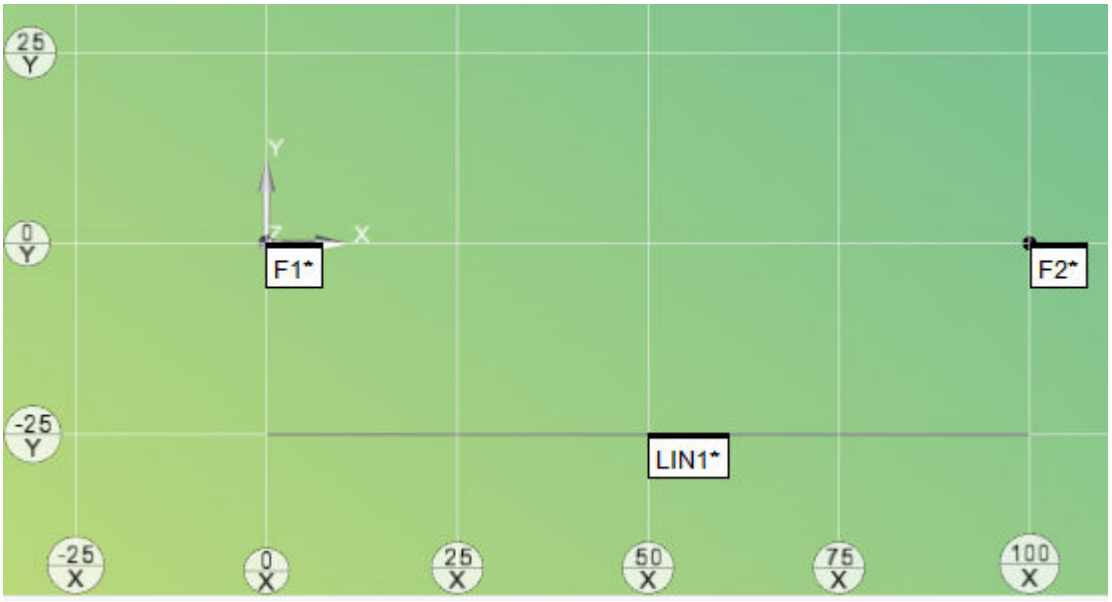
Example 2 - F1 and F2 are the inputs. The F1 offset is set to 0. The F2 offset is set to 25:



Example 3 - F1 and F2 are the inputs. The F1 offset is set to 0. The F2 offset is set to -25:



Example 4 - F1 and F2 are the inputs. Both offsets are set to -25:



Changing Offsets Directly to Calculate Nominals

To enter new offset values:

1. Click the **Offset** button from the **Construct Line** dialog box (**Insert | Feature | Constructed | Line**) to open the **Line Offsets** dialog box.
2. From the **Line Offsets** dialog box, select the **Calculate nominals** option. The offsets portion of the dialog box becomes editable.
3. In the **Offset** column, click on a 0.000000 value to highlight it.
4. Click again on the offset so you can edit it.
5. Type a new value and press the Enter key to accept the value.

6. If desired, modify the other offset.
7. Click the **Calculate** button to update the nominal values based on your offset values.
8. Click **OK** to save the offset.

Example of Calculating Nominals

The **Calculate** button calculates the X, Y, and Z nominal values from new offsets entered.

For example, suppose you construct an offset line between two circles (CIR1 and CIR2). After you select the features and click the **Offsets** button, you have X, Y, and Z nominals of:

X = 4.5040

Y = 3

Z = 0.1582

If you change the offset values by two for each circle and click the **Calculate Noms** button, the X, Y, and Z update to:

X = 4.5040

Y = 5

Z = 0.1582

If you then click **OK** and construct the offset line, you'll notice that the newly constructed line lies two units higher in the Y axis.

Only the Y axis is offset for line offsets.

Changing Nominals Directly to Calculate Offsets

To enter new offset values:

1. Click the **Offset** button from the **Construct Line** dialog box (**Insert | Feature | Constructed | Line**) to open the **Line Offsets** dialog box.
2. Select the **Calculate offsets** option. The nominals portion of the dialog box becomes available to edit.
3. Change the **XYZ**, **IJK**, or **Surface IJK** values.
4. Click the **Calculate** button to update the offset values based on any nominals you changed.
5. Click **OK** to save the offset.

Example of Calculating Offsets

The **Calculate Offsets** button calculates the offset values that appear in the **Offset** column when you change the nominal value.

For example, suppose you construct an offset line between two circles (CIR1 and CIR2). After you select the features and click the **Offsets** button, you have X, Y, and Z nominals of:

X = 4.5040

Y = 3

Z = 0.1582

If you change the X, Y, and Z nominals to:

X = 4.5040

Y = 4.5

Z = 0.1582

and click the **Calculate Offsets** button, the offsets for the two circles update to:

1.500000 CIR1

1.500000 CIR2

If you then click **OK** and construct the offset line, you'll notice that the line is constructed at 1.5 units higher in the Y axis.

Constructing a Secondary Datum Line

You can construct a Secondary Datum Line from a plane, line, or set of points. The set of points can be multiple selected points, a constructed set of points, or a scan feature that contains multiple points.

The secondary datum construction uses the points within the input feature (or features) as well as the plane from the primary datum input to create an "orientation constrained" and "external to material" 2D line. You can use this line in alignments to simulate a secondary datum feature.

- "Orientation constrained" means that the input points are forced perpendicular to the primary datum.
- "External to material" means that the resulting line contacts the highest point or points from the input feature (or features), subject to the orientation constraint and the selected math type.

PC-DMIS constructs the secondary datum line in the plane that you select as the primary datum.

Examples

The examples below show the points as if viewed from the selected plane.

- Constrained MinMax is the default math type specified by the ISO 1101 standard.
- Constrained L2 is the default math type specified by the ASME Y14.5 standard.

L∞

The red line is the L∞ plane targeting the external envelope (constrained MinMax type in PC-DMIS)

L2

The green line is the constrained L2 plane targeting the external envelope (constrained L2 math type in PC-DMIS)

How to Construct a Secondary Datum Line

1. Open the **Construct Line** dialog box (**Insert | Feature | Constructed | Line**).
2. From the **Method** list, select **Secondary Datum**.
3. From the **Feature** list, select the input feature (or features). For valid input feature types, see the table in the "Constructing a Line Feature" topic.
4. From the **Primary datum** list, select the primary datum. This datum can be either a plane from the measurement routine, or a workplane from the active alignment.
5. From the **Math Type** area, select the math type (**CONSTRAINED_L2** or **CONSTRAINED_MINMAX**) from the first list.
6. From the **Math Type** area, select a probe compensation option (**BF** for best fit or **BFRE** for best fit recompensate) from the second list.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

7. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
8. Click the **Create** button to insert the constructed line feature into your measurement routine.

The Edit window command line for this option is:

```
CONSTR/LINE,SECONDARY_DATUM, feat_1,feat_2, …
MATH_TYPE/TOG1,TOG2
PRIMARY DATUM PLANE/TOG3,TOG4
```

TOG1 = CONSTRAINED_L2 or CONSTRAINED_MINMAX

TOG2 = BF or BFRE

TOG3 = FEATURE or WORKPLANE

TOG4 = This is the list of workplanes if TOG3 is a WORKPLANE, or it's the Feature ID if TOG3 is a plane FEATURE.

Variations

The example below shows the Edit window when you switch TOG4 to BND.

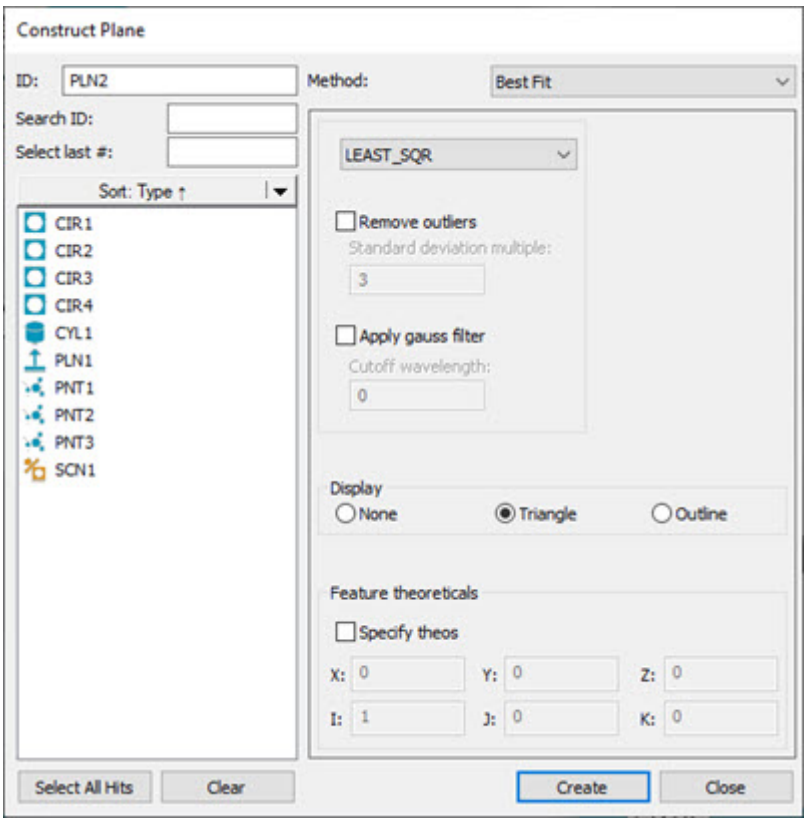
- The first x, y, z indicates the first point on the line.
- The second x, y, z indicates the ending point on the same line.
- The last value represents the theoretical or actual length of the line.

```
feature_name=FEAT/LINE,TOG1,BND
THEO/x_cord,y_cord,z_cord,x_cord,y_cord,z_cord,length
ACTL/x_cord,y_cord,z_cord,x_cord,y_cord,z_cord,length
CONSTR/TOG2,TOG3,...,length
```

The example below shows the unbounded line format:

```
feature_name=FEAT/LINE,TOG1,UNBND
THEO/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec
ACTL/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec
CONSTR/TOG2,TOG3,...
```

Constructing a Plane Feature



Construct Plane Dialog Box

There are several methods to use PC-DMIS to construct a plane. The following table lists the various types of constructed planes along with their necessary inputs. Some features may require no inputs, while others may require three or more inputs. In the following table, the term "Any" indicates that the construction can take any type of feature as input for construction. PC-DMIS allows you to select the features in any order.

Construct Feature Type	Edit Window Symbol	Number of Required Input Features	Primary Feature	Secondary Feature	Tertiary Feature	Comments
Auto Plane	-	-	-	-	-	See "Auto Plane Construction".
Alignment Plane	ALIGN	0	-	-	-	Constructs a plane at alignment origin.
Best Fit Plane	BF	At least three inputs are needed.	-	-	-	Constructs best fit plane using the given inputs. See the Note below for recommended inputs.
Best Fit with Recomp Plane	BFRE	At least three inputs are needed (one must be a point).	-	-	-	Constructs a best fit plane using the given inputs. See the Note below for recommended inputs.
Cast Plane	CAST	1	Any	-	-	Constructs a plane at the centroid of the input feature.
Primary Datum Plane	PRIMARY DATUM	3 or 1	Any (one of three) Or if only one input: one feature set, one plane, or one scan	Any (2 of 3)	(Any 3 of 3)	Constructs a plane tangent to the highest available points.
Mid Plane	MID	2	Any	Any	-	Constructs a mid plane between the centroids of the inputs.

Offset Plane	OFFSET	3 or 1	Any (one of three) Or plane feature if only one input	Any (2 of 3)	Any (3 of 3)	Constructs a plane offset from the input features (or from single plane feature).
Parallel Plane	PLTO	2	Any	Any	-	Constructs a plane parallel to the first feature and passing through the second feature.
Perpendicular Plane	PRTO	2	Line or Axis Element	Any	-	Constructs a plane perpendicular to the first feature and passing through the second feature.
Reverse Plane	REV	1	Plane	-	-	Constructs a plane passing through the input with a reversed vector.
Translated Plane	TRANSLATED	1	Plane with point data	-	-	Constructs a plane at an offset from the input plane.
Extracted Plane	EXTRACTED_PLANE	1	COP or Mesh	-	-	Constructs an extracted plane from the COP or Mesh object at the specified width and length properties.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

If you select inappropriate feature types, PC-DMIS displays this message on the Status bar:

"Cannot construct [feature]. Combination of input features not accepted."

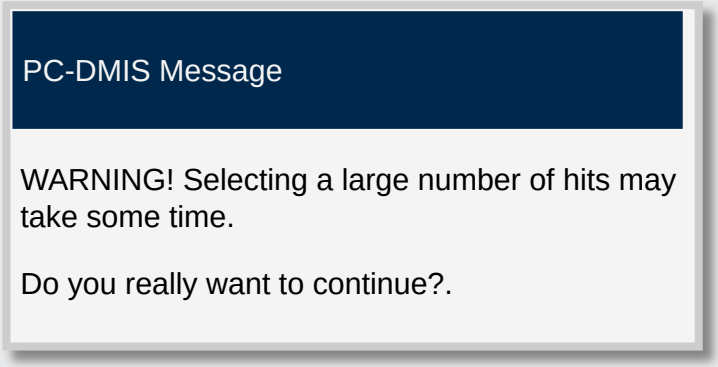
To construct a plane, do the following:

1. Open the **Construct Plane** dialog box (**Insert | Feature | Constructed | Plane**).
2. Use the **Method** list to select the method type for the constructed plane. The available options are:
    - Auto Plane
    - Alignment Plane
    - Best Fit Plane
    - Best Fit Recompensate Plane
    - Cast Plane
    - Mid Plane
    - Perpendicular Plane
    - Parallel Plane
    - Reverse Plane
    - Primary Datum Plane
    - Offset Plane

- Translated Plane
- Extracted Plane

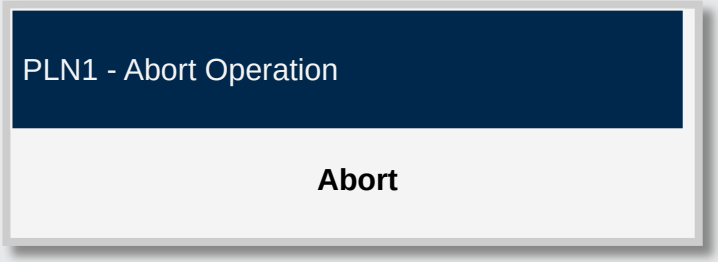
If you select the **Best Fit** or the **BF Recomp** (Best Fit Recomp) method for this feature, PC-DMIS allows you to click the **Select All Hits** button to create the construction from the individual hits of the input features instead of their centroids.

If there are a large number of points involved (about 10,000 or more), PC-DMIS shows a message asking if you are sure you want to proceed as this may take some time to complete.



Click **Yes** to proceed, click **No** to abort the process. You can select the **Don't ask me again** check box to prevent this message from recurring.

If you click **Yes**, another message is shown similar to the one shown below to let you know that PC-DMIS is generating the features from the hit points.

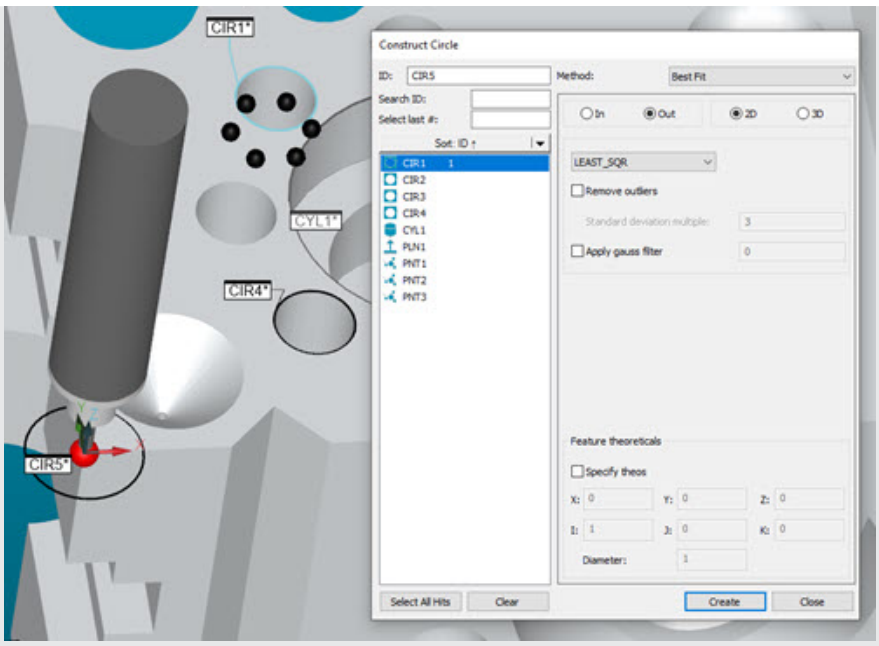


Once all the constructed features are created, the message disappears.

You can click the **Abort** button at any time to stop the process. Any features created up to this point are listed in the **Feature list** area of the dialog box.

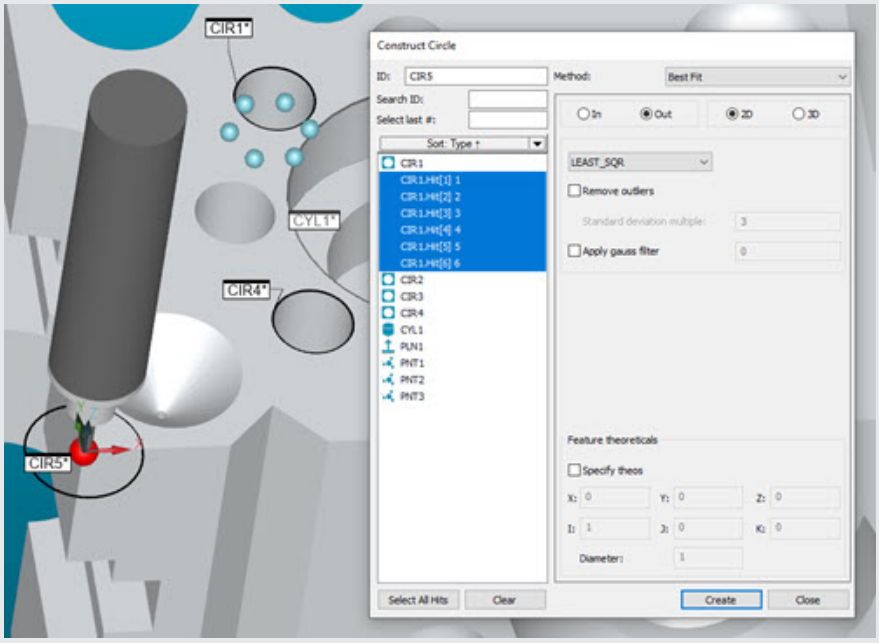
To create constructed features from the individual hits of the input features, do this:

1. From the **Feature list**, select the feature or features that you want to use to create the constructed feature.



Example showing a selected feature prior to clicking the Select All Hits button.

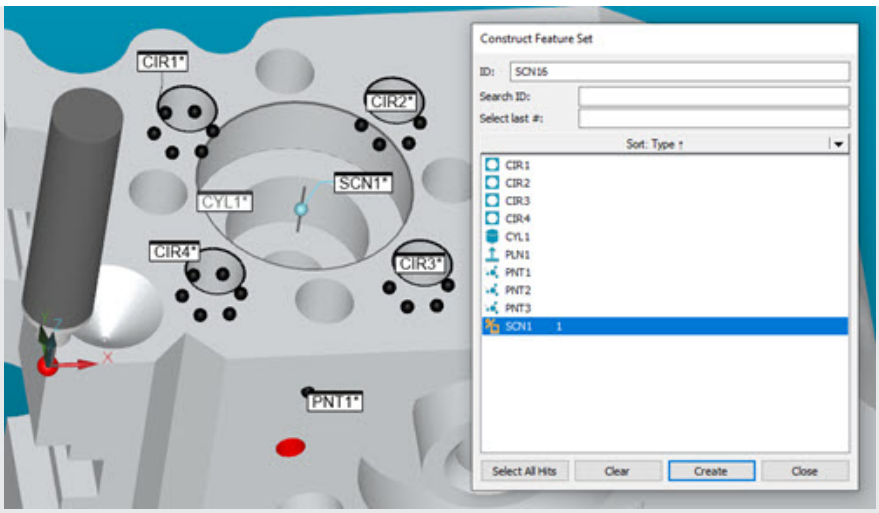
2. Click the **Select All Hits** button to display all the components that comprise the selected feature or features.



Display of items that make up the selected feature are highlighted in the dialog box and in the Graphic Display window.

PC-DMIS displays and highlights all the components of the selected feature (or features) in the **Feature list** are of the dialog box. You can select or de-select any of the features or feature components shown in the list to include or exclude them.

3. Click the **Create** button to create the Constructed feature based on the final features and feature components that you selected.



Constructed feature created based on the selected items from the Feature list.

3. Use the table above to select the appropriate features from the **Feature** list for the constructed plane based on the selected method.
4. Make the necessary changes to other options that become available based on the selected method for the constructed plane. These are described in the topic specific to the method you selected.
5. From the **Display** area, select how you want PC-DMIS to display the constructed plane. For details, see the "Using the Display Area" topic in this documentation.
6. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
7. Click the **Create** button.

The Edit window command line for a sample plane construction would read:

```
feature_name=FEAT/PLANE,TOG
THEO/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec
ACTL/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec
CONSTR/TOG2,TOG3,...
```

If TOG2 = PLANE and TOG3 = BF or BFRE, the command has the following format:

```
feature_name=FEAT/PLANE,TOG1,TOG6
THEO/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec
ACTL/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec
CONSTR/PLANE,TOG3
OUTLIER_REMOVAL/TOG5,stdDevMultiplier
FILTER/TOG5,WAVELENGTH= cutoffWavelength
```

The actual Edit report displays in all capital letters.

AUTO is the default method of construction. This option automatically determines the best way to construct a plane using the input feature(s). See "Auto Plane Construction".

TOG1= POLR or CARTESIAN

TOG2 = PLANE

TOG3 = ALIGN / BF / BFRE / CAST / TANGENT / MID / OFFSET / PLTO / PROJ / PRTO / REV / TRANSLATED

TOG5 = ON / OFF

TOG6 = LEAST_SQR / MIN_SEP

stdDevMultiplier = This option is only available for Best Fit and Best Fit Recompensate methods. It determines whether or not a measured point is an outlier. If the point from the plane is further than the standard deviation multiplied by this, then it is an outlier and will be removed if you have selected the **Remove Outlier** option.

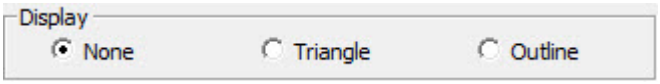
cutoffWavelength = This option is only available for Best Fit and Best Fit Recompensate methods. It controls the amount of data smoothing. The longer the wavelength, the more smoothing there is.

The first three lines that display in the Edit window are the same for constructed planes. The fourth line is slightly different, according to the type of feature you are constructing. To switch between the different types of planes, place the cursor on *TOG3* and press F7 or F8. (See "Command Mode Keyboard Functions" in the "Using the Edit Window" chapter.)

When two or more features are involved, PC-DMIS automatically determines the necessary order of the input features. This improves the accuracy of the measurement process.

The following subtopics describe the available options for constructing a plane:

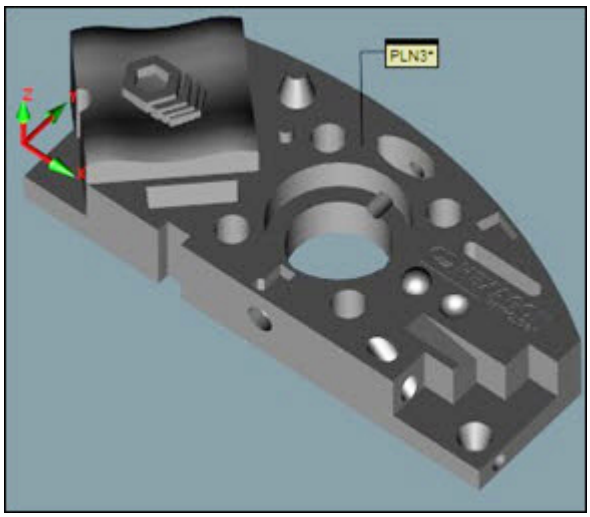
Using the Display Area



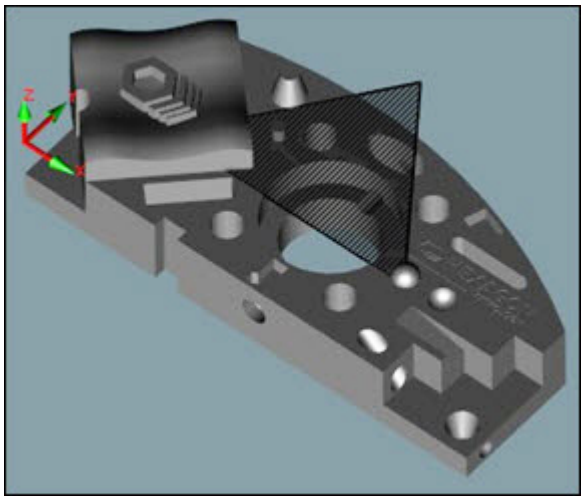
Display Area

This area defines how the plane feature draws in the Graphic Display window. It contains these options:

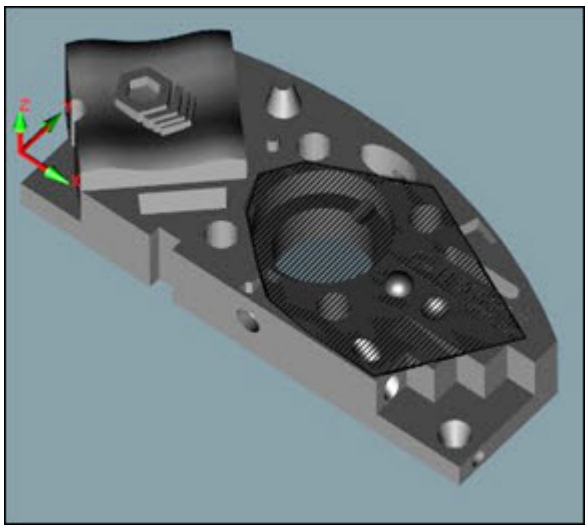
None - PC-DMIS only displays the ID of the constructed plane in the Graphic Display window. It does not display a drawing or outline of the constructed plane.



Triangle - PC-DMIS draws the constructed plane as a shaded triangle. The size of the constructed plane depends on the number of hits that make up the plane.



Outline - PC-DMIS draws the constructed plane as an outline from all the hits. The size depends on the number of hits that make up the constructed plane.



The Display Outline of Plane or Do Not Display Plane options on the **General** tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**) define the default display state for future measured or constructed planes. They do not affect the display state of existing planes.

Auto Plane Construction

The "Input Feature List" table shows the type of plane you can construct when you select the specified inputs and select the **Auto** option. The order of the selected features is not important. If you select an incorrect input feature, PC-DMIS displays an error message and does not automatically construct the indicated feature type.

To allow PC-DMIS to automatically determine the best method of construction:

1. Open the **Construct Plane** dialog box (**Insert | Feature | Constructed | Plane**).
2. From the **Method** list, select the **Auto** option from the list of options.
3. From the **Feature** list, select the desired feature or features based on the "Input Feature List" table below.
4. From the **Display** area, select how you want PC-DMIS to display the constructed plane. For details, see the "Using the Display Area" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

Input Feature List

Input Feature(s)	Constructs
Three or more features that are not all measured Points	Best Fit Plane
Any one feature (except Plane or Set)	Cast Plane
Any one Set	Best Fit Plane
All measured Points	Best Fit Recompensate Plane
One Plane	Reverse Plane
One COP or Mesh object	Extracted Plane

Constructing a Plane from an Alignment

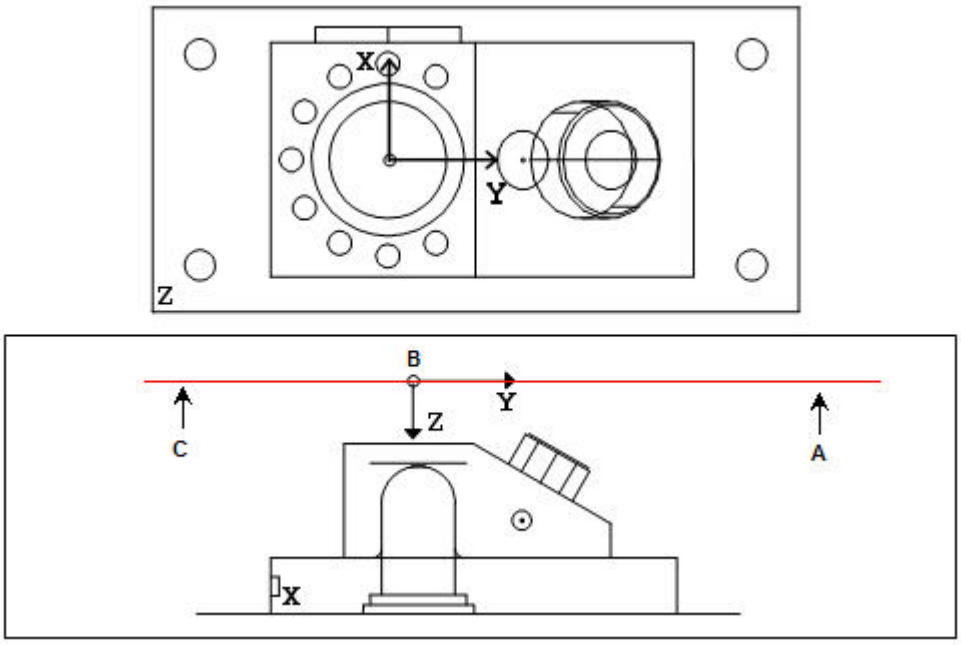
You can construct a plane through the current origin and parallel to the current workplane. (Input features do not need to be provided.)

To construct an alignment plane:

1. Open the **Construct Plane** dialog box (**Insert | Feature | Constructed | Plane**).
2. From the **Method** list, select the **Alignment** option.
3. Do not select any features from the **Feature** list.
4. From the **Display** area, select how you want PC-DMIS to display the constructed plane. For details, see the "Using the Display Area" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/PLANE,ALIGN
```



Constructing a Plane from an Alignment

A - Plane constructed parallel to the top (XY+Z) workplane and through the origin

B - Origin (0,0,0)

C - Current workplane

Constructing a Best Fit or Best Fit Recompensate Plane

You can construct a "best fit" plane through three or more features.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

To construct a best fit or a best fit recompensate constructed plane:

1. Open the **Construct Plane** dialog box (**Insert | Feature | Constructed | Plane**).
2. From the **Method** list, select either the **Best Fit** or **BF Recomp** option.
3. From the **Feature** list, select at least three features.

4. Select the type of Best Fit construction from the **Best Fit Type** list. For information on the different types, see "Best Fit Type (for Plane)".

5. From the **Display** area, select how you want PC-DMIS to display the constructed plane. For details, see the "Using the Display Area" topic in this documentation.

6. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.

7. Click the **Create** button.

   If you chose **LEAST_SQR** as the best fit type, PC-DMIS computes a *least squares* plane, one for which PC-DMIS minimizes the average squared perpendicular distance from the data points to the plane.

   If you chose **MIN_SEP**, PC-DMIS creates a minimum separated plane.

For the Best Fit method, the Edit window command line for this option would read:

```
CONSTR/PLANE,BF, feat_1,feat_2, …

OUTLIER_REMOVAL/(ON | OFF), stdDevMultiple

FILTER/(ON | OFF), WAVELENGTH= cutoffWavelength
```

PC-DMIS uses the actual measured points for construction.

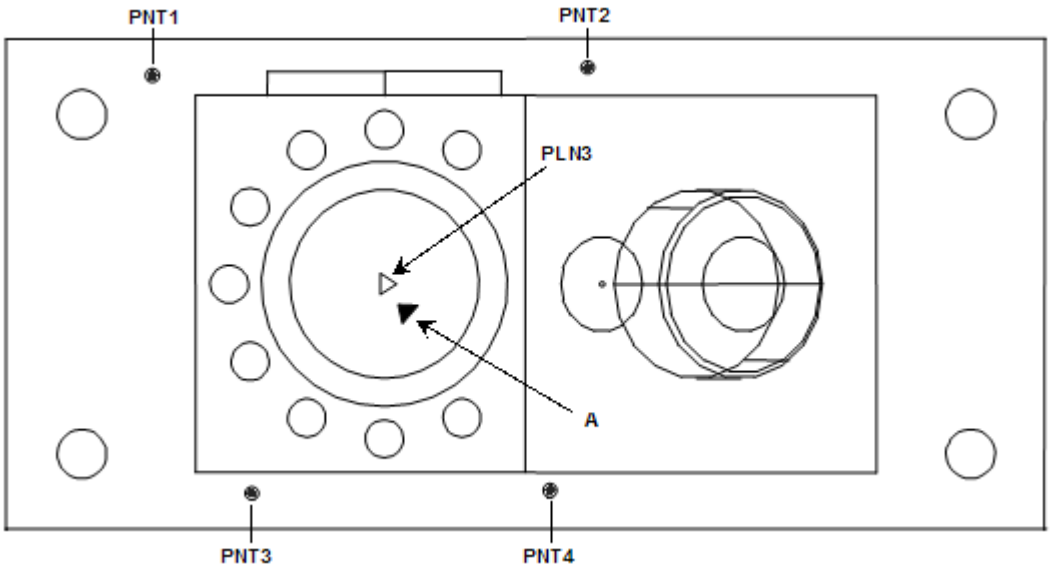
For the Best Fit Recompensate method, the Edit window command line for this option would read:

```
CONSTR/PLANE,BFRE, feat_1,feat_2, …

OUTLIER_REMOVAL/(ON | OFF), stdDevMultiple

FILTER/(ON | OFF), WAVELENGTH= cutoffWavelength
```

PC-DMIS uses the probe's center for measurement purposes.



A - Best Fit Plane Constructed from Four Points (PNT1, PNT2, PNT3, and PNT4)
Constructing a Plane from three or more Points

Remove Outliers / Standard Deviation Multiple

For a Best Fit (BF) or Best Fit Recompensate (BFRE) plane, you can choose to remove outliers based on the distance from the best fit feature. This allows the removal of anomalies that arise in the measurement process.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

PC-DMIS first fits a plane to the data and then determines which points are outliers based on the standard deviation multiple. It then does the following:

1. Recalculates the best fit plane with those outliers removed.
2. Checks for outliers again.
3. Recalculates the best fit plane.
4. Continues to repeat this process until no more outliers exist or until PC-DMIS cannot compute the plane. (PC-DMIS can't compute the plane if there are fewer than three data points.)

Best Fit Type (for Plane)

This list becomes available if you select the **Best Fit** or **BF Recomp** method for constructed planes. It allows you to specify the type of Best Fit construction used. Available types include:

- LEAST_SQR
- MIN_SEP

These types are discussed below:

LEAST_SQR
Least Squares - This calculation type provides a method of fitting in which the average squared radial distance from the data points to the plane is minimized. The square root of this quantity is the Root Mean Square (RMS) distance. Since the RMS distance is based on an average, some points may be further than the RMS distance from the computed plane.

MIN_SEP
Minimum Separation - This calculation type generates a plane from the input features containing the data points, with the difference of their radii as small as possible. The Min/Max math used by the MIN_SEP calculation minimizes the maximum error, or deviation, from the input data to the plane. The Min/Max error is one-half of the minimal separation. No input data points (or input features) lie farther than the Min/Max error from the Min/Max plane. This calculation determines whether or not all the input data (or input features) are within the given tolerances.

Apply Gauss Filter / Cutoff Wavelength

The Best Fit (BF) and Best Fit Recompensate (BFRE) constructed planes have the option of filtering the deviations of the measured data points from the best fit plane computed from the measured data.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

Apply Gauss Filter - If you select this check box, PC-DMIS applies a Gaussian filter with a cutoff wavelength. Generally, a larger cutoff wavelength produces smoother filtered data.

Remove Outliers - If you select this check box and you are filtering the data, PC-DMIS removes outlier data prior to filtering. For additional information on Gaussian filtering, see the "Gaussian" topic under "Constructing a Filter Set".

Constructing a Cast Plane

A plane can be constructed by changing any feature into a plane. PC-DMIS constructs the plane at the centroid of the input feature.

To construct a cast plane:

1. Open the **Construct Plane** dialog box (**Insert | Feature | Constructed | Plane**).
2. From the **Method** list, select the **Cast** option.
3. From the **Feature** list, select one feature of any type.
4. From the **Display** area, select how you want PC-DMIS to display the constructed plane. For details, see the "Using the Display Area" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/PLANE,CAST, feat_1
```

Constructing a Mid Plane

A plane can be constructed from any two features. The resultant plane (mid plane) is equally spaced from the centroids of the two specified input features.

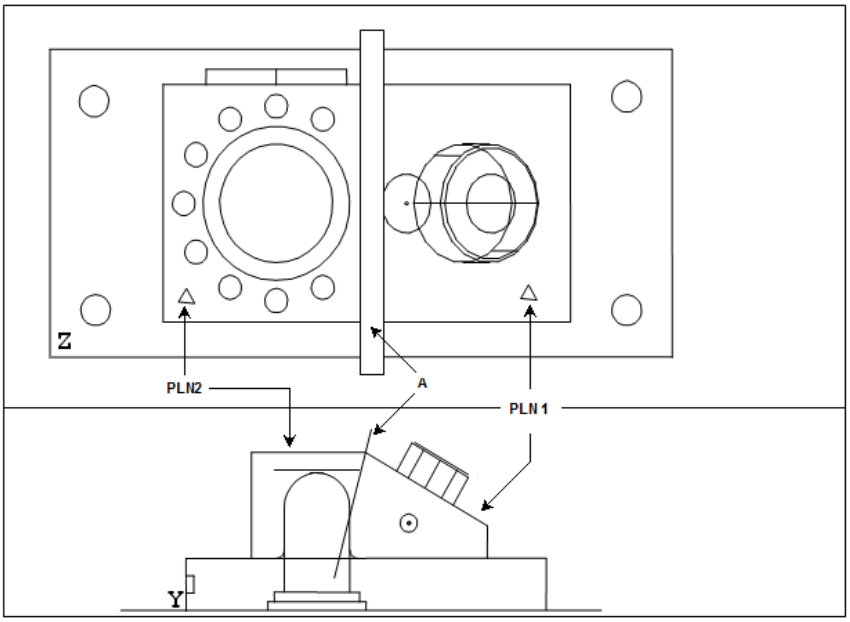
To construct a mid plane:

1. Open the **Construct Plane** dialog box (**Insert | Feature | Constructed | Plane**).
2. From the **Method** list, select the **Midplane** option.
3. From the **Feature** list, select two features of any type.
4. From the **Display** area, select how you want PC-DMIS to display the constructed plane. For details, see the "Using the Display Area" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.

6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/PLANE,MID, feat_1,feat_2
```



Constructing a Plane from Two Planes

A - Constructed plane equally spaced between two planes (PLN1 and PLN2).

The constructed plane and its vector depends on the input features used:

- *If you select planes for both input features*, then the mid plane is located where it bisects the smaller included angle between the two input planes.
- *If you don't select a plane for both input features*, then the constructed mid-plane passes through the point midway between the centroids of the two input features. The constructed plane's vector runs from the first input feature's centroid to the second input feature's centroid.

Constructing a Perpendicular Plane

A plane can be constructed between supported features. PC-DMIS creates a plane perpendicular to the first input feature and passing through the centroid of the second input feature.

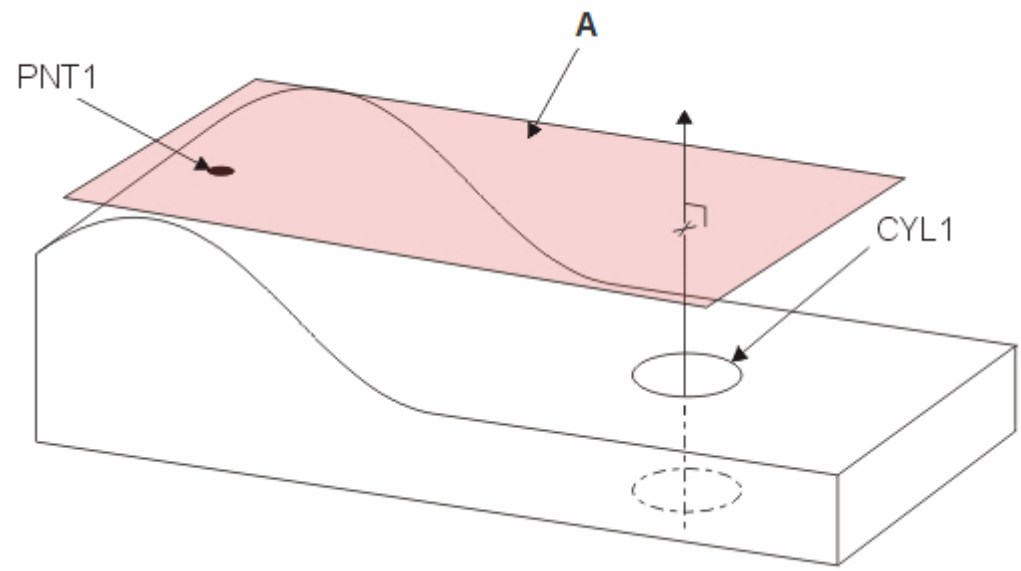
To construct a perpendicular plane:

1. Open the **Construct Plane** dialog box (**Insert | Feature | Constructed | Plane**).
2. From the **Method** list, select the **Perpendicular** option.

3. From the **Feature** list, select the first feature type. This must be a plane, line, or axis element.
4. From the **Feature** list, select a second feature of any type.
5. From the **Display** area, select how you want PC-DMIS to display the constructed plane. For details, see the "Using the Display Area" topic in this documentation.
6. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
7. Click the **Create** button.

The Edit window command line for this option reads:

```
CONSTR/PLANE,PRTO, feat_1,feat_2
```



Constructing a Perpendicular Plane

A - Plane constructed perpendicular to a cylinder feature (CYL1) and through a High Point feature (PNT1). Note that CYL1 contains an axis element.

By default, PC-DMIS calculates the vector of the constructed plane based on the vector from the first feature to the second feature. You may not always want this. The **Coplaner with line** check box lets you specify how PC-DMIS calculates the vector of the resulting plane. PC-DMIS enables this check box only when these conditions are met:

- The first feature is a plane-type feature (Plane, Circle, or Slot).
- The second feature is a line-type feature (Line, Cylinder, or Cone).
- The vectors of the two features are not parallel.

If you mark this check box, PC-DMIS constructs the resulting plane to be coplaner with the second feature.

Constructing a Parallel Plane

A plane can be constructed parallel to any two features. PC-DMIS creates a plane parallel to the first input feature and passing through the centroid of the second input feature.

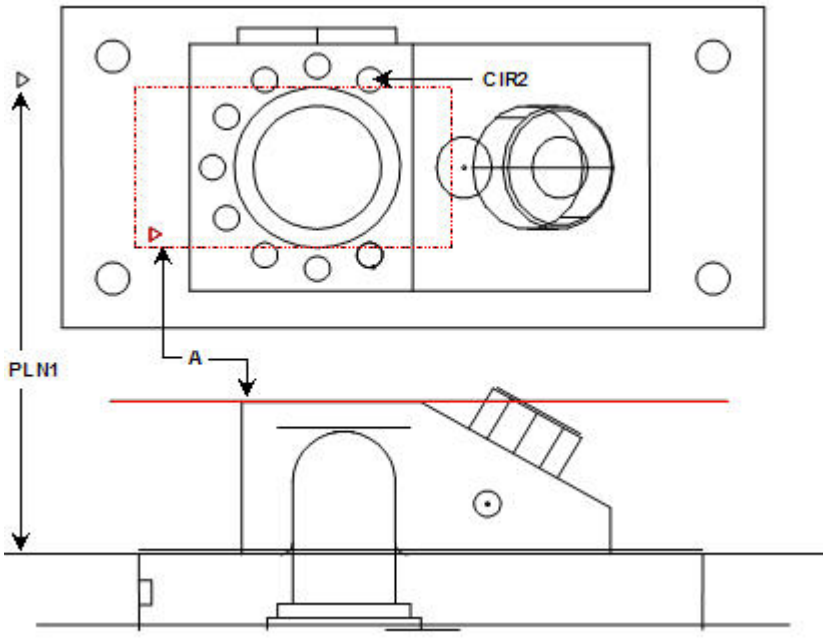
To construct a parallel plane:

1. Open the **Construct Plane** dialog box (**Insert | Feature | Constructed | Plane**).
2. From the **Method** list, select the **Parallel** option.
3. From the **Feature** list, select two features of any type.
4. From the **Display** area, select how you want PC-DMIS to display the constructed plane. For details, see the "Using the Display Area" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/PLANE,PLTO, feat_1,feat_2,
```

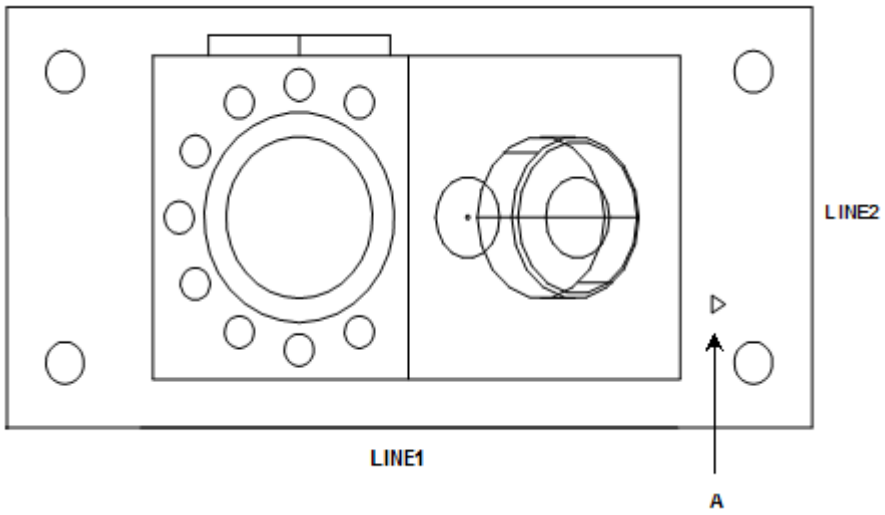
Example 1:



A - *Plane constructed parallel to the first feature, a plane (PLN1) and through the second feature, a circle (CIR2)*

Constructing a Parallel Plane Using Two Planes

Example 2:



A - *Plane constructed through the first feature, a line (LINE1) and parallel to a second line (LINE2)*
Constructing a Parallel Plane Using Two Lines

Changing the Direction of a Plane

A plane can be constructed with a reversed vector.

To construct a reverse plane:

1. Open the **Construct Plane** dialog box (**Insert | Feature | Constructed | Plane**).
2. From the **Method** list, select the **Reverse** option.
3. From the **Feature** list, select a Plane feature. It must be a plane.
4. From the **Display** area, select how you want PC-DMIS to display the constructed plane. For details, see the "Using the Display Area" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/PLANE,REV, feat_1
```

Constructing a Primary Datum Plane

Prior to version 2019 R1, the Primary Datum Plane was referred to as the "Tangent Plane" or "High Point Plane".

You can construct a plane that is external to the material (tangent to the peaks or the high points) on a surface. You can then use this feature as a datum in alignments or dimensions. Do not dimension a primary datum plane. That is not its purpose. You should use it only as a datum feature.

To construct a Primary Datum plane:

1. Open the **Construct Plane** dialog box (**Insert | Feature | Constructed | Plane**).
2. From the **Method** list, select the **Primary Datum** option.
3. From the **Feature** list, select the input features from one of these options:
    - Three or more features (you may use any feature type).
    - Any single feature Set. For information on feature sets, see "Constructing a Set of Features".
    - Any Plane feature.
    - Any scan.
4. Select a math type from the first list in the **Math Type** area. The available options are:
    - **CONSTRAINED_L1**
    - **CONSTRAINED_L2**
    - **CONSTRAINED_MINMAX**

    For information on these math types, see the "Primary Datum Plane Math Types" topic in this documentation.
5. Select either **BF** (Best Fit) or **BFRE** (Best Fit Recompensate) from the second list in the **Math type** area.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

For information on Best Fit planes, see "Constructing a Best Fit or Best Fit Recompensate Plane".

6. From the **Display** area, select how you want PC-DMIS to display the constructed plane. For details, see the "Using the Display Area" topic in this documentation.
7. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
8. Click the **Create** button.

After you click the **Create** button, PC-DMIS performs these steps to construct the Primary Datum Plane:

1. First, PC-DMIS constructs a Best Fit plane from the input features according to the math type.
2. Next, PC-DMIS rotates to the Best Fit plane.
3. Then, PC-DMIS finds the optimal primary datum plane from the highest points.

The Edit window command line for this option reads:

```
CONSTR/PLANE,PRIMARY DATUM, feat_1, feat_2, feat_3,…
```

Primary Datum Plane Math Types

The **Math Types** area of the constructed Primary Datum Plane provides three different math types. These math types support the ASME and ISO datum plane standards.

The three math types in the first drop-down list of the **Math Types** are:

- **CONSTRAINED_L1**
- **CONSTRAINED_L2**

- **CONSTRAINED_MINMAX**

Definitions

These terms correspond to the following definitions in the standards:

PC-DMIS	ASME Y14.5	ISO 5459
Constrained L1	Alternative Math Type	Alternative Math Type
Constrained L2 (default)	Default Math Type	Alternative Math Type
Constrained minmax	Alternative Math Type	Default Math Type

Before you choose a math type, you need to understand the concepts of void filtering (external envelope), norms, and outside-material constraint (constrained fit). These are covered below:

Void Filtering

Void filtering is also known as the external envelope.

In reality, surfaces of planar features are not planar. Surfaces have both convex and concave regions (peaks and valleys). The concave regions are guaranteed to never contact a perfectly flat surface plate. These are known as "voids". The software can filter out these voids by interpolating over them. Since the voids do not affect how the part interacts with an ideal surface plate, you may want to filter out the voids:

Illustration of a void-filtered surface. The dotted gray line is the real surface feature. The solid black line is the void filtered surface. The space between the real feature surface and the void filtered surface are the voids.

Norms

In general, ideal geometric shapes are fitted to non-ideal surfaces by minimizing the distances between the ideal shape and the non-ideal surface. In reality, there are an infinite number of distances between the two surfaces. Norms are mathematical concepts that transform these distances into a single distance while satisfying certain mathematical properties. The constructed PC-DMIS Primary Datum Plane supports three norms:

- **L1** - This is equal to the sum of the distances.
- **L2** - This is equal to the square-root of the sum of the squares of the distances. Minimizing the L2 norm is the same as a least-squares fit.

- **L∞** - This is equal to the maximum distances between the ideal surface and the non-ideal surface. Minimizing the L∞ norm is the same as minimizing the maximum deviation, so we use the term "minmax" for this norm.

The fitting process minimizes the distances according to the selected norm.

Outside-Material Constraint

Outside-material constraint is also known as a constrained fit. When fitting ideal geometric shapes to non-ideal surfaces, it is possible to add constraints to the fitting process. An outside material constraint means the fitting process is constrained while minimizing the norm. The constraint is that the ideal surface must lie outside the real surface. This is similar to a surface plate. A surface plate is always outside the part. For example, a constrained L∞ plane minimizes the maximum deviation out of all planes that lie external to the part.

Putting It All Together

The PC-DMIS Primary Datum Plane uses the concepts of void filtering, norms, and outside-material constraint together. From the provided measurements of the actual surface, the Primary Datum Plane first filters out the voids. It then finds the plane that minimizes the chosen norm of the distances to the void-filtered surface, subject to an outside material constraint.

Examples

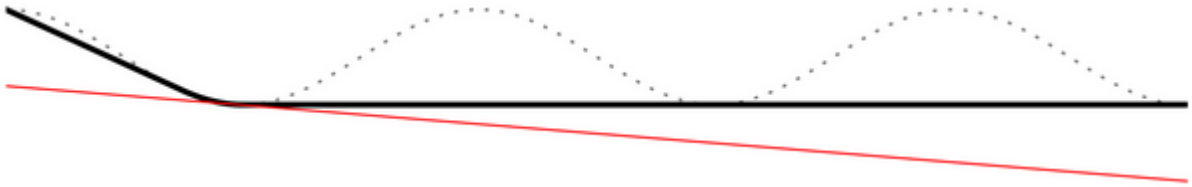
The three math types that the Primary Datum Plane exposes have different behaviors in different circumstances. These examples illustrate those circumstances. They also demonstrate how the L2 algorithm gives a repeatable approximation of a physical datum (such as a surface plate).

- L∞ usually gives a result controlled by the edges of the part. This makes it undesirable in most cases.
- L1 behaves somewhat like how a part would rest on a surface plate under the influence of gravity, but it does not handle rocker conditions gracefully. A rocker condition is when a part might rock on a surface plate instead of having obvious stable contact points. A convex datum plane results in a rocker condition.
- L2 performs much like L1 in many cases, but in rocker conditions, it always gives an equalized solution. This is the recommended norm for most applications.

Sinusoidal Surface Profile Examples

In each illustration, the dotted gray line is the real surface feature. The solid black line is the void-filtered surface (the external envelope).

L∞



The red line is the constrained L∞ plane targeting the external envelope (constrained minmax type in PC-DMIS). Observe how this plane is tilted with respect to how a surface plate would work.

L1

The blue line is the constrained L1 plane targeting the external envelope (constrained L1 math type in PC-DMIS).

L2

The green line is the constrained L2 plane targeting the external envelope (constrained L2 math type in PC-DMIS)

V-Like Surface Profile Examples

In each illustration, the solid black line is the void-filtered surface (the external envelope).

L∞

The red line is the L∞ plane targeting the external envelope (constrained minmax type in PC-DMIS). Observe how this plane equalizes the rocking condition.

L1

The blue line is the constrained L1 plane targeting the external envelope (constrained L1 math type in PC-DMIS).

L2

The green line is the constrained L2 plane targeting the external envelope (constrained L2 math type in PC-DMIS). Observe how this plane equalizes the rocking condition.

Wiggly Surface Profile Examples

In each illustration, the dotted gray line is the real surface feature. The solid black line is the void-filtered surface (the external envelope).

L∞

The red line is the L∞ plane targeting the external envelope (constrained minmax type in PC-DMIS). Observe how this plane is tilted with respect to how a surface plate would work.

L1

The blue line is the constrained L1 plane targeting the external envelope (constrained L1 math type in PC-DMIS).

L2

The green line is the constrained L2 plane targeting the external envelope (constrained L2 math type in PC-DMIS).

Migration

From earlier PC-DMIS versions to PC-DMIS 2019 R1:

A High Point Plane feature becomes a Primary Datum Plane feature *with a constrained L1 math type*.

A Tangent Plane becomes a Primary Datum Plane feature and the math type is preserved.

From PC-DMIS 2019 R1 to PC-DMIS 2017 R1 through PC-DMIS 2018 R2:

The Primary Datum Plane feature becomes a Tangent Plane feature.

From PC-DMIS 2019 R1 to PC-DMIS version 2016.0 (or earlier):

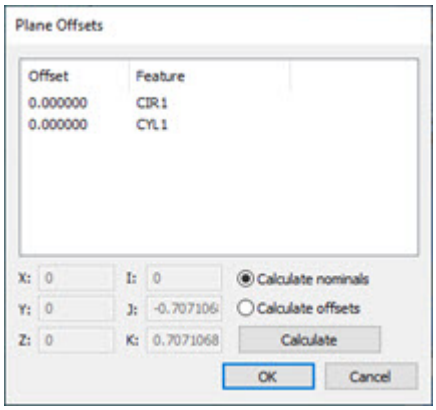
If the PC-DMIS version supports the High Point Plane, the Tangent Plane feature becomes a High Point Plane feature.

Constructing an Offset Plane

A plane can be constructed a specified distance from the input feature or features.

To construct an offset plane:

1. Open the **Construct Plane** dialog box (**Insert | Feature | Constructed | Plane**).
2. From the **Method** list, select the **Offset** option.
3. From the **Feature** list, select a single plane feature or at least three features of any type.
4. Click the **Offsets** button to open the **Plane Offsets** dialog box.



Plane Offsets Dialog Box

5. Click the **Calculate Noms** option and enter the offset values for the input feature or features in the offset field, or click the **Calculate Offsets** option and change the nominal values (see the procedures below).
6. Click **Calculate** to calculate either the nominal values or the offset values.
7. Click the **OK** button to close the **Plane Offsets** dialog box.
8. From the **Display** area, select how you want PC-DMIS to display the constructed plane. For details, see the "Using the Display Area" topic in this documentation.

9. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.

10. Click the **Create** button. PC-DMIS creates the offset plane based on the input feature or features.

Using a Single Plane Input Feature

PC-DMIS creates a parallel plane at the offset distance.

The Edit window command line for this option would read:

```
CONSTR/PLANE,OFFSET
ID=id1,,, …
OFFSET=val1…
```

Using Three Input Features

PC-DMIS iterates and constructs a plane such that the shortest distance from each input feature to the plane is the corresponding offset amount. PC-DMIS applies negative offsets in the same general direction that the points are measured. Positive offset values are applied opposite the probing direction. If there is no probing direction (for example, the input points were constructed), PC-DMIS uses the current workplane to determine the general direction for applying the offsets. Positive offsets are applied in the plus direction of the third axis of the current workplane. Negative offsets are applied in the minus direction of the third axis of the current workplane.

The sign (positive or negative) of the offset value controls on which side of the input features the plane is constructed. If you get the opposite plane than was expected, cancel the feature and reconstruct it, reversing the sign of the keyed in offsets. For example, if the offsets are 1.0, 2.5, 3.5, change them to -1.0, -2.5, -3.5.

The Edit window command line for this option would read:

```
CONSTR/PLANE,OFFSET
ID= id1, id2, id3, …
OFFSET= val1, val2, val3, …
```

Changing Offsets Directly to Calculate Nominals

To enter new offset values:

1. Click the **Offsets** button from the **Construct Plane** dialog box (**Insert | Feature | Constructed | Plane**) to open the **Plane Offsets** dialog box.
2. In the **Offset** column, click on the **0.000000** value (or current value) to select it.
3. Type a new value.
4. Press the Enter key.
5. Click **Calculate** to update the nominal values based on any offset(s) you chose.
6. Click **OK** to save the offset.

Example of Calculating Nominals

The **Calculate** button on the **Plane Offsets** dialog box (**Insert | Feature | Constructed | Plane**) allows you to calculate the X, Y, and Z nominal values from new offsets entered.

For example, suppose you construct an offset plane between three circles (CIR1, CIR2, and CIR3). After you select the features and click the **Offsets** button, you have X, Y, and Z nominals of:

X = 6

Y = 2

Z = 0.95

If you change the offset values by 3.0 for each circle and click the **Calculate** button, the X, Y, and Z are updated to:

X = 6

Y = 2

Z = 3.95

If you then click **OK** and construct the offset plane, you'll notice that the newly constructed plane lies 3.0 units higher in the Z axis.

Plane offsets only apply the offset in the Z axis.

Changing Nominals Directly to Calculate Offsets

To enter new offset values:

1. From the **Construct Plane** dialog box (**Insert | Feature | Constructed | Plane**), click **Offsets** to open the **Plane Offsets** dialog box.
2. Select the **Calculate offsets** option. The nominals portion of the dialog box becomes editable.

3. Change the **XYZ** or **IJK** values.
4. Click **Calculate** to update the offset values based on any nominals you've changed.
5. Click **OK** to save the offset.

Example of Calculating Offsets

The **Calculate** button on the **Plane Offsets** dialog box (**Insert | Feature | Constructed | Plane**) allows you to calculate the offset values appearing in the **Offset** column when you change the nominal value.

For example, suppose you construct an offset plane between three circles (CIR1, CIR2, and CIR3). After you select the features and click the **Offsets** button, you have X, Y, and Z nominals of:

X = 6

Y = 2

Z = 0.95

If you change the X, Y, and Z nominals to:

X = 6

Y = 2

Z = 3.95

and click the **Calculate** button, the offsets for the three circles are updated to:

3.000000 CIR1

3.000000 CIR2

3.000000 CIR3

If you then click **OK** and construct the offset plane, you'll notice that the plane is constructed at 3.0 units higher in the Z axis.

Constructing a Translated Plane

You can construct a Translated Plane feature from another input plane feature. The input plane feature must contain point data. Valid plane features with point data are Constructed Best Fit (BF), Constructed Best Fit Recompensate (BFRE), Measured, or Auto plane features. Invalid plane features do not contain point data (such as Cast, Mid, or Perpendicular).

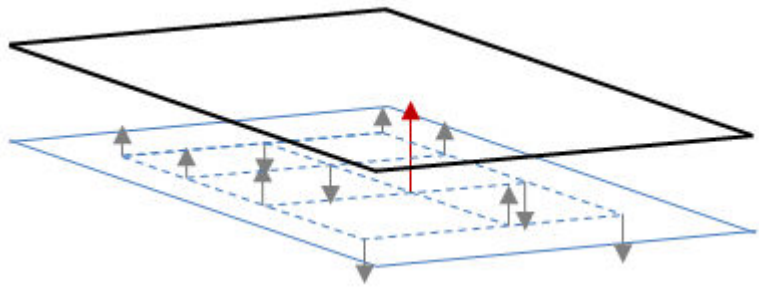
For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

PC-DMIS moves the translated constructed plane from the input plane in the direction of the input plane vector based on the calculation method:

- If you choose **Maximum Deviation**, PC-DMIS translates the plane to the maximal deviation point.
- If you choose **Standard Deviation**, PC-DMIS calculates the translation by multiplying the **Standard deviation multiple** value by the standard deviation.

The Translated Plane is offset from the input plane by the maximum deviation. The Standard Deviation plane is similarly offset, but the distance is a multiple of the standard deviation, as described above.



In this figure, the light blue plane represents the input feature, the black plane represents the maximum deviation plane, and the red arrow represents the maximum deviation.

To construct a translated plane:

1. Open the **Construct Plane** dialog box (**Insert | Feature | Constructed | Plane**).
2. From the **Method** list, select the **Translated Plane** option.
3. From the **Feature** list, select the input feature. This must be a Plane feature with point data.
4. Select the calculation method. The available options are **Maximum Deviation** or **Standard Deviation**.

5. If the calculation method is **Standard Deviation**, type the **Standard deviation multiple** value.
6. From the **Display** area, select how you want PC-DMIS to display the constructed plane. For details, see the "Using the Display Area" topic in this documentation.
7. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
8. Click **Create** to insert the constructed Translated Plane command into the Edit window.

The Edit window command line for this option reads:

```
CONSTR/PLANE,TRANSLATED,feat_1,

METHOD/( MAXIMUM_DEVIATION | STANDARD_DEVIATION),
standardDeviationMultiple
```

Constructing an Extracted Plane

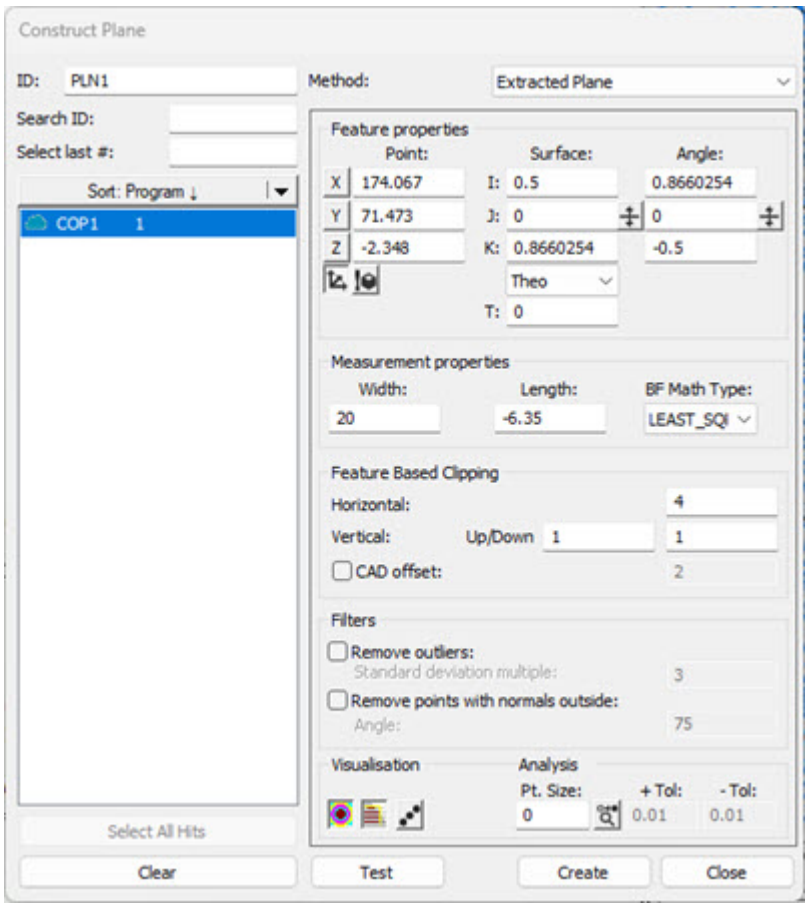
For details on extracting Auto features from a Mesh, see the "Extracting Auto Features from a Mesh" topic in the PC-DMIS Laser documentation.

For details on extracting Auto features from a Pointcloud (COP), see the "Extracting Auto Features from Pointclouds" topic in the PC-DMIS Laser documentation.

You can construct a plane that PC-DMIS extracts from a scanned pointcloud (COP) or mesh.

To do this, follow these steps:

1. Ensure that your measurement routine has a Pointcloud (COP) or Mesh command.
2. Open the **Construct Plane** dialog box (**Insert | Feature | Constructed | Plane**) or from the **Constructed Feature** toolbar (**View | Toolbars | Constructed Features**).



Construct Plane Dialog Box - Extracted Plane Option

3. From the **Method** list, select the **Extracted Plane** option.
4. From the **Reference** area, select the COP or Mesh that you want to use to extract the plane from.
5. Click on the CAD model or data to define the nominal or, in the **Point** section of the **Feature properties** area, type the nominal location in the **X**, **Y**, and **Z** boxes.
6. From the **Surface** section of the **Feature properties** area, define the surface vector in the **I**, **J**, and **K** boxes. You can use the **Material Thickness Type** list and the **T** box below it to define the material thickness value. For details, see the "Use Thickness" topic in this documentation.

   You can use these controls to perform the associated functions:

   Flip Vectors

   Polar/Cartesian

   Find Nearest CAD element

   For details on these controls, see the appropriate topic in the "Feature Properties Area" section of the "Creating Auto Features" chapter of the PC-DMIS Core documentation."

7. In the **Measurement properties** area, type the properties for the plane in the **Width** and **Length** boxes. Also, select the type of Best Fit algorithm to use to construct the plane from the **BF Math Type** list. For details on the algorithm types, see the "Best Fit Type (for Plane)" topic in this documentation.

   PC-DMIS draws the extraction zone and centers it around the XYZ location point. This box defines the zone that PC-DMIS uses for the extracted plane.

   - The black outline is the surface.
   - The green boundary represents the horizontal and vertical boundary zones.
   - The orange points are the candidate points that the extraction considers.

   
   Example of an extracted plane showing the candidate points.

8. From the **Feature Based Clipping** area, define the **Horizontal**, **Vertical**, and **Vertical Up/Down** values. This sets the dimensions for the extraction zone region. Consider part variability when you define the extraction zone.

   Alternatively, you can clip data within an offset boundary around all the CAD elements on a surface with the **CAD offset** option. This is also called *CAD segregation*. For details, see the "CAD offset" section of the "Feature Based Clipping Parameters" topic in the PC-DMIS Laser documentation.

   If you want to filter out any points that are outside of a maximum incidence angle, from the **Filters** area, select the **Remove points with normals outside** check box and type the value in the **Angle** (Max Incidence Angle) box.

The Max Incidence Angle filter was initially designed to compare the incidence direction of the laser (which is roughly the laser sensor orientation) to the estimated normal of the segregated points. For 3D laser features (Laser Auto Cone, Cylinder, Plane, Sphere, Surface Point and Constructed Extracted Cone, Cylinder, Plane, Sphere, Surface Point), the filter now compares the estimated normal of the pointcloud point to the nominal normal of the feature, which greatly improves the results. 2D laser features remain unchanged, using the legacy incidence angle filter method.

For details on the **Filters** area, see the "Filters" topic in the PC-DMIS Laser documentation.

9. If you want to filter out any outlier points, from the **Filters** area, select the **Remove outliers** check box and define the **Standard deviation multiple** to determine which points PC-DMIS excludes as outliers.

10. In the **Visualisation** section, PC-DMIS provides these options to perform the described function:

    Visualisation Tools On/Off - This button toggles the display of the colored visualisation tools. For more information, see "Understanding the Visualisation Tools".

    Show/Hide segregated points - This button toggles the display of the points that the software passes to the feature extractor engine based on the current settings.

    Show/Hide measured points - This button toggles the display of the measured points. It remains greyed out until you click **Test** or **Create**. For more information, see the "Show Measured Points" topic in the PC-DMIS Core documentation.

    
    - The **Analysis** area allows you to determine how each measured hit/point is displayed. For more information, see the “Analysis Area” topic in the PC-DMIS Core documentation.

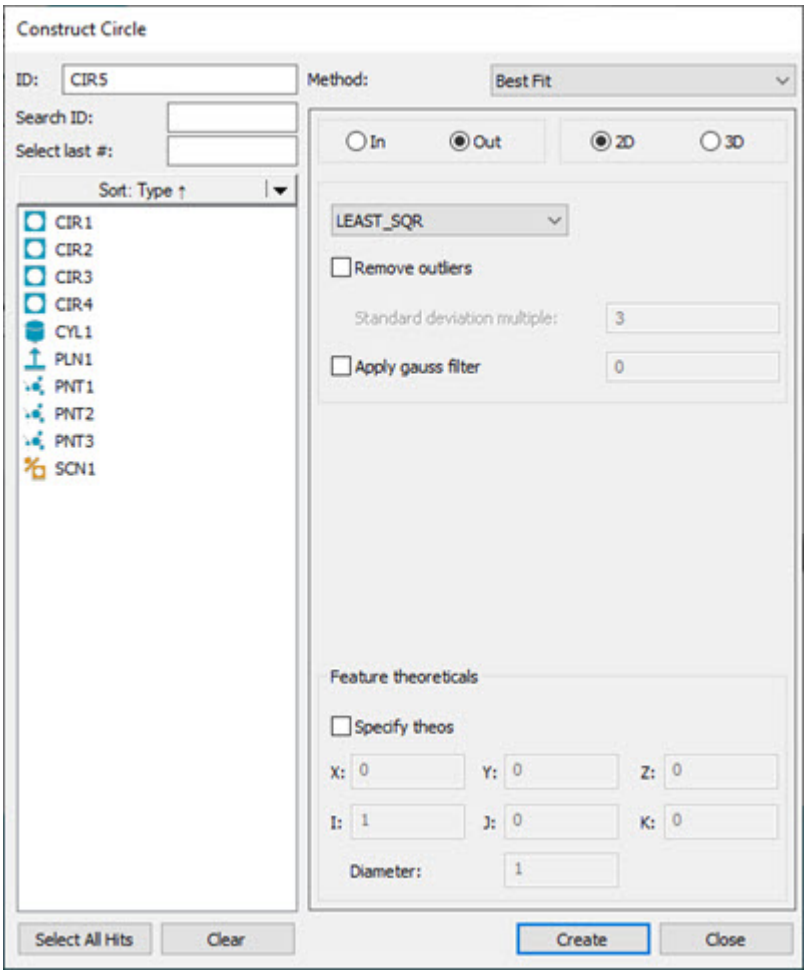
11. Click the **Test** button to test a feature's creation and preview its dimensional data before you create it. PC-DMIS performs a measurement using the current parameters. You can change the parameters and click **Test** repeatedly until you have an acceptable measurement. Then, when you click **Create**, the software converts the temporary feature into a normal feature in the measurement routine.

12. Click the **Create** button. Based on the parameters that you specified in the dialog box, PC-DMIS does an analysis of the candidate points and returns (or extracts) each measured point and projects them to the surface.

    PC-DMIS creates the command in the Edit window:

```
PLN3=FEAT/POINT,CARTESIAN,LEAST_SQR
   THEO/<73.598,33.658,0>,<0,0,1>,<1,0,0>
   ACTL/
<74.116,36.299,0.001>,<-0.0004985,0.0007789,0.9999996>
   WIDTH=5,LENGTH=5,
   THEO_THICKNESS,0,
   HORIZONTAL CLIPPING=3,VERTICAL CLIPPING=2,
   USE OUTLIER REMOVAL=ON,0.125,
   REMOVE POINTS WITH NORMALS OUTSIDE=ON,25,
   CONSTR/PLANE,EXTRACTED_PLANE,REF=COP1
```

Constructing a Circle Feature



Construct Circle Dialog Box

There are several ways to use PC-DMIS to construct a circle. The following table shows the types of constructed circles found in the **Method** list and their required inputs. Some constructed circles may require no inputs while others may require three or more. The term "Any" in the following table indicates that the construction can take any type of feature as input for construction. You can select the input features in any order.

Method	SYMBOL IN EDIT WINDOW	# OF INPUT FEATS	FEAT #1:	FEAT #2:	FEAT #3:	COMMENTS
Auto Circle	-	-	-	-	-	See "Auto Circle Construction".
Best Fit Circle	BF	At least 3 inputs are needed.	-	-	-	Constructs a best fit circle using the given inputs. See the Note below for recommended inputs.
Best Fit with Recompensate Circle	BFRE	At least 3 inputs are needed. (1 must be a point)	-	-	-	Constructs a best fit circle using the given inputs. See the Note below for recommended inputs.
Intersect Circle	INTOF	2	Circle, Sphere, Cone, or Cylinder	Plane	-	Constructs a circle at the intersection of a circular feature with a plane, cone, or cylinder.
			Plane	Circle, Sphere, Cone, or Cylinder		
			Cone	Cone or Cylinder		
			Cylinder	Cone		
Cast Circle	CAST	1	Any	-	-	Constructs a circle at the centroid of the input feature.
Project Circle	PROJ	1 or 2	Any	Plane	-	One input feature will project the circle to the workplane.
Reverse Circle	REV	1	Circle	-	-	Constructs a circle with a reversed vector.

Tangent 2 Lines	TANLINES	2	Line	Line	-	Constructs a circle tangent to the two lines at a given diameter.
Tangent 3 Lines	TANLINES	3	Line	Line	Line	Constructs a circle tangent to the three lines.
Tangent 3 Circles	TANCIRCLES	3	Circle	Circle	Circle	Constructs a circle tangent to the three circles.
Scan Segment Circle	SCAN_SEGMENT	1	Scan	-	-	Constructs an arc from a part of a Linear Open or Linear Close scan.
Scan Minimum	SCAN_MINIMUM	1	Scan Minimum	-	-	Constructs a 2D circle of a given radius at a minimum point along a linear scan.
Cone Circle - also known as Gage Diameter	CONE	1	Cone	-	-	Constructs a circle at the specified diameter or height of the cone.
Sphere Circle	SPHERE	1	Sphere	-	-	Constructs a circle at the specified diameter or height of the sphere.
Cylinder Circle	CYLINDER	1	Cylinder	-	-	Constructs a circle at the specified diameter or height of the cylinder.

Extracted Circle	EXTRACTED_CIRCLE	1	COP or Mesh	-	-	Constructs an extracted circle from the COP or Mesh object at the specified diameter or height of the cylinder.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

If you select inappropriate feature types, PC-DMIS displays this message on the Status bar:

"Cannot construct [feature]. Combination of input features not accepted."

To construct a circle:

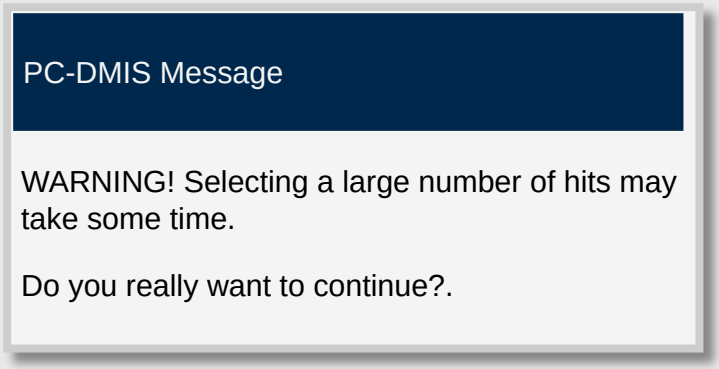
1. Open the **Construct Circle** dialog box (**Insert | Feature | Constructed | Circle**).
2. Input the desired features.
3. Select the **In** or **Out** option.
4. Select the method of construction. Available options include:
    - * Auto Circle
    - Best Fit or Best Fit Recompensate Circle
    - Intersect Circle
    - Cast Circle
    - Projected Circle

- Reverse Direction Circle
- Tangent 2 Lines
- Tangent 3 Lines
- Tangent 3 Circles
- Scan Segment
- Scan Minimum Point
- Circle from a Cone
- Circle from Sphere
- Circle from Cylinder
- Extracted Circle

** Auto is the default method of construction. See "Auto Circle Construction".*

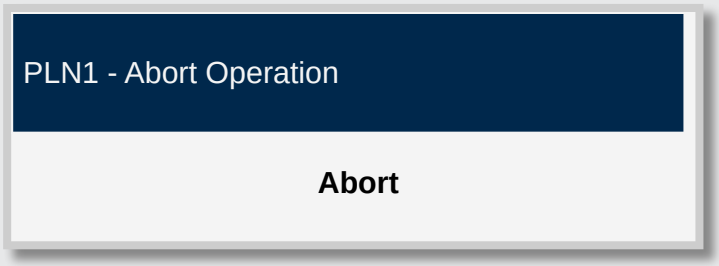
If you select the **Best Fit** or the **BF Recomp** (Best Fit Recomp) method for this feature, PC-DMIS allows you to click the **Select All Hits** button to create the construction from the individual hits of the input features instead of their centroids.

If there are a large number of points involved (about 10,000 or more), PC-DMIS shows a message asking if you are sure you want to proceed as this may take some time to complete.



Click **Yes** to proceed, click **No** to abort the process. You can select the **Don't ask me again** check box to prevent this message from recurring.

If you click **Yes**, another message is shown similar to the one shown below to let you know that PC-DMIS is generating the features from the hit points.

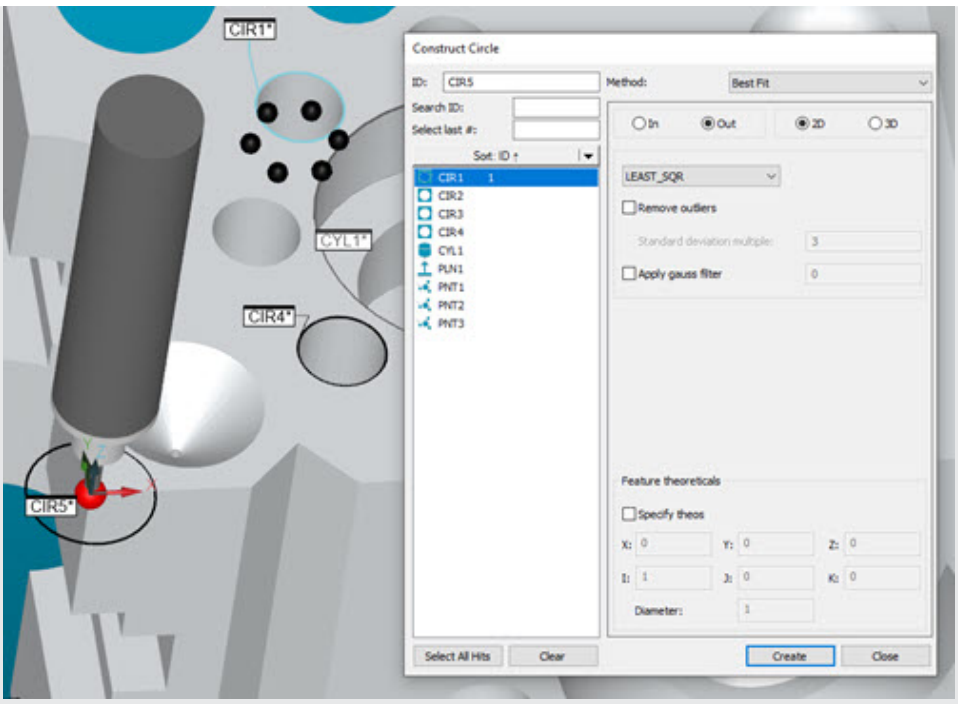


Once all the constructed features are created, the message disappears.

You can click the **Abort** button at any time to stop the process. Any features created up to this point are listed in the **Feature list** area of the dialog box.

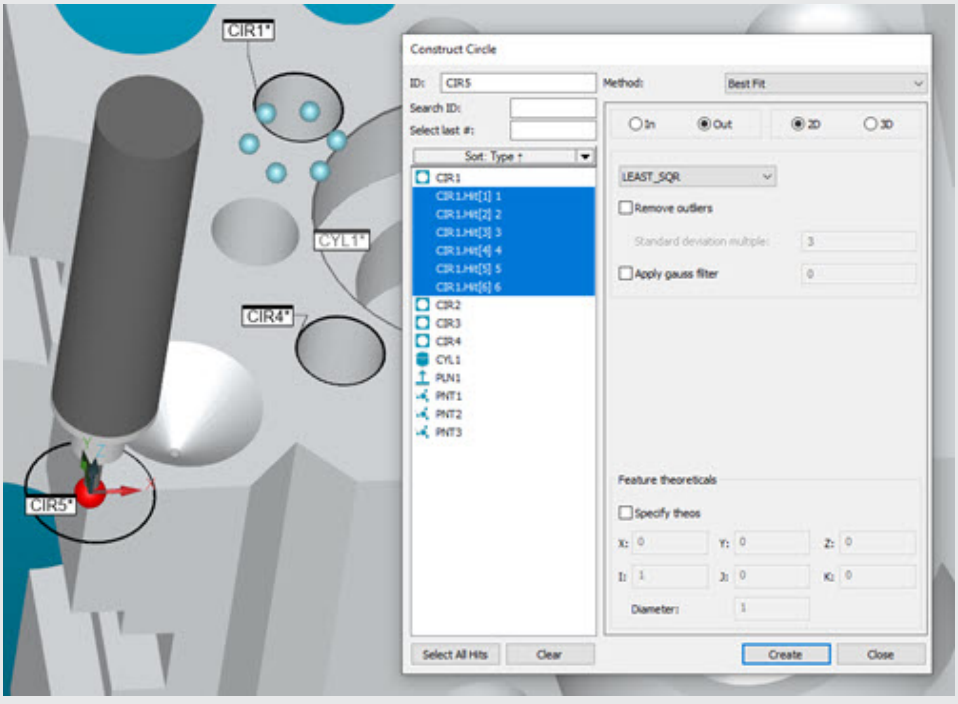
To create constructed features from the individual hits of the input features, do this:

1. From the **Feature list**, select the feature or features that you want to use to create the constructed feature.



Example showing a selected feature prior to clicking the Select All Hits button.

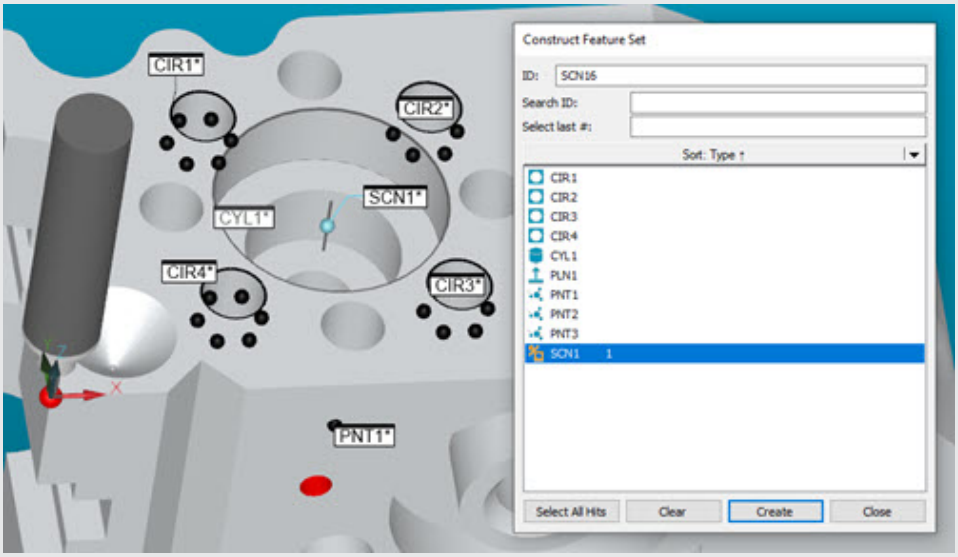
2. Click the **Select All Hits** button to display all the components that comprise the selected feature or features.



Display of items that make up the selected feature are highlighted in the dialog box and in the Graphic Display window.

PC-DMIS displays and highlights all the components of the selected feature (or features) in the **Feature list** are of the dialog box. You can select or de-select any of the features or feature components shown in the list to include or exclude them.

3. Click the **Create** button to create the Constructed feature based on the final features and feature components that you selected.



Constructed feature created based on the selected items from the Feature list.

5. Some circle types have additional options or items that appear in the dialog box when selected. Select or use these options as needed.

6. Click the **Create** button.

The Edit window command line for a sample Circle Construction would read:

```
feature_name=FEAT/CIRCLE,TOG1,TOG4,TOG5
THEO/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,diam
ACTL/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,diam
CONSTR/TOG2,TOG3
```

If TOG2 = CIRCLE and TOG3 = BF or BFRE then the command has the following format:

```
feature_name=FEAT/CIRCLE,TOG1,TOG4,TOG5
THEO/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,diam
ACTL/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,diam
CONSTR/CIRCLE,TOG3,TOG7,feat_1,feat_2, …
OUTLIER_REMOVAL/TOG6, stdDevMultiplier
FILTER/TOG6, UPR =cutoffFrequency
```

The actual Edit report displays in all capital letters.

TOG1= POLR or RECT

TOG2 = CIRCLE

TOG3 = BF / BFRE / CAST / CONE / INTOF / PROJ / REV / TANLINES / TANCIRCLES / SCAN_SEGMENT

TOG4 = IN / OUT

TOG5 = LEAST_SQR / MAX_INSC / MIN_CIRCSC / MIN_SEP / FIXED_RAD (only for measured, BF and BFRE circles)

TOG6 = ON or OFF

TOG7 = 2D or 3D (This appears only if TOG3 reads BF or BFRE)

stdDevMultiplier = This multiplier value determines whether or not a measured point is an outlier. If the point from the circle is further than the standard deviation multiplied by this, then it is an outlier and will be removed if you have selected the **Remove Outlier** option.

cutoffWavelength = This value controls the amount of data smoothing. The longer the wavelength, the more the smoothing.

The first three lines displayed in the Edit window will be the same for constructed circles. The fourth line will be slightly different, according to the type of feature you are constructing. You can switch between the different types of circles by placing the cursor on *TOG3* and pressing F7 or F8. (See "Command Mode Keyboard Functions" in the "Using the Edit Window" chapter.)

When two or more features are involved, PC-DMIS automatically determines the necessary order of the input features. This improves the accuracy of the measurement process.

The following describe the available options for constructing a circle:

In / Out Circle

The **In** and **Out** options tell PC-DMIS whether to construct the circle as an internal or an external circle.

- If you select **In**, PC-DMIS constructs the circle as an internal circle.
- If you select **Out**, PC-DMIS constructs the circle as an external circle, or pin.

2D / 3D Circle

The **2D** and **3D** options tell PC-DMIS whether to construct the feature as a 2D or 3D circle. These options become available if you select the **Best Fit** or **BF Recomp** option from the **Method** list.

- If you select **2D**, PC-DMIS constructs the circle, projecting it onto the workplane.
- If you select **3D**, PC-DMIS constructs a best fit plane from the inputs. Those inputs are then projected to the plane, and a constructed circle is created from the projected points.

Auto Circle Construction

The list below indicates the type of circle that the software constructs when you select certain input features along with the **Auto** option. The order of the selected features is not important. If you select an incorrect input feature or features, PC-DMIS display an error message and does not automatically construct the indicated feature type.

To allow PC-DMIS to automatically determine the best method of construction:

1. Access the **Construct Circle** dialog box (**Insert | Feature | Constructed | Circle**).
2. From the **Method** list, select the **Auto** option.
3. Select the desired feature or features based on the table below.
4. Click the **Create** button.

Input Feature List

	Circle	Cone	Cylinder	Ellipse	Line	Plane	Point	Set	Slot	Sphere
Circle						Project Circle				
Cone		Intersect Circle	Intersect Circle			Intersect Circle				Intersect Circle
Cylinder		Intersect Circle								Intersect Circle
Ellipse						Project Circle				
Line						Project Circle				
Plane	Project Circle	Intersect Circle		Project Circle	Project Circle	Project Circle	Project Circle	Project Circle	Project Circle	Intersect Circle
Point						Project Circle				
Set						Project Circle				
Slot						Project Circle				
Sphere		Intersect Circle	Intersect Circle			Intersect Circle				

Any 1 Circle	Reverse Circle
Any 1 Cone (with Diameter)	Cone Circle
Any 1 Feature (Except Circle, Cone and Set)	Cast Circle
Any 1 Set	Best Fit Circle
One COP or Mesh object	Extracted Circle

Constructing a Best Fit or Best Fit Recompensate Circle

You can construct a "best fit" circle from three or more features. The constructed circle's vector is normal to the current workplane.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

To construct a Best Fit Circle or a Best Fit Recompensate Circle:

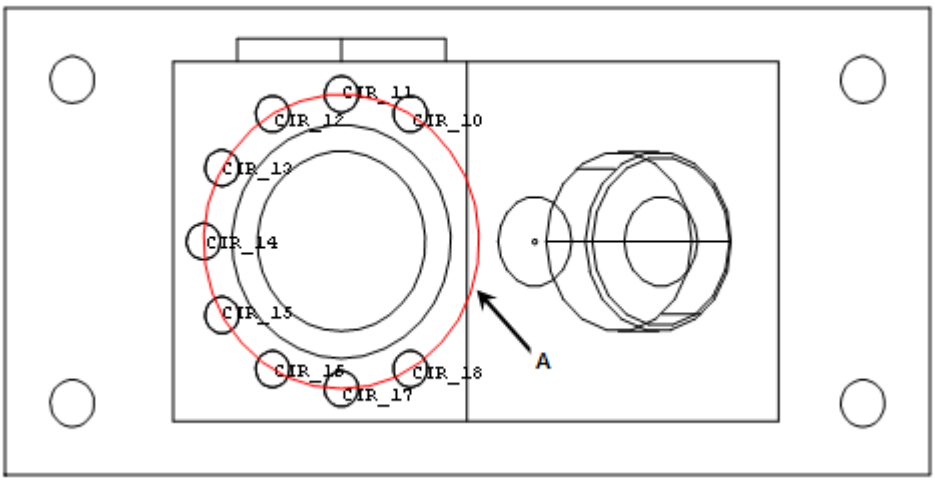
1. Open the **Construct Circle** dialog box (**Insert | Feature | Constructed | Circle**).
2. From the **Method** list, select either the **Best Fit** or **BF Recomp** option.
3. Select the type of Best Fit construction from the **Best Fit Type** list. For information on the different types, see "Best Fit Type (for Circle)".
4. Select at least three features.
5. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/CIRCLE, BF,  feat_1, feat_2, …

OUTLIER_REMOVAL/ (OFF | ON),  stdDevMultiple

FILTER/(OFF | ON), UPR = cutoffFrequency
```



A - Best fit circle constructed from three or more features (in this example from three or more circle features)

Outlier removal and Filtering are described in the topics below:

Best Fit Type (for Circle)

This list becomes available if you select **Best Fit** or **BF Recomp** options when constructing the circle. It allows you to specify the type of Best Fit construction used. Available types include:

- LEAST_SQR
- MIN_SEP

- MAX_INSC
- MIN_CIRCSC
- FIXED_RAD

These types are discussed below:

LEAST_SQR
Least Squares - This calculation type provides a method of fitting in which the average squared radial distance from the data points to the circle is minimized. The square root of this quantity is the Root Mean Square (RMS) distance. Since the RMS distance is based on an average, some points may be further than the RMS distance from the computed circle.

MIN_SEP
Minimum Separation - This calculation type generates a circle that is halfway between two concentric circles containing the data points, with the difference of their radii as small as possible. The Min/Max math used by the MIN_SEP calculation minimizes the maximum error, or deviation, from the input data to the circle. The Min/Max error is one-half of the minimal separation. No input data points (or input features) lie farther than the Min/Max error from the Min/Max circle. This calculation determines whether or not all the input data (or input features) are within the given tolerances.

MAX_INSC
Maximum Inscribed - This calculation type generates an empty circle with the largest possible diameter that lies within the data. PC-DMIS first computes a Minimum Circumscribed circle and requires that the center of the Maximum Inscribed circle lies within it. This option could be used for a circular feature that requires a mating stud. For example, if the input data represents a hole, then this calculation returns a circle with the diameter of the largest stud that will fit inside the hole. Do not use this calculation type for arcs of less than 90 degrees.

MIN_CIRCSC
Minimum Circumscribed - This calculation type generates a circle with the smallest possible diameter that encloses the input data (or input features). This option could be used when measuring a stud that would fit into a mating circular feature. The resulting feature would be the smallest hole into which the stud would fit. Do not use this calculation type for arcs of less than 180 degrees.

FIXED_RAD
Fixed Radius - This calculation type creates a circle of a given diameter, positioned so that the maximal radial distance from the data points to the circle is minimized. It is similar to the Max/Min math used in the MIN_SEP calculation except that, since the diameter is known in advance, the radius cannot vary. Only the circle's position is allowed to vary.

For legacy Form dimensions (Circularity, Cylindricity, Flatness, and Straightness), as well as a Location dimension's RN Line, PC-DMIS uses the feature solution to compute the dimension. By default, this is Least Squares. However, you can choose to solve the feature using Minimum Separation, Maximum Inscribed, Minimum Circumscribed, or Fixed Radius regression algorithms.

PC-DMIS computes Geometric Tolerance Form commands, on the other hand, using the Chebyshev algorithm (Min/Max) as required by the Y14.5 standard. Because of the change in calculation, PC-DMIS generally computes Geometric Tolerance Form dimension commands to a slightly smaller value than their legacy counterparts.

Remove Outliers / Standard Deviation Multiple for a Constructed Circle

For a best fit (BF) or best fit recompensate (BFRE) circle, you can choose to remove outliers based on the distance from the best fit feature. This allows the removal of anomalies that arise in the measurement process.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

PC-DMIS first fits a circle to the data, then determines which points are outliers based on the standard deviation multiple. It then does the following:

- Recalculates the best fit circle with those outliers removed.
- Checks for outliers again.
- Recalculates the best fit circle.
- Continues repeating this process until no more outliers exist or until PC-DMIS cannot compute the circle (PC-DMIS can't compute the circle if there are fewer than three data points).

Apply Gauss Filter / Cutoff Frequency

The Best Fit (BF) and Best Fit Recompensate (BFRE) constructed circles have the option of filtering the deviations of the measured data points from the best fit circle computed from the measured data.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

Apply Gauss Filter - If you mark this check box, PC-DMIS applies a Gaussian filter with a cutoff frequency input as undulations per revolution (UPR). Generally, a lower cutoff frequency produces smoother filtered data.

Remove Outliers - If you mark this check box and you are filtering the data, it removes the outlier data prior to filtering.

Constructing an Intersect Circle

You can construct a circle between a cone (circle, cylinder, sphere) and a plane. It can also be created between two concentric cones or a concentric cone/cylinder combination.

PC-DMIS creates a circle at the intersection of the circular feature and the plane or between the cone/cone or cone/cylinder combinations.

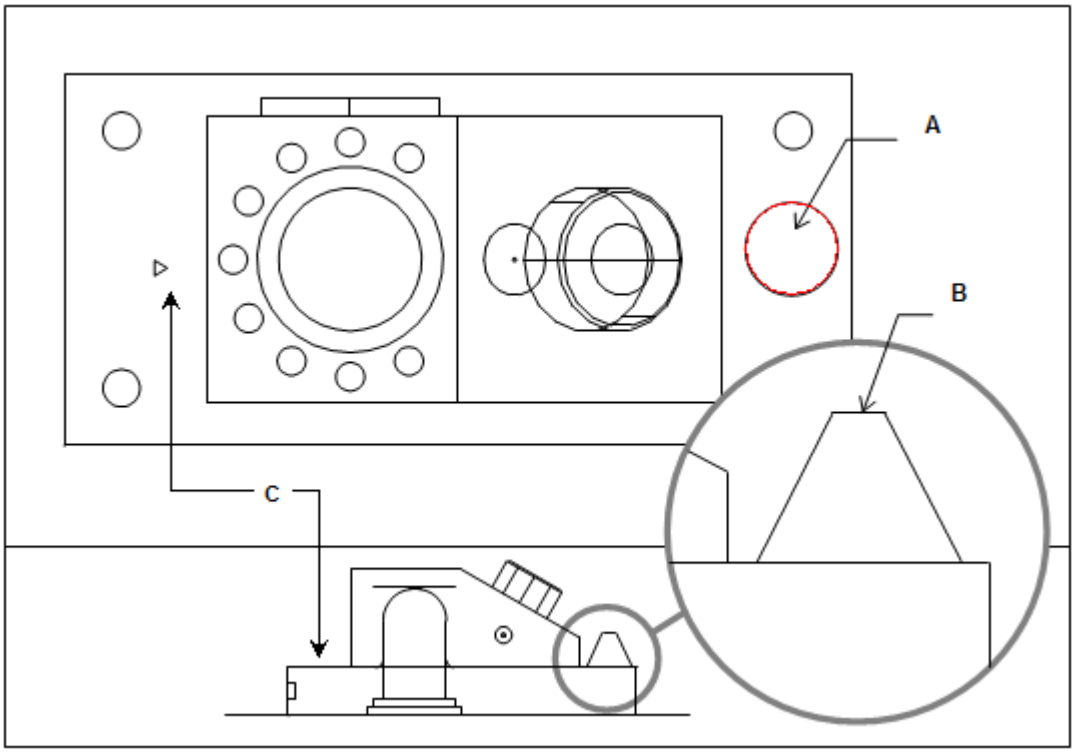
- In the case of a circular feature and a plane intersection, PC-DMIS always makes a true circle (not an ellipse) even if the circular feature is not exactly perpendicular to the plane. The center point of the new circle is at the pierce point of the circular feature's centerline and the plane. The vector of the circle is the vector of the piercing circular feature.
- In the case of a cone/cone or cone/cylinder combination, a true circle is created even if the intersecting features do not form a true circle.

To construct an intersect circle:

1. Access the **Construct Circle** dialog box (**Insert | Feature | Constructed | Circle**).
2. From the **Method** list, select the **Intersect** option.
3. Select the first feature. It must be either a Circle, Cone, Cylinder, or Sphere.

4. Select the second feature. It must be a Plane.
5. Click the **Create** button.

The Edit window command line for this option would read:
```
CONSTR/CIRCLE,INTOF,feat_1,feat_2
```



A - Circle Constructed from the intersection of a cone and a plane.
B - Cone feature
C - Plane feature
Constructing a Circle from a Cone and a Plane

Constructing a Cast Circle

You can construct a circle by changing any given feature into a circle. PC-DMIS constructs the circle at the centroid of the input feature. If you use a sheet metal point, the diameter is the probe diameter. For some sheet metal features (such as slots and notches), PC-DMIS uses the width as the diameter. For features that do not have diameters (lines, points, etc.), PC-DMIS uses a value that is four times the probe diameter.

You can modify the diameter of the circle; this changes the circle from DEPENDENT to INDEPENDENT. This means that when the circle is executed, the diameter does not change based on the input feature but is independent of the input feature, while the position and vector remain dependent on the input feature. This allows you to have control over the diameter in cases where the input feature doesn't really have a diameter, such as a point. The DEPENDENT/INDEPENDENT field is a toggle field that you can change.

PC-DMIS uses this diameter value for all calculations instead of using the default diameter value as described above.

To construct a cast circle:

1. Open the **Construct Circle** dialog box (**Insert | Feature | Constructed | Circle**).
2. From the **Method** list, select the **Cast** option.
3. Select at least one feature of any type.
4. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/CIRCLE,CAST,feat_1,(DEPENDENT | INDEPENDENT)
```

Constructing a Projected Circle

You can construct a circle from any feature and a plane. PC-DMIS will project the centroid of the given feature onto the plane, creating a circle. If there is only one input feature, the projection will be to the current workplane. The diameter of the projected circle will be four times the probe's diameter.

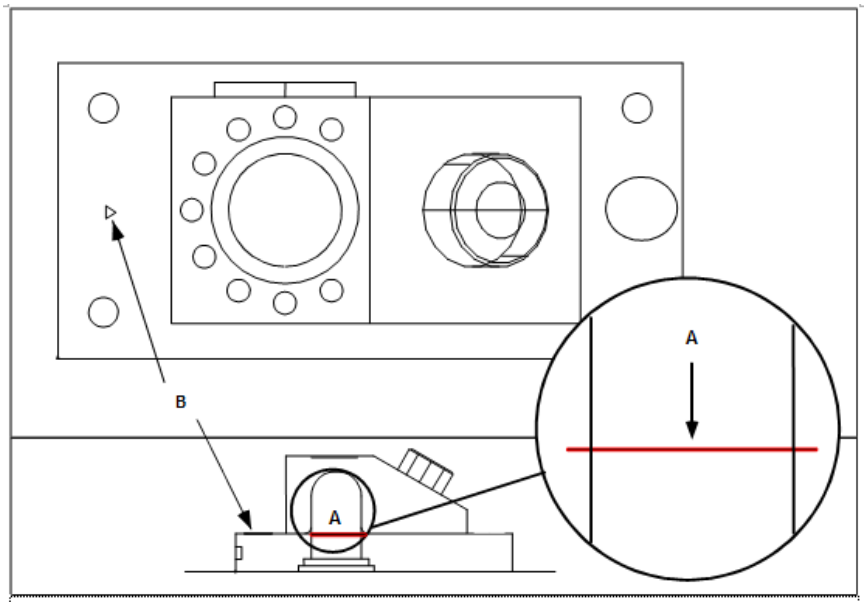
To construct a projected circle:

1. Open the **Construct Circle** dialog box (**Insert | Feature | Constructed | Circle**).
2. From the **Method** list, select the **Projection** option.
3. Select a feature of any type.

   You can select a second feature, but it must be a Plane.

4. Click the **Create** button.

The Edit window command line for this option would read:
`CONSTR/CIRCLE,PROJ,` *feat_1,(feat_2)*



A - Circle constructed from the projection of a circle and a plane.
B - Plane feature.
Example of a circle feature constructed from a circle and a plane.

Changing the Direction of a Circle

You can construct a circle with a reversed vector.

To change the direction of a circle:

1. Access the **Construct Circle** dialog box (**Insert | Feature | Constructed | Circle**).
2. From the **Method** list, select the **Reverse** option.
3. Select one feature. It must be a circle.
4. Click the **Create** button.

The Edit window command line for this option would read:
```
CONSTR/CIRCLE,REV,feat_1
```

Constructing a Tangent Circle

You can construct the following three types of tangent circles using the **Construct Circle** dialog box (**Insert | Feature | Constructed | Circle**):

- **Tangent 2 Lines** - This option constructs a circle tangent to two lines. The exact location is determined by the size of the circle and the direction of the lines. Type a **Diameter** value for the construction after selecting the two input lines, and then click **Create**. If PC-DMIS doesn't show the constructed circle where you expect it to be, change the direction of one of the lines.

Examples of a Circle Feature Constructed Tangent to 2 Lines

Circle 7 Constructed Tangent to Lines 5 and 6	Circle 7 Constructed Tangent to Lines 5 and 7	Circle 7 Constructed Tangent to Lines 6 and 7	Circle 7 Constructed Tangent to Lines 6 and 7. Note the difference from the above example. Because the direction of Line 6 changed, the location of the constructed circle changed.	
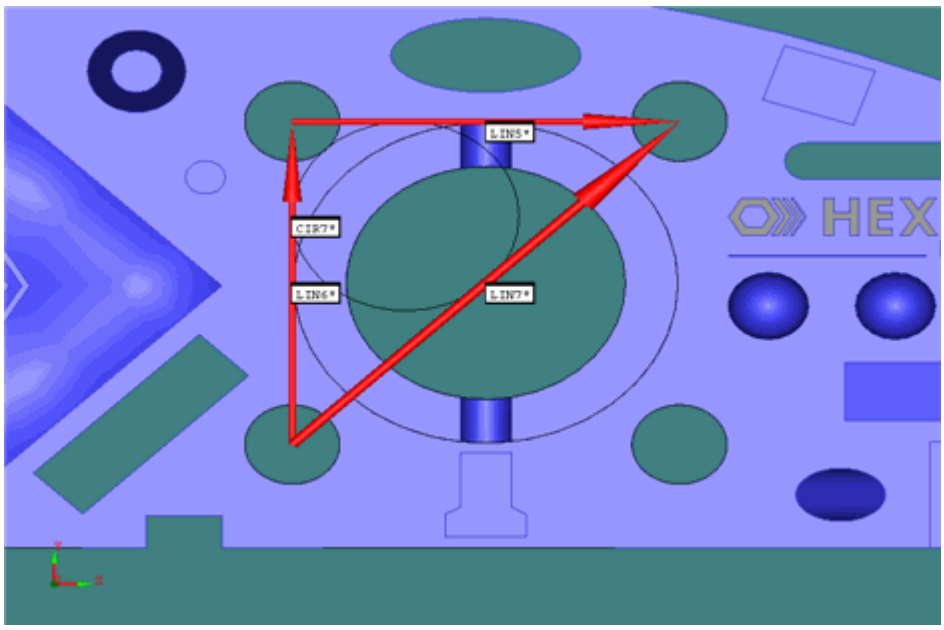
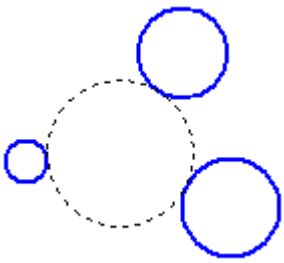
- **Tangent 3 Lines** - This option constructs a circle tangent to three input lines that form a triangle. Select the three input lines, and then click **Create**.

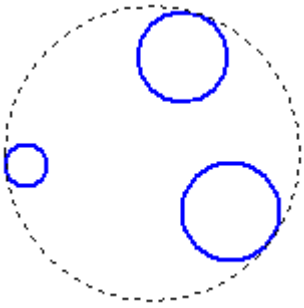
Example of a Circle Feature Constructed Tangent to 3 Lines



- **Tangent 3 Circles** - This option constructs a circle tangent to three input circles. Select the three input circles, and then click **Create**. The tangent circle can either contain all three circles (circumscribed circle) or none of the three (inscribed circle).



Example of an inscribed circle tangent to three input circles



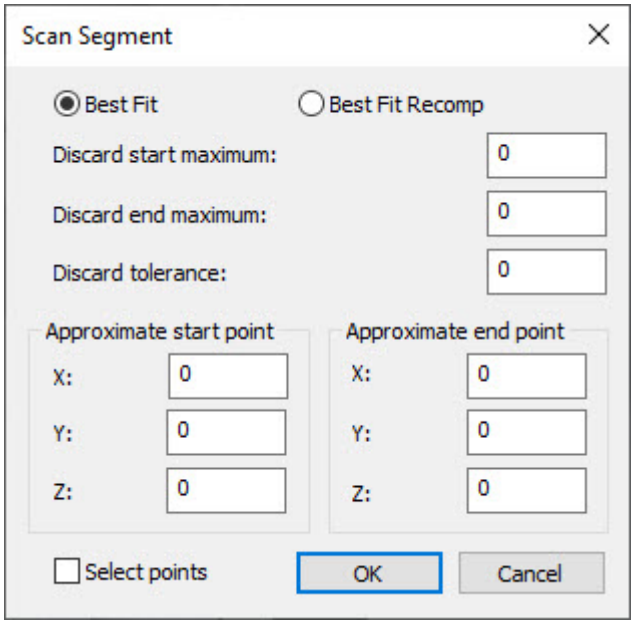
Example of a circumscribed circle tangent to three input circles

Constructing an Arc from Part of a Scan

You can construct a circle from a segment of a Linear Open, Linear Close, or Basic Circle scan. PC-DMIS creates an arc from part of the scan.

To construct a scan segment circle:

1. Open the **Construct Circle** dialog box (**Insert | Feature | Constructed | Circle**).
2. From the **Method** list, select the **Scan Segment** option.
3. Select a previously created Linear Open, Linear Close, or Basic Circle scan.
4. Click the **Segment Data** button to open the **Scan Segment** dialog box.



Scan Segment Dialog Box

5. Select either the **Best Fit** or **BF Recomp** option.
6. Select the portion of the scan used in the construction from this dialog box.
7. Type the number of points to potentially discard in the **Discard Start** and **Discard End Maximum** boxes.
8. Type a distance from the best fit circle into the **Discard Tolerance** box. This tolerance is a form tolerance; it allows you to control what end points PC-DMIS accepts as part of the arc. If the distance from the scan point to the best fit arc is greater than this tolerance value, then PC-DMIS discards the end point.
9. Select the **Select Points** check box to input the **Approximate Start** and **End Points** of the scan, and then click in the Graphic Display window to fill in the X, Y, and Z fields. You can click anywhere in the Graphic Display window; however, PC-DMIS places the point on the scan nearest to where you clicked. You can also type in the point values.
10. Click **OK** to accept the data and close the **Scan Segment** dialog box.
11. Click **Create** to construct the arc from the scan.

The Edit window command line for this option reads:

```
 CONSTR/
CIRCLE,SCAN_SEGMENT,fit_type,feat_1,start_x,start_y,start_z,end_x,end_y,en
```

If you want more than one arc or line from a given scan, you need to add another command for a different section of the scan.

Determining the Data Used to Construct the Arc

The software determines the data used to construct the arc as follows:

- First, the software determines a segment of the scan using a starting point and an ending point within the scan. The software chooses the starting and ending points as the point in the scan nearest `[start_x, start_y, start_z]` and the point nearest `[end_x, end_y, end_z]` respectively.
- The software then discards the points from the start and end points of the scan. The number of points discarded from the start is `discard_start` and from the end is `discard_end` . An arc is then fitted to this set of points.
- Finally, the software adds the starting and ending points back in if they are within the defined tolerance. The arc is then re-fitted once more to the new set of points.

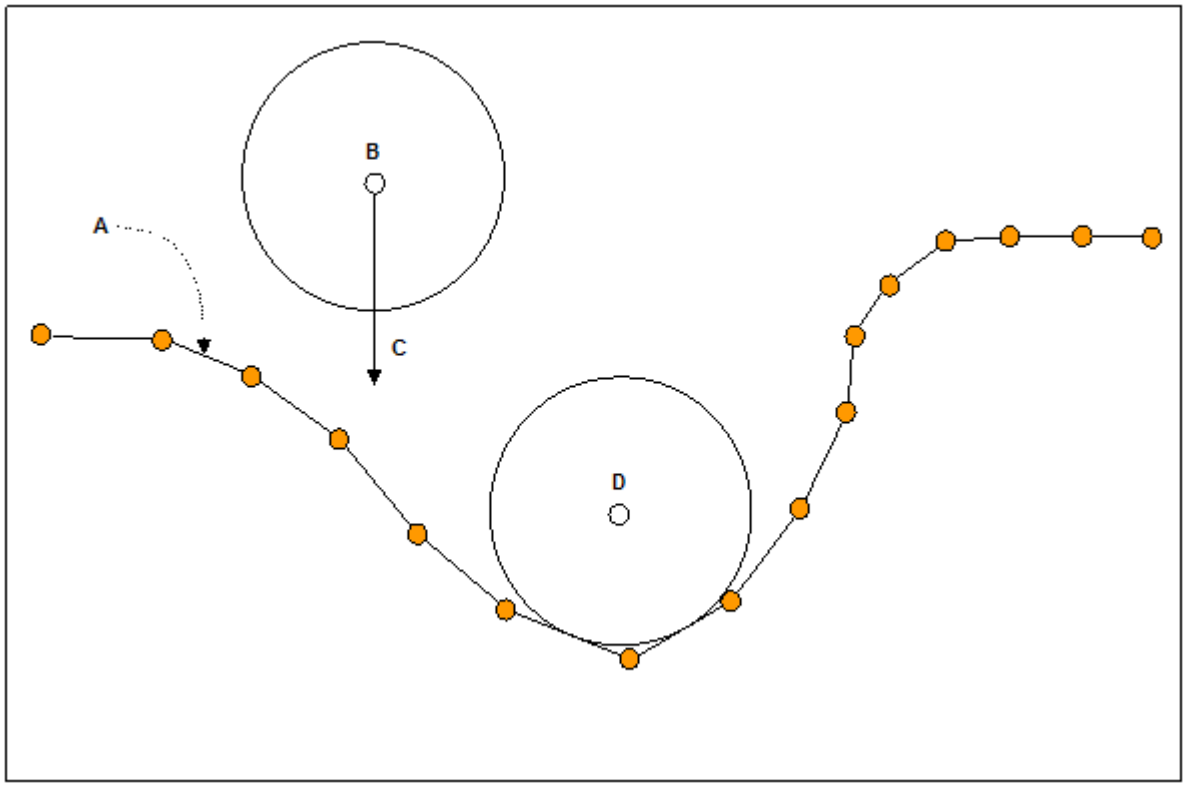
The value of `fit_type` may be `BF` (Best Fit) or `BFRE` (Best Fit Recompensate). This determines whether the software performs a best fit or best fit with recompensation when calculating the arc. For a description of Best Fit and Best Fit Recompensate, see "Constructing a Best Fit or Best Fit Recompensate Circle".

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

Constructing a Circle at a Scan's Minimum Point

This feature lets you construct a 2D circle of a given radius at a minimum point along a linear scan. PC-DMIS finds the minimum point using a starting point and a downward direction vector (as shown below). Think of the downward vector as a gravity vector. In a sense, the circle will be "pulled" in that direction.



A - Scan
B - Start Point
C - Down Vector
D - Final Position
Minimum point of a circle along a scan with a defined downward vector and starting point.

PC-DMIS projects the scan to the current workplane and the circle will lie in a plane parallel to the workplane. The software interprets the scan as a line between consecutive points (piecewise linear). Thus, the circle that the software places at the minimum point along the scan will not "fall" between two consecutive scan points, but instead is constrained to touch a line that connects the two points.

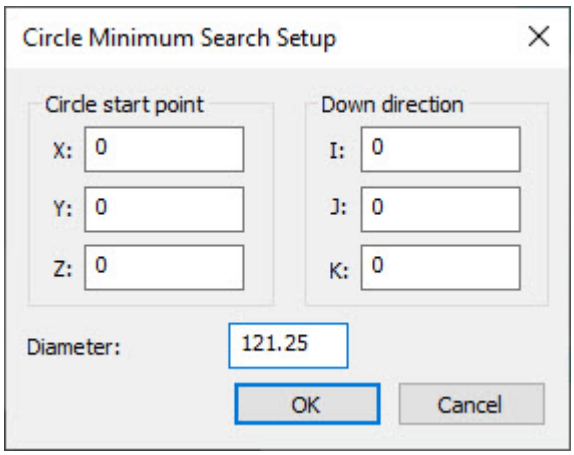
Valid Input Types

The input for this construction *must be a line type scan*. This *excludes* all scans designed to scan a surface, such as Patch, UV, Grid, Multisection, Manual laser, and Cylinder scans.

Construction Procedure

To start this construction:

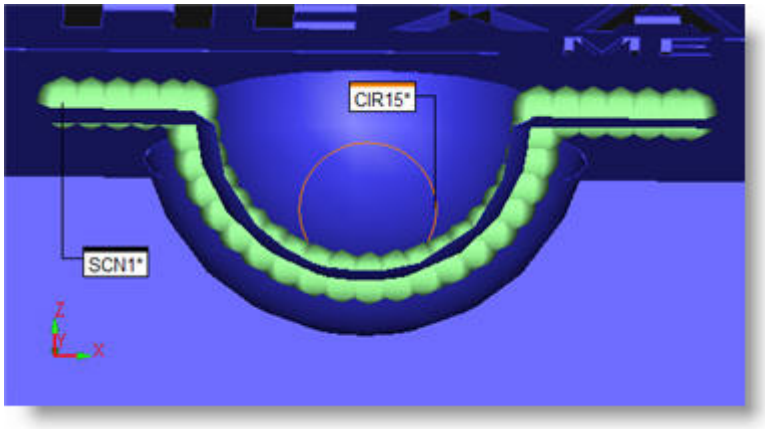
1. Access the **Construct Circle** dialog box (**Insert | Feature | Constructed | Circle**).
2. From the **Method** list, select the **Scan Minimum** option.
3. Select a linear scan from the feature list. You cannot use a surface scan.
4. Click the **Search Setup** button.
5. The **Circle Minimum Search Setup** dialog box appears:



Circle Minimum Search Setup dialog box

6. Define the circle's start point, its down direction, and its diameter.

7. Click **OK** to construct the circle. PC-DMIS constructs the circle and inserts the construction command into the Edit window:

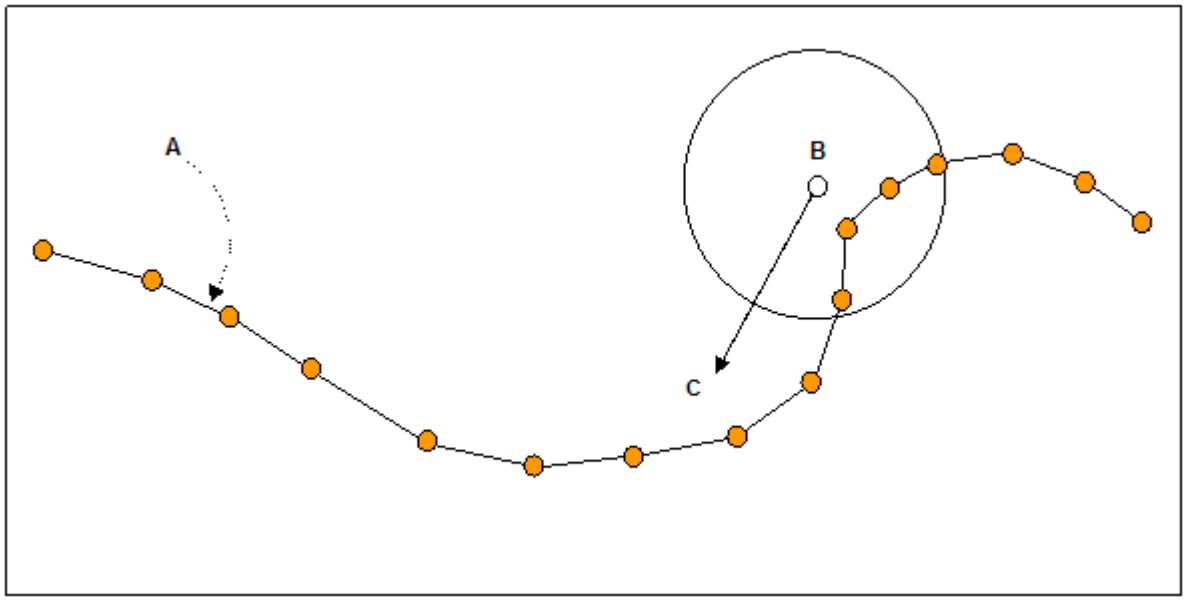


Cutaway view showing a circle (CIR15) constructed at the minimum point on the scan line (SCN1)

Rules for Construction

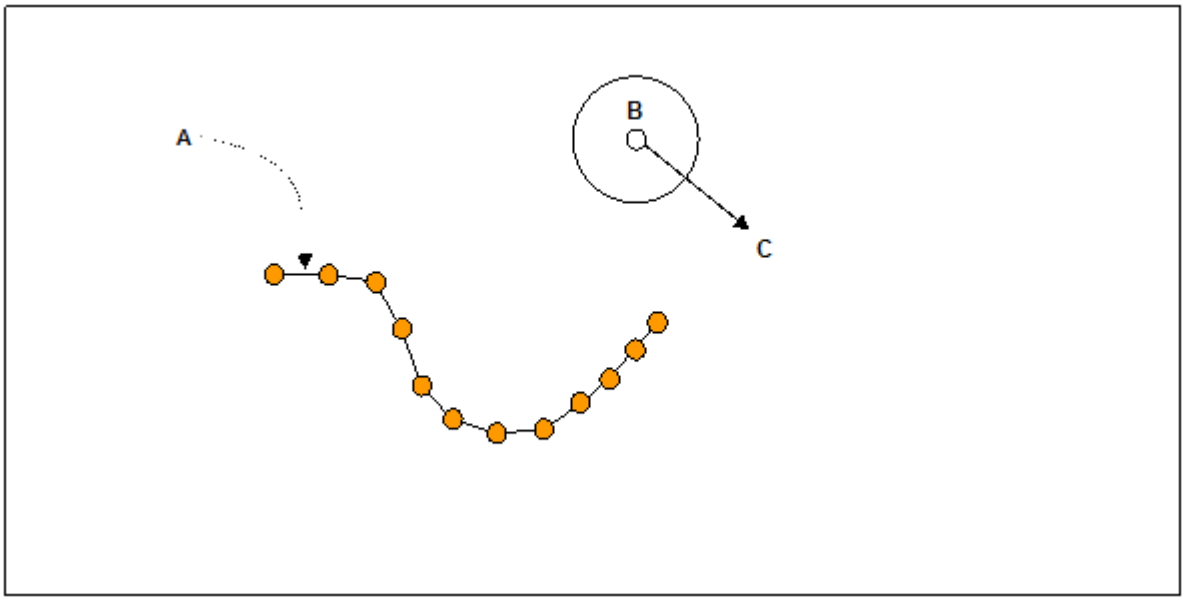
A valid starting point and vector follow two rules:

First, a circle of the given diameter and starting point should not intersect the scan. The image below shows a violation of this rule.



A - Scan
B - Start Point
C - Down Vector
Invalid starting point due to intersection with the scan

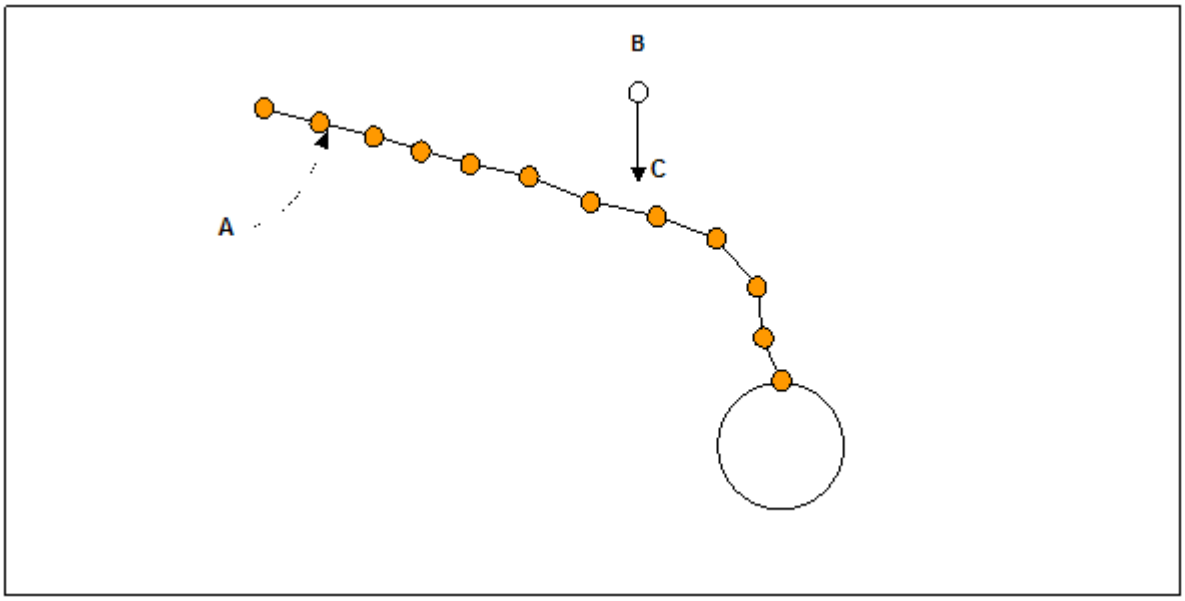
Second, the circle projected from the start point along the down vector must intersect the scan. The image below shows a violation of this rule.



A - Scan
B - Start Point
C - Down Vector
Invalid starting point due to the circle missing the scan

No Local Minimum

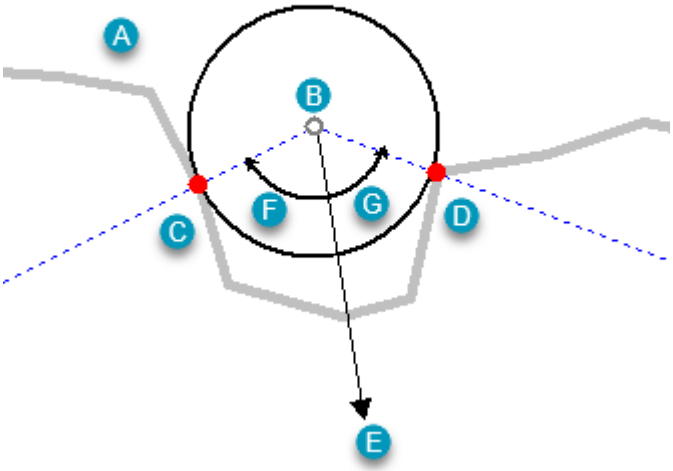
If the scan has no local minimum, or a natural resting place for the circle, then the circle follows the scan to its lowest point while still in contact with the scan.



A - Scan
B - Start Point
C - Down Vector
Example of a scan without a local minimum.

Edit Window Command for a Constructed Scan Minimum Circle

```
CIR1        =FEAT/CIRCLE,RECT,OUT
             THEO/<tx,ty,tz>,<ti,tj,tk>,td,ta1,ta2
             ACTL/<mx,my,mz>,<mi,mj,mk>,md,ma1,ma2
             CONSTR/CIRCLE,SCAN_MINIMUM,Scan ID
             CONTACT POINT/
<tcp1x,tcp1y,tcp1z>,<mcp1x,mcp1y,mcp1z>
             START ANGLE/tca1,mca1
             CONTACT POINT/
<tcp2x,tcp2y,tcp2z>,<mcp2x,mcp2y,mcp2z>
             END ANGLE/tca2,mca2
             TOLERANCE/tol
             START/xSP, xSP, xSP
             DOWN/iDV, iDV, iDV
```



A - Scan line
B - Circle's final position
C - Contact Point 1
D - Contact Point 2
E - Down Vector
F - Contact Angle 1
G - Contact Angle 2

tx,ty,tz
These represent the theoretical circle position.

ti,tj,tk
These represent the theoretical circle vector.

td
This represents the theoretical circle diameter.

ta1
This represents the theoretical angle 1 value.

ta2
This represents the theoretical angle 2 value.

mx,my,mz
These represent the measured circle position.

mi,mj,mk
These represent the measured circle vector.

md
This represents the measured circle diameter.

ma1
This represents the measured angle 1 value.

ma2
This represents the measured angle 2 value.

Scan ID
This represents the id of the scan to be used.

tcp1x,tcp1y,tcp1z
These represent the theoretical XYZ position for contact point 1.

mcp1x,mcp1y,mcp1z
These represent the measured XYZ position for contact point 1.

tca1
This represents the theoretical contact angle 1 value.

mca1
This represents the measured contact angle 1 value.

tcp2x,tcp2y,tcp2z
These represent the measured XYZ position for contact point 2.

mcp2x,mcp2y,mcp2z
These represent the measured XYZ position for contact point 2.

tca2
This represents the theoretical contact angle 2 value.

mca2
This represents the measured contact angle 2 value.

tol
This represents the tolerance value to use when locating the two contact points. PC-DMIS recomputes the contact points by averaging all the points that fall within the tolerance given.

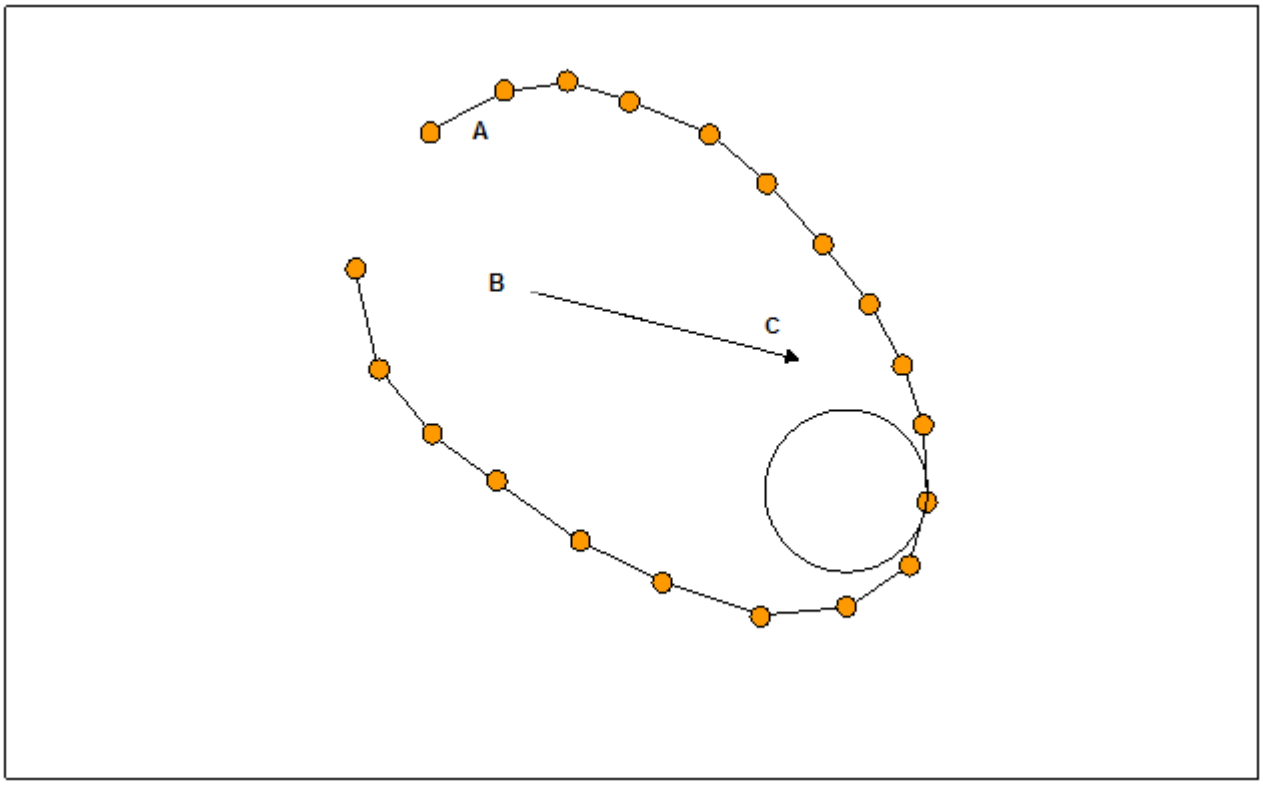
xSP, xSP, xSP
These represent the starting point for finding the minimum.

iDV, iDV, iDV
This represent the downward direction vector.

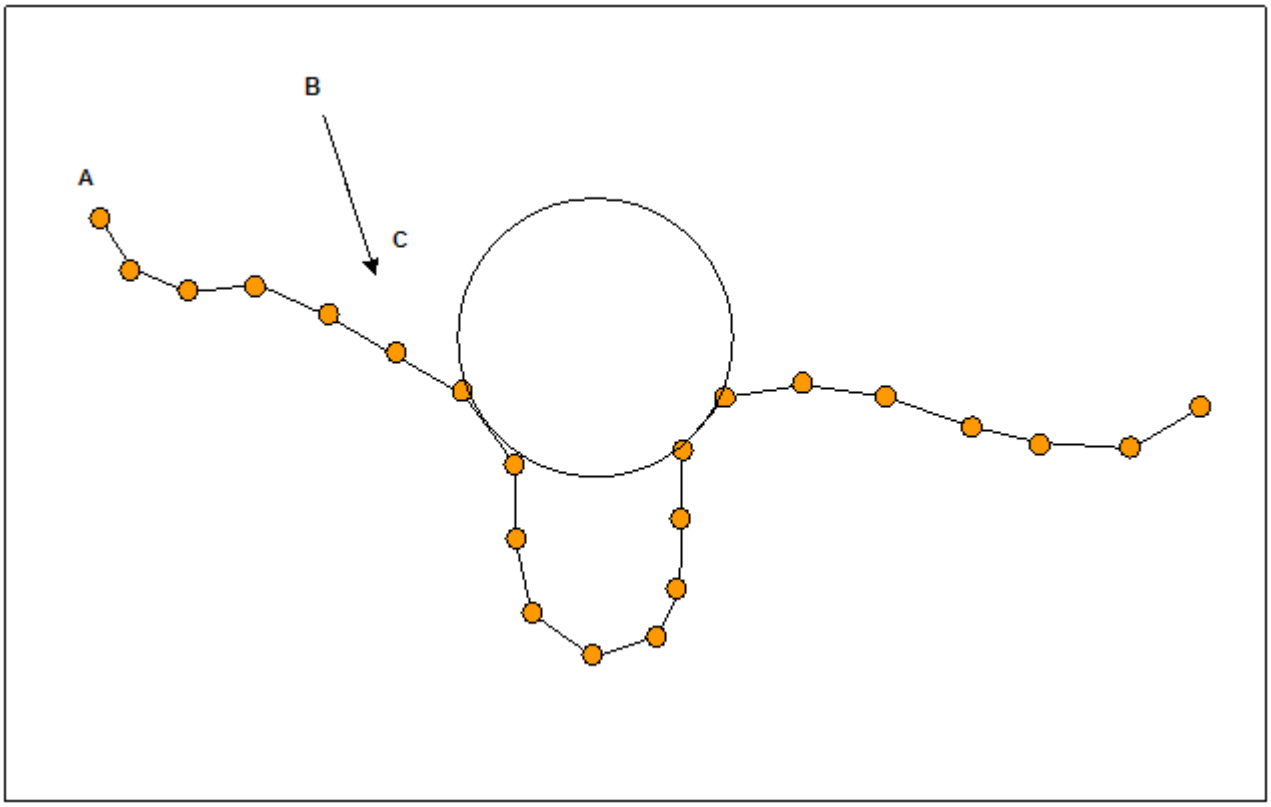
Using Expressions

You can also use expressions within the Edit window to pull information from a Constructed Scan Minimum Circle. See "Accessing Information from a Constructed Scan Minimum Circle" in "Using Expressions and Variables".

Additional Examples



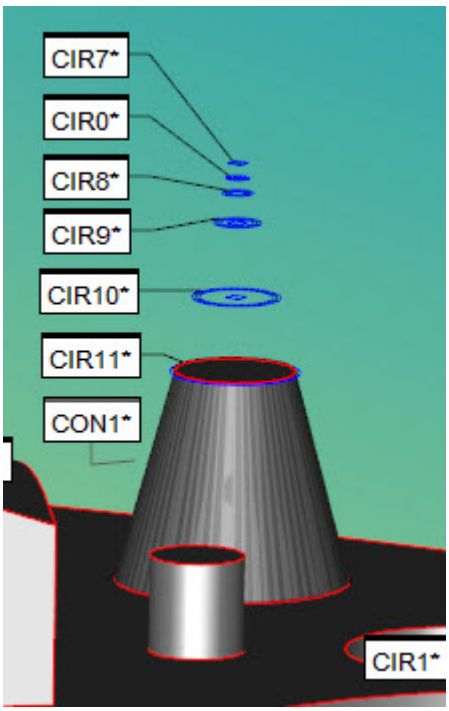
A - Scan
B - Starting Point
C - Down Vector
Starting point inside of a scan



A - Scan
B - Starting Point
C - Down Vector
Scan where not all points are reachable given the circle size

Constructing a Circle from a Cone

You can construct a circle from a cone at a specified diameter of the cone, or you can construct a circle at a given height along that cone from the current alignment plane. A Cone Circle feature that you construct at a given height is sometimes known as a "gage diameter" or "gage point".



Example showing multiple circles created at different heights from the cone input feature (CON1).

Understanding the Height Value

If you construct a circle at a given height, PC-DMIS calculates the circle in this way:

- It creates a plane from the reference point and the reference vector.
- It then creates a parallel offset plane from this plane by the height value. This parallel plane intersects with the cone axis, and the intersection creates the location of the resulting circle feature. The diameter of the circle is the diameter of the cone at that intersection point.

Available reference point (REF_POINT) options:

- CONE_VERTEX
- CONE_START
- CONE_END
- ORIGIN

Available reference vector (REF_VECTOR) options:

- CONE_VECTOR
- WORKPLANE
- ZPLUS
- ZMINUS

- XPLUS
- XMINUS
- YPLUS
- YMINUS

For example, if you use the origin as a reference point and ZPLUS as your reference vector, PC-DMIS creates a plane from the origin point and the ZPLUS vector. Then it creates a parallel plane at the given height value, and where it intersects with the cone, it creates the circle feature. Your Edit window's code might look something like this:

```
CIR2=FEAT/CIRCLE,RECT,OUT

THEO/-67.295,2.595,-7.152,0.0310723,-0.0214397,-0.9992872,29
.411

ACTL/-67.295,2.595,-7.152,0.0310723,-0.0214397,-0.9992872,29
.411
   CONSTR/CIRCLE,CONE,CON2,HEIGHT,5,REF_POINT =
ORIGIN,REF_VECTOR = ZPLUS
```

To construct a Cone Circle:

1. Open the **Construct Circle** dialog box (**Insert | Feature | Constructed | Circle**).
2. From the **Method** list, select the **Cone** option.
3. Select one feature. The type must be a cone.
4. Select either **DIAMETER** or **HEIGHT** from the **Type** list.
5. Type a value for the diameter or height into the **Value** box.
6. If you selected **Height**:
    - Select a reference point from the **Point** list.
    - Select a reference vector from the **Vector** list.
7. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/CIRCLE,CONE,DIAMETER,feat_1
```

or

```
CONSTR/
CIRCLE,CONE,HEIGHT,value,REF_POINT=point,REF_VECTOR=vector,f
eat_1
```

Constructing a Circle from a Sphere

You can construct a circle from a sphere at a specified diameter of the sphere, or you can construct it at a given height from the sphere centroid.

Valid input feature type

Sphere

Valid construct type

Diameter or Height

Available reference point (REF_POINT) options:

- SPHERE_CENTROID

Available reference vector (REF_VECTOR) options:

- SPHERE_VECTOR
- WORKPLANE
- ZPLUS
- XPLUS
- YPLUS
- ZMINUS
- XMINUS
- YMINUS

Construct type input value overview

When you use a Diameter construct type, the input value is the diameter of the resultant sphere circle.

PC-DMIS uses the input value as the diameter of the resolved circle. It then calculates the centroid along the reference vector from the reference point that fits the diameter so that it is equal to the input value.

If you use a Height construct type, the input value represents the distance along the reference vector from the reference point, which is the sphere centroid.

PC-DMIS uses the value points as the offset from the reference point along the reference vector. The resultant centroid and diameter are identical after the offset is applied.

To Construct a Sphere Circle

1. Open the **Construct Circle** dialog box (**Insert | Feature | Constructed | Circle**).
2. From the **Method** list, select the **Sphere** option.
3. Select one feature. The type must be a sphere.
4. Select either **DIAMETER** or **HEIGHT** from the **Type** drop-down list.
5. Type a value for the diameter or height into the **Value** box.
6. If you selected **Height**:
    - Select a reference point from the **Point** list.
    - Select a reference vector from the **Vector** list.
7. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/CIRCLE,SPHERE,feat_1,DIAMETER,REF_VECTOR = ZPLUS
```

or

```
CONSTR/CIRCLE,SPHERE,feat_1,HEIGHT,0,REF_POINT =
SPHERE_CENTROID,REF_VECTOR = vector
```

Constructing a Circle from a Cylinder

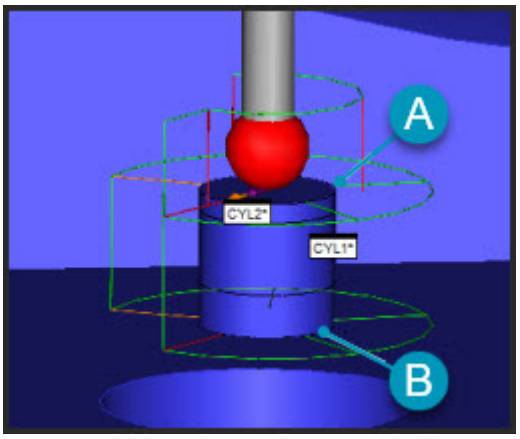
Similar to the cone and sphere circle constructions, this type of construction creates a circle from a cylinder at a height (or distance) along the defined vector. The resulting circle feature will have the same diameter as the reference cylinder. This type of construction takes three inputs: a height **Value**, a reference **Point**, and a **Vector**.

Value - This box lets you type the height value. PC-DMIS constructs the circle at this distance from the selected reference point and along the selected vector. A positive value uses the same direction as the vector. A negative value will use the opposite direction along that vector.

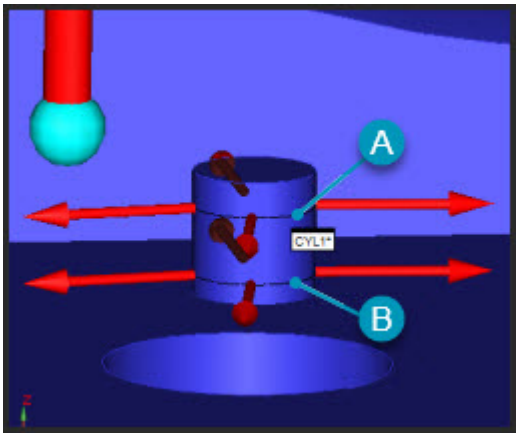
Point - This list lets you define a reference point from which PC-DMIS constructs the circle. It has these options:

- CYLINDER_START - The start location of the cylinder. This point is located at the centroid of the circle defined from the first level of hits.
- CYLINDER_END - The end location of the cylinder. This point is located at the centroid of the circle defined from the last level of hits.
- ORIGIN - The origin of your coordinate system.

These images show some sample start and end locations for different cylinder types:



***A** - A sample CYLINDER_START location for an Auto Cylinder*
***B** - A sample CYLINDER_END location for an Auto Cylinder*



***A** - A sample CYLINDER_START location for a Measured Cylinder*
***B** - A sample CYLINDER_END location for a Measured Cylinder*

Vector - This defines the vector of the constructed circle and the vector along which the height value is applied. Eight reference vectors are available: CYLINDER_VECTOR, WORKPLANE, ZPLUS, ZMINUS, XPLUS, XMINUS, YPLUS, and YMINUS.

To construct a cylinder circle:

1. Access the **Construct Circle** dialog box (**Insert | Feature | Constructed | Circle**).
2. From the **Method** list, select the **Cylinder** option.
3. Select a single cylinder feature.

4. Select the reference point from the **Point** list.
5. Select a reference vector from the **Vector** list. The direction on which the cross section is taken is chosen from the **Vector** list.
6. Type a distance into the **Value** box.
7. Click the **Create** button.

The Edit window command line for this option would read:
`CONSTR/CIRCLE,CYLINDER,feat1,HEIGHT,value,REF_POINT = point,REF_VECTOR = vector`

Constructing an Extracted Circle

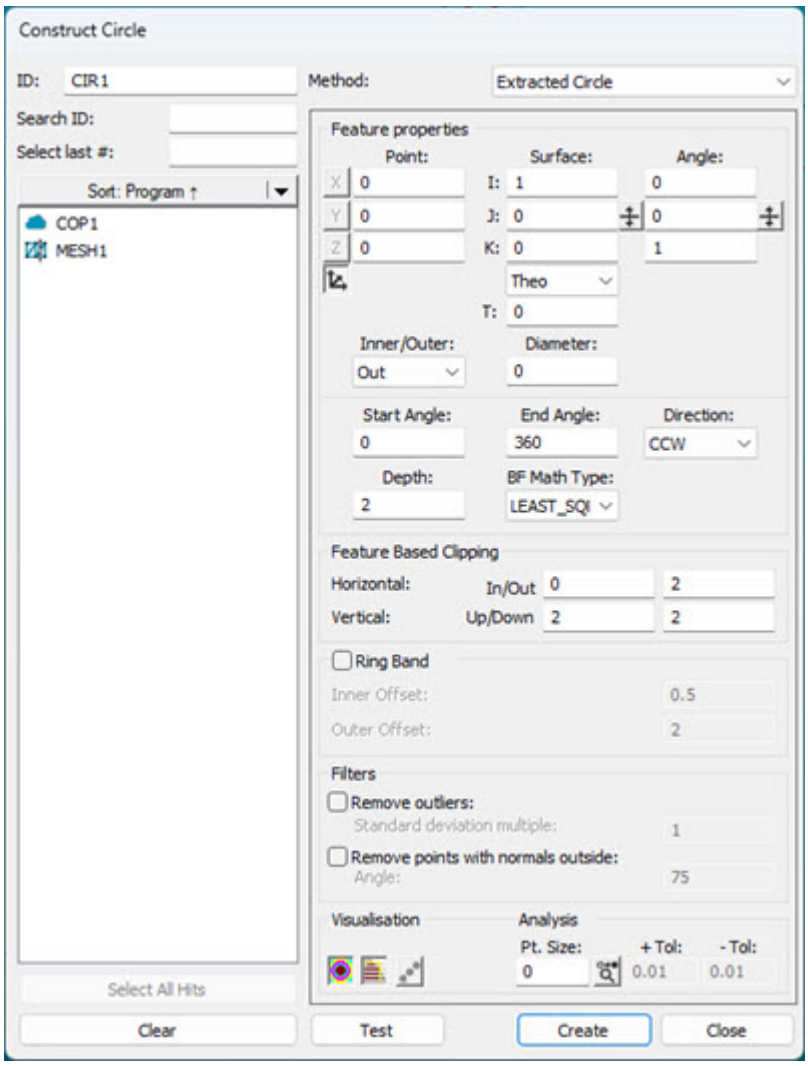
For details on extracting Auto features from a Mesh, see the "Extracting Auto Features from a Mesh" topic in the PC-DMIS Laser documentation.

For details on extracting Auto features from a Pointcloud (COP), see the "Extracting Auto Features from Pointclouds" topic in the PC-DMIS Laser documentation.

You can construct a circle that is extracted from a scanned pointcloud (COP) or mesh.

To do this, follow these steps:

1. Ensure that your measurement routine has a Pointcloud (COP) or Mesh command.
2. Open the **Construct Circle** dialog box (**Insert | Feature | Constructed | Circle**) or from the **Constructed Feature** toolbar (**View | Toolbars | Constructed Features**).



Construct Circle Dialog Box - Extracted Circle Option

3. From the **Method** list, select the **Extracted Circle** option.

4. From the **Reference** area, select the COP or Mesh you want to use to extract the circle from.

5. Click on the CAD model or data to define the nominal or, in the **Point** section of the **Feature properties** area, type the nominal location in the **X**, **Y**, and **Z** boxes.

6. From the **Surface** section of the **Feature properties** area, define the surface vector in the **I**, **J**, and **K** boxes. You can use the **Material Thickness Type** list and the **T** box below it to type in a material thickness value. For details, see the "Use Thickness" topic in this documentation.

   You can use these controls to perform the associated functions:

   Flip Vectors

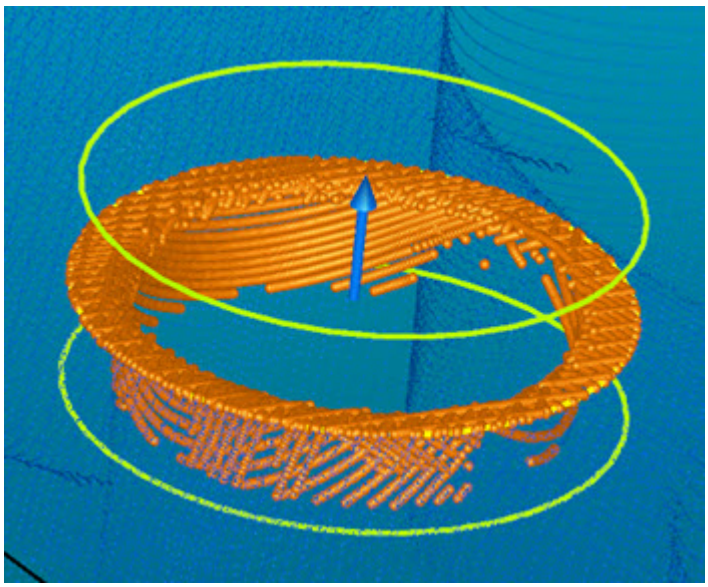
   Polar/Cartesian

For details on these controls, see the appropriate topic in the "Feature Properties Area" section of the "Creating Auto Features" chapter of the PC-DMIS Core documentation.

7. Select whether the extracted circle is an inner or outer circle type from the **Inner/ Outer** list.

8. Enter the diameter of the circle in the **Diameter** box.

   PC-DMIS draws the extraction zone and centers it around the XYZ location point. This box defines the cylinder zone that PC-DMIS uses for the extracted circle. The yellow cylinder is the surface. The yellow cylinder is also the horizontal zone and the green cylinder is the vertical zone. The orange points are the candidate points that the extraction considers.



Example of an extracted circle showing the candidate points.

9. From the **Feature Based Clipping** area, define the **Horizontal In/Out** and **Horizontal** values, and the **Vertical Up/Down** and **Vertical** values. This sets the dimensions for the green extraction zone region. Consider part variability when you define the extraction zone.

10. If you want to define the Ring Band offsets, click the **Ring Band** check box and type the **Inner Offset** and **Outer Offset** values. For details on how the **Ring Band** works, see the "Ring Band Parameters" topic in the PC-DMIS Laser documentation.

11. If you want to filter out any outlier points, from the **Filters** area, select the **Remove outliers** check box and define the **Standard deviation multiple** to determine which points PC-DMIS excludes as outliers.

12. If you want to filter out any points that are outside of a maximum incidence angle, from the **Filters** area, select the **Remove points with normals outside** check box and type the value in the **Angle** (Max Incidence Angle) box.

The Max Incidence Angle filter was initially designed to compare the incidence direction of the laser (which is roughly the laser sensor orientation) to the estimated normal of the segregated points. For 3D laser features (Laser Auto Cone, Cylinder, Plane, Sphere, Surface Point and Constructed Extracted Cone, Cylinder, Plane, Sphere, Surface Point), the filter now compares the estimated normal of the pointcloud point to the nominal normal of the feature, which greatly improves the results. 2D laser features remain unchanged, using the legacy incidence angle filter method.

For details on the **Filters** area, see the "Filters" topic in the PC-DMIS Laser documentation.

13. In the **Visualisation** section, PC-DMIS provides these options to perform the described function:

    Visualisation Tools On/Off - This button toggles the display of the colored visualisation tools. For more information, see "Understanding the Visualisation Tools".

    Show/Hide segregated points - This button toggles the display of the points that the software passes to the feature extractor engine based on the current settings.

    Show/Hide measured points - This button toggles the display of the measured points. It remains greyed out until you click **Test** or **Create**. For more information, see the "Show Measured Points" topic in the PC-DMIS Core documentation.

    
    - The **Analysis** area allows you to determine how each measured hit/point is displayed. For more information, see the “Analysis Area” topic in the PC-DMIS Core documentation.

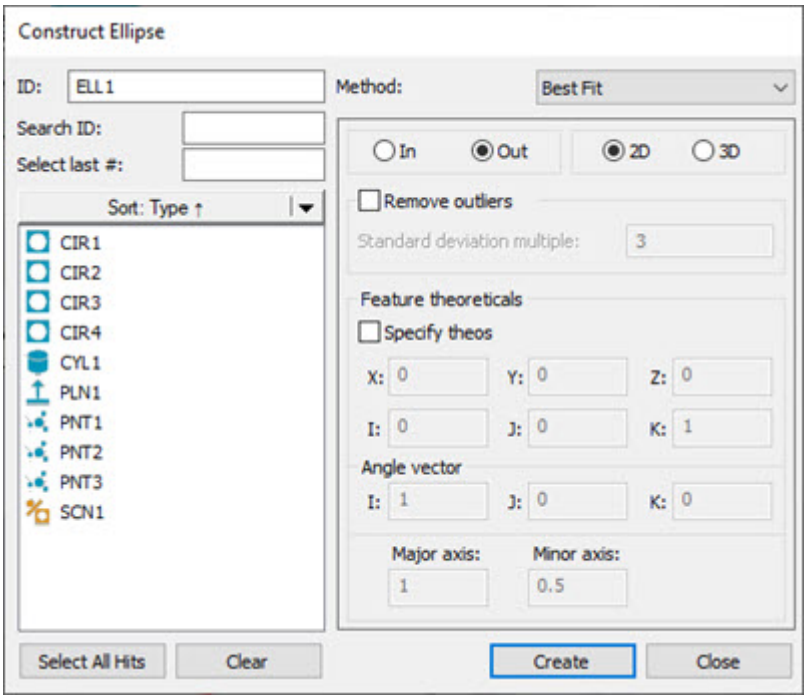
14. Click the **Test** button to test a feature's creation and preview its dimensional data before you create it. PC-DMIS performs a measurement using the current parameters. You can change the parameters and click **Test** repeatedly until you have an acceptable measurement. Then, when you click **Create**, the software converts the temporary feature into a normal feature in the measurement routine.

15. Click the **Create** button. Based on the parameters that you specified in the dialog box, PC-DMIS does an analysis of the candidate points and returns (or extracts) each measured point and projects them to the surface.

    PC-DMIS creates the command in the Edit window:

```
CIR1=FEAT/CIRCLE,CARTESIAN,INNER,LEAST_SQR
   THEO/<25.504,15.504,0>,<0,0,1>,8.2
   ACTL/<25.504,15.504,0>,<0,0,1>,1.768
   ANGLE VEC=<1,0,0>
   DEPTH=0,START ANG=0,END ANG=360
   DIRECTION=CCW
   THEO_THICKNESS,0,
   HORIZONTAL CLIPPING=1,VERTICAL CLIPPING=2,INNER
HORIZONTAL CLIPPING=0
   USE OUTLIER REMOVAL=YES,0,
   REMOVE POINTS WITH NORMALS OUTSIDE=YES,0,
   RINGBAND=ON,INNER OFFSET=0,OUTER OFFSET=0
   CONSTR/CIRCLE,EXTRACTED_CIRCLE,REF=COP1
```

Constructing an Ellipse Feature



Construct Ellipse Dialog Box

There are several ways to construct an ellipse using PC-DMIS. The following table lists the various types of constructed ellipses, along with their necessary inputs. Some features may require no inputs while others may require three inputs or more. The term "Any" in the following table indicates that the construction can take any type of feature as input for construction. PC-DMIS allows you to select the features in any order.

Construct Feature Type	Symbol in the Edit Window	Number of Input Features	Feature #1:	Feature #2:	Comments
Auto Ellipse	-	-	-	-	See "Auto Ellipse Construction".
Best fit Ellipse	BF	At least 4 inputs are needed or a scan or set with at least 4 points.	-	-	Constructs a best fit ellipse using the given inputs. See the Note below for recommended inputs.
Best fit with Recompensate Ellipse	BFRE	At least 4 inputs are needed, with one input being a point or a scan or set with at least 4 points.	-	-	Constructs a best fit ellipse using the given inputs. See the Note below for recommended inputs.
Intersection	INT	2	Cylinder	Plane	Constructs an ellipse at the intersection of the input features.
Cast Ellipse	CAST	1	Any	-	Constructs an ellipse at the centroid of the input feature.
Project Ellipse	PROJ	1 or 2	Any	Plane	One input feature will project the ellipse to the workplane.
Reverse Ellipse	REV	1	Ellipse	-	Constructs an ellipse with a reversed vector.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

If you select inappropriate feature types, PC-DMIS displays this message on the Status bar:

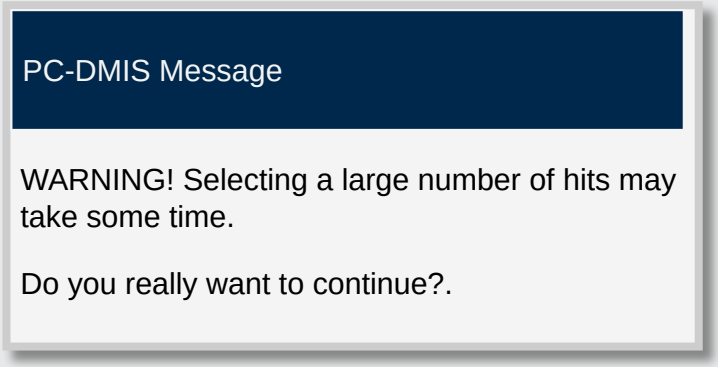
"Cannot construct [feature]. Combination of input features not accepted."

To construct an ellipse:

1. Open the **Construct Ellipse** dialog box (**Insert | Feature | Constructed | Ellipse**).
2. From the **Method** list, select the method of the constructed ellipse. The available options are:
    - Auto
    - Best Fit
    - BF Recomp
    - Intersection
    - Cast
    - Projection
    - Reverse

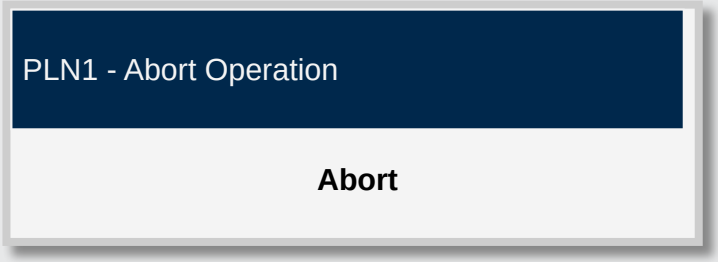
If you select the **Best Fit** or the **BF Recomp** (Best Fit Recomp) method for this feature, PC-DMIS allows you to click the **Select All Hits** button to create the construction from the individual hits of the input features instead of their centroids.

If there are a large number of points involved (about 10,000 or more), PC-DMIS shows a message asking if you are sure you want to proceed as this may take some time to complete.



Click **Yes** to proceed, click **No** to abort the process. You can select the **Don't ask me again** check box to prevent this message from recurring.

If you click **Yes**, another message is shown similar to the one shown below to let you know that PC-DMIS is generating the features from the hit points.

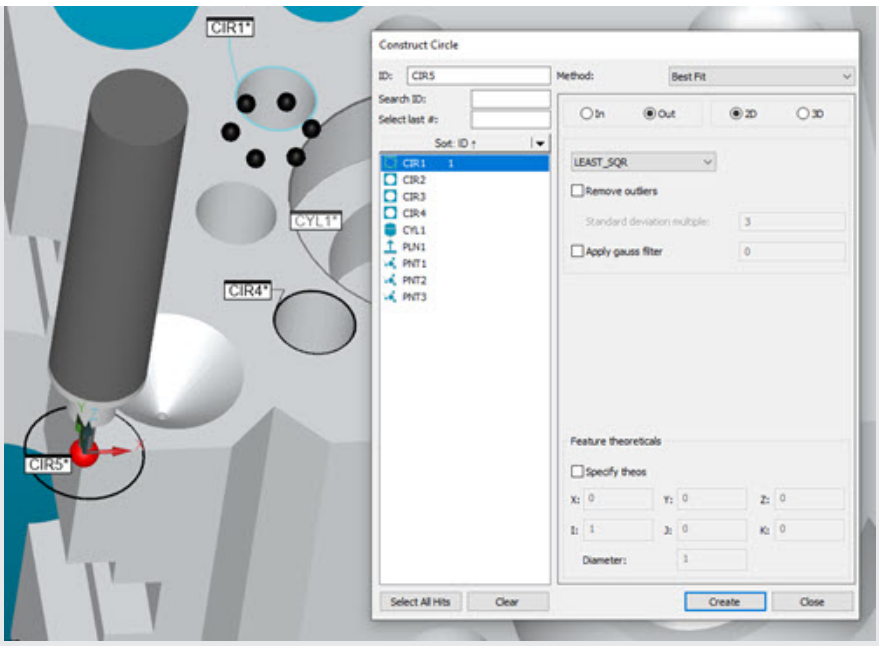


Once all the constructed features are created, the message disappears.

You can click the **Abort** button at any time to stop the process. Any features created up to this point are listed in the **Feature list** area of the dialog box.

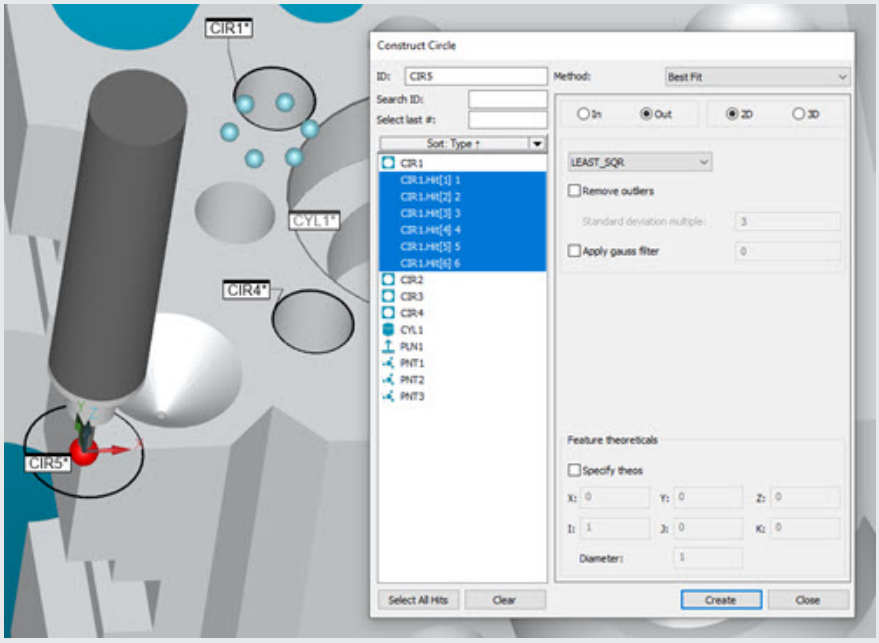
To create constructed features from the individual hits of the input features, do this:

1. From the **Feature list**, select the feature or features that you want to use to create the constructed feature.



Example showing a selected feature prior to clicking the Select All Hits button.

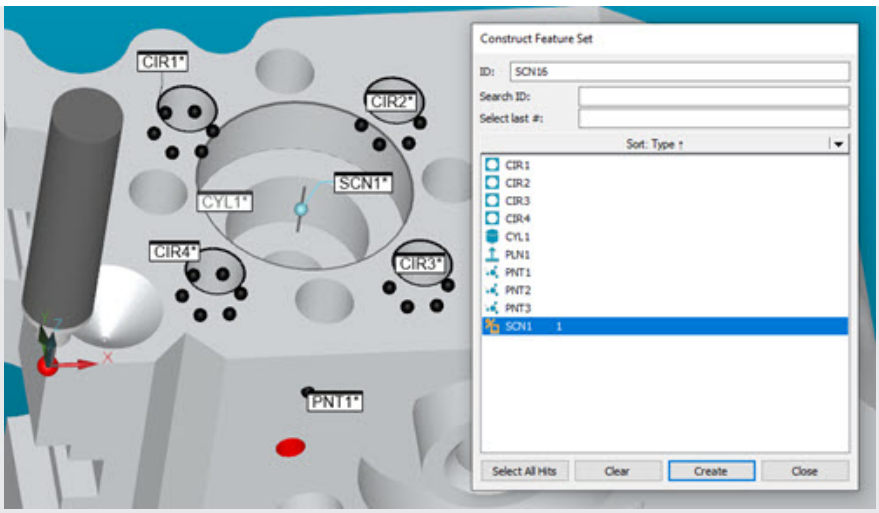
2. Click the **Select All Hits** button to display all the components that comprise the selected feature or features.



Display of items that make up the selected feature are highlighted in the dialog box and in the Graphic Display window.

PC-DMIS displays and highlights all the components of the selected feature (or features) in the **Feature list** are of the dialog box. You can select or de-select any of the features or feature components shown in the list to include or exclude them.

3. Click the **Create** button to create the Constructed feature based on the final features and feature components that you selected.



Constructed feature created based on the selected items from the Feature list.

3. From the **Feature** list, use the table above to select the features based on the selected method.
4. Select the **In** or **Out** option. For details, see the "In / Out Ellipse" topic in this documentation.
5. Some ellipse types have additional options or items that appear in the dialog box. Select or use these options as needed.
6. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
7. Click the **Create** button.

The Edit window command line for a sample Ellipse Construction would read:

```
 feature_name=FEAT/Ellipse,TOG1,TOG4
THEO/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,major diam,minor
diam,i angle vec, j angle vec, k angle vec
ACTL/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,major diam,minor
diam,i angle vec,j angle vec,k angle vec
CONSTR/TOG2,TOG3,TOG5,feat_1,feat_2, ...
```

The actual Edit report displays in all capital letters.

Auto is the default method of construction. For information on the Auto method, see "Auto Ellipse Construction".

TOG1= POLR or RECT

TOG2 = ELLIPSE

TOG3 = BF / BFRE / CAST / INT / PROJ / REV

TOG4 = IN / OUT

TOG5 = 2D / 3D (This appears only if TOG3 reads BF or BFRE)

The first three lines in the Edit window will be the same for constructed ellipses. The fourth line will be slightly different according to the type of feature you are constructing. You can switch between the different types of ellipses by placing the cursor on *TOG3* and pressing F7 and F8. (See "Command Mode Keyboard Functions" in the "Using the Edit Window" chapter.)

When two or more features are involved, PC-DMIS automatically determines the necessary order of the input features. This improves the accuracy of the measurement process.

The following topics describe the available options for constructing an ellipse:

In / Out Ellipse

The **In** and **Out** options tell PC-DMIS whether to construct the ellipse as an internal or an external ellipse.

- If you select **In**, PC-DMIS constructs the ellipse as an internal ellipse.
- If you select **Out**, PC-DMIS constructs the ellipse as an external ellipse or pin.

2D / 3D Ellipse

The **2D** and **3D** options specify whether PC-DMIS constructs the feature as a 2D or 3D ellipse. These options become available when you select the **Best Fit** or **BF Recomp** option.

- If you select **2D**, PC-DMIS constructs the ellipse, projecting it onto the workplane.
- If you select **3D**, PC-DMIS constructs a best fit plane from the inputs. PC-DMIS then projects these inputs onto the plane and creates a constructed ellipse from the projected points.

Auto Ellipse Construction

The "Input Feature List" table indicates the type of ellipse that you can construct based on the selected features when you choose the **Auto** option from the **Method** list. The order of the selected features is not important. If you select an incorrect input feature or features, PC-DMIS shows an error message and will not construct the indicated feature type.

To allow PC-DMIS to automatically determine the best method of construction:

1. Open the **Construct Ellipse** dialog box (**Insert | Feature | Constructed | Ellipse**).
2. From the **Method** list, select the **Auto** option.
3. From the **Feature** list, select the desired feature or features based on the "Input Feature List" table below.
4. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
5. Click the **Create** button.

The following lists the constructed features you can create based on the input feature(s) you select:

Input Feature List

Input Feature(s)	Constructs
Any One Set =	Best Fit Ellipse
Any One Ellipse =	Reverse Ellipse
Any One Feature (except Ellipse or Set) =	Cast Ellipse
Plane + Any Feature =	Projected Ellipse
Set + Set =	Best Fit Ellipse
Three or more Features =	Best Fit Ellipse

Constructing a Best Fit or Best Fit Recompensate Ellipse

You can construct a "best fit" ellipse from three or more features. The ellipse lies in the current workplane. PC-DMIS computes a *least squares* ellipse, one for which PC-DMIS minimizes the average squared distance from the data points to the ellipse.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

To construct a Best Fit Ellipse or a Best Fit Recompensate Ellipse:

1. Open the **Construct Ellipse** dialog box (**Insert | Feature | Constructed | Ellipse**).
2. From the **Method** list, select either the **Best Fit** or **BF Recomp** option.
3. From the **Feature** list, select at least four features, a scan, or a set comprised of at least four points.
4. Select the **In** or **Out** option. For details, see the "In / Out Ellipse" topic in this documentation.
5. Select the **2D** or **3D** option. For details, see the "2D / 3D Ellipse" topic in this documentation.
6. Select the **Remove outliers** check box if you want to remove outliers based on the distance from the best fit feature. For details, see the "Remove Outliers / Standard Deviation Multiple for a Constructed Ellipse" topic in this documentation.
7. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
8. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/ELLIPSE,BF, feat_1,feat_2,feat_3...
```

(Uses the actual measured points for construction.)

or

```
CONSTR/ELLIPSE,BFRE, feat_1,feat_2,feat_3...
```

(Uses the center of the probe for measurement.)

Remove Outliers / Standard Deviation Multiple for a Constructed Ellipse

For a best fit (BF) or best fit recompensate (BFRE) ellipse, you can choose to remove outliers based on the distance from the best fit feature. This allows the removal of anomalies that arise in the measurement process.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

PC-DMIS first fits an ellipse to the data and then determines which points are outliers based on the standard deviation multiple. It then does the following:

- Recalculates the best fit ellipse with those outliers removed.
- Checks for outliers again.
- Recalculates the best fit ellipse.
- Continues repeating this process until no more outliers exist or until PC-DMIS cannot compute the ellipse (PC-DMIS can't compute the ellipse if there are fewer than 4 data points).

Constructing an Intersect Ellipse

You can construct an ellipse from the intersection of a non-parallel plane and cylinder.

To construct an intersect ellipse:

1. Open the **Construct Ellipse** dialog box (**Insert | Feature | Constructed | Ellipse**).
2. From the **Method** list, select the **Intersect** option.
3. From the **Feature** list, select the first feature; it can be either a cylinder or a plane.
4. From the **Feature** list, select the second feature.
    - If you selected a cylinder as the first feature, then this must be a plane.
    - If you selected a plane as the first feature, then this must be a cylinder.

5. Select the **In** or **Out** option. For details, see the "In / Out Ellipse" topic in this documentation.

6. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.

7. Click the **Create** button. PC-DMIS constructs the ellipse at the intersection of the two features. The constructed ellipse will have the plane's normal vector.

The Edit window command block for a sample ellipse would look something like this:

```
ID      =FEAT/ELLIPSE,CARTESIAN,OUT,NO
         THEO/X,Y,Z,I,J,K
         ACTL/X,Y,Z,I,J,K
         CONSTR/ELLIPSE,INT,feat1,feat2
```

Constructing a Cast Ellipse

You can construct an ellipse by changing any given feature into an ellipse. PC-DMIS constructs the ellipse at the centroid of the input feature. If you use a sheet metal point, the major diameter is the probe diameter. For some sheet metal features (such as slots and notches), PC-DMIS uses the width as the major diameter. For features that do not have a width (lines, points, etc.), PC-DMIS uses a value that is four times the probe diameter. The minor diameter is the length of the input feature. For features that do not have a length (points, circles, etc.) PC-DMIS uses a default length of 1.

You can modify the major and minor diameters of the ellipse; this changes the ellipse from DEPENDENT to INDEPENDENT. This means that when you execute the ellipse, the major and minor diameters do not change based on the input feature but are independent of the input feature, while the position and vector remain dependent on the input feature. This allows you to have control over the diameters in cases where the input feature doesn’t really have a diameter, such as a point. The DEPENDENT/INDEPENDENT field is a toggle field you may change.

PC-DMIS uses these diameter values for all calculations instead of the default diameter values described above.

To construct a cast ellipse:

1. Open the **Construct Ellipse** dialog box (**Insert | Feature | Constructed | Ellipse**).

2. From the **Method** list, select the **Cast** option.

3. From the **Feature** list, select at least one feature of any type.

4. Select the **In** or **Out** option. For details, see the "In / Out Ellipse" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/ELLIPSE,CAST, feat_1 ,(DEPENDENT | INDEPENDENT)
```

Constructing a Projected Ellipse

You can project an ellipse onto a plane. PC-DMIS projects the centroid of the given feature onto the plane, creating an ellipse. If there is only one input feature, the projection is to the current workplane. The major diameter of the projected ellipse is the width of the projected feature, or the probe's diameter (for features without a defined width). The minor diameter is the length of the input feature, or unit 1 (for features without a length defined).

To construct a projected ellipse:

1. Open the **Construct Ellipse** dialog box (**Insert | Feature | Constructed | Ellipse**).
2. From the **Method** list, select the **Projection** option.
3. From the **Feature** list, select a feature of any type.

   You can also select a second feature. It must be a plane.

4. Select the **In** or **Out** option. For details, see the "In / Out Ellipse" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/ELLIPSE,PROJ, feat_1,(feat_2)
```

Changing the Direction of an Ellipse

You can construct an ellipse with a reversed vector.

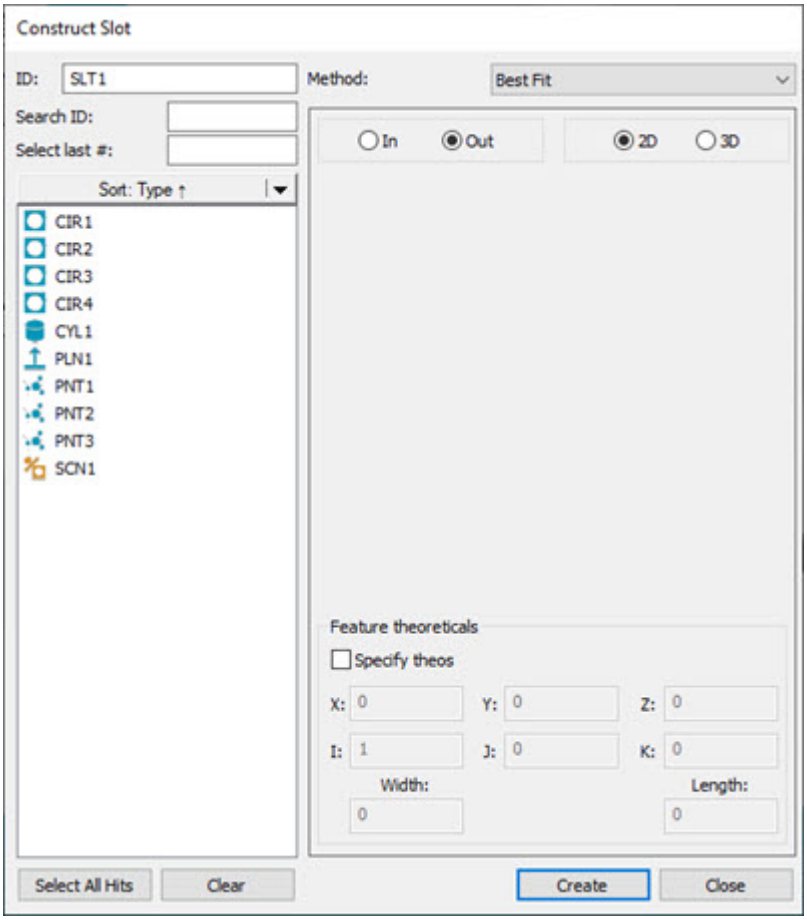
To change the direction of a ellipse:

1. Open the **Construct Ellipse** dialog box (**Insert | Feature | Constructed | Ellipse**).
2. From the **Method** list, select the **Reverse** option.
3. From the **Feature** list, select one feature. It must be an ellipse.
4. Select the **In** or **Out** option. For details, see the "In / Out Ellipse" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/ELLIPSE,REV,feat_1
```

Constructing a Round Slot Feature



Construct Slot Dialog Box

There are two round slot types in PC-DMIS:

- A round slot created from two circles (**Circles** option)
- A round slot created from four or more inputs (**Best Fit** or **BF Recomp** option).

The table below shows the inputs for the slot and the editor definitions.

Construct Feature Type	Edit Window Symbol	Number of Required Input Features	Primary Feature	Secondary Feature	Comments
Circles	CIRCLES	2	Circle	Circle	Constructs a slot in the plane of the first circle from center to center.
Best Fit Round Slot	BF	4 or more	-	-	Constructs a Best Fit slot using the given inputs. See the Note below for recommended inputs.
Best Fit Recompensate Round Slot	BFRE	4 or more	-	-	Constructs a Best Fit Recompensate slot using the given inputs. See the Note below for recommended inputs.
Projected Round Slot	PROJ	2	Slot	Plane	Constructs a Projected Round Slot onto the plane.
Cast Round Slot	CAST	1	Any	-	Constructs a round slot at the centroid of the input feature.
Extracted Round Slot	EXTRACTED_ROUND_SLOT	1	COP or Mesh	-	Constructs an extracted round slot from the COP or Mesh object at the specified diameter or height.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

If you select inappropriate feature types, PC-DMIS displays this message on the Status bar:

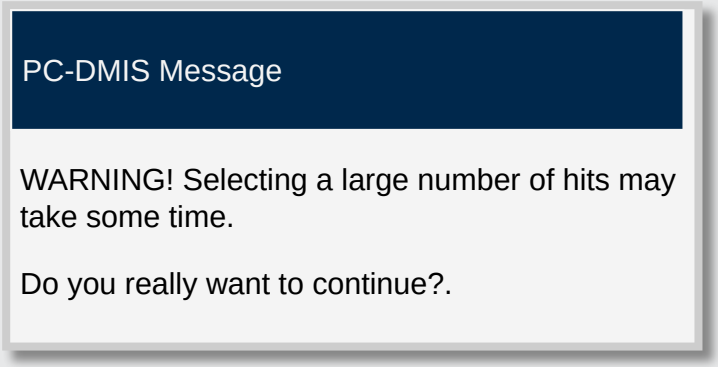
"Cannot construct [feature]. Combination of input features not accepted."

To construct a round slot:

1. Open the **Construct Round Slot** dialog box (**Insert | Feature | Constructed | Round Slot**).
2. From the **Method** list, select the method of the constructed round slot. The available options are:
    - Circles
    - Best Fit
    - BF Recomp
    - Projection
    - Cast
    - Extracted Round Slot

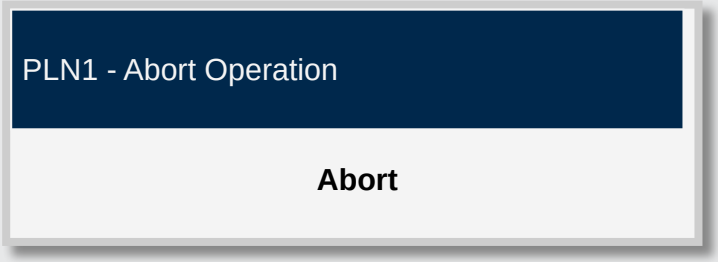
If you select the **Best Fit** or the **BF Recomp** (Best Fit Recomp) method for this feature, PC-DMIS allows you to click the **Select All Hits** button to create the construction from the individual hits of the input features instead of their centroids.

If there are a large number of points involved (about 10,000 or more), PC-DMIS shows a message asking if you are sure you want to proceed as this may take some time to complete.



Click **Yes** to proceed, click **No** to abort the process. You can select the **Don't ask me again** check box to prevent this message from recurring.

If you click **Yes**, another message is shown similar to the one shown below to let you know that PC-DMIS is generating the features from the hit points.

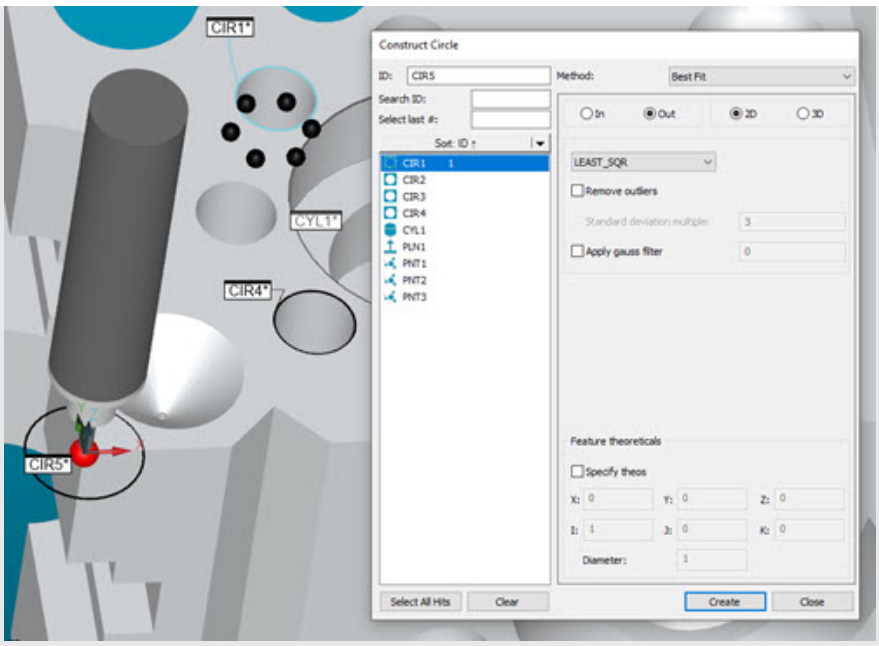


Once all the constructed features are created, the message disappears.

You can click the **Abort** button at any time to stop the process. Any features created up to this point are listed in the **Feature list** area of the dialog box.

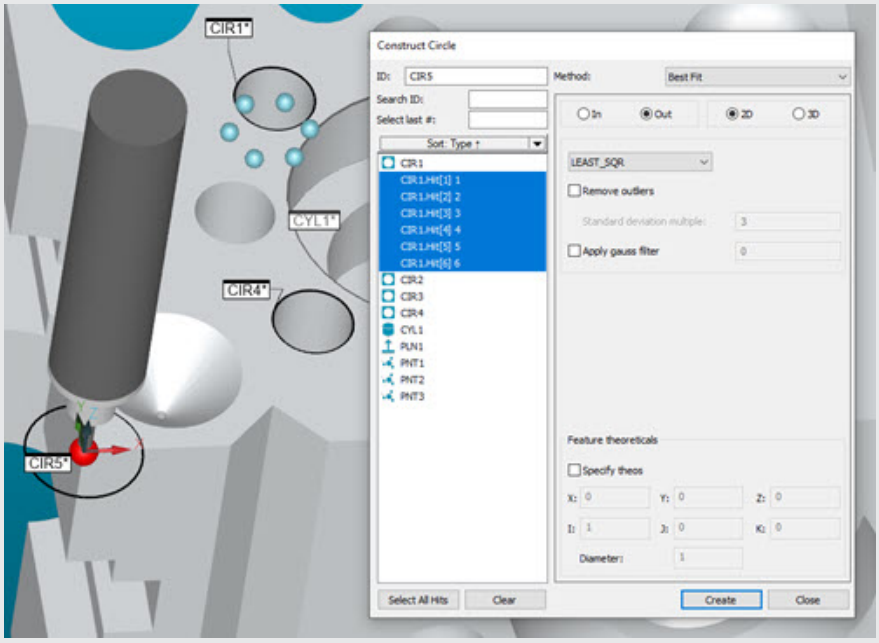
To create constructed features from the individual hits of the input features, do this:

1. From the **Feature list**, select the feature or features that you want to use to create the constructed feature.



Example showing a selected feature prior to clicking the Select All Hits button.

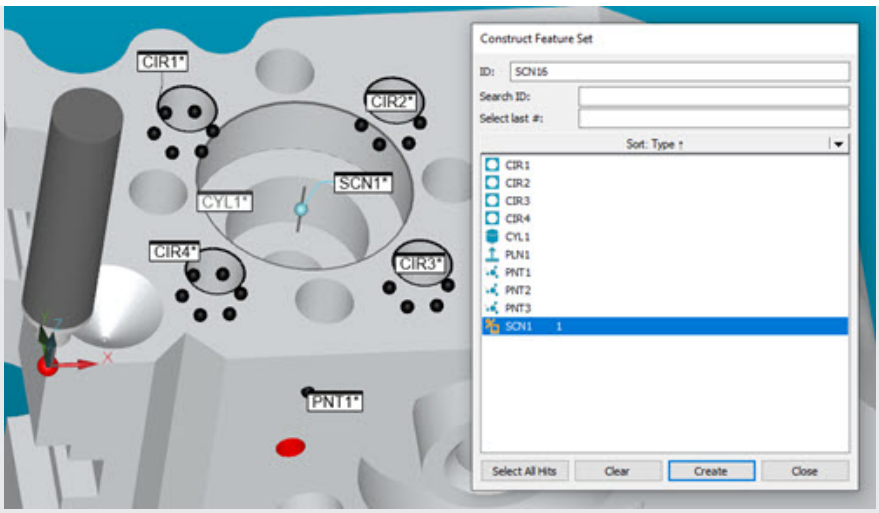
2. Click the **Select All Hits** button to display all the components that comprise the selected feature or features.



Display of items that make up the selected feature are highlighted in the dialog box and in the Graphic Display window.

PC-DMIS displays and highlights all the components of the selected feature (or features) in the **Feature list** are of the dialog box. You can select or de-select any of the features or feature components shown in the list to include or exclude them.

3. Click the **Create** button to create the Constructed feature based on the final features and feature components that you selected.



Constructed feature created based on the selected items from the Feature list.

3. Using the table above, select the features from the **Feature** list based on the selected method.
4. Select the **In** or **Out** option. For details, see the "In / Out Slot" topic in this documentation.
5. If you chose one of the best fit methods, select either the **2D** or **3D** option. For details, see the "2D / 3D Slot" topic in this documentation.
6. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
7. Click the **Create** button.

The Edit window command line for a sample Slot Construction would read:

```
feature_name=FEAT/SLOT,TOG1,TOG2,TOG3
THEO/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,width,length
ACTL/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,width,length
CONSTR/TOG4,TOG5,TOG6,TOG7,feat_1,feat_2, …
```

The actual report displays in all capital letters.

TOG1 = CARTESIAN or POLAR

TOG2 = OUT or IN

TOG3 = YES or NO

TOG4 = SLOT (or other construction type)

TOG5 = ROUND or SQUARE

TOG6 = CIRCLES or BF or BFRE or PROJ

TOG7 = 2D or 3D (This appears only if TOG6 reads BF or BFRE)

In / Out Slot

The **In** and **Out** options tell PC-DMIS whether to construct the slot as an internal or an external slot.

- If you select **In**, PC-DMIS constructs the slot as an internal slot.
- If you select **Out**, PC-DMIS constructs the slot as an external slot.

2D / 3D Slot

The **2D** and **3D** options tell PC-DMIS whether to construct the feature as a 2D or 3D slot. These options become available if you select the **Best Fit** or **BF Recomp** option.

- If you select **2D**, PC-DMIS constructs the slot, projecting it onto the workplane.
- If you select **3D**, PC-DMIS constructs a best fit plane from the inputs. Those inputs are then projected to the plane, and a constructed slot is created from the projected points.

Constructing a Circle Slot

PC-DMIS defines the round slot constructed from two circles by the first circle selected. PC-DMIS constructs the slot in the same plane as the first circle. PC-DMIS also determines the width of the slot by the diameter of the first circle. The software only uses the second circle to determine the length of the slot. The length is the distance from the center of the first circle to center of the second plus the diameter of the first circle.

If the two input circles are not coplanar, PC-DMIS projects the center of the second circle perpendicularly onto the plane of the first circle. The software then calculates the distance from the center of the first circle to the projected center of the second circle.

To construct a round slot from circles:

1. Open the **Construct Slot** dialog box (**Insert | Feature | Constructed | Slot**).
2. From the **Method** list, select the **Circles** option.
3. From the **Feature** list, select two circle features for inputs.
4. Select the **In** or **Out** option. For details, see the "In / Out Slot" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for the Round Slot would read:
```
CONSTR/SLOT,CIRCLES,feat_1,feat_2
```

Constructing a Best Fit or Best Fit Recompensate Slot

The Best Fit (BF) and the Best Fit Recompensate (BFRE) are constructed from five or more features. The constructed slots vector is normal (perpendicular) to the workplane. The BFRE construction uses the ball center combined with the probe radius to compute the slot. The compensation is an integral part of the fitting. The BF construction compensates the measured points prior to fitting.

The height of the slot from the workplane is the average of all the input features.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

To construct a Best Fit or Best Fit Recompensate slot:

1. Open the **Construct Slot** dialog box (**Insert | Feature | Constructed | Slot**).
2. From the **Method** list, select either the **Best Fit** or **Best Fit Recompensate** option (shown as **Best Fit** and **BF Recomp**).
3. From the **Feature** list, select at least four features. They can be any feature type.

4. Select the **In** or **Out** option. For details, see the "In / Out Slot" topic in this documentation.
5. Select either the **2D** or **3D** option. For details, see the "2D / 3D Slot" topic in this documentation.
6. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
7. Click the **Create** button.

The Edit window command line for the Best Fit or Best Fit Recompensate Slot would read:
```
CONSTR/SLOT,BF (or BFRE),feat_1,feat_2, ...
```

Constructing a Projected Slot

Similar to a Projected Circle, PC-DMIS can create a slot feature projected onto a specified plane.

To construct a projected slot:

1. Open the **Construct Round Slot** dialog box (**Insert | Feature | Constructed | Round Slot**).
2. From the **Method** list, select the **Projection** option.
3. From the **Feature** list, select two features. The first feature should be a slot. The second feature should be a plane.
4. Select the **In** or **Out** option. For details, see the "In / Out Slot" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button. The slot is constructed projected onto the specified plane.

The Edit window command line for the projected slot would read:
```
CONSTR/SLOT,ROUND,PROJ,feat_1,feat_2, ...
```

Constructing a Cast Round Slot

Similar to a Cast Circle, you can construct a Cast Round Slot by changing any given feature into a slot. PC-DMIS uses the Cast option from the **Construct Round Slot** dialog box to construct the slot at the centroid of the input feature.

Guidelines when you construct a cast slot:

- The software uses the diameter or width of the input feature as the width of the slot.
- The software uses the length of the input feature as the length of the slot.
- If the width or diameter of the input feature is 0 (zero), the width of the slot is the probe's diameter.
- If the length of the input feature is 0 (zero), the length of the slot is set to three time the probe's diameter.
- The software uses the vector of a line feature as the slot's angle vector; the software uses the vector of any other feature types as the slot's surface vector.

To construct a cast round slot:

1. Open the **Construct Round Slot** dialog box (**Insert | Feature | Constructed | Round Slot**).
2. From the **Method** list, select the **Cast** option.
3. From the **Feature** list, select one feature of any type.
4. Select the **In** or **Out** option. For details, see the "In / Out Slot" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for the Cast Round Slot would read:

```
CONSTR/SLOT,ROUND,CAST,feat_1,DEPENDENT
```

Constructing an Extracted Round Slot

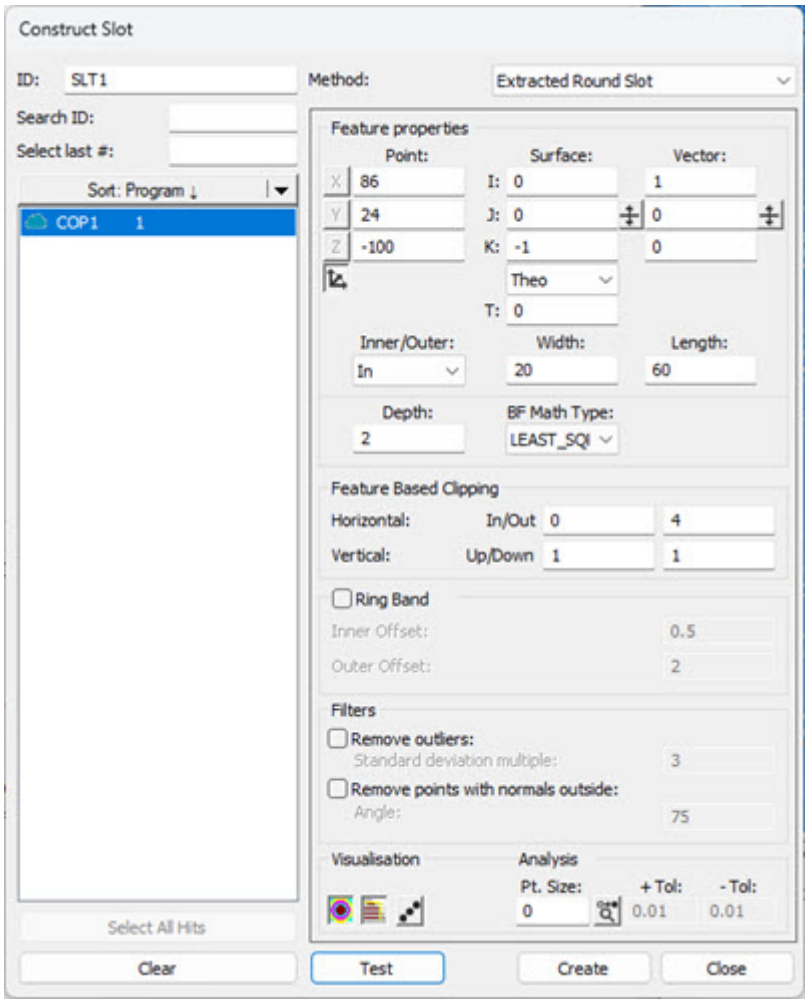
For details on extracting Auto features from a Mesh, see the "Extracting Auto Features from a Mesh" topic in the PC-DMIS Laser documentation.

For details on extracting Auto features from a Pointcloud (COP), see the "Extracting Auto Features from Pointclouds" topic in the PC-DMIS Laser documentation.

You can construct a round slot that is extracted from a scanned pointcloud (COP) or mesh.

To do this, follow these steps:

1. Ensure that your measurement routine has a Pointcloud (COP) or Mesh command.
2. Open the **Construct Slot** dialog box (**Insert | Feature | Constructed | Round Slot**) or from the **Constructed Feature** toolbar (**View | Toolbars | Constructed Features**).



Construct Slot Dialog Box - Extracted Round Slot Option

3. From the **Method** list, select the **Extracted Round Slot** option.
4. From the **Reference** area, select the COP or Mesh that you want to use to extract the round slot from.
5. Click on the CAD model or data to define the nominal or, in the **Point** section of the **Feature properties** area, type the nominal location in the **X**, **Y**, and **Z** boxes.
6. From the **Surface** section of the **Feature properties** area, define the surface vector in the **I**, **J**, and **K** boxes. In the **Angle** section, enter the corresponding vector angle values. You can use the **Material Thickness Type** list and the **T** box below it to type in a material thickness value. For details, see the "Use Thickness" topic in this documentation.

   You can use these controls to perform the associated functions:

Flip Vectors

Polar/Cartesian

For details on these controls, see the appropriate topic in the "Feature Properties Area" section of the "Creating Auto Features" chapter of the PC-DMIS Core documentation.

7. Select whether the extracted round slot is an inner or outer round slot type from the **Inner/Outer** list.

8. Enter the width and length of the round slot in the respective boxes. The **Width** value defines the width of the round slot, and the **Length** value defines the length or the longest side of the round slot.

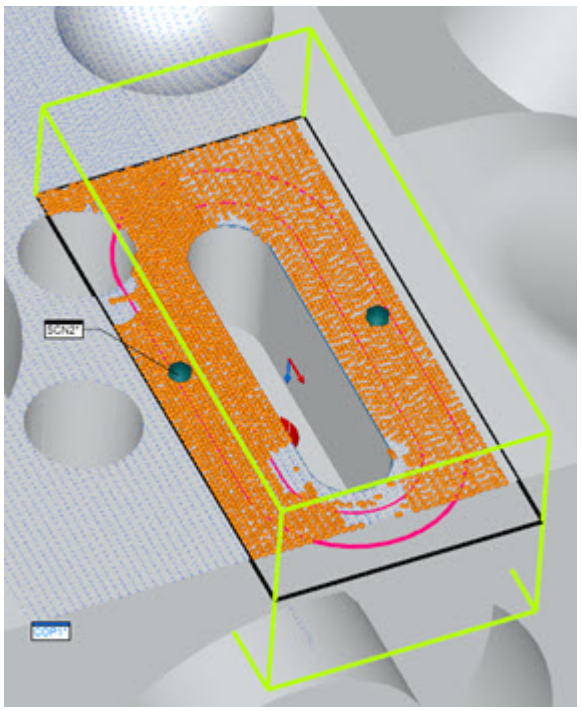
9. Enter the **Depth** value. This parameter controls the location of the laser focal point in relation to the round slot's outside diameter (outer round slots) or the round slot's center axis (inner round slots). This allows you to control how the laser stripes fall on the round slot's surface by specifying how far or close the laser is to the round slot's surface. A depth of 0 (zero) causes this feature to be calculated at the surface plane height using data found at the lowest possible depth from the surface plane. A depth of any other value causes the software to perform the calculation at that depth.

10. From the **BF Math Type** list, select the type of Best Fit algorithm to use to construct the round slot. The available options are:

    LEAST_SQR
    Least Squares - This calculation type provides a method of fitting in which the average squared radial distance from the data points to the round slot is minimized. The square root of this quantity is the Root Mean Square (RMS) distance. Since the RMS distance is based on an average, some points may be further than the RMS distance from the computed round slot.

    MAX_INSC
    Maximum Inscribed - For Inner slots, this calculation type generates a slot with the largest possible footprint that lies within the data. PC-DMIS first computes a Minimum Circumscribed slot and requires that the center of the Maximum Inscribed slot lies within it. Do not use this calculation type for arcs of less than 90 degrees.

    MIN_CIRCSC
    Minimum Circumscribed - For Outer slots, this calculation type generates a slot with the smallest possible footprint that encloses the input data (or input features). This option could be used when measuring a stud that would fit into a mating feature. The resulting feature would be the smallest slot into which the mating feature would fit. Do not use this calculation type for arcs of less than 180 degrees.



Example of a constructed extracted round slot showing the candidate points.

11. From the **Feature Based Clipping** area, define the **Horizontal In/Out** and **Horizontal** values, and the **Vertical Up/Down** and **Vertical** values. These values set the dimensions for the green extraction zone region. Consider part variability when you define the extraction zone.

12. If you want to define the Ring Band offsets, click the **Ring Band** check box and type the **Inner Offset** and **Outer Offset** values. For details on how the **Ring Band** works, see the "Ring Band Parameters" topic in the PC-DMIS Laser documentation.

13. If you want to filter out any outlier points, from the **Filters** area, select the **Remove outliers** check box and define the **Standard deviation multiple** to determine which points PC-DMIS excludes as outliers.

14. If you want to filter out any points that are outside of a maximum incidence angle, from the **Filters** area, select the **Remove points with normals outside** check box and type the value in the **Angle** (Max Incidence Angle) box.

The Max Incidence Angle filter was initially designed to compare the incidence direction of the laser (which is roughly the laser sensor orientation) to the estimated normal of the segregated points. For 3D laser features (Laser Auto Cone, Cylinder, Plane, Sphere, Surface Point and Constructed Extracted Cone, Cylinder, Plane, Sphere, Surface Point), the filter now compares the estimated normal of the pointcloud point to the nominal normal of the feature, which greatly improves the results. 2D laser features remain unchanged, using the legacy incidence angle filter method.

For details on the **Filters** area, see the "Filters" topic in the PC-DMIS Laser documentation.

15. In the **Visualisation** section, PC-DMIS provides these options to perform the described function:

    Visualisation Tools On/Off - This button toggles the display of the colored visualisation tools. For more information, see "Understanding the Visualisation Tools".

    Show/Hide segregated points - This button toggles the display of the points that the software passes to the feature extractor engine based on the current settings.

    Show/Hide measured points - This button toggles the display of the measured points. It remains greyed out until you click **Test** or **Create**. For more information, see the "Show Measured Points" topic in the PC-DMIS Core documentation.

    
    - The **Analysis** area allows you to determine how each measured hit/point is displayed. For more information, see the “Analysis Area” topic in the PC-DMIS Core documentation.

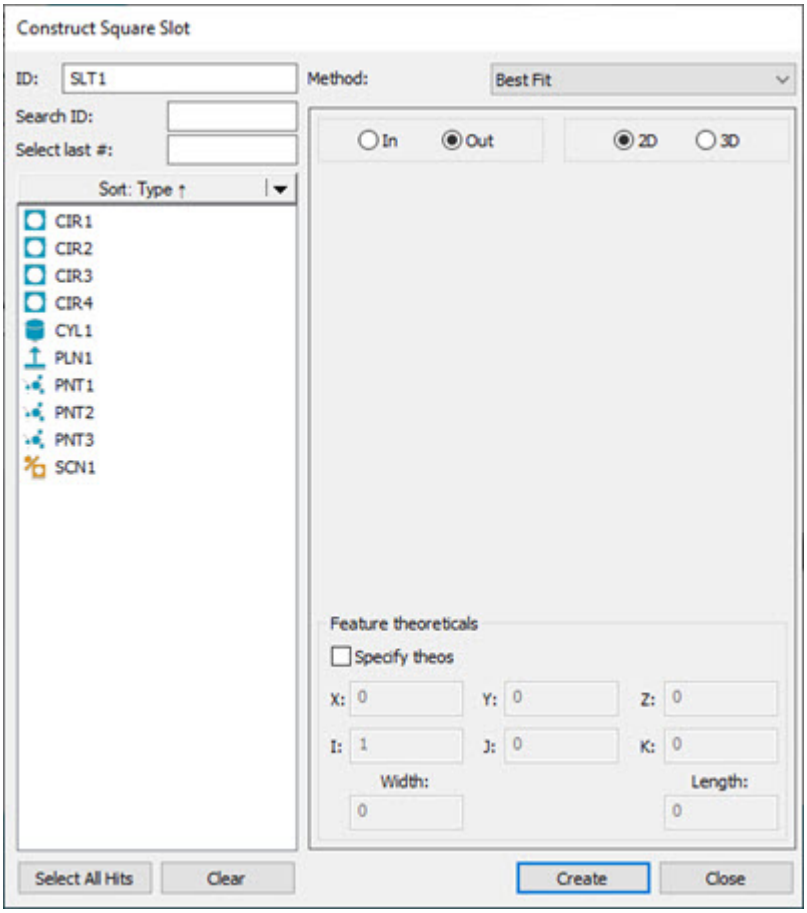
16. Click the **Test** button to test a feature's creation and preview its dimensional data before you create it. PC-DMIS performs a measurement using the current parameters. You can change the parameters and click **Test** repeatedly until you have an acceptable measurement. Then, when you click **Create**, the software converts the temporary feature into a normal feature in the measurement routine.

17. Click the **Create** button. Based on the parameters that you specified in the dialog box, PC-DMIS does an analysis of the candidate points and returns (or extracts) each measured point and projects them to the surface.

    PC-DMIS creates the command in the Edit window:

```
SLT1=FEAT/ROUND_SLOT,CARTESIAN,INNER,LEAST_SQR
   THEO/<70,15.9,0>,<0,0,-1>,<0,-1,0>,6,26
   MEAS/<70,15.9,0>,<0,0,-1>,<0,-1,0>,6,26
   DEPTH=0
   THEO_THICKNESS,0
   HORIZONTAL CLIPPING=7,VERTICAL CLIPPING=9,INNER
HORIZONTAL CLIPPING=0
   RINGBAND=ON,INNER OFFSET=2,OUTER OFFSET=5
   USE OUTLIER REMOVAL=ON,0
   REMOVE POINTS WITH NORMALS OUTSIDE=ON,1
   CONSTR/SLOT,ROUND,EXTRACTED,COP1
```

Constructing a Square Slot Feature



Construct Square Slot Dialog Box

The table below shows the inputs for the slot and the editor definitions.

Construct Feature Type	Edit Window Symbol	Number of Required Input Features	Primary Feature	Secondary Feature	Comments
Best Fit Square Slot	BF	5 or more	-	-	Constructs a Best Fit slot using the given inputs. See the Note below for recommended inputs.
Best Fit Recompensate Square Slot	BFRE	5 or more	-	-	Constructs a Best Fit Recompensate slot using the given inputs. See the Note below for recommended inputs.
Projected Square Slot	PROJ	2	Slot	Plane	Constructs a Projected Square Slot onto the plane.
Cast Square Slot	CAST	1	Any	-	Constructs a Square Slot at the centroid of the input feature.
Extracted Square Slot	EXTRACTED_SQUARE_SLOT	1	COP or Mesh	-	Constructs an extracted square slot from the COP or Mesh object at the specified diameter or height.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

If you select inappropriate feature types, PC-DMIS displays this message on the Status bar:

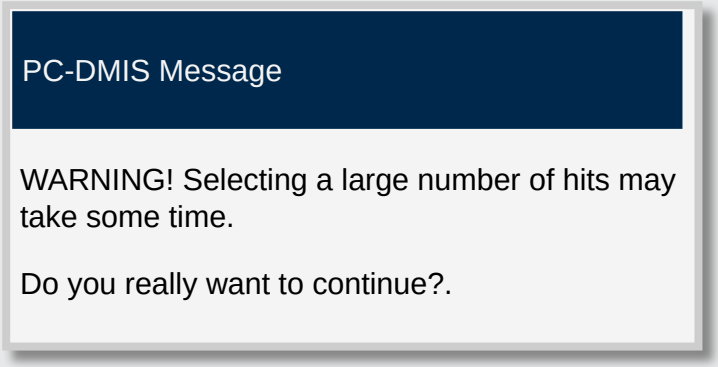
"Cannot construct [feature]. Combination of input features not accepted."

To construct a square slot:

1. Open the **Construct Square Slot** dialog box (**Insert | Feature | Constructed | Square Slot**).
2. From the **Method** list, select the method of the constructed square slot. The available options are:
    - Best Fit
    - BF Recomp
    - Projection
    - Cast
    - Extracted Square Slot

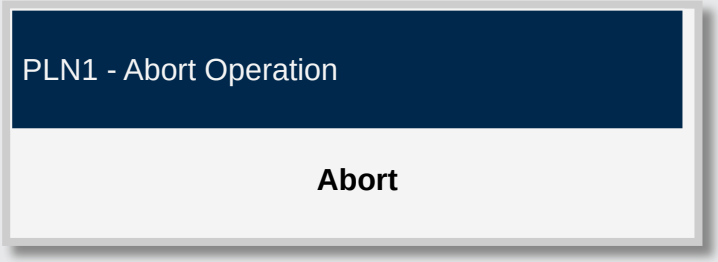
If you select the **Best Fit** or the **BF Recomp** (Best Fit Recomp) method for this feature, PC-DMIS allows you to click the **Select All Hits** button to create the construction from the individual hits of the input features instead of their centroids.

If there are a large number of points involved (about 10,000 or more), PC-DMIS shows a message asking if you are sure you want to proceed as this may take some time to complete.



Click **Yes** to proceed, click **No** to abort the process. You can select the **Don't ask me again** check box to prevent this message from recurring.

If you click **Yes**, another message is shown similar to the one shown below to let you know that PC-DMIS is generating the features from the hit points.

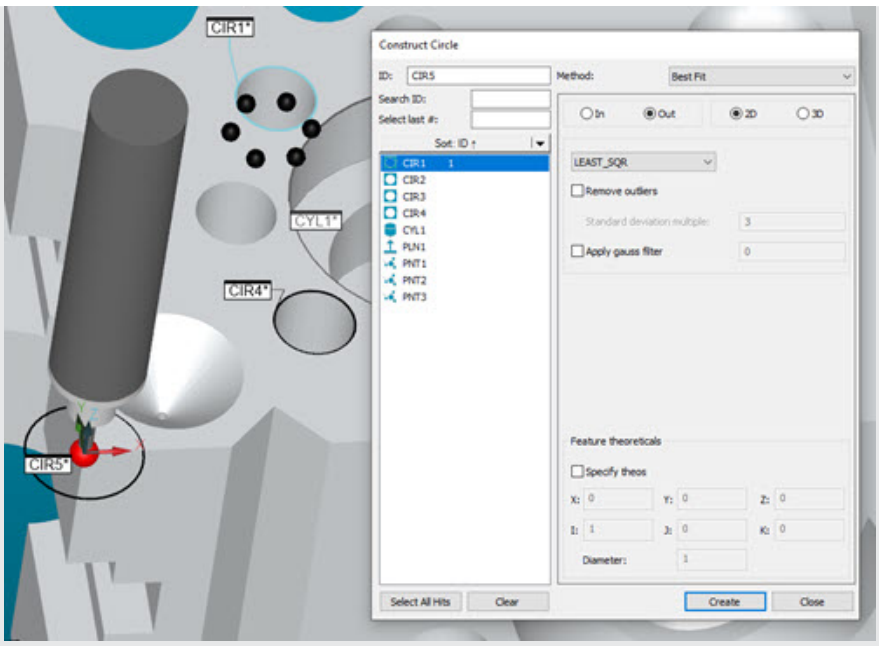


Once all the constructed features are created, the message disappears.

You can click the **Abort** button at any time to stop the process. Any features created up to this point are listed in the **Feature list** area of the dialog box.

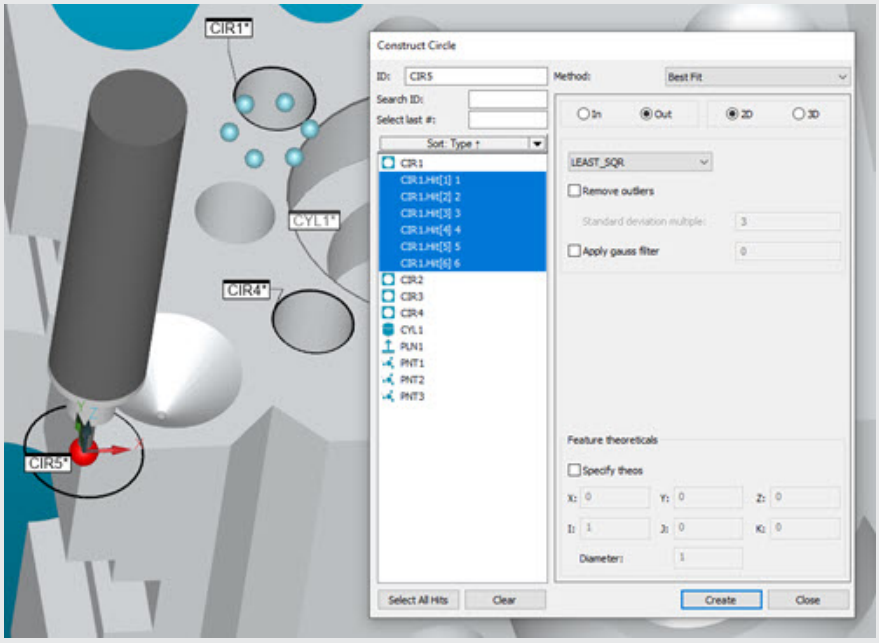
To create constructed features from the individual hits of the input features, do this:

1. From the **Feature list**, select the feature or features that you want to use to create the constructed feature.



Example showing a selected feature prior to clicking the Select All Hits button.

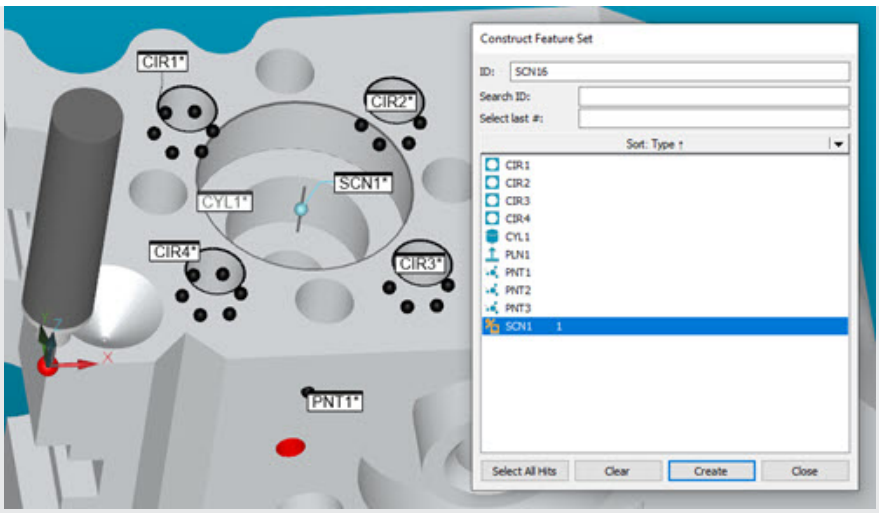
2. Click the **Select All Hits** button to display all the components that comprise the selected feature or features.



Display of items that make up the selected feature are highlighted in the dialog box and in the Graphic Display window.

PC-DMIS displays and highlights all the components of the selected feature (or features) in the **Feature list** are of the dialog box. You can select or de-select any of the features or feature components shown in the list to include or exclude them.

3. Click the **Create** button to create the Constructed feature based on the final features and feature components that you selected.

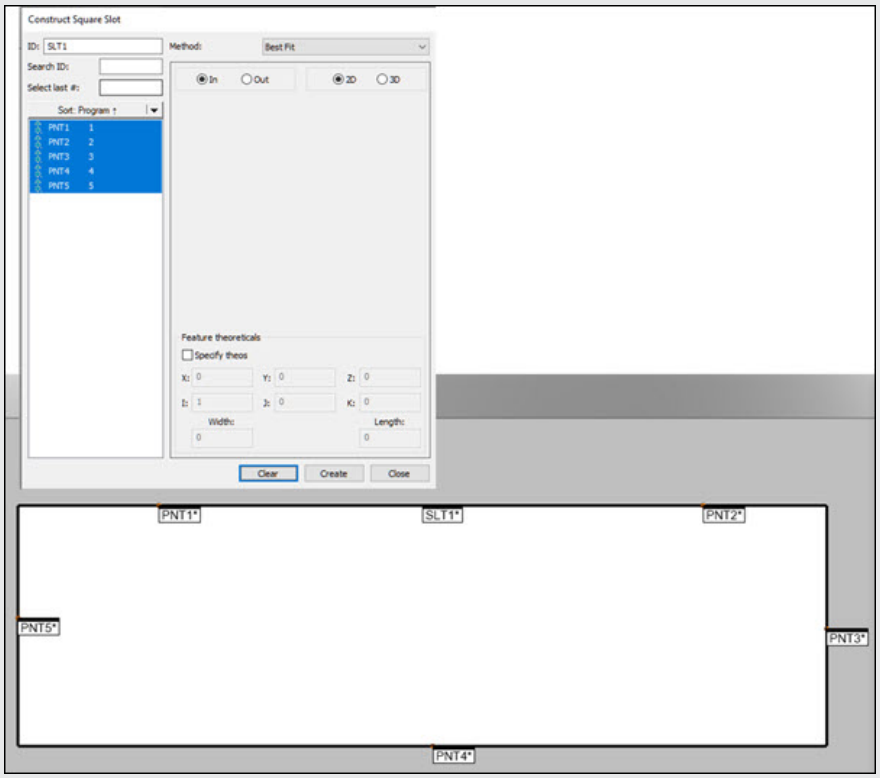


Constructed feature created based on the selected items from the Feature list.

3. Using the table above, select the features from the **Feature** list based on the selected method.

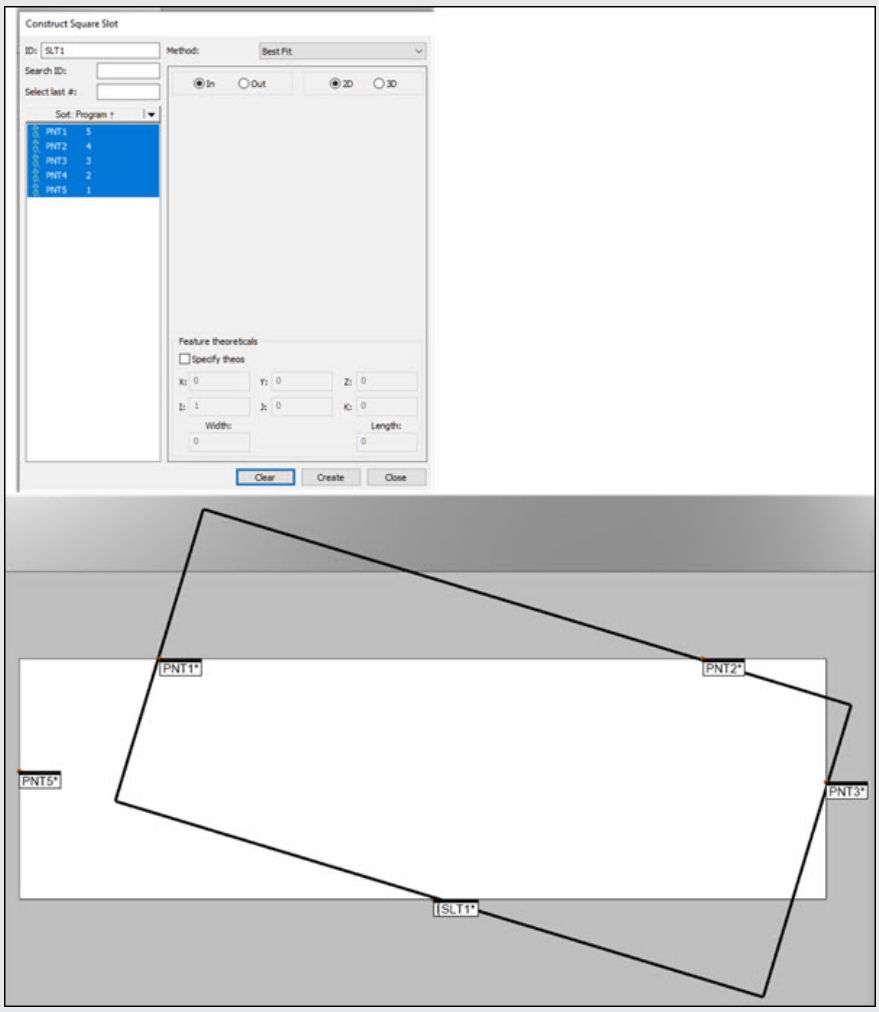
Remember, the order you select the features from the list determines the orientation (CW or CCW) of the Constructed Square Slot. See the examples below.

Example of a Correct Order of Selection



Example showing the correct order of feature selection to orient the slot from the first and second points and resolves the correct length and width.

Example of an Incorrect Order of Selection



Example of an incorrect order of selection that resolves the wrong orientation and incorrect length and width.

4. Select the **In** or **Out** option. For details, see the "In / Out Slot" topic in the PC-DMIS Core documentation.

5. If you chose one of the best fit methods, select either the **2D** or **3D** option. For details, see the "2D / 3D Slot" topic in the PC-DMIS Core documentation.

6. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.

7. Click the **Create** button.

The Edit window command line for a sample slot construction would read:

```
feature_name=FEAT/SLOT,TOG1,TOG2,TOG3
THEO/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,width,length
ACTL/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,width,length
CONSTR/TOG4,TOG5,TOG6,TOG7,feat_1,feat_2, …
```

The actual report displays in all capital letters.

TOG1 = CARTESIAN or POLAR

TOG2 = OUT or IN

TOG3 = YES or NO

TOG4 = SLOT (or other construction type)

TOG5 = ROUND or SQUARE

TOG6 = BF or BFRE or PROJ

TOG7 = 2D or 3D (This appears only if TOG6 reads BF or BFRE)

In / Out Square Slot

The **In** and **Out** options tell PC-DMIS whether to construct the slot as an internal or an external slot.

- If you select **In**, PC-DMIS constructs the slot as an internal slot.
- If you select **Out**, PC-DMIS constructs the slot as an external slot.

2D / 3D Square Slot

The **2D** and **3D** options tell PC-DMIS whether to construct the feature as a 2D or 3D slot. These options become available if you select the **Best Fit** or **BF Recomp** option.

- If you select **2D**, PC-DMIS constructs the slot, projecting it onto the workplane.
- If you select **3D**, PC-DMIS constructs a best fit plane from the inputs. Those inputs are then projected to the plane, and a constructed slot is created from the projected points.

Constructing a Best Fit or Best Fit Recompensate Square Slot

The Best Fit (BF) and the Best Fit Recompensate (BFRE) are constructed from five or more features. The constructed slots vector is normal (perpendicular) to the workplane. The BFRE construction uses the ball center combined with the probe radius to compute the slot. The compensation is an integral part of the fitting. The BF construction compensates the measured points prior to fitting.

The height of the slot from the workplane is the average of all the input features.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

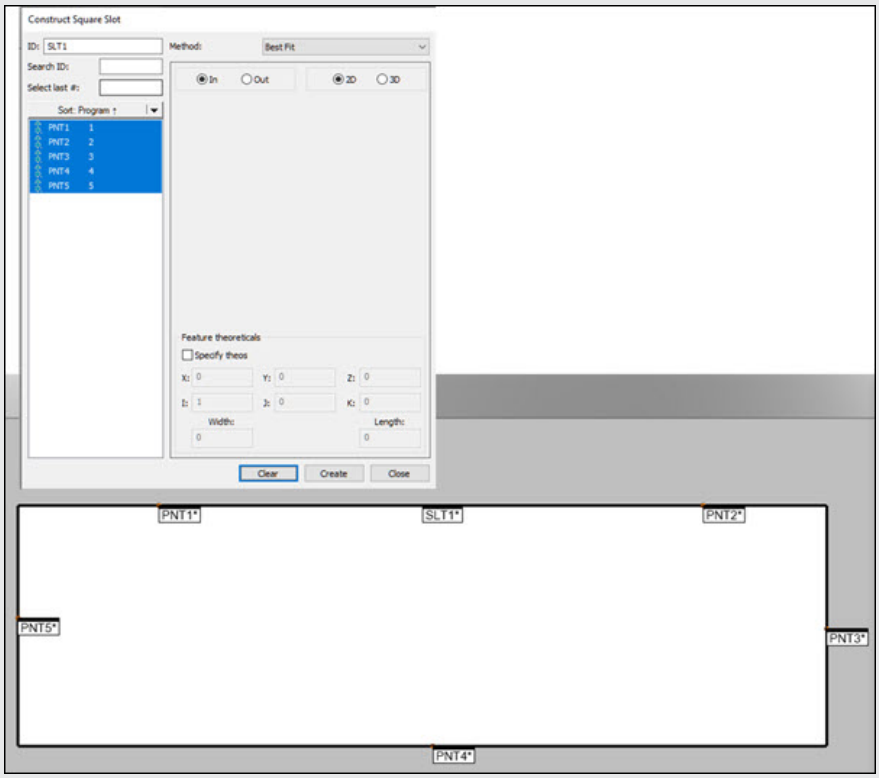
For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

To construct a Best Fit or Best Fit Recompensate square slot:

1. Open the **Construct Slot** dialog box (**Insert | Feature | Constructed | Slot**).
2. From the **Method** list, select either the **Best Fit** or **Best Fit Recompensate** option (shown as **Best Fit** and **BF Recomp**).
3. From the **Feature** list, select at least five features.

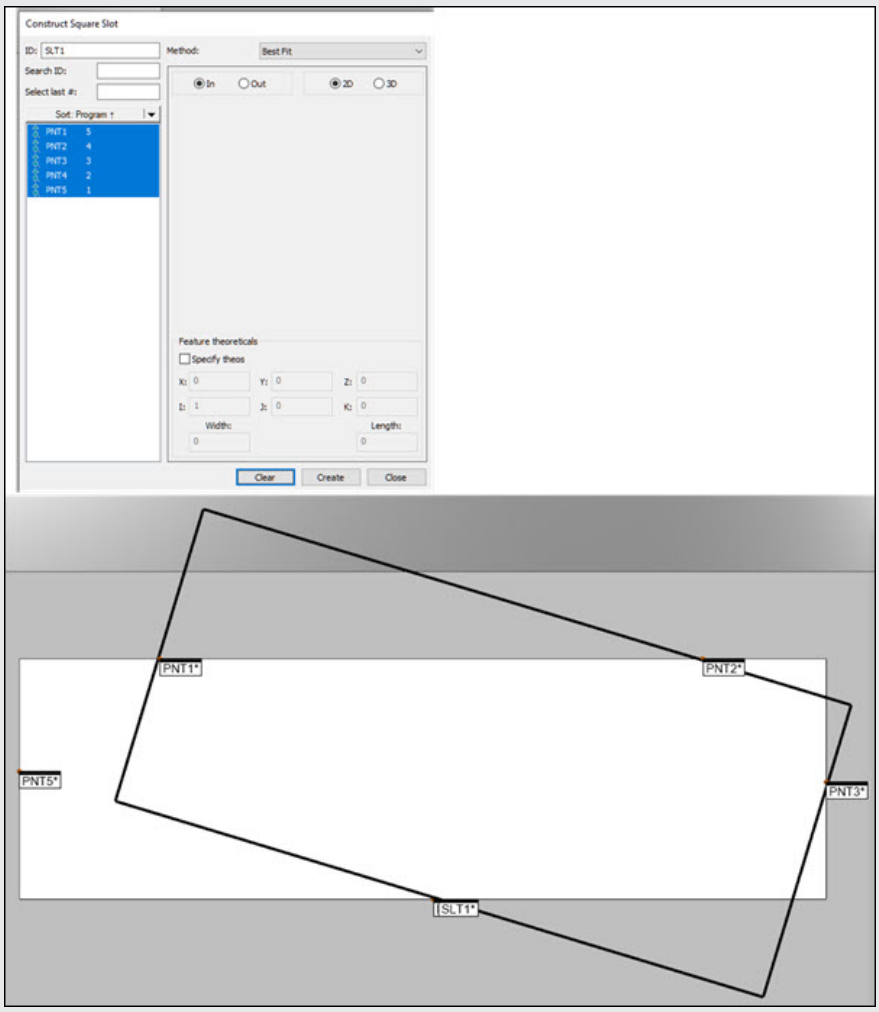
Remember, the order you select the features from the list determines the orientation (CW or CCW) of the Constructed Square Slot. See the examples below.

Example of a Correct Order of Selection



Example showing the correct order of feature selection to orient the slot from the first and second points and resolves the correct length and width.

Example of an Incorrect Order of Selection



Example of an incorrect order of selection that resolves the wrong orientation and incorrect length and width.

4. Select the **In** or **Out** option. For details, see the "In / Out Square Slot" topic in this documentation.

5. Select either the **2D** or **3D** option. For details, see the "2D / 3D Square Slot" topic in the PC-DMIS Core documentation.

6. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.

7. Click the **Create** button.

The Edit window command line for the Best Fit or Best Fit Recompensate Slot would read:

```
CONSTR/SLOT,BF (or BFRE),feat_1,feat_2, ...
```

Constructing a Projected Square Slot

Similar to a Projected Circle, PC-DMIS can create a slot feature projected onto a specified plane.

To construct a projected square slot:

1. Open the **Construct Square Slot** dialog box (**Insert | Feature | Constructed | Square Slot**).
2. From the **Method** list, select the **Projected** option.
3. From the **Feature** list, select two features. The first should be a slot. The second should be a plane.
4. Select the **In** or **Out** option. For details, see the "In / Out Square Slot" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button. The slot is constructed projected onto the specified plane.

The Edit window command line for the Projected Square Slot would read:

```
CONSTR/SLOT,SQUARE,PROJ,feat_1,feat_2, ...
```

Constructing a Cast Square Slot

Similar to a Cast Circle, you can construct a Cast Square Slot by changing any given feature into a slot. Using the Cast option from the **Construct Square Slot** dialog box, PC-DMIS constructs the slot at the centroid of the input feature.

Guidelines when you construct a cast slot:

- The software uses the diameter or width of the input feature as the width of the slot.
- The software uses the length of the input feature as the length of the slot.
- If the width or diameter of the input feature is 0 (zero), the width of the slot is the probe's diameter.
- If the length of the input feature is 0 (zero), the length of the slot is set to three time the probe's diameter.
- The software uses the vector of a line feature as the slot's angle vector; the software uses the vector of any other feature types as the slot's surface vector.

To construct a Cast Square Slot:

1. Open the **Construct Square Slot** dialog box (**Insert | Feature | Constructed | Square Slot**).
2. From the **Method** list, select the **Cast** option.
3. From the **Feature** list, select one feature of any type.
4. Select the **In** or **Out** option. For details, see the "In / Out Slot" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for the Cast Square Slot would read:

```
CONSTR/SLOT,SQUARE,CAST,feat_1,DEPENDENT
```

Constructing an Extracted Square Slot

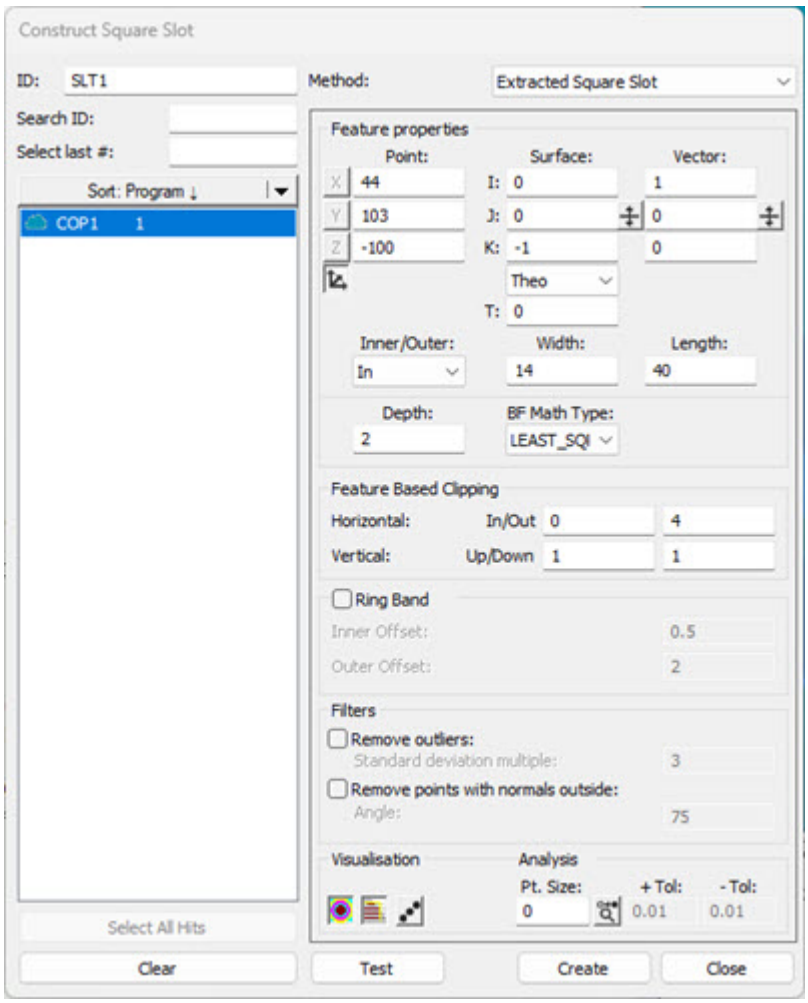
For details on extracting Auto features from a Mesh, see the "Extracting Auto Features from a Mesh" topic in the PC-DMIS Laser documentation.

For details on extracting Auto features from a Pointcloud (COP), see the "Extracting Auto Features from Pointclouds" topic in the PC-DMIS Laser documentation.

You can construct a square slot that is extracted from a scanned pointcloud (COP) or mesh.

To do this, follow these steps:

1. Ensure that your measurement routine has a Pointcloud (COP) or Mesh command.
2. Open the **Construct Square Slot** dialog box (**Insert | Feature | Constructed | Square Slot**) or from the **Constructed Feature** toolbar (**View | Toolbars | Constructed Features**).



Construct Square Slot dialog box - Extracted Square Slot

3. From the **Method** list, select the **Extracted Square Slot** option.

4. From the **Reference** area, select the COP or Mesh that you want to use to extract the square slot from.

5. Click on the CAD model or data to define the nominal or, in the **Point** section of the **Feature properties** area, type the nominal location in the **X**, **Y**, and **Z** boxes.

6. From the **Surface** section of the **Feature properties** area, define the surface vector in the **I**, **J**, and **K** boxes. In the **Angle** section, enter the corresponding vector angle values. You can use the **Material Thickness Type** list and the **T** box below it to type in a material thickness value. For details, see the "Use Thickness" topic in this documentation.

   You can use these controls to perform the associated functions:

   Flip Vectors

   Polar/Cartesian

For details on these controls, see the appropriate topic in the "Feature Properties Area" section of the "Creating Auto Features" chapter of the PC-DMIS Core documentation.

7. Select whether the extracted square slot is an inner or outer square slot type from the **Inner/Outer** list.

8. Enter the width and length of the square slot in the respective boxes. The **Width** value defines the width of the square slot, and the **Length** value defines the length or the longest side of the square slot.

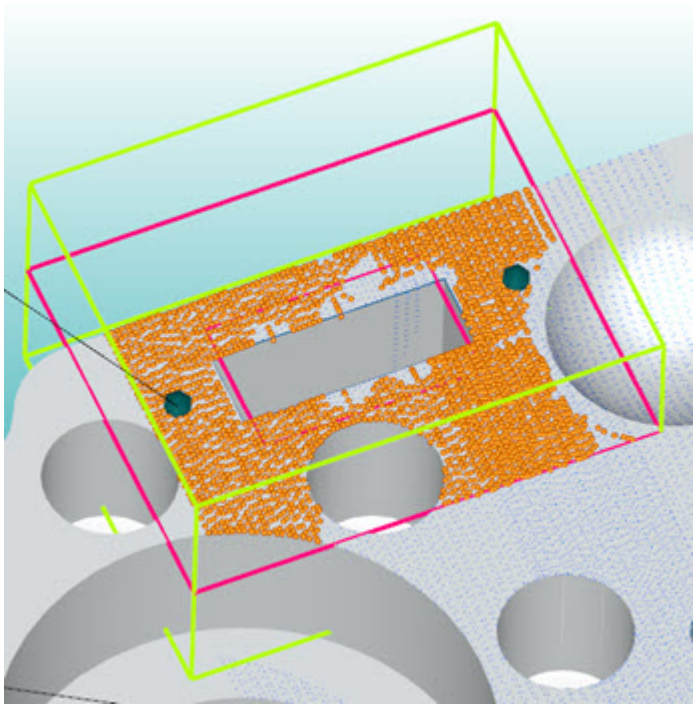
9. Enter the **Depth** value. This parameter controls the location of the laser focal point in relation to the square slot's outside diameter (outer square slots) or the square slot's center axis (inner square slots). This allows you to control how the laser stripes fall on the square slot's surface by specifying how far or close the laser is to the square slot's surface. A depth of 0 (zero) causes this feature to be calculated at the surface plane height using data found at the lowest possible depth from the surface plane. A depth of any other value causes the software to perform the calculation at that depth.

10. From the **BF Math Type** list, select the type of Best Fit algorithm to use to construct the square slot. The available options are:

    LEAST_SQR
    Least Squares - This calculation type provides a method of fitting in which the average squared radial distance from the data points to the square slot is minimized. The square root of this quantity is the Root Mean Square (RMS) distance. Since the RMS distance is based on an average, some points may be further than the RMS distance from the computed square slot.

    MAX_INSC
    Maximum Inscribed - For Inner slots, this calculation type generates a slot with the largest possible footprint that lies within the data. PC-DMIS first computes a Minimum Circumscribed slot and requires that the center of the Maximum Inscribed slot lies within it. Do not use this calculation type for arcs of less than 90 degrees.

    MIN_CIRCSC
    Minimum Circumscribed - For Outer slots, this calculation type generates a slot with the smallest possible footprint that encloses the input data (or input features). This option could be used when measuring a stud that would fit into a mating feature. The resulting feature would be the smallest slot into which the mating feature would fit. Do not use this calculation type for arcs of less than 180 degrees.



Example of a Constructed Extracted Square Slot showing the candidate points

11. From the **Feature Based Clipping** area, define the **Horizontal In/Out** and **Horizontal** values, and the **Vertical Up/Down** and **Vertical** values. These values set the dimensions for the green extraction zone region. Consider part variability when you define the extraction zone.

12. If you want to define the Ring Band offsets, click the **Ring Band** check box and enter the **Inner Offset** and **Outer Offset** values. For details on how the **Ring Band** works, see the "Ring Band Parameters" topic in the PC-DMIS Laser documentation.

13. If you want to filter out any outlier points, from the **Filters** area, select the **Remove outliers** check box and define the **Standard deviation multiple** to determine which points PC-DMIS excludes as outliers.

14. If you want to filter out any points that are outside of a maximum incidence angle, from the **Filters** area, select the **Remove points with normals outside** check box and type the value in the **Angle** (Max Incidence Angle) box.

The Max Incidence Angle filter was initially designed to compare the incidence direction of the laser (which is roughly the laser sensor orientation) to the estimated normal of the segregated points. For 3D laser features (Laser Auto Cone, Cylinder, Plane, Sphere, Surface Point and Constructed Extracted Cone, Cylinder, Plane, Sphere, Surface Point), the filter now compares the estimated normal of the pointcloud point to the nominal normal of the feature, which greatly improves the results. 2D laser features remain unchanged, using the legacy incidence angle filter method.

For details on the **Filters** area, see the "Filters" topic in the PC-DMIS Laser documentation.

15. In the **Visualisation** section, PC-DMIS provides these options to perform the described function:

    Visualisation Tools On/Off - This button toggles the display of the colored visualisation tools. For more information, see "Understanding the Visualisation Tools".

    Show/Hide segregated points - This button toggles the display of the points that the software passes to the feature extractor engine based on the current settings.

    Show/Hide measured points - This button toggles the display of the measured points. It remains greyed out until you click **Test** or **Create**. For more information, see the "Show Measured Points" topic in the PC-DMIS Core documentation.

    
    - The **Analysis** area allows you to determine how each measured hit/point is displayed. For more information, see the “Analysis Area” topic in the PC-DMIS Core documentation.

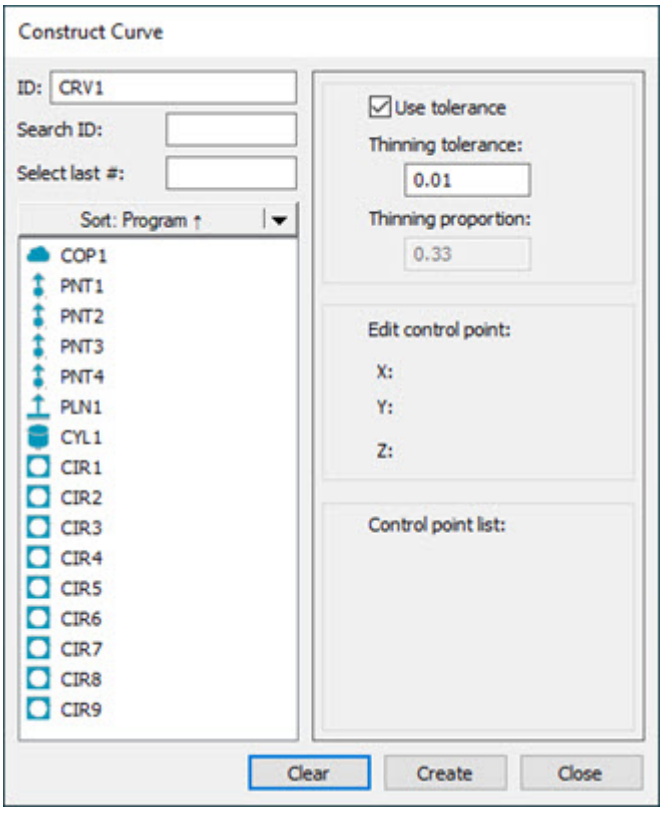
16. Click the **Test** button to test a feature's creation and preview its dimensional data before you create it. PC-DMIS performs a measurement using the current parameters. You can change the parameters and click **Test** repeatedly until you have an acceptable measurement. Then, when you click **Create**, the software converts the temporary feature into a normal feature in the measurement routine.

17. Click the **Create** button. Based on the parameters that you specified in the dialog box, PC-DMIS does an analysis of the candidate points and returns (or extracts) each measured point and projects them to the surface.

    PC-DMIS creates the command in the Edit window:

```
SLT1        =FEAT/SQUARE_SLOT,CARTESIAN,INNER,LEAST_SQR
             THEO/<56.303,53.462,0>,<0,0,1>,<1,0,0>,5,15
             MEAS/
<56.152,53.463,0>,<0,0,1>,<0.999733,-0.0231079,0>,5.123,
15.343
             DEPTH=50
             THEO_THICKNESS,0
             HORIZONTAL CLIPPING=7,VERTICAL
CLIPPING=9,INNER HORIZONTAL CLIPPING=0
             RINGBAND=ON,INNER OFFSET=2,OUTER OFFSET=10
             USE OUTLIER REMOVAL=ON,1
             REMOVE POINTS WITH NORMALS OUTSIDE=ON,0.5
             CONSTR/SLOT,SQUARE,EXTRACTED,COP1
```

Constructing a Curve



Construct Curve Dialog Box

Two types of constructed curves (Independent Curves and Dependent Curves) are available in PC-DMIS. The following table displays the two curves along with their necessary inputs. All curves require a set as input. The set can be a measured set, a constructed set, or a scan. The input set must contain at least four features (or input points in the case of a scan).

Construct Feature Type	the Edit Window Symbol	Number of Required Input Sets	Input Set	Comments
Dependent Curve	DEPENDENT	1	Set containing at least 4 inputs	The Curve updates as the input changes. Editing a curve changes a dependent curve to an independent curve.
Independent Curve	INDEPENDENT	1	Set containing at least 4 inputs	Uses the input feature for construction only. You can manually edit control points of the curve.

The Edit window command line for a sample Curve Construction using a *dependent curve type* would read:

```
feature_name=FEAT/CURVE, DEPENDENT, num_control_points,
num_input_feats, thinning_parameter

CONSTR/CURVE,INPUT_TYPE, input_id
```

For an independent curve type the Edit window command line would read:

```
feature_name=FEAT/CURVE, INDEPENDENT, num_control_points,
num_input_feats, thinning_parameter

CONSTR/CURVE,
```

num_control_points = This is the number of control points that define the curve. More control points allow the curve to more closely pass through the features, but too may cause unexpected behavior

num_input_feats = This is the number of features that the curve is attempting to fit.

These two parameters are not editable in the Edit window.

input_id = This is the ID of the set containing the features to be fitted.

thinning_parameter = For information about the thinning parameters, see the "Thinning Parameters" topic in the PC-DMIS Core documentation.

The actual Edit report displays in all capital letters.

Constructing a Dependent / Independent Curve

If you select inappropriate feature types, PC-DMIS displays this message on the Status bar:

"Cannot construct [feature]. Combination of input features not accepted."

To construct a curve:

1. Open the **Construct Curve** dialog box (**Insert | Feature | Constructed | Curve**).
2. From the **Feature** list, select the desired set.
3. Select the **Use tolerance** check box and then set the value in the **Thinning Tolerance** box. Update the **Thinning proportion** value if necessary. For details, see the "Thinning Parameters" topic in this documentation.
4. Edit the control points if necessary. For details, see the "Edit Control Point" topic in this documentation.
5. Click the **Create** button.

All constructed curves start out as DEPENDENT curves and must be created from a single input, a set. The set can be one of three types:

- A measured set

- A constructed set
- A scan containing a single row of points. (See "Constructing a Set of Features".)

The input set must contain at least four features or points (in the case of a scan).

The resulting curve depends on the order that the features are added to the set (first to last).

You can also construct a curve by simply selecting multiple features from the feature list box rather than selecting a constructed set from the list. In this case, the command's `INPUT_TYPE` field will be empty when viewing the command in the Edit window.

The following paragraphs describe the options for constructing a curve.

Thinning Parameters (Thinning Tolerance or Thinning Proportion)

You can use one of two types of thinning parameters: Thinning Tolerance or Thinning Proportion. The **Use tolerance** check box on the **Construct Surface** and **Construct Curve** dialog boxes (**Insert | Feature | Constructed | Surface** and **Insert | Feature | Constructed | Curve**, respectively) lets you switch between either tolerance or proportion:

- *Thinning tolerance* controls the tightness (or exactness) of the curve or surface fit. Valid thinning tolerances range from 0.0 to 5.0, with the default being 0.01. The smaller the thinning tolerance, the closer the curve comes to passing through the centroids of the features included in the input set. If the thinning tolerance is 0.0, the curve or surface will pass through all of the centroids. A larger thinning tolerance will result in a curve or surface that has fewer fluctuations (at the expense of not lying near the input set's features). To see this, construct a curve or surface and then change the input tolerance and examine how its shape changes.
- *Thinning proportion*, alternately, may be used to control the quality of the fit. Valid thinning proportions range from between 0.0 and 1.0, with a default value of 0.33. The thinning proportion determines the number of degrees of freedom available in fitting the curve or surface to the centroids. At the lower extreme of 0, the algorithm will attempt to fit a straight line or plane to the centroids. At 1, it will compute a fit that passes through all of the centroids.

To make a DEPENDENT curve an INDEPENDENT curve (so that it is no longer associated with the input set):

1. Open the Edit window (**View | Edit Window**).
2. Select the curve feature that you constructed.
3. Navigate to the DEPENDENT field of that feature.
4. Press F7. It will change from DEPENDENT to INDEPENDENT.

You can change the shape of the curve by editing its control points.

Edit Control Point

If you select a preexisting curve, the **Construct Curve** dialog box (**Insert | Feature | Constructed | Curve**) also contains a list of control points in **Control Point list**. Select one of the control points. PC-DMIS places the corresponding values in the **X**, **Y**, and **Z** boxes so that you can edit them.

To edit these control points:

1. Ensure that a curve feature already exists.
2. Open the Edit window (**View | Edit Window**).
3. Select the curve in the Edit window.
4. Press F9 to activate the **Construct Curve** dialog box.
5. Select the control point to be changed in **Control Point list**. For details, see the "Control Point List" topic in this documentation.
6. Edit the individual X, Y, and Z components of the point.
7. Click the **OK** button.

The curve is then updated to reflect the changes.

If you edit the control points on a dependent curve, it automatically becomes an independent curve because it is no longer based on the input set.

Control Point List

The **Control Point list** option in the **Construct Curve** dialog box (**Insert | Feature | Constructed | Curve**) is only visible when there is an existing curve associated with the dialog box. If a curve exists and you want to edit the control points of that curve, the **Control Point list** displays all of the control points for that curve.

Determining the Length Between Two Points on a Scan

To determine the length between two points on a scan, do the following:

1. Open the **Construct Curve** dialog box (**Insert | Feature | Constructed | Curve**).
2. Select a previously created scan for your input.
3. Click the **Create** button. PC-DMIS inserts a constructed curve into the Edit window.

4. On the Edit window (**View | Edit Window**), in Command Mode, locate the last line of the constructed curve code block:
   `CONSTR/CURVE`

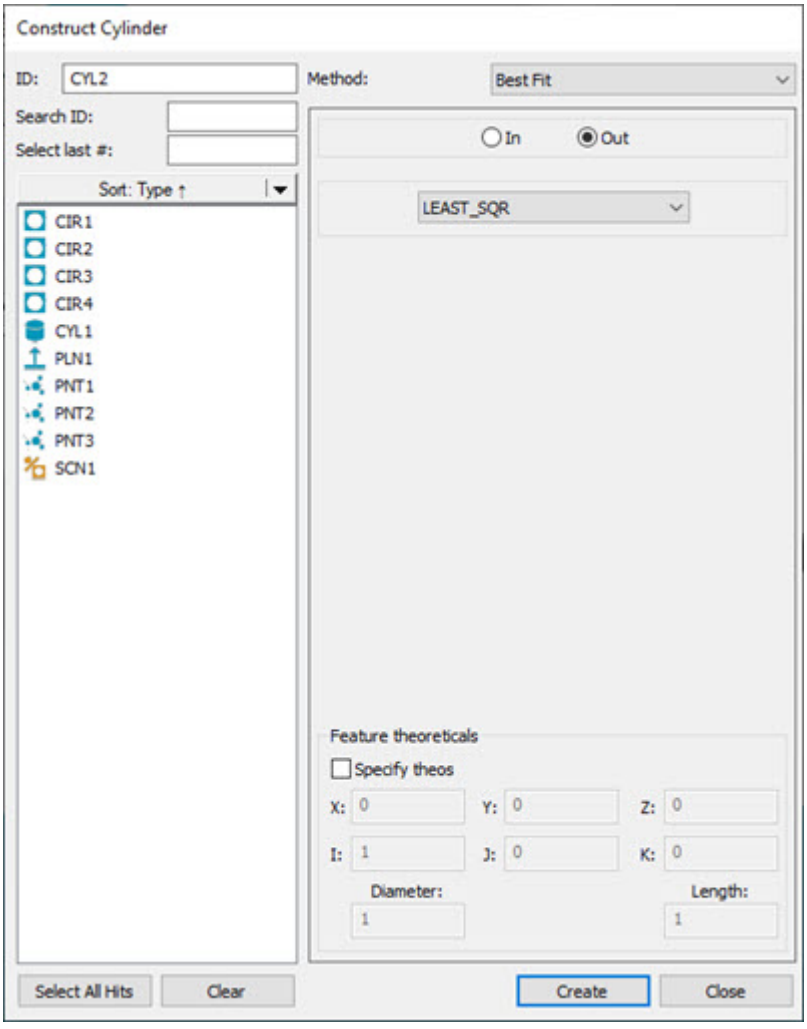
5. Press the Tab key on your keyboard until PC-DMIS highlights the ID for the scan you selected to use as the input.

6. Change the input ID to use specific points from the scan by typing `SCN1.HITS[n..m]` where SCN1 represents your scan ID and n and m represent a range between two points (or hits) on the scan. For example, if you wanted to get the length between hits 50 and 80 of the scan with an ID of SCN12, you would type, `SCN12.HITS[50..80]` .

7. Create a Location dimension and use the constructed curve as the input. Use the dimension to report the L axis (L for Length). The location dimensions would then display the length of the spline between the two hits you specified.

If you omit steps 4, 5, and 6, PC-DMIS reports the entire length of the scan (or curve).

Constructing a Cylinder Feature



Construct Cylinder Dialog Box

PC-DMIS allows several methods for constructing a cylinder. The following table lists the various types of constructed cylinders, along with their necessary inputs. Some features may require no inputs while others may require six inputs or more. In the following table, the term "Any" indicates that the construction can take any type of feature as input for the construction. PC-DMIS allows you to select the features in any order.

Construct Feature Type	Edit Window Symbol	Number of Required Input Features	Primary Feature	Secondary Feature	Comments
Auto Cylinder	-	-	-	-	See "Auto Cylinder Construction".
Best Fit Cylinder	BF	At least 6 inputs are needed. See Notes below.	-	-	Constructs a best fit cylinder using the given inputs.
Best Fit Recomp Cylinder	BFRE	At least 6 inputs are needed. (1 must be a point) See Notes below.	-	-	Constructs a best fit cylinder using the given inputs.
Cast Cylinder	CAST	1	Any	-	Constructs a cylinder at the centroid of the input feature.
Project Cylinder	PROJ	1 or 2	Any	Plane	One input feature will project the cylinder to the workplane.
Reverse Cylinder	REV	1	Cylinder, Cone, Line, Slot	-	Constructs a cylinder with a reversed vector.
Extracted Cylinder	EXTRACTED_CYL	1	COP or Mesh	-	Constructs an extracted cylinder from the COP or Mesh object at the specified diameter or height.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

You can construct Best Fit and Best Fit Recompensate Cylinders from two circles. The input circles must be of type Constructed Best Fit (BF) / Best Fit Recompensate (BFRE) or Measured circles. The total amount of hits in each circle must be at least three.

If you select inappropriate feature types, PC-DMIS displays this message on the Status bar:

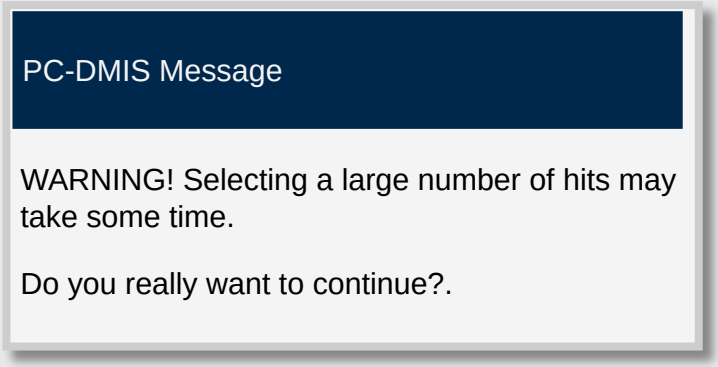
"Cannot construct [feature]. Combination of input features not accepted."

To construct a cylinder:

1. Open the **Construct Cylinder** dialog box (**Insert | Feature | Constructed | Cylinder**).
2. From the **Method** list, select the method of the constructed cylinder. The available options are:
    - Best Fit or Best Fit Recompensate Cylinder
    - Cast Cylinder
    - Projected Cylinder
    - Reversed direction Cylinder
    - Auto Cylinder
    - Extracted Cylinder

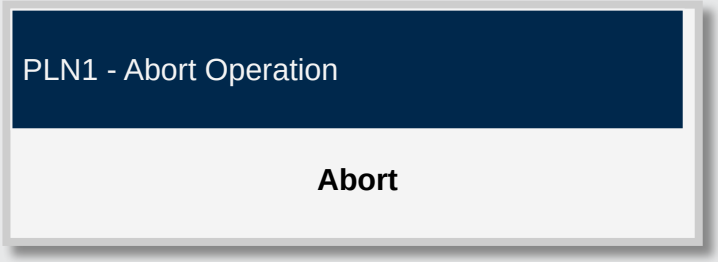
If you select the **Best Fit** or the **BF Recomp** (Best Fit Recomp) method for this feature, PC-DMIS allows you to click the **Select All Hits** button to create the construction from the individual hits of the input features instead of their centroids.

If there are a large number of points involved (about 10,000 or more), PC-DMIS shows a message asking if you are sure you want to proceed as this may take some time to complete.



Click **Yes** to proceed, click **No** to abort the process. You can select the **Don't ask me again** check box to prevent this message from recurring.

If you click **Yes**, another message is shown similar to the one shown below to let you know that PC-DMIS is generating the features from the hit points.

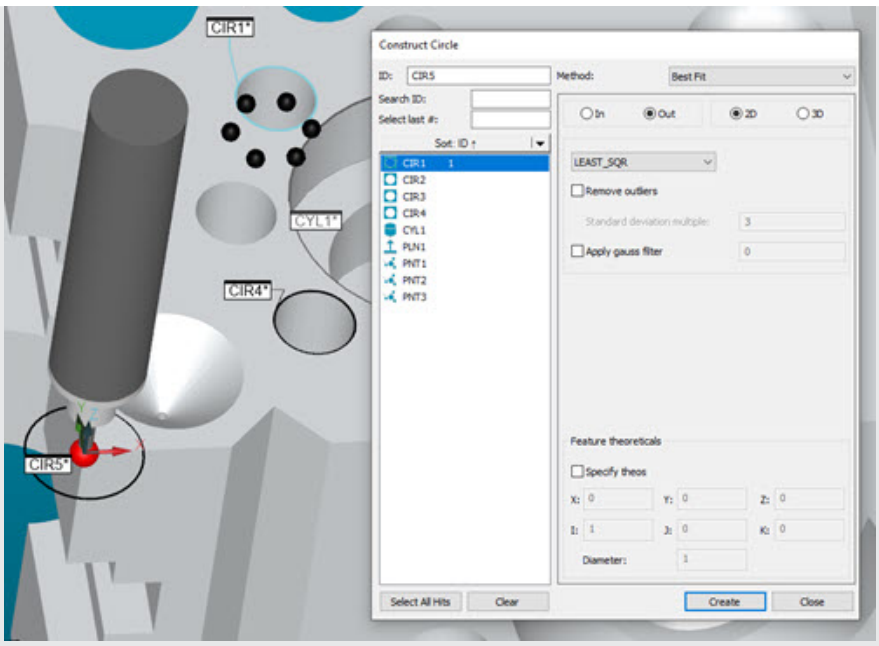


Once all the constructed features are created, the message disappears.

You can click the **Abort** button at any time to stop the process. Any features created up to this point are listed in the **Feature list** area of the dialog box.

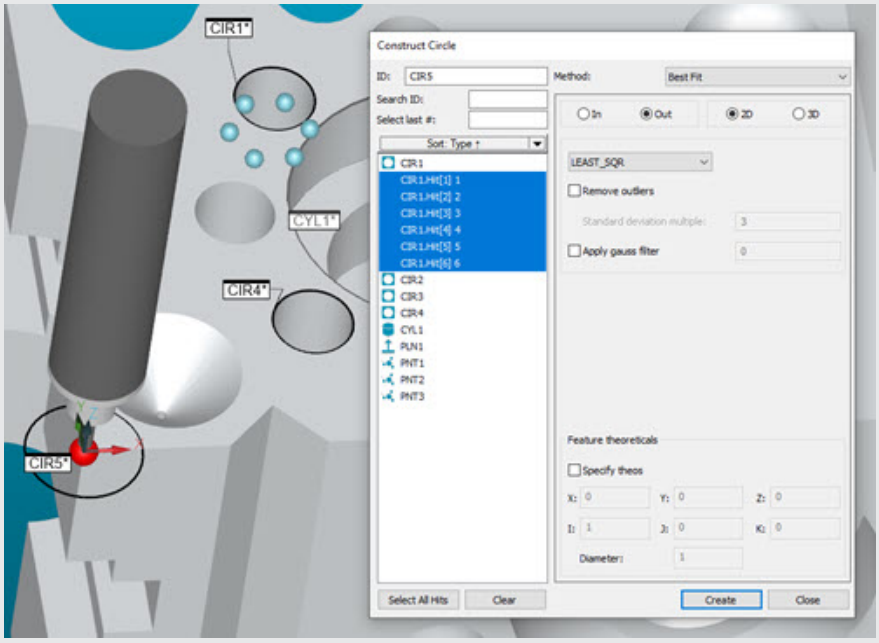
To create constructed features from the individual hits of the input features, do this:

1. From the **Feature list**, select the feature or features that you want to use to create the constructed feature.



Example showing a selected feature prior to clicking the Select All Hits button.

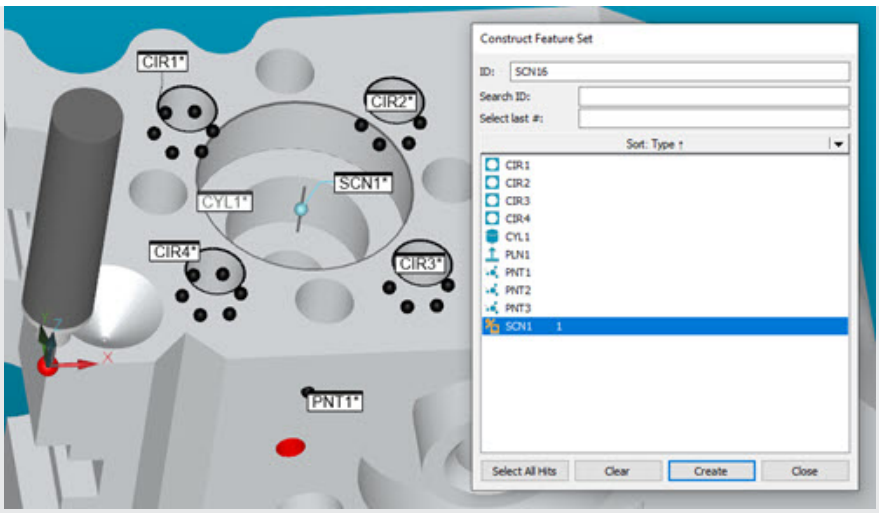
2. Click the **Select All Hits** button to display all the components that comprise the selected feature or features.



Display of items that make up the selected feature are highlighted in the dialog box and in the Graphic Display window.

PC-DMIS displays and highlights all the components of the selected feature (or features) in the **Feature list** are of the dialog box. You can select or de-select any of the features or feature components shown in the list to include or exclude them.

3. Click the **Create** button to create the Constructed feature based on the final features and feature components that you selected.



Constructed feature created based on the selected items from the Feature list.

3. Using the table above, select the features from the **Feature** list based on the selected method.
4. Select the **In** or **Out** option. For details, see the "In / Out Cylinder" topic in this documentation.
5. If you selected either the Best Fit or Best Fit Recompensate methods, from the **Best Fit Type** list, select the type of best fit algorithm to use. For details, see the "Best Fit Type" topic in this documentation.
6. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
7. Click the **Create** button.

The Edit window command line for a sample Cylinder Construction would read:

```
feature_name=FEAT/CYLINDER, TOG1,TOG4,TOG5

THEO/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,diam,length

ACTL/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,diam,length

CONSTR/ TOG2,TOG3,.....
```

The actual Edit report displays in all capital letters.

AUTO is the default method of construction. This option automatically determines the best way to construct a cylinder using the input feature(s). See "Auto Cylinder Construction"

The following text is the basic format for cylinders.

TOG1 = POLR or RECT

TOG2 = CYLINDER

TOG3 = BF / BFRE / CAST / PROJ / REV

TOG4 = IN / OUT

TOG5 = LEAST_SQR / MAX_INSC / MIN_CIRCSC / MIN_SEP / FIXED_RAD (only for measured, BF and BFRE circles)

length = This value is measured between the first measured circle (first three hits) and the furthest point away from the first three hits.

The first three lines displayed in the Edit window will be the same for constructed cylinders. The fourth line will be slightly different, according to the type of feature you are constructing. You can switch between the different types of cylinders by placing the cursor on TOG3 and pressing F7 or F8. (See "Command Mode Keyboard Functions" in the "Using the Edit Window" chapter.)

When two or more features are involved, PC-DMIS automatically determines the necessary order of the input features. This improves the accuracy of the measurement process.

The following topics describe the available options for constructing a cylinder:

In / Out Cylinder

The **In** and **Out** options tell PC-DMIS whether to construct the cylinder as an internal or an external cylinder.

- If you select **In**, PC-DMIS constructs the cylinder as an internal cylinder.
- If you select **Out**, PC-DMIS constructs the cylinder as an external cylinder.

Auto Cylinder Construction

The following list indicates the type of cylinder that PC-DMIS constructs when you select the specified inputs and choose the **Auto** method. The order of the selected features is not important. If you choose an incorrect input feature, PC-DMIS displays an error message and does not automatically construct the indicated feature type.

Be aware that certain patterns of points, such as two rows of three equally spaced points or two rows of four equally spaced points, result in multiple ways to construct or measure a cylinder. The Best Fit algorithm may then construct or measure the cylinder using an unexpected solution. For best results, measured or constructed cylinders should use a pattern of points that will eliminate unwanted solutions.

To allow PC-DMIS to automatically determine the best method of construction:

1. Open the **Construct Cylinder** dialog box (**Insert | Feature | Constructed | Cylinder**).
2. From the **Method** list, select the **Auto** option.
3. From the **Feature** list, select the desired feature or features based on the "Input Feature List" table below.
4. Select the **In** or **Out** option. For details, see the "In / Out Cylinder" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

Input Feature List

Input Feature(s)	Constructs
Five or more Features =	Best Fit Cylinder
Any One Cylinder =	Reverse Cylinder
Any One Feature (except Cylinder or Set) =	Cast Cylinder
Any One Set =	Best Fit Cylinder
Plane + Any Feature =	Project Cylinder

Constructing a Best Fit or Best Fit Recompensate Cylinder

You can construct a best fit cylinder from six or more points. The first three points must be on an approximately planar cross section of the cylinder that is normal to its centerline. PC-DMIS computes a *least squares* cylinder, one for which PC-DMIS minimizes the average squared distance from the data points to the cylinder.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

Be aware that certain patterns of points, such as two rows of three equally spaced points or two rows of four equally spaced points, result in multiple ways to construct or measure a cylinder. The Best Fit algorithm may then construct or measure the cylinder using an unexpected solution. For best results, measured or constructed cylinders should use a pattern of points that will eliminate unwanted solutions.

To construct a Best Fit or Best Fit Recompensate Cylinder:

1. Open the **Construct Cylinder** dialog box (**Insert | Feature | Constructed | Cylinder**).
2. From the **Method** list, select either the **Best Fit** or **BF Recomp** option.
3. From the **Feature** list, select your input features by either choosing at least two appropriate circle features or at least six features of any type.
    - *For at least two circle features*, they *must* be constructed Best Fit (BF) / constructed Best Fit Recompensate (BFRE), or measured circles. The total amount of hits in each circle must be at least three.
    - *For at least six features*, they can be of any type.
    - However, if you selected **BF Recomp**, at least one feature must be a point.
4. From the **Best Fit Type** list, select the type of best fit algorithm to use. For details, see the "Best Fit Type" topic in this documentation.

5. Click the **Create** button.

> The math routine that PC-DMIS uses to get the points from the input features behaves differently depending on the type of input feature. Constructed features other than the appropriate input circles described above return a single point. The constructed BF circles, constructed BFRE circles, or measured circles described above return their input points.

The Edit window command line for this option would read:

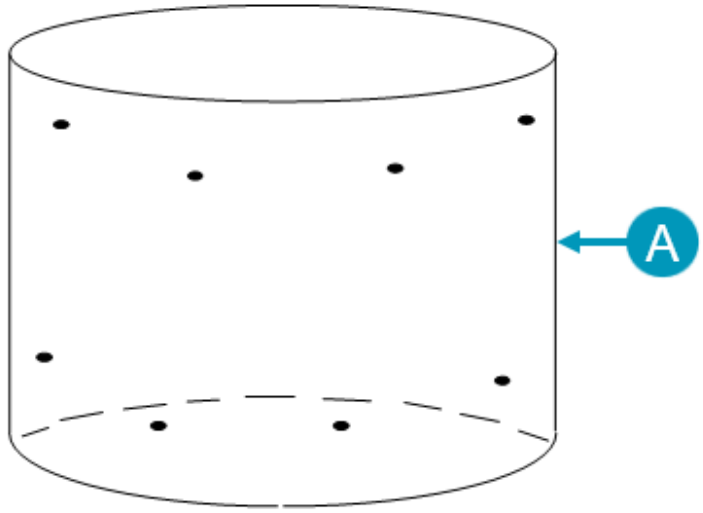
```
CONSTR/CYLINDER,BF, feat_1,feat_2,feat_3,feat_4,feat_5,feat_6
```

(Uses the actual measured points for construction.)

or

```
CONSTR/CYLINDER,BFRE, feat_1,feat_2,feat_3,feat_4,feat_5,...
```

(Uses the center of the probe for measurement.)



A - *Best Fit Cylinder constructed from eight points*
Constructing a Cylinder from Six or More Points

Best Fit Type

This list becomes available if you select **Best Fit** or **BF Recomp** options when you construct the cylinder. It allows you to specify the type of Best Fit construction used. The types are:

- LEAST_SQR
- MIN_SEP
- MAX_INSC

- MIN_CIRCSC
- FIXED_RAD

These calculation types are discussed in the "Best Fit Type" topic for a constructed circle feature.

Constructing a Projected Cylinder

You can construct a cylinder from any feature and a plane. The diameter of the projected cylinder is the diameter of the first input feature (if circular) or twice the probe diameter if not a circular feature. You need to input the length and diameter for bound measurements. If there is only one input feature, the projection is to the workplane.

To construct a Projected Cylinder:

1. Open the **Construct Cylinder** dialog box (**Insert | Feature | Constructed | Cylinder**).
2. From the **Method** list, select the **Projection** option.
3. From the **Feature** list, select *either* one or two features. If one feature is selected, the feature can be of any type. If two features are selected, the first feature can be of any type. The second feature *must* be a plane.
4. Select the **In** or **Out** option. For details, see the "In / Out Cylinder" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:
`CONSTR/CYLINDER,PROJ,` *feat_1,(feat_2)*

Constructing a Cast Cylinder

You can construct a cylinder by changing any given feature into a cylinder. PC-DMIS constructs the cylinder at the centroid of the input feature. If a sheet metal point is used, the diameter is the probe diameter. For some sheet metal features (such as slots and notches) the width will be used as the diameter. For features that do not have diameters (lines, points, etc.), a value that is four times the probe diameter is used.

You can change the size of the cylinder; this changes the cylinder from DEPENDENT to INDEPENDENT. This means that when the cylinder is executed, the length and diameter do not change based on the input feature but remain independent of the input feature,

while the position and vector stay dependent on the input feature. This allows you to have control over the cylinder size in cases where the input feature doesn't really have a length and diameter, such as a point. The DEPENDENT/INDEPENDENT field is a toggle field that you may change.

PC-DMIS uses the new attributes for all calculations (for example, if the diameter is changed) instead of the default values as described above.

To construct a Cast Cylinder:

1. Open the **Construct Cylinder** dialog box (**Insert | Feature | Constructed | Cylinder**).
2. From the **Method** list, select the **Cast** option.
3. From the **Feature** list, select one feature. The feature can be of any type.
4. Select the **In** or **Out** option. For details, see the "In / Out Cylinder" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/CYLINDER,CAST, feat_1 , (DEPENDENT | INDEPENDENT)
```

Changing the Direction of a Cylinder

You can construct a cylinder with a reversed vector.

To construct a cylinder with reverse vectors, follow these steps:

1. Open the **Construct Cylinder** dialog box (**Insert | Feature | Constructed | Cylinder**).
2. From the **Method** list, select the **Reverse** option.
3. From the **Feature** list, select one feature. It *must* be a cylinder.
4. Select the **In** or **Out** option. For details, see the "In / Out Cylinder" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.

6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/CYLINDER,REV, feat_1
```

Constructing an Extracted Cylinder

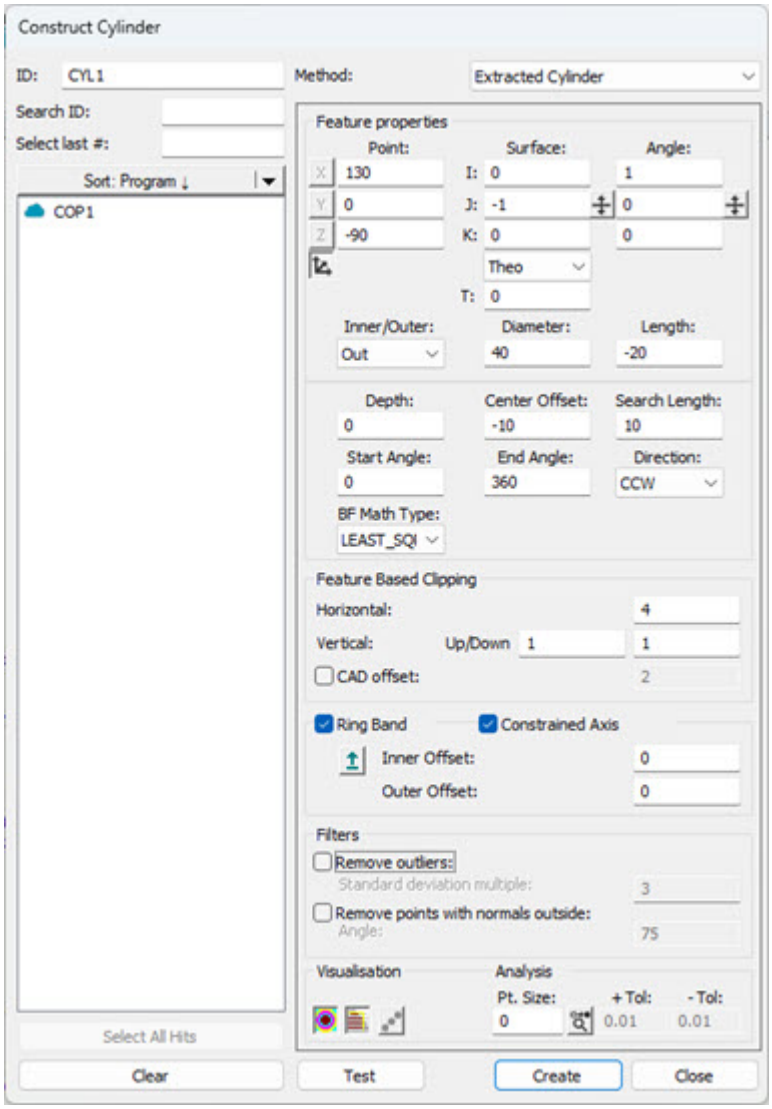
For details on extracting Auto features from a Mesh, see the "Extracting Auto Features from a Mesh" topic in the PC-DMIS Laser documentation.

For details on extracting Auto features from a Pointcloud (COP), see the "Extracting Auto Features from Pointclouds" topic in the PC-DMIS Laser documentation.

You can construct a cylinder that is extracted from a scanned pointcloud (COP) or mesh.

To do this, follow these steps:

1. Ensure that your measurement routine has a Pointcloud (COP) or Mesh command.
2. Open the **Construct Cylinder** dialog box (**Insert | Feature | Constructed | Cylinder**) or from the **Constructed Feature** toolbar (**View | Toolbars | Constructed Features**).



Construct Cylinder Dialog Box - Extracted Cylinder Option

3. From the **Method** list, select the **Extracted Cylinder** option.

4. From the **Reference** area, select the COP or Mesh that you want to use to extract the cylinder from.

5. Click on the CAD model or data to define the nominal or, in the **Point** section of the **Feature properties** area, type the nominal location in the **X**, **Y**, and **Z** boxes.

6. From the **Surface** section of the **Feature properties** area, define the surface vector in the **I**, **J**, and **K** boxes. In the **Angle** section, enter the corresponding vector angle values. You can use the **Material Thickness Type** list and the **T** box below it to type in a material thickness value. For details, see the "Use Thickness" topic in this documentation.

   You can use these controls to perform the associated functions:

   Flip Vectors

   Polar/Cartesian

For details on these controls, see the appropriate topic in the "Feature Properties Area" section of the "Creating Auto Features" chapter of the PC-DMIS Core documentation.

7. Select whether the extracted cylinder is an inner or outer cylinder type from the **Inner/Outer** list.

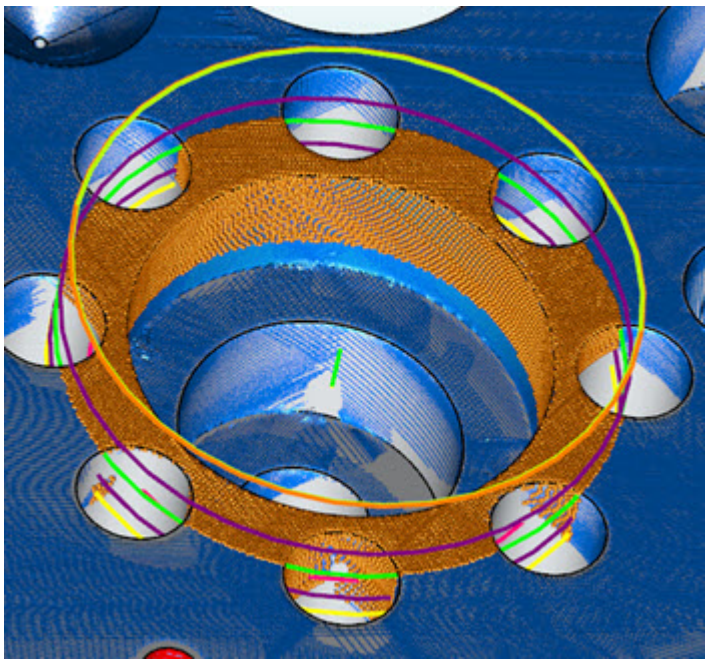
8. Enter the diameter and length of the cylinder in the respective boxes. The **Diameter** value defines the cylinder's initial diameter, and the **Length** value defines the length (height) of the cylinder's axis. The **Length** parameter is only valid as nominal. PC-DMIS does not perform an actual length measurement.

9. Enter the **Depth** value. This parameter controls the location of the laser focal point in relation to the cylinder's outside diameter (outer cylinders) or the cylinder's center axis (inner cylinders). This allows you to control how the laser stripes fall on the cylinder's surface by specifying how far or close the laser is to the cylinder's surface. A depth of 0 (zero) causes this feature to be calculated at the surface plane height using data found at the lowest possible depth from the surface plane. A depth of any other value causes the software to perform the calculation at that depth.

10. Enter the **Center Offset** value. This value identifies the center location of where the laser starts to measure the cylinder. If you do not enter a **Search Length** value, this value defines where the measurement begins.

11. Enter the **Search Length** value. This value defines the distance from the **Center Offset** the laser measures for the cylinder. For example, if you have a **Center Offset** value of zero and a **Search Length** value of 20, the laser begins measuring +20 units from the **Center Offset** value.

    PC-DMIS draws the extraction zone and centers it around the XYZ location point. This box defines the zone that PC-DMIS uses for the extracted cylinder. The yellow cylinder is the surface. The yellow cylinder is also the horizontal zone and the green cylinder is the vertical zone. The orange points are the candidate points that the extraction considers.



Example of a constructed extracted cylinder showing the candidate points.

12. The **Start Angle** and **End Angle** boxes allow you to change the default starting and ending angles on the feature. For details on these boxes, see the "Start and End Angles" topic in this documentation.

13. You can use the **Direction** list to specify the direction in which PC-DMIS takes the hits. For details, see "Direction List" in this documentation.

14. You can use the **BF Math type** to select the type of best fit algorithm to use. For details see the "Best Fit Type" topic in this documentation.

15. From the **Feature Based Clipping** area, define the **Horizontal**, **Vertical Up/Down**, and **Vertical** values. These values set the dimensions for the green extraction zone region. Consider part variability when you define the extraction zone.

    Alternatively, you can clip data within an offset boundary around all the CAD elements on a surface with the **CAD offset** option. This is also called *CAD segregation*. For details, see the "CAD offset" section of the "Feature Based Clipping Parameters" topic in the PC-DMIS Laser documentation.

15. If you want to define the Ring Band offsets, click the **Ring Band** check box and type the **Inner Offset** and **Outer Offset** values. Click the **Constrained Axis** check box to constrain the Cylinder feature to the vector of the plane surrounding the cylinder. For details on how the **Ring Band** works, see the "Ring Band Parameters" topic in the PC-DMIS Laser documentation.

16. If you want to filter out any outlier points, from the **Filters** area, select the **Remove outliers** check box and define the **Standard deviation multiple** to determine which points PC-DMIS excludes as outliers.

17. If you want to filter out any points that are outside of a maximum incidence angle, from the **Filters** area, select the **Remove points with normals outside** check box and type the value in the **Angle** (Max Incidence Angle) box.

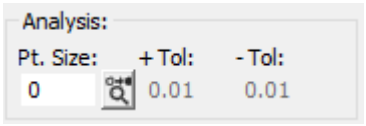
> The Max Incidence Angle filter was initially designed to compare the incidence direction of the laser (which is roughly the laser sensor orientation) to the estimated normal of the segregated points. For 3D laser features (Laser Auto Cone, Cylinder, Plane, Sphere, Surface Point and Constructed Extracted Cone, Cylinder, Plane, Sphere, Surface Point), the filter now compares the estimated normal of the pointcloud point to the nominal normal of the feature, which greatly improves the results. 2D laser features remain unchanged, using the legacy incidence angle filter method.
>
> For details on the **Filters** area, see the "Filters" topic in the PC-DMIS Laser documentation.

18. In the **Visualisation** section, PC-DMIS provides these options to perform the described function:

Visualisation Tools On/Off - This button toggles the display of the colored visualisation tools. For more information, see "Understanding the Visualisation Tools".

Show/Hide segregated points - This button toggles the display of the points that the software passes to the feature extractor engine based on the current settings.

Show/Hide measured points - This button toggles the display of the measured points. It remains greyed out until you click **Test** or **Create**. For more information, see the "Show Measured Points" topic in the PC-DMIS Core documentation.

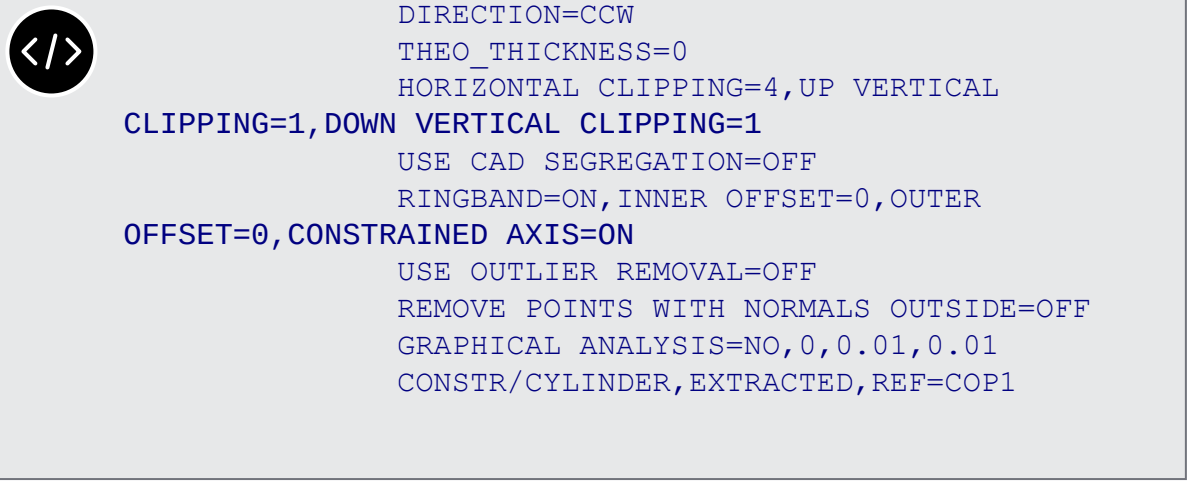


- The **Analysis** area allows you to determine how each measured hit/point is displayed. For more information, see the “Analysis Area” topic in the PC-DMIS Core documentation.

19. Click the **Test** button to test a feature's creation and preview its dimensional data before you create it. PC-DMIS performs a measurement using the current parameters. You can change the parameters and click **Test** repeatedly until you have an acceptable measurement. Then, when you click **Create**, the software converts the temporary feature into a normal feature in the measurement routine.

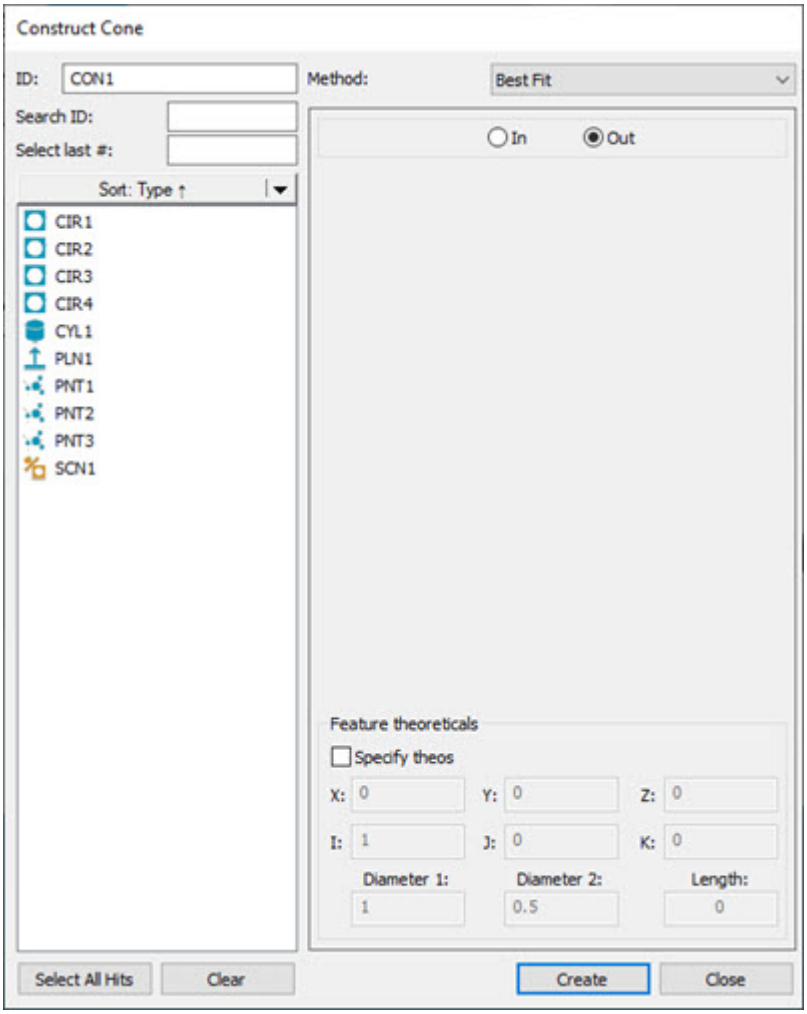
20. Click the **Create** button. Based on the parameters that you specified in the dialog box, PC-DMIS does an analysis of the candidate points and returns (or extracts) each measured point and projects them to the surface.

    PC-DMIS creates the command in the Edit window:



```
CYL1       =FEAT/CYLINDER,CARTESIAN,OUT,LEAST_SQR
            THEO/<120,0,-90>,<0,-1,0>,40,20
            ACTL/<120,0,-90>,<0,-1,0>,40,20
            ANGLE VEC=<1,0,0>
            DEPTH=0
            CENTER OFFSET=-10
            SEARCH LENGTH=10
            START ANG=0,END ANG=360
            DIRECTION=CCW
            THEO_THICKNESS=0
            HORIZONTAL CLIPPING=4,UP VERTICAL
CLIPPING=1,DOWN VERTICAL CLIPPING=1
            USE CAD SEGREGATION=OFF
            RINGBAND=ON,INNER OFFSET=0,OUTER
OFFSET=0,CONSTRAINED AXIS=ON
            USE OUTLIER REMOVAL=OFF
            REMOVE POINTS WITH NORMALS OUTSIDE=OFF
            GRAPHICAL ANALYSIS=NO,0,0.01,0.01
            CONSTR/CYLINDER,EXTRACTED,REF=COP1
```

Constructing a Cone Feature



Construct Cone Dialog Box

PC-DMIS allows several methods for constructing a cone. The following table lists the various types of constructed cones, along with their necessary inputs. Some features may require no inputs while others may require six inputs or more. The term "Any" in the table below indicates that the construction can take any type of feature as input for construction. PC-DMIS allows you to select the features in any order.

Construct Feature Type	Edit Window Symbol	Number of Required Input Features	Primary Feature	Secondary Feature	Comments
Auto Cone	-	-	-	-	See "Auto Cone Construction".
Best Fit Cone	BF	At least 6 inputs are needed.	-	-	Constructs a best fit cone using the given inputs. See the Note below for recommended inputs.
Best Fit with Recomp Cone	BFRE	At least 6 inputs are needed. (1 must be a point)	-	-	Constructs a best fit cone using the given inputs. See the Note below for recommended inputs.
Cast Cone	CAST	1	Any	-	Constructs a cone at the centroid of the input feature.
Project Cone	PROJ	1 or 2	Any	Plane	Using one input feature, projects the cone to the workplane.
Reverse Cone	REV	1	Cone	-	Constructs a cone with a reversed vector for the axis.
Extracted Cone	EXTRACTED_CONE	1	COP or Mesh	-	Constructs an extracted cone from the COP or Mesh object at the specified diameter or height of the cone.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

If you select inappropriate feature types, PC-DMIS displays this message on the Status bar:

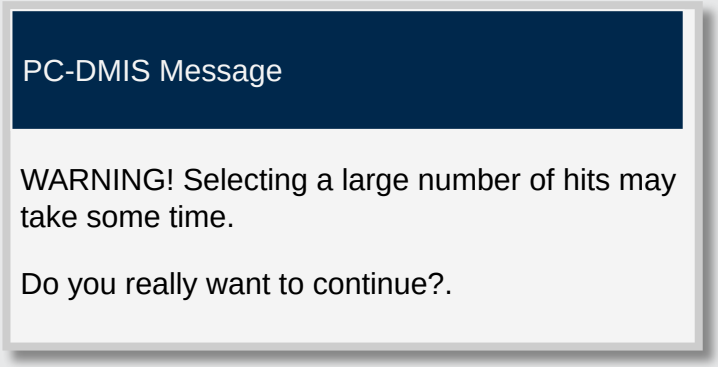
"Cannot construct [feature]. Combination of input features not accepted."

To construct a cone:

1. Open the **Construct Cone** dialog box (**Insert | Feature | Constructed | Cone**).
2. From the **Method** list, select the method of the constructed cone. The available options are:
    - Auto Cone
    - Best Fit
    - Best Fit Recompensate Cone
    - Projected Cone
    - Cast Cone
    - Reversed direction Cone
    - Extracted Cone

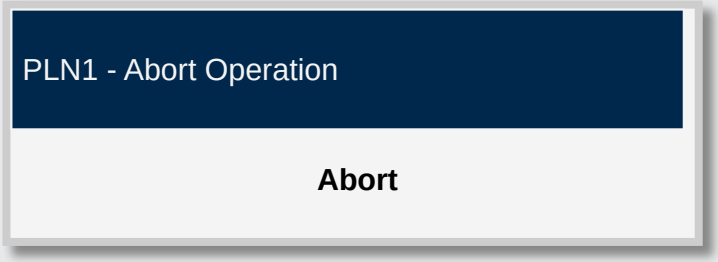
If you select the **Best Fit** or the **BF Recomp** (Best Fit Recomp) method for this feature, PC-DMIS allows you to click the **Select All Hits** button to create the construction from the individual hits of the input features instead of their centroids.

If there are a large number of points involved (about 10,000 or more), PC-DMIS shows a message asking if you are sure you want to proceed as this may take some time to complete.



Click **Yes** to proceed, click **No** to abort the process. You can select the **Don't ask me again** check box to prevent this message from recurring.

If you click **Yes**, another message is shown similar to the one shown below to let you know that PC-DMIS is generating the features from the hit points.

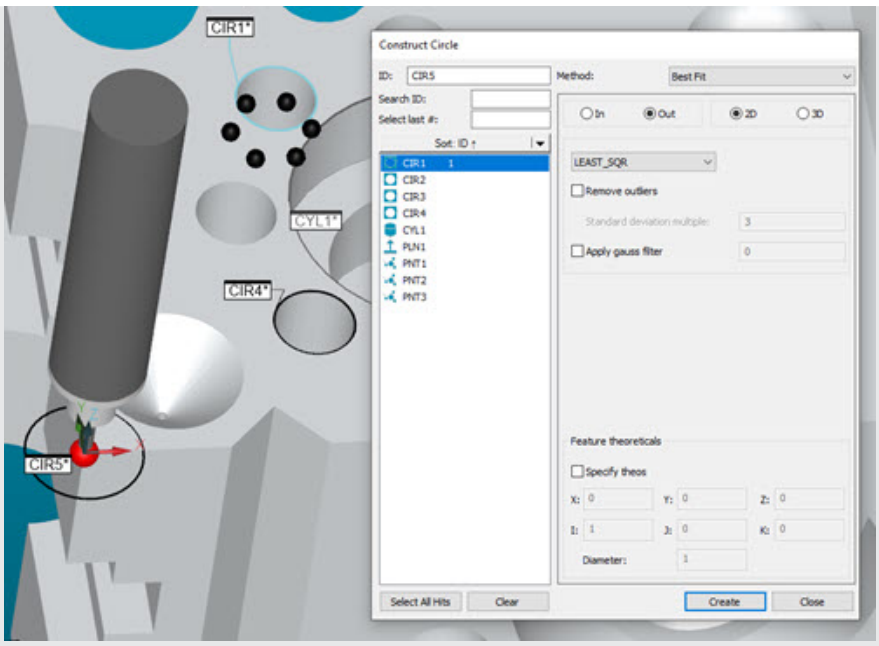


Once all the constructed features are created, the message disappears.

You can click the **Abort** button at any time to stop the process. Any features created up to this point are listed in the **Feature list** area of the dialog box.

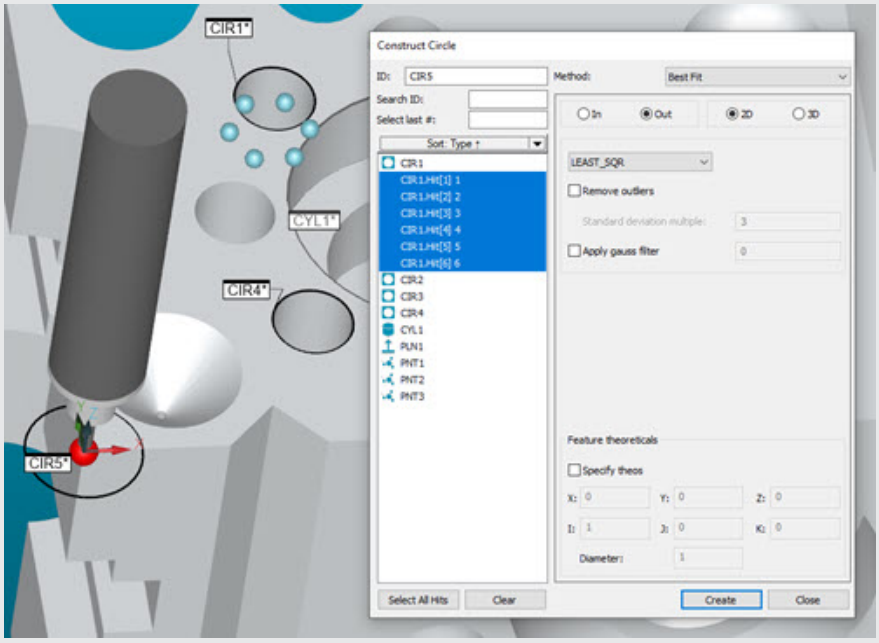
To create constructed features from the individual hits of the input features, do this:

1. From the **Feature list**, select the feature or features that you want to use to create the constructed feature.



Example showing a selected feature prior to clicking the Select All Hits button.

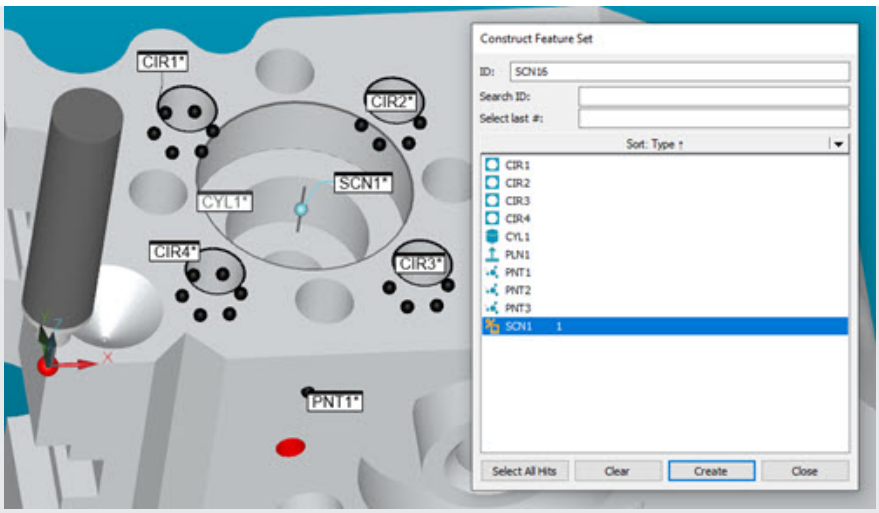
2. Click the **Select All Hits** button to display all the components that comprise the selected feature or features.



Display of items that make up the selected feature are highlighted in the dialog box and in the Graphic Display window.

PC-DMIS displays and highlights all the components of the selected feature (or features) in the **Feature list** are of the dialog box. You can select or de-select any of the features or feature components shown in the list to include or exclude them.

3. Click the **Create** button to create the Constructed feature based on the final features and feature components that you selected.



Constructed feature created based on the selected items from the Feature list.

3. Use the table above to select the features from the **Feature** list based on the selected method.
4. Select the **In** or **Out** option. For details, see the "In / Out Cone" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:

```
 feature_name=FEAT/CONE, TOG1,TOG4,ANG
THEO/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,ang
ACTL/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,ang
CONSTR/ TOG2,TOG3,.....
```

```
 feature_name=FEAT/CONE, TOG1,TOG4,LENG
THEO/x_cord,y_cord,z_cor,i_vec,j_vec,k_vec,leng,diam_1,diam_2
ACTL/x_cord,y_cord,z_cor,i_vec,j_vec,k_vec,leng,diam_1,diam_2
CONSTR/ TOG2,TOG3,.....
```

The actual Edit report displays in all capital letters.

TOG1 **= POLR or RECT**

TOG2 **= CONE**

TOG3 **= BF / BFRE / CAST / PROJ / REV**

TOG4 **= IN / OUT**

TOG5 **= ANG / LENG**

The first three lines that display in the Edit window are similar for constructed cones. If the feature is bound or unbound, the theoretical and actual values that are displayed will vary. The fourth line will be slightly different, according to the type of feature you are constructing. You can switch between the different types of cones by placing the cursor on TOG and clicking the left mouse button. The keyboard can also be used to switch toggle fields. (See "Command Mode Keyboard Functions" in the "Using the Edit Window" chapter.)

When two or more features are involved, PC-DMIS automatically determines the necessary order of the input features. This improves the accuracy of the measurement process.

Auto is the default method for constructed cones. This option automatically determines the best way to construct a cone using the input feature(s). See "Auto Cone Construction"

The following paragraphs describe the available options for constructing a cone:

In / Out Cone

The **In** and **Out** options tell PC-DMIS whether to construct the cone as an internal or an external cone.

- If you select **In**, PC-DMIS constructs the cone as an internal cone.
- If you select **Out**, PC-DMIS constructs the cone as an external cone.

Auto Cone Construction

The "Input Feature List" table indicates the type of cone that you can construct when you select the specified inputs and choose the **Auto** method. The order that you select the features is not important. If you select an incorrect input feature(s), PC-DMIS displays an error message and does not automatically construct the indicated feature type.

To allow PC-DMIS to automatically determine the best method of construction:

1. Open the **Construct Cone** dialog box (**Insert | Feature | Constructed | Cone**).
2. From the **Method** list, select the **Auto** option.
3. From the **Feature** list, select the desired feature or features based on the "Input Feature List" table below.

4. Select the **In** or **Out** option. For details, see the "In / Out Cone" topic in this documentation.

5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.

6. Click the **Create** button.

Input Feature List

Input Feature(s)	Constructs
Six or more Features	Best Fit Cone
Any One Cone	Reverse Cone
Any One Feature (except Cone or Set)	Cast Cone
Any One Set	Best Fit Cone
Plane + Any Feature	Project Cone

Constructing a Best Fit or Best Fit Recompensate Cone

You can construct a best fit cone using six or more features. The first three inputs must be on an approximately planar cross section of the cone that is normal to its center line. The remainder of the points should lie either above or below the plane defined by the first three points, but not on both sides of the plane. This method of measuring yields the best results. PC-DMIS computes a *least squares* cone, one for which PC-DMIS minimizes the average squared distance from the data points to the cone.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

To Construct a Best Fit or Best Fit Recompensate Cone:

1. Open the **Construct Cone** dialog box (**Insert | Feature | Constructed | Cone**).
2. From the **Method** list, select either the **Best Fit** or **BF Recomp** option.
3. From the **Feature** list, select at least six features.
4. Select the **In** or **Out** option. For details, see the "In / Out Cone" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

For a Best Fit constructed cone feature, the Edit window command line would read:

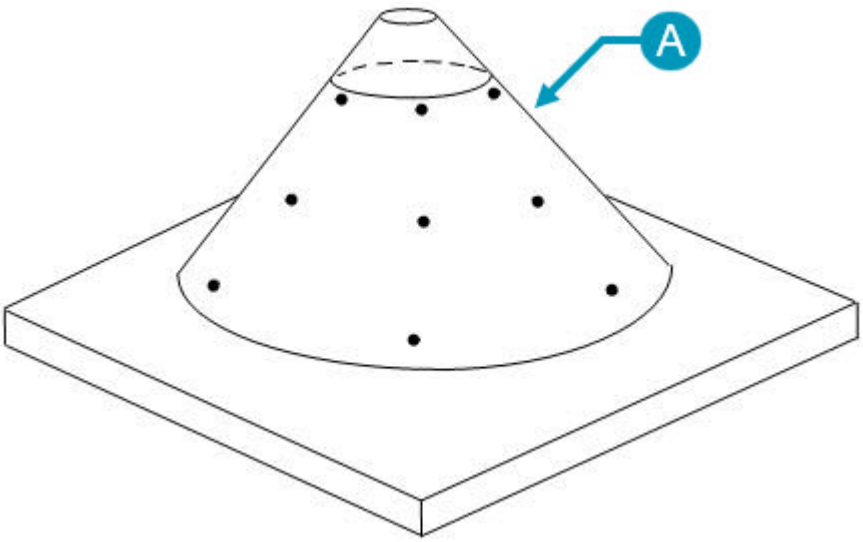
```
CONSTR/CONE,BF, feat_1,feat_2,feat_3,feat_4,feat_5,feat_6
```

PC-DMIS uses the actual measured points for construction.

For a Best Fit Recompensate constructed cone feature, the Edit window command line would read:

```
CONSTR/CONE,BFRE, feat_1,feat_2,feat_3,feat_4,feat_5,feat_6
```

PC-DMIS uses the center of the probe for measurement.



A - *Best Fit Constructed Cone from Nine Points*
Constructing a Cone from Six or More Points

Constructing a Projected Cone

You can construct a cone by projecting any feature onto a plane. If the projected input feature is not a cone, PC-DMIS uses default values for the included angle and two axis lengths. The first length is the distance between the vertex and the first circle. The second

length is the distance between the two circles. If there is only one input, the projection is to the current workplane.

To construct a Projected Cone:

1. Open the **Construct Cone** dialog box (**Insert | Feature | Constructed | Cone**).
2. From the **Method** list, select the **Projection** option.
3. From the **Feature** list, select *either* one or two features. If you only select one feature, the feature can be of any type. If you select two features, the first feature can be of any type, but the second feature *must* be a plane.
4. Select the **In** or **Out** option. For details, see the "In / Out Cone" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/CONE,PROJ, feat_1,(feat_2)
```

Constructing a Cast Cone

You can construct a cone by changing any given feature into a cone. PC-DMIS constructs the cone at the centroid of the input feature. If the input feature is not a cone, PC-DMIS uses a default value for the included angle. If the input feature is not a line element (line, cylinder, or slot), PC-DMIS uses a default length for the axis length.

You can change the size of the cone; this changes the cone from DEPENDENT to INDEPENDENT. This means that when the cone is executed that the size does not change based on the input feature, but is independent of the input feature, while the position and vector remain dependent on the input feature. This allows you to have control over the cone's size in cases where the input feature doesn't really have a size, such as a point. The DEPENDENT/INDEPENDENT field is a toggle field that you may change.

PC-DMIS uses the new attributes for all calculations (for example, if the half angle is changed) instead of the default values as described above.

To construct a Cast Cone:

1. Open the **Construct Cone** dialog box (**Insert | Feature | Constructed | Cone**).
2. From the **Method** list, select the **Cast** option.
3. From the **Feature** list, select one feature of any type.

4. Select the **In** or **Out** option. For details, see the "In / Out Cone" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/CONE,CAST, feat_1 , (DEPENDENT | INDEPENDENT)
```

Changing the Direction of a Cone

You can construct a cone with a reversed vector.

To construct a Reverse Cone:

1. Open the **Construct Cone** dialog box (**Insert | Feature | Constructed | Cone**).
2. From the **Method** list, select the **Reverse** option.
3. From the **Feature** list, select one feature. It *must* be a cone.
4. Select the **In** or **Out** option. For details, see the "In / Out Cone" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/CONE,REV, feat_1
```

Constructing an Extracted Cone

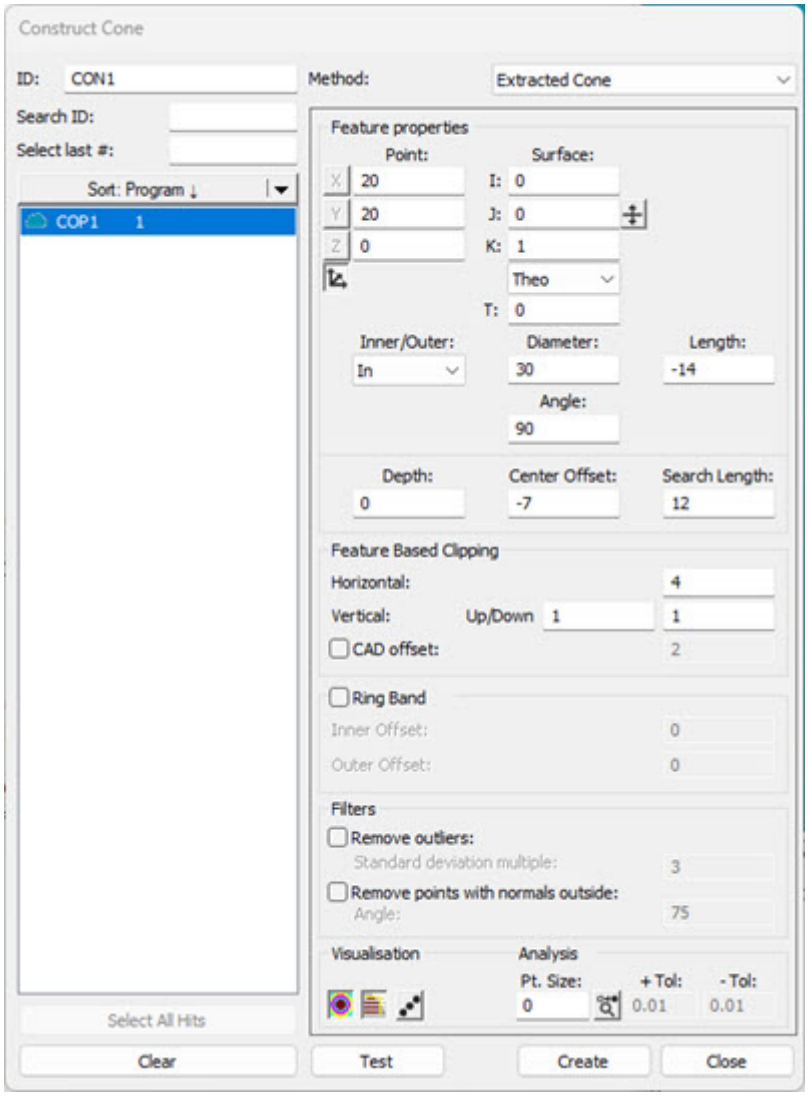
For details on extracting Auto features from a Mesh, see the "Extracting Auto Features from a Mesh" topic in the PC-DMIS Laser documentation.

For details on extracting Auto features from a Pointcloud (COP), see the "Extracting Auto Features from Pointclouds" topic in the PC-DMIS Laser documentation.

You can construct a cone that is extracted from a scanned pointcloud (COP) or mesh.

To do this, follow these steps:

1. Ensure that your measurement routine has a Pointcloud (COP) or Mesh command.
2. Open the **Construct Cone** dialog box (**Insert | Feature | Constructed | Cone**) or from the **Constructed Feature** toolbar (**View | Toolbars | Constructed Features**).



Construct Cone Dialog Box - Extracted Cone Option

3. From the **Method** list, select the **Extracted Cone** option.
4. From the **Reference** area, select the COP or Mesh that you want to use to extract the cone from.
5. Click on the CAD model or data to define the nominal or, in the **Point** section of the **Feature properties** area, type the nominal location in the **X**, **Y**, and **Z** boxes.
6. From the **Surface** section of the **Feature properties** area, define the surface vector in the **I**, **J**, and **K** boxes. In the **Angle** section, enter the corresponding vector angle values. You can use the **Material Thickness Type** list and the **T** box below it to type

in a material thickness value. For details, see the "Use Thickness" topic in this documentation.

You can use these controls to perform the associated functions:

Flip Vectors

Polar/Cartesian

For details on these controls, see the appropriate topic in the "Feature Properties Area" section of the "Creating Auto Features" chapter of the PC-DMIS Core documentation.

7. Select whether the extracted cone is an inner or outer cone type from the **Inner/ Outer** list.

8. Enter the diameter and length of the cone in the respective boxes. The **Diameter** value defines the cone's initial diameter, and the **Length** value defines the length (height) of the cone's axis. The **Length** parameter is only valid as nominal. PC-DMIS does not perform an actual length measurement.

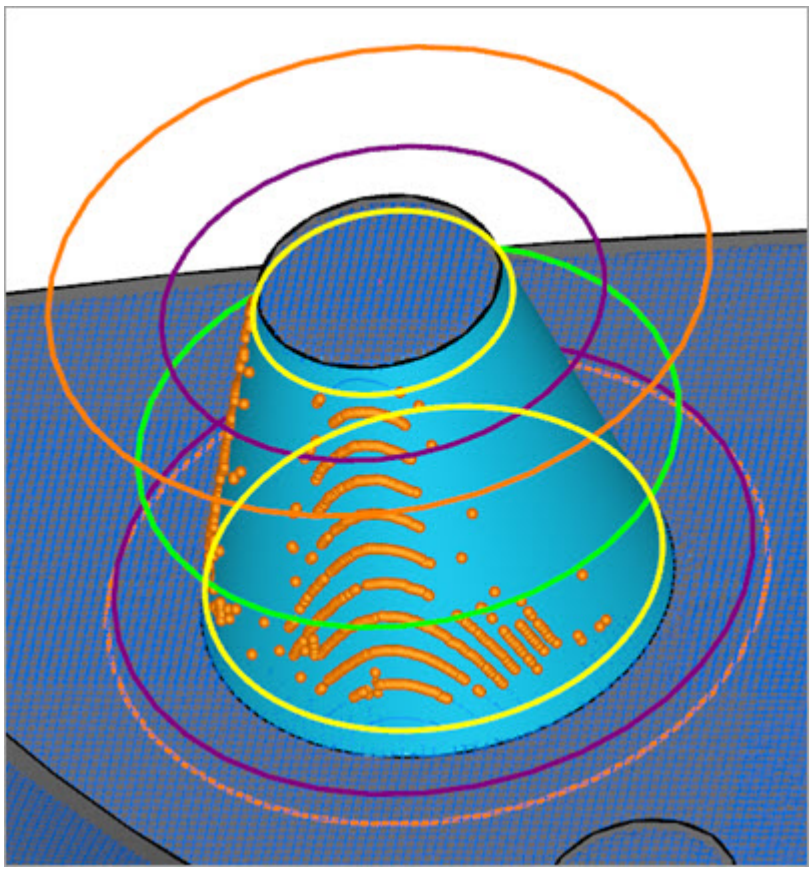
9. Enter the **Angle** value. This is the included angle of the cone.

10. Enter the **Depth** value. This parameter controls the location of the laser focal point in relation to the cone's outside diameter (outer cones) or the cone's center axis (inner cones). This allows you to control how the laser stripes fall on the cone's surface by specifying how far or close the laser is to the cone's surface. A depth of 0 (zero) causes this feature to be calculated at the surface plane height using data found at the lowest possible depth from the surface plane. A depth of any other value causes the software to perform the calculation at that depth.

11. Enter the **Center Offset** value. This value identifies the center location where the laser starts to measure the cone. If you do not enter a **Search Length** value, this value defines where the measurement begins.

12. Enter the **Search Length** value. This value defines the distance from the **Center Offset** the laser measures for the cone. For example, if you have a **Center Offset** value of zero and a **Search Length** value of 20, the laser begins measuring +20 units from the **Center Offset** value.

    PC-DMIS draws the extraction zone and centers it around the XYZ location point. This box defines the cylinder zone that PC-DMIS uses for the extracted cone. The yellow cylinder is the surface. The yellow cylinder is also the horizontal zone and the green cylinder is the vertical zone. The orange points are the candidate points that the extraction considers.



Example of an extracted cone showing the candidate points.

13. From the **Feature Based Clipping** area, define the **Horizontal**, **Vertical Up/Down**, and **Vertical** values. These values set the dimensions for the green extraction zone region. Consider part variability when you define the extraction zone.

    Alternatively, you can clip data within an offset boundary around all the CAD elements on a surface with the **CAD offset** option. This is also called *CAD segregation*. For details, see the "CAD offset" section of the "Feature Based Clipping Parameters" topic in the PC-DMIS Laser documentation.

14. If you want to define the Ring Band offsets, click the **Ring Band** check box and enter the **Inner Offset** and **Outer Offset** values. For details on how the **Ring Band** works, see the "Ring Band Parameters" topic in the PC-DMIS Laser documentation.

15. If you want to filter out any outlier points, from the **Filters** area, select the **Remove outliers** check box and define the **Standard deviation multiple** to determine which points PC-DMIS excludes as outliers.

16. If you want to filter out any points that are outside of a maximum incidence angle, from the **Filters** area, select the **Remove points with normals outside** check box and type the value in the **Angle** (Max Incidence Angle) box.

The Max Incidence Angle filter was initially designed to compare the incidence direction of the laser (which is roughly the laser sensor orientation) to the estimated normal of the segregated points. For 3D laser features (Laser Auto Cone, Cylinder, Plane, Sphere, Surface Point and Constructed Extracted Cone, Cylinder, Plane, Sphere, Surface Point), the filter now compares the estimated normal of the pointcloud point to the nominal normal of the feature, which greatly improves the results. 2D laser features remain unchanged, using the legacy incidence angle filter method.

For details on the **Filters** area, see the "Filters" topic in the PC-DMIS Laser documentation.

17. In the **Visualisation** section, PC-DMIS provides these options to perform the described function:

    Visualisation Tools On/Off - This button toggles the display of the colored visualisation tools. For more information, see "Understanding the Visualisation Tools".

    Show/Hide segregated points - This button toggles the display of the points that the software passes to the feature extractor engine based on the current settings.

    Show/Hide measured points - This button toggles the display of the measured points. It remains greyed out until you click **Test** or **Create**. For more information, see the "Show Measured Points" topic in the PC-DMIS Core documentation.

    
    - The **Analysis** area allows you to determine how each measured hit/point is displayed. For more information, see the “Analysis Area” topic in the PC-DMIS Core documentation.

18. Click the **Test** button to test a feature's creation and preview its dimensional data before you create it. PC-DMIS performs a measurement using the current parameters. You can change the parameters and click **Test** repeatedly until you have an acceptable measurement. Then, when you click **Create**, the software converts the temporary feature into a normal feature in the measurement routine.

19. Click the **Create** button. Based on the parameters that you specified in the dialog box, PC-DMIS does an analysis of the candidate points and returns (or extracts) each measured point and projects them to the surface.

    PC-DMIS creates the command in the Edit window:

```
CON1=FEAT/CONE,CARTESIAN,OUT
   THEO/<69,90,13.995>,<0,0,-1>,30,13.995,8
   ACTL/
<68.873,89.926,13.994>,<0.0061449,0.0001119,-0.9999811>,
30.367,13.995,7.893
   DEPTH=0
   CENTER OFFSET=6.998
   SEARCH LENGTH=11.995
   THEO_THICKNESS,0
   USE CAD SEGREGATION=ON,CAD OFFSET=1
   HORIZONTAL CLIPPING=3,VERTICAL CLIPPING=1
   RINGBAND=OFF
   USE OUTLIER REMOVAL=OFF
   REMOVE POINTS WITH NORMALS OUTSIDE=OFF
   CONSTR/CONE,EXTRACTED,REF=COP1
```

Variations

This first example shows the unbounded format for a constructed cone command in the Edit window with TOG5 changed to ANG.

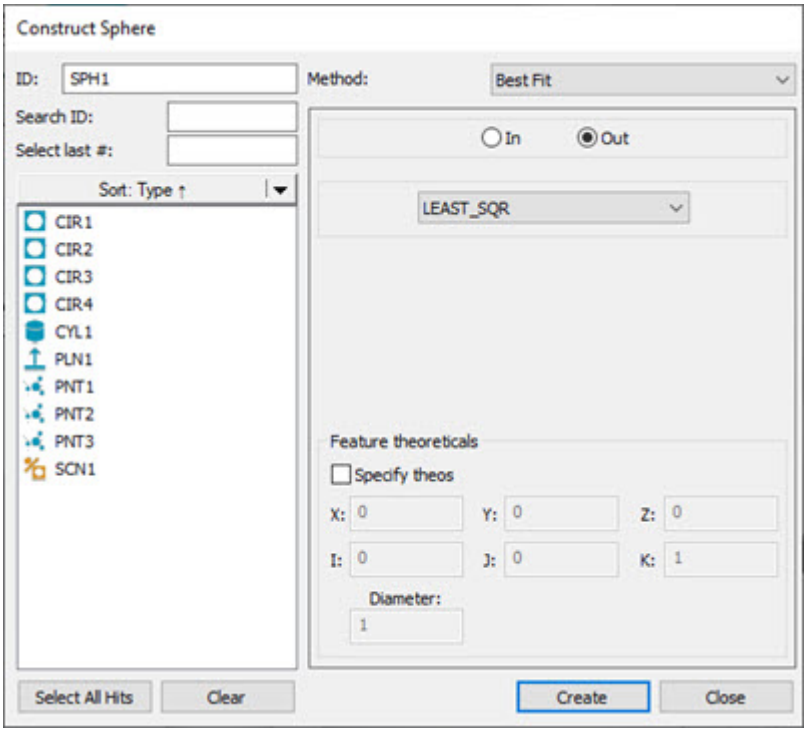
```
feature_name=FEAT/CONE,TOG1,TOG4,ANG THEO/
x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,ang
 ACTL/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,ang CONSTR/TOG2,T
OG3,......
```

This example shows the bounded cone format for a constructed cone command in the Edit window with TOG5 changed to LENG.

- Diam_1 is the diameter of the height of the first three hits.
- Diam_2 is the diameter of the furthest point away from the first diameter.
- Length is the distance between the two diameters.

```
feature_name=FEAT/CONE,TOG1,TOG4,LENG THEO/
x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,length,diam_1,diam_2
 ACTL/
x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,length,diam_1,diam_2
CONSTR/TOG2,TOG3,......
```

Constructing a Sphere Feature



Construct Sphere Dialog Box

There are several ways to construct a sphere using PC-DMIS. The following table lists the various types of constructed spheres, along with their necessary inputs. Some features may require no inputs while others may require five inputs or more. The term "Any" indicates that the construction can take any type of feature as input for construction. PC-DMIS allows the features to be selected in any order.

Construct Feature Type	Edit Window Symbol	Number of Required Input Features	Primary Feature	Secondary Feature	Comments
Auto Sphere	-	-	-	-	See "Auto Sphere Construction".
Best Fit Sphere	BF	At least 5 inputs are needed.	-	-	Constructs a best fit sphere using the given inputs. See the Note below for recommended inputs.
Best Fit with Recomp Sphere	BFRE	At least 5 inputs are needed. (1 must be a point)	-	-	Constructs a best fit sphere using the given inputs. See the Note below for recommended inputs.
Cast Sphere	CAST	1	Any	-	Constructs a sphere at the centroid of the input feature.
Projected Sphere	PROJ	1 or 2	Any	Plane	One input feature will project the sphere to the workplane.
Reverse Sphere	REV	1	Sphere	-	Constructs a sphere with a reversed vector.
Extracted Sphere	EXTRACTED_SPHERE	1	COP or Mesh	-	Constructs an extracted sphere from the COP or Mesh object at the specified diameter or height.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

If you select inappropriate feature types, PC-DMIS displays this message on the Status bar:

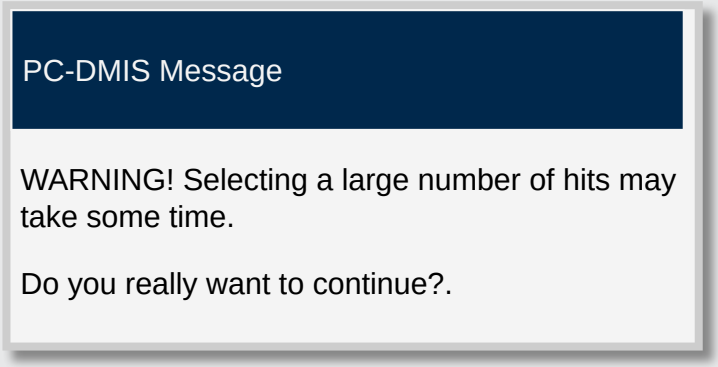
"Cannot construct [feature]. Combination of input features not accepted."

To construct a sphere:

1. Open the **Construct Sphere** dialog box (**Insert | Feature | Constructed | Sphere**).
2. From the **Method** list, select the method of the constructed sphere. The available options are:
    - Auto Sphere
    - Best Fit
    - Best Fit Recompensate Sphere
    - Projected Sphere
    - Cast Sphere
    - Reversed direction Sphere
    - Extracted Sphere

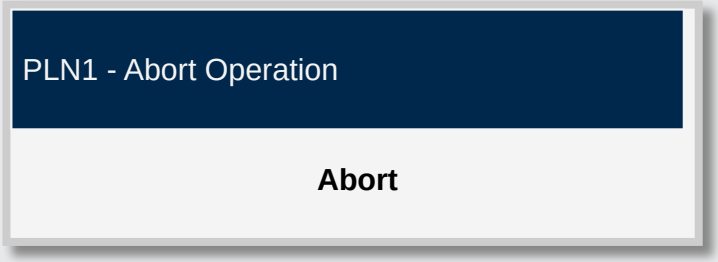
If you select the **Best Fit** or the **BF Recomp** (Best Fit Recomp) method for this feature, PC-DMIS allows you to click the **Select All Hits** button to create the construction from the individual hits of the input features instead of their centroids.

If there are a large number of points involved (about 10,000 or more), PC-DMIS shows a message asking if you are sure you want to proceed as this may take some time to complete.



Click **Yes** to proceed, click **No** to abort the process. You can select the **Don't ask me again** check box to prevent this message from recurring.

If you click **Yes**, another message is shown similar to the one shown below to let you know that PC-DMIS is generating the features from the hit points.

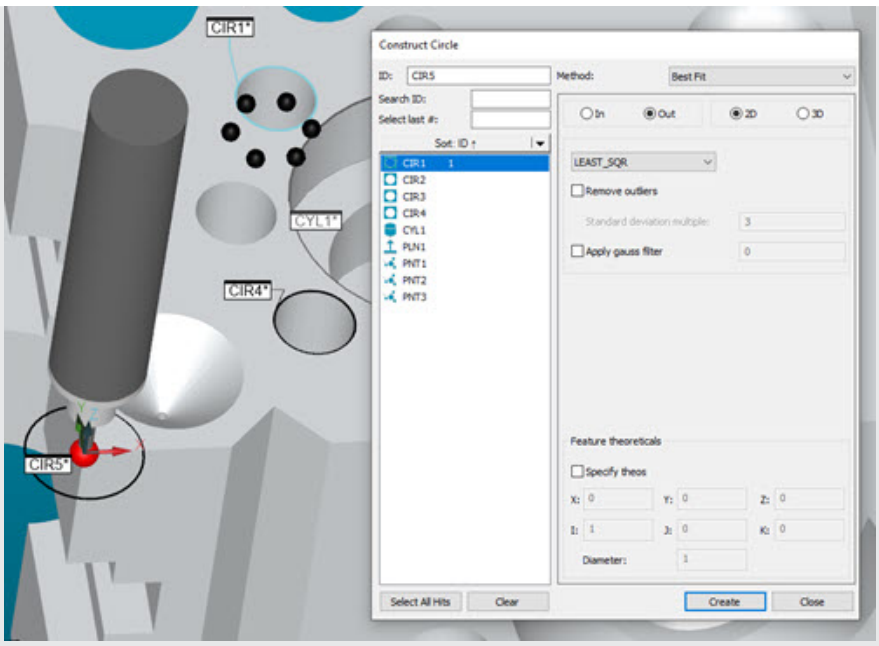


Once all the constructed features are created, the message disappears.

You can click the **Abort** button at any time to stop the process. Any features created up to this point are listed in the **Feature list** area of the dialog box.

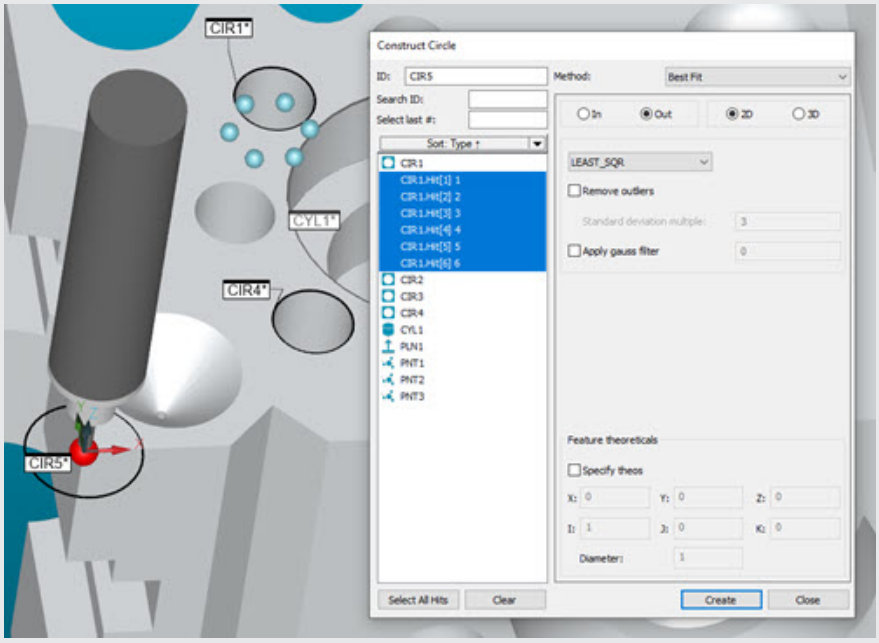
To create constructed features from the individual hits of the input features, do this:

1. From the **Feature list**, select the feature or features that you want to use to create the constructed feature.



Example showing a selected feature prior to clicking the Select All Hits button.

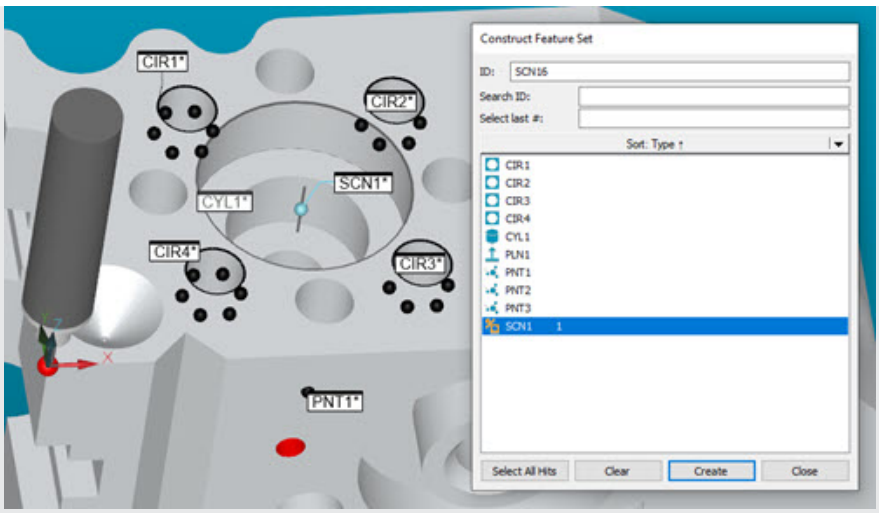
2. Click the **Select All Hits** button to display all the components that comprise the selected feature or features.



Display of items that make up the selected feature are highlighted in the dialog box and in the Graphic Display window.

PC-DMIS displays and highlights all the components of the selected feature (or features) in the **Feature list** are of the dialog box. You can select or de-select any of the features or feature components shown in the list to include or exclude them.

3. Click the **Create** button to create the Constructed feature based on the final features and feature components that you selected.



Constructed feature created based on the selected items from the Feature list.

3. Use the table above to select the features from the **Feature** list based on the selected method.
4. Select the **In** or **Out** option. For details, see the "In / Out Sphere" topic in this documentation.
5. If you selected either the Best Fit or Best Fit Recompensate methods, from the **Best Fit Type** list, select the type of best fit algorithm to use. For details, see the "Best Fit Type" topic in this documentation.
6. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
7. Click the **Create** button.

The Edit window command line for a sample Sphere Construction would read:

```
feature_name=FEAT/SPHERE, TOG1,TOG4

THEO/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,diam

ACTL/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,diam

CONSTR/ TOG2,TOG3
```

The actual Edit report displays in all capital letters.

TOG1= POLR or RECT

TOG2 = SPHERE

TOG3 = BF / BFRE / CAST / PROJ / REV

TOG4 = IN / OUT

The first three lines that display in the Edit window are the same for constructed spheres. The fourth line is slightly different, according to the type of feature you are constructing. To switch between the different types of spheres, place the cursor on TOG3 and press F7 or F8. (See "Command Mode Keyboard Functions" in the "Using the Edit Window" chapter.)

When two or more features are involved, PC-DMIS automatically determines the necessary order of the input features. This improves the accuracy of the measurement process.

Auto is the default method of construction. This option automatically determines the best way to construct a sphere using the input feature(s). See "Auto Sphere Construction".

The following topics describe the available options for constructing a sphere.

In / Out Sphere

The **In** and **Out** options tell PC-DMIS whether to construct the sphere as an internal or an external sphere.

- If you select **In**, PC-DMIS constructs the sphere as an internal sphere.
- If you select **Out**, PC-DMIS constructs the sphere as an external sphere.

Auto Sphere Construction

The "Input Feature List" table indicates the type of sphere that PC-DMIS constructs when you select the specified inputs and choose the **Auto** option. The order of the selected features is not important. If you choose an incorrect input feature, PC-DMIS displays an error message and does not automatically construct the indicated feature type.

To allow PC-DMIS to automatically determine the best method of construction:

1. Open the **Construct Sphere** dialog box (**Insert | Feature | Constructed | Sphere**).
2. From the **Method** list, select the **Auto** option.
3. From the **Feature** list, select the desired feature or features based on the "Input Feature List" table below.
4. Select the **In** or **Out** option. For details, see the "In / Out Sphere" topic in this documentation.

5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.

6. Click the **Create** button.

Input Feature List

Input Feature(s)	Constructs
Four or more Features	Best Fit Sphere
Any One Sphere	Reverse Sphere
Any One Feature (except Sphere or Set)	Cast Sphere
Any One Set	Best Fit Sphere
Plane + Any Feature	Project Sphere

Constructing a Best Fit or Best Fit Recompensate Sphere

You can construct a "best fit" sphere using five or more features. PC-DMIS computes a *least squares* sphere, one for which PC-DMIS minimizes the average squared distance from the data points to the sphere.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

To construct a Best Fit or a Best Fit Recompensate Sphere:

1. Open the **Construct Sphere** dialog box (**Insert | Feature | Constructed | Sphere**).

2. From the **Method** list, select either the **Best Fit** or **Best Fit Recompensate** option (shown as **Best Fit** and **BF Recomp**).

3. From the **Feature** list, select five or more features.
4. Select the **In** or **Out** option. For details, see the "In / Out Sphere" topic in this documentation.
5. From the **Best Fit Type** list, select the type of best fit algorithm to use. For details, see the "Best Fit Type (for Sphere)" topic in this documentation.
6. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
7. Click the **Create** button.

For a Best Fit constructed sphere, the **Edit** window command line would read:

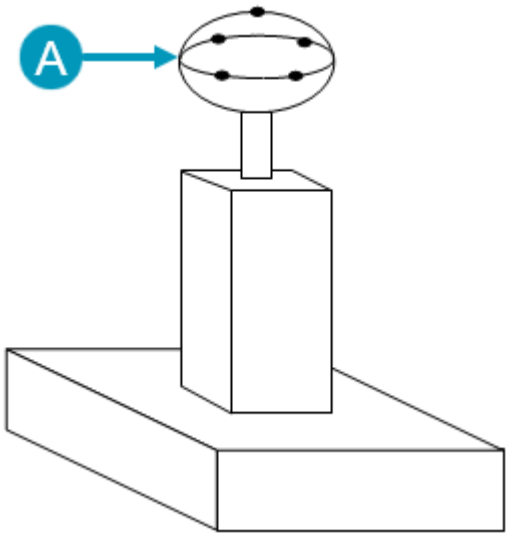
```
CONSTR/SPHERE,BF,feat_1,feat_2,feat_3,feat_4,feat_5...
```

PC-DMIS uses the actual measured points for construction.

For a Best Fit Recompensate constructed sphere, the **Edit** window command line would read:

```
CONSTR/SPHERE,BFRE,feat_1,feat_2,feat_3,feat_4,feat_5...
```

PC-DMIS uses the center of the probe for measurement.



A - *Best Fit Sphere Constructed from Five Points.*
Constructing a Sphere from Five or more Points

Best Fit Type (for Sphere)

A list of Best Fit types becomes available if you select the **Best Fit** or the **BF Recomp** methods when constructing a sphere.

The available Best Fit types for a constructed sphere are:

- LEAST_SQR
- MIN_SEP
- MAX_INSC
- MIN_CIRCSC
- FIXED_RAD
- MIN_BOUND_SPH

These types are discussed below:

LEAST_SQR
Least Squares - This calculation type provides a method of fitting in which the average squared radial distance from the data points to the sphere is minimized. The square root of this quantity is the Root Mean Square (RMS) distance. Since the RMS distance is based on an average, some points may be further than the RMS distance from the computed sphere.

MIN_SEP
Minimum Separation - This calculation type generates a sphere that is halfway between two concentric spheres containing the data points, with the difference of their radii as small as possible. The Min/Max math used by the MIN_SEP calculation minimizes the maximum error, or deviation, from the input data to the sphere. The Min/Max error is one-half of the minimal separation. No input data points (or input features) lie farther than the Min/Max error from the Min/Max sphere. This calculation determines whether or not all the input data (or input features) are within the given tolerances.

MAX_INSC
Maximum Inscribed - This calculation type generates an empty sphere with the largest possible diameter that lies within the data. PC-DMIS first computes a Minimum Circumscribed sphere and requires that the center of the Maximum Inscribed sphere lies within it. This option could be used for an internal spherical feature that requires a mating external sphere. For example, if the input data represents an internal sphere, then this calculation returns a sphere with the diameter of the largest external sphere that will fit inside the internal sphere. Do not use this calculation type for arcs of less than 90 degrees.

MIN_CIRCSC
Minimum Circumscribed - This calculation type generates a sphere with the smallest possible diameter that encloses the input data (or input features). This option could be used when measuring an external sphere that would fit into a mating internal spherical feature. The resulting feature would be the smallest internal sphere into which the external sphere would fit. Do not use this calculation type for arcs of less than 180 degrees.

FIXED_RAD
Fixed Radius - This calculation type creates a sphere of a given diameter, positioned so that the maximal radial distance from the data points to the sphere is minimized. It is similar to the Max/Min math used in the MIN_SEP calculation except that, since the

diameter is known in advance, the radius cannot vary. Only the sphere's position is allowed to vary.

MIN_BOUND_SPH
Minimum Bound Sphere - This calculates the smallest sphere that contains the input points. This is the required math type for ISO 10360 – XX acceptance testing. The input features should be spheres, not points.

For legacy Form dimensions (Circularity, Cylindricity, Flatness, and Straightness), as well as a Location dimension's RN Line, PC-DMIS uses the feature solution to compute the dimension. By default, this is Least Squares. However, you can choose to solve the feature using Minimum Separation, Maximum Inscribed, Minimum Circumscribed, or Fixed Radius regression algorithms.

PC-DMIS computes Geometric Tolerance Form commands, on the other hand, using the Chebyshev algorithm (Min/Max) as required by the Y14.5 standard. Because of the change in calculation, PC-DMIS generally computes Geometric Tolerance Form dimension commands to a slightly smaller value than their legacy counterparts.

Constructing a Projected Sphere

You can construct a sphere by projecting any feature into the current workplane. PC-DMIS projects the point where the plane intersects the point. If you only have one input feature, it projects the point to the workplane. You should input the desired diameter when projecting a feature into the workplane; otherwise, PC-DMIS uses the probes' diameter.

To construct a projected sphere:

1. Open the **Construct Sphere** dialog box (**Insert | Feature | Constructed | Sphere**).
2. From the **Method** list, select the **Projection** option.
3. From the **Feature** list, select either one or two features. The first feature can be of any type. The second feature must be a plane.
4. Select the **In** or **Out** option. For details, see the "In / Out Sphere" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/SPHERE,PROJ, feat_1,(feat_2)
```

Constructing a Cast Sphere

You can construct a sphere by changing any given feature into a sphere. PC-DMIS constructs the sphere at the centroid of the input feature. If a sheet metal point is used, the diameter is the probe diameter. For some sheet metal features (such as slots and notches), the width is used as the diameter. For features that do not have diameters (lines, points, etc.), a value that is four times the probe diameter is used.

You can modify the diameter of the sphere; this changes the sphere from DEPENDENT to INDEPENDENT. This means that when the sphere is executed that diameter will not change based on the input feature but will be independent of the input feature, while the position and vector remain dependent on the input feature. This allows you to have control over the diameter in cases where the input feature doesn't really have a diameter, such as a point. The DEPENDENT/INDEPENDENT field is a toggle field you may change.

PC-DMIS uses this diameter value for all calculations instead of using the default diameter value as described above.

To construct a Cast Sphere:

1. Open the **Construct Sphere** dialog box (**Insert | Feature | Constructed | Sphere**).
2. From the **Method** list, select the **Cast** option.
3. From the **Feature** list, select one feature of any type.
4. Select the **In** or **Out** option. For details, see the "In / Out Sphere" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/SPHERE,CAST, feat_1,  (Dependent | Independent)
```

Changing the Direction of a Sphere

You can construct a sphere with a reversed vector.

To construct a Reverse Sphere:

1. Open the **Construct Sphere** dialog box (**Insert | Feature | Constructed | Sphere**).

2. From the **Method** list, select the **Reverse** option.
3. From the **Feature** list, select one feature. It must be a sphere.
4. Select the **In** or **Out** option. For details, see the "In / Out Sphere" topic in this documentation.
5. If you want to change the feature theoretical values, select the **Feature theoreticals** check box and type in the values. For details, see the "Specifying Feature Theoreticals" topic in the PC-DMIS Core documentation.
6. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/SPHERE,REV, feat_1
```

Constructing an Extracted Sphere

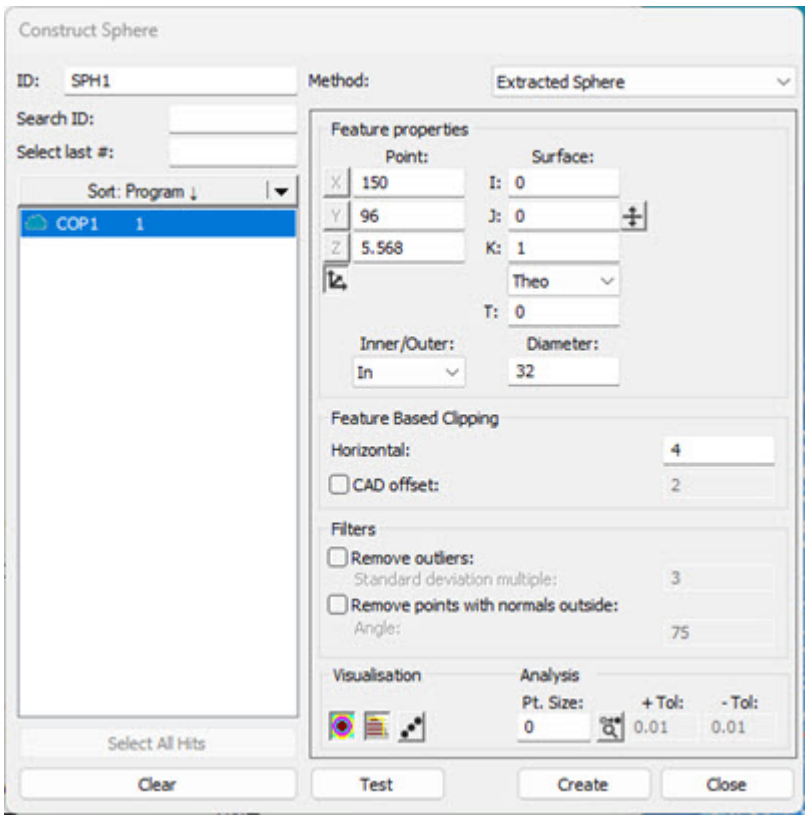
For details on extracting Auto features from a Mesh, see the "Extracting Auto Features from a Mesh" topic in the PC-DMIS Laser documentation.

For details on extracting Auto features from a Pointcloud (COP), see the "Extracting Auto Features from Pointclouds" topic in the PC-DMIS Laser documentation.

You can construct a sphere that is extracted from a scanned pointcloud (COP) or mesh.

To do this, follow these steps:

1. Ensure that your measurement routine has a Pointcloud (COP) or Mesh command.
2. Open the **Construct Sphere** dialog box (**Insert | Feature | Constructed | Sphere**) or from the **Constructed Feature** toolbar (**View | Toolbars | Constructed Features**).



Construct Sphere Dialog Box - Extracted Sphere Option

3. From the **Method** list, select the **Extracted Sphere** option.

4. From the **Reference** area, select the COP or Mesh that you want to use to extract the sphere from.

5. Click on the CAD model or data to define the nominal or, in the **Point** section of the **Feature properties** area, type the nominal location in the **X**, **Y**, and **Z** boxes.

6. From the **Surface** section of the **Feature properties** area, define the surface vector in the **I**, **J**, and **K** boxes. In the **Angle** section, enter the corresponding vector angle values. You can use the **Material Thickness Type** list and the **T** box below it to type in a material thickness value. For details, see the "Use Thickness" topic in this documentation.

   You can use these controls to perform the associated functions:

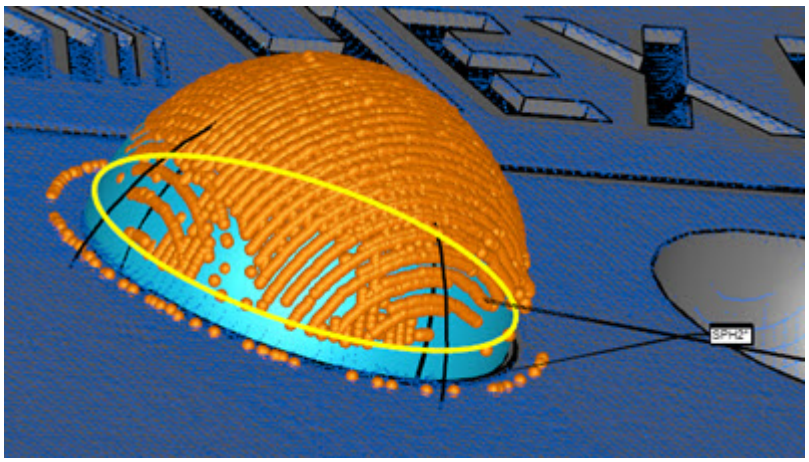
   Flip Vectors

   Polar/Cartesian

   For details on these controls, see the appropriate topic in the "Feature Properties Area" section of the "Creating Auto Features" chapter of the PC-DMIS Core documentation.

7. Select whether the extracted sphere is an inner or outer sphere type from the **Inner/ Outer** list.

8. Type the diameter of the sphere in the **Diameter** box.



Example of a Constructed Extracted Sphere showing the candidate points

9. From the **Feature Based Clipping** area, define the **Horizontal** value. This sets the dimensions for the extraction zone region. Consider part variability when you define the extraction zone.

   Alternatively, you can clip data within an offset boundary around all the CAD elements on a surface with the **CAD offset** option. This is also called *CAD segregation*. For details, see the "CAD offset" section of the "Feature Based Clipping Parameters" topic in the PC-DMIS Laser documentation.

10. If you want to filter out any outlier points, from the **Filters** area, select the **Remove outliers** check box and define the **Standard deviation multiple** to determine which points PC-DMIS excludes as outliers.

11. If you want to filter out any points that are outside of a maximum incidence angle, from the **Filters** area, select the **Remove points with normals outside** check box and type the value in the **Angle** (Max Incidence Angle) box.

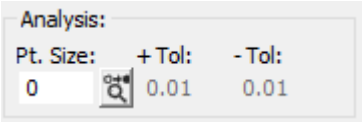
> The Max Incidence Angle filter was initially designed to compare the incidence direction of the laser (which is roughly the laser sensor orientation) to the estimated normal of the segregated points. For 3D laser features (Laser Auto Cone, Cylinder, Plane, Sphere, Surface Point and Constructed Extracted Cone, Cylinder, Plane, Sphere, Surface Point), the filter now compares the estimated normal of the pointcloud point to the nominal normal of the feature, which greatly improves the results. 2D laser features remain unchanged, using the legacy incidence angle filter method.
>
> For details on the **Filters** area, see the "Filters" topic in the PC-DMIS Laser documentation.

12. In the **Visualisation** section, PC-DMIS provides these options to perform the described function:

Visualisation Tools On/Off - This button toggles the display of the colored visualisation tools. For more information, see "Understanding the Visualisation Tools".

Show/Hide segregated points - This button toggles the display of the points that the software passes to the feature extractor engine based on the current settings.

Show/Hide measured points - This button toggles the display of the measured points. It remains greyed out until you click **Test** or **Create**. For more information, see the "Show Measured Points" topic in the PC-DMIS Core documentation.



- The **Analysis** area allows you to determine how each measured hit/point is displayed. For more information, see the "Analysis Area" topic in the PC-DMIS Core documentation.

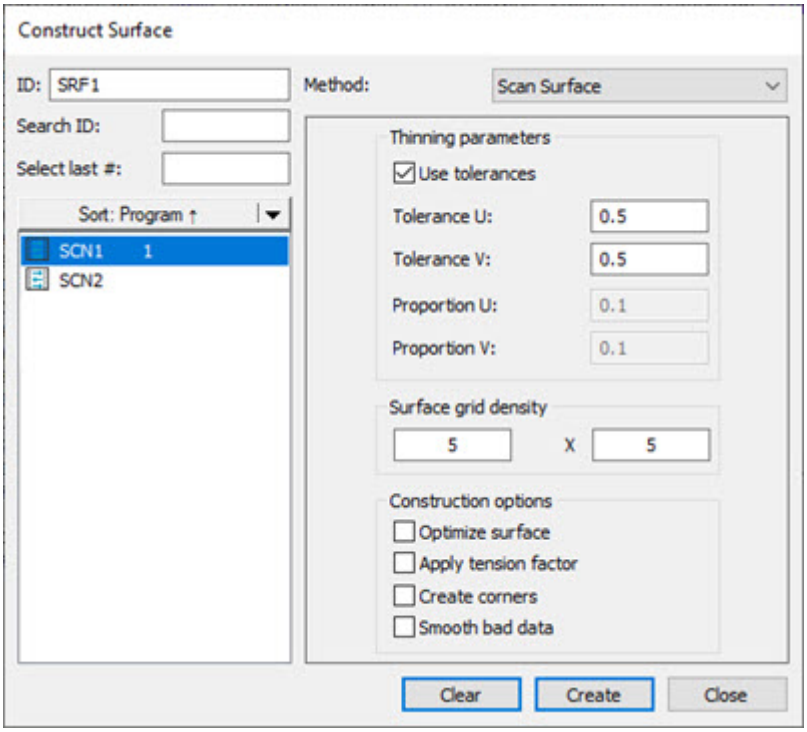
13. Click the **Test** button to test a feature's creation and preview its dimensional data before you create it. PC-DMIS performs a measurement using the current parameters. You can change the parameters and click **Test** repeatedly until you have an acceptable measurement. Then, when you click **Create**, the software converts the temporary feature into a normal feature in the measurement routine.

14. Click the **Create** button. Based on the parameters that you specified in the dialog box, PC-DMIS does an analysis of the candidate points and returns (or extracts) each measured point and projects them to the surface.

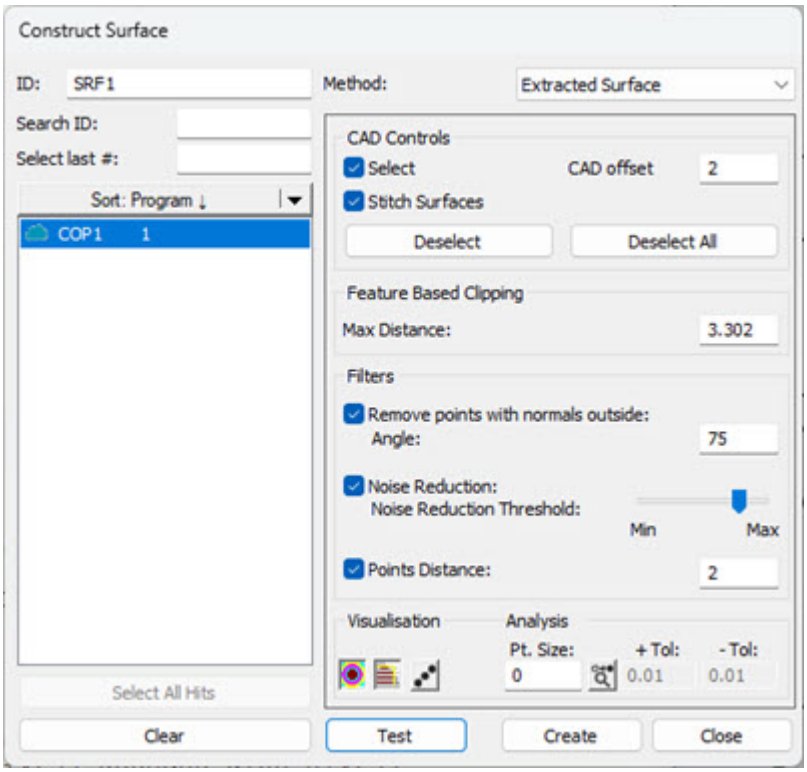
    PC-DMIS creates the command in the Edit window:

```
SPH1        =FEAT/SPHERE,CARTESIAN,OUTER
             THEO/
<168.5,45.66,0>,<0.0021447,0.0058276,0.9999807>,12.7
             ACTL/
<168.586,45.406,0.05>,<0.0021447,0.0058276,0.9999807>,12
.781
             THEO_THICKNESS,0
             USE CAD SEGREGATION=ON,CAD OFFSET=1
             HORIZONTAL CLIPPING=3
             USE OUTLIER REMOVAL=OFF
             REMOVE POINTS WITH NORMALS OUTSIDE=OFF
             CONSTR/SPHERE,EXTRACTED,REF=COP1
```

Constructing a Surface



Construct Surface Dialog Box - Scan Surface Method



Construct Surface Dialog Box - Extracted Surface Method

There are two types of constructed surfaces available in PC-DMIS: **Scan Surface** and **Extracted Surface**.

You typically use the **Scan Surface** for reverse engineering and can be dependent or independent.

Use the **Extracted Surface** for reporting surface profile dimensions and is always dependent.

The following table shows the two surfaces, along with their necessary inputs. The only input that the **Scan Surface** takes is a patch scan. The scan must contain at least two rows of four points per row. The only inputs that an **Extracted Surface** takes are a COP or Mesh object.

Construct Feature Type	Edit Window Symbol	Number of Input Sets	Input Set	Comments
Scan Surface	DEPENDENT	1	Patch scan containing at least 2 rows with 4 points per row	The surface will update as the input feature changes.
	INDEPENDENT	1	Patch scan containing at least 2 rows with 4 points per row.	This uses the input feature for construction only.
Extracted Surface	CONSTR/ SURFACE,EXTRACTED	1	COP or Mesh object	Constructs an extracted surface from the COP or Mesh object.

If you select inappropriate feature types, PC-DMIS displays this message on the Status bar:

"Cannot construct [feature]. Combination of input features not accepted."

To construct a Surface:

1. Select the **Insert | Feature | Constructed | Surface** menu option to open the **Construct Surface** dialog box.

2. Select the type of constructed surface (**Scan Surface** or **Extracted Surface**) from the **Method** list.
3. Select the appropriate feature from the **Feature** list:
    - For the **Scan Surface** method, select the patch scan.
    - For the **Extracted Surface** method, select the Pointcloud or Mesh.
4. Select the various construction options. For details on the options available, see the following topics in this section of the PC-DMIS Core documentation.
5. Click the **Create** button.

The Edit window command line for a Constructed Surface using the **Scan Surface** method would read:

```
feature_name=FEAT/SURFACE,TOG1,CONTROL POINTS U,
             CONTROL POINTS V, NUM POINTS FIT,TOG2
             THINNING PARAMETER U, THINNING PARAMETER V
             CONSTR/SURFACE, INPUT TYPE, INPUT ID
```

The actual Edit report displays in all capital letters.

DEPENDENT is the default construction type for the Scan Surface method. You can use the TOG1 parameter to switch between Dependent and Independent.

TOG1 = Dependent or Independent.

TOG2 = Tolerance or Proportion

The Edit window command line for a Constructed Surface using the **Extracted Surface** method would read:

```
SRF1=FEAT/SURFACE,THEO_THICKNESS=0,MAX DISTANCE=2
     CAD OFFSET=2,REMOVE POINTS WITH NORMALS OUTSIDE=ON,75
     NOISE REDUCTION=ON,20,DISTANCE=ON,2
     CONSTR/SURFACE,EXTRACTED,REF=COP1,SIZE=0
```

Notice that there is no Dependent or Independent toggle for an Extracted Surface. This is because the Extracted Surface is always dependent – it is always associated with the COP or MESH you use to create it and updates if you change the input.

The following topics describe the available options for constructing a surface:

Constructing a Dependent/Independent Scan Surface

All constructed scan surfaces start out as dependent surfaces and must be created from a single input -- a patch scan. The patch scan must contain at least two rows with four points per row. PC-DMIS uses thinning tolerances to control the tightness of the surface fit.

- **Small tolerances:** If the thinning tolerances are small, the algorithm attempts to fit the surface through all of the points in the scan.
- **Large tolerances:** If the thinning tolerances are large, the surface is more of an approximation to the scan. The best way to see this is to construct a surface, change the thinning tolerances, and see how the shape of the surface changes.

The smaller the thinning tolerance, the longer it takes to create the surface. Be aware that the small tolerances (.01 - .05) may take a considerable amount of time (one hour) to create the surface if the input scan is large or not well behaved. Valid thinning tolerances range from 0.01 to 5.0 with a default of 0.5.

You can control the appearance of the surface with the surface grid density values. The surface displays as an N x M mesh of polylines with the default being a 5x5 mesh and the lowest value being a 2x2 mesh. To make a dependent surface independent so that it is no longer associated with the input scan, change the DEPENDENT field in the Edit window.

The shape of the surface cannot be changed.

To construct a Dependent or Independent Surface:

1. Open the **Construct Surface** dialog box (**Insert | Feature | Constructed | Surface**).
2. Select the **Scan Surface** option from the **Method** list.
3. Set the value for the **Thinning Tol U:** box.
4. Set the value for the **Thinning Tol V:** box. This applies a tolerance value to the V axis.
5. Set the values for the surface grid density.

6. Select the desired construction options. These include:
    - Optimize Surface
    - Apply Tension Factor
    - Create Corners
    - Smooth Bad Data
7. Select a patch scan feature set that contains at least two rows with four points per row.
8. Click the **Create** button.

Thinning Parameters (Thinning Tolerance or Thinning Proportion)

You can use one of two types of thinning parameters: Thinning Tolerance or Thinning Proportion. The **Use tolerance** check box on the **Construct Surface** and **Construct Curve** dialog boxes (**Insert | Feature | Constructed | Surface** and **Insert | Feature | Constructed | Curve**, respectively) lets you switch between either tolerance or proportion:

- *Thinning tolerance* controls the tightness (or exactness) of the curve or surface fit. Valid thinning tolerances range from 0.0 to 5.0, with the default being 0.01. The smaller the thinning tolerance, the closer the curve comes to passing through the centroids of the features included in the input set. If the thinning tolerance is 0.0, the curve or surface will pass through all of the centroids. A larger thinning tolerance will result in a curve or surface that has fewer fluctuations (at the expense of not lying near the input set's features). To see this, construct a curve or surface and then change the input tolerance and examine how its shape changes.
- *Thinning proportion*, alternately, may be used to control the quality of the fit. Valid thinning proportions range from between 0.0 and 1.0, with a default value of 0.33. The thinning proportion determines the number of degrees of freedom available in fitting the curve or surface to the centroids. At the lower extreme of 0, the algorithm will attempt to fit a straight line or plane to the centroids. At 1, it will compute a fit that passes through all of the centroids.

To make a DEPENDENT curve an INDEPENDENT curve (so that it is no longer associated with the input set):

1. Open the Edit window (**View | Edit Window**).
2. Select the curve feature that you constructed.
3. Navigate to the DEPENDENT field of that feature.
4. Press F7. It will change from DEPENDENT to INDEPENDENT.

    You can change the shape of the curve by editing its control points.

Thinning Parameter U

This box in the **Construct Surface** dialog box (**Insert | Feature | Constructed | Surface**) enables you to set a thinning parameter value applying to the U axis of the surface.

Thinning Parameter V

This box in the **Construct Surface** dialog box (**Insert | Feature | Constructed | Surface**) enables you to set a thinning parameter value applying to the V axis of the surface.

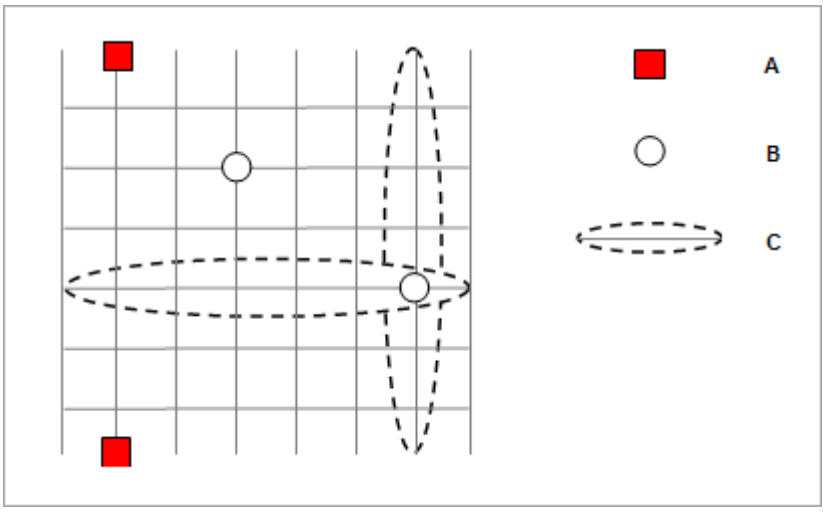
Surface Grid Density

This box in the **Construct Surface** dialog box (**Insert | Feature | Constructed | Surface**) enables you to set the density of a surface scan. The higher the values, the more splines there will be.

Optimize Surface

Control Points are points that mark begin and end points of splines in a surface grid.

This check box in the **Construct Surface** dialog box (**Insert | Feature | Constructed | Surface**) attempts to optimize the knots and control points of the initial splines from which the surface is constructed.



Example showing the surface grid with control points (A), knots (B), and splines (C).

Apply Tension Factor

Surfaces that you create by using the **Apply tension factor** check box in the **Construct Surface** dialog box (**Insert | Feature | Constructed | Surface**) tend to be tauter (tighter) and shorter, but may fit the data slightly less closely.

Create Corners

This check box in the **Construct Surface** dialog box (**Insert | Feature | Constructed | Surface**) enables corners to be added to the surface at areas where the data seems to make an abrupt change in direction.

Smooth Bad Data

This check box in the **Construct Surface** dialog box (**Insert | Feature | Constructed | Surface**) attempts to throw out bad data. Bad data is evaluated as data that has an abrupt change in direction. This option is almost the opposite of the Create Corners option above.

Constructing an Extracted Surface

For details on extracting Auto features from a Mesh, see the "Extracting Auto Features from a Mesh" topic in the PC-DMIS Laser documentation.

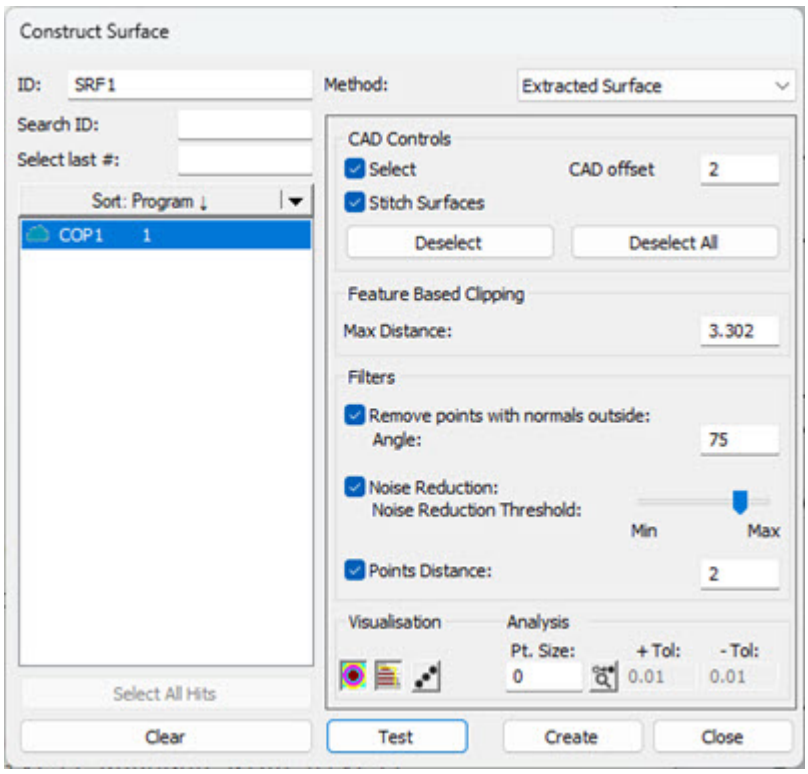
For details on extracting Auto features from a Pointcloud (COP), see the "Extracting Auto Features from Pointclouds" topic in the PC-DMIS Laser documentation.

A Constructed Extracted Surface is a collection of segregated points related to a surface on the CAD model. It does not create a CAD surface. Its intended use is for dimensioning purposes only.

You can construct a surface that is extracted from a scanned pointcloud (COP) or mesh.

To do this, follow these steps:

1. Ensure that your measurement routine has a Pointcloud (COP) or Mesh command.
2. Open the **Construct Surface** dialog box (**Insert | Feature | Constructed | Surface**) or from the **Constructed Feature** toolbar (**View | Toolbars | Constructed Features**) and select the **Extracted Surface** option from the **Method** list.



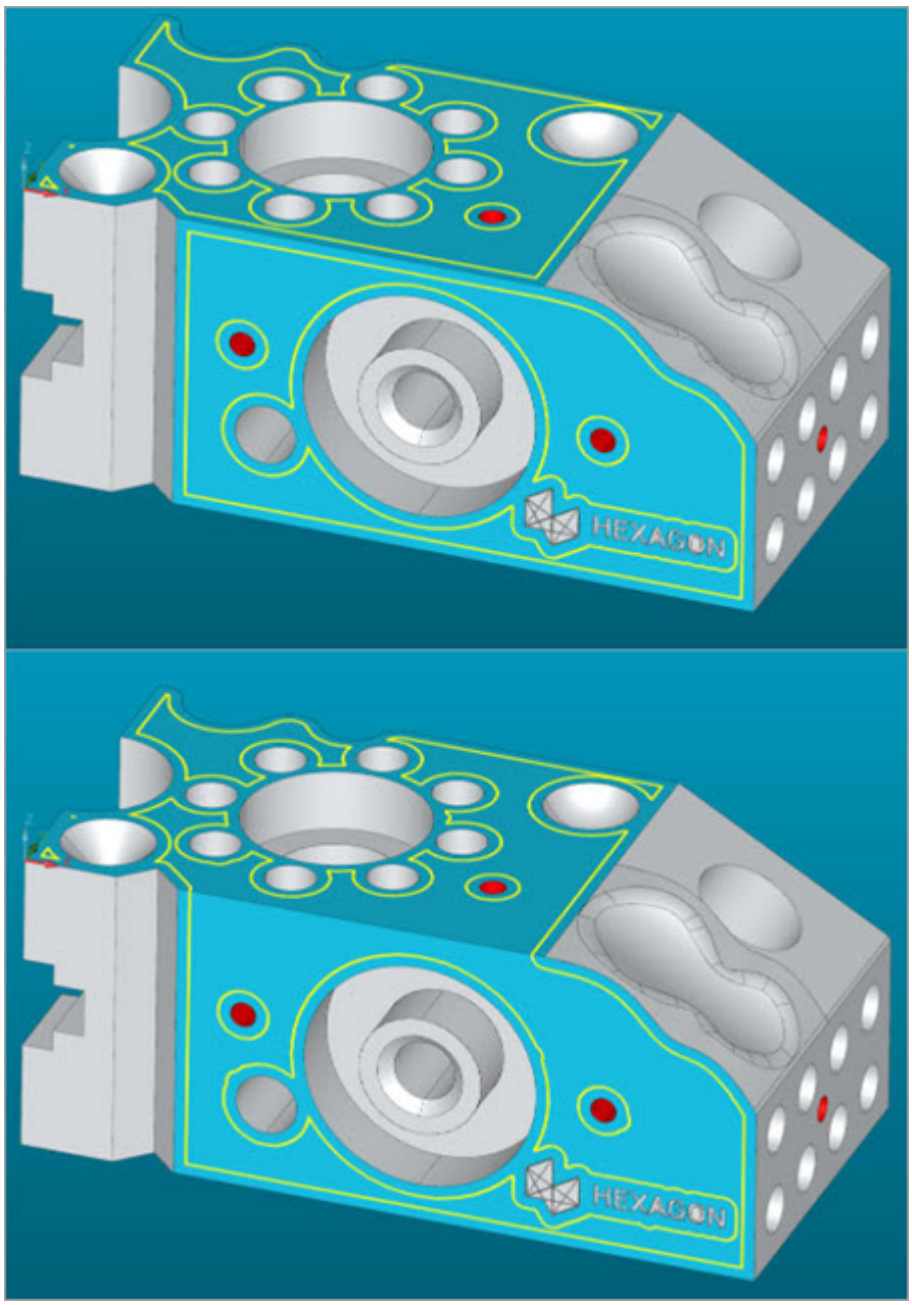
Construct Surface dialog box for Extracted Surface method

3. From the **Reference** area, select the COP or Mesh that you want to use to extract the surface from.

4. From the **CAD Controls** area, select the **Select** check box to select the CAD surface(s) in the Graphic Display window that you want to use to extract the Constructed Surface from.

5. You can clip data within an offset boundary around all the CAD elements on the selected surface(s) with the **CAD offset** option in the **CAD Controls** area. This is also called *CAD segregation*. For details, see the "CAD offset" section of the "Feature Based Clipping Parameters" topic in the PC-DMIS Laser documentation.

6. You can stitch surfaces together with the **Stitch Surfaces** option. If you select multiple contiguous surfaces on the CAD model, the software stitches these surfaces together and processes them as one surface.



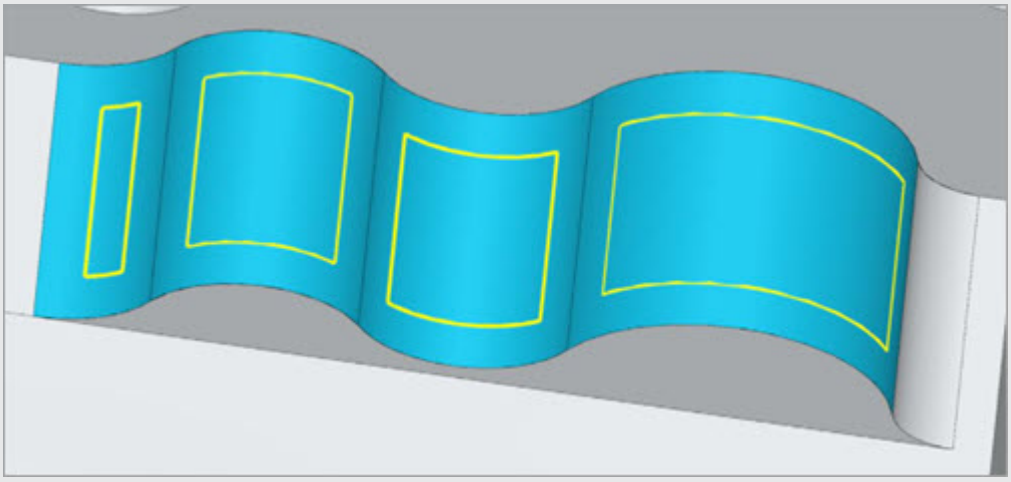
Examples before (top) and after (bottom) applying the Stitching Surfaces option

The advantage of stitching surfaces together is that you would get one continuous pointcloud rather than one with gaps where the surfaces meet if they were processed as individual surfaces.

This is especially evident with the Extracted Surface command. The main aim of the Extracted Surface command is to provide a way for you to report the profile of a surface. Stitching ensures that there is no loss of data where the surfaces meet.

If you want to check the transition between the surfaces of each of the curves on a CAD model, stitching provides a way for you to detect whether there was a smooth transition or a step.

In the image below, you can see that without stitching, there are gaps (twice the CAD offset) between each curve:



7. In the **Feature Based Clipping** area, type the **Max Distance** value. This is the maximum distance in measurement routine units that a point can be from the CAD model to be considered a valid point.

8. If you want to filter out any points that are outside of a maximum incidence angle, from the **Filters** area, select the **Remove points with normals outside** check box and type the value in the **Angle** (Max Incidence Angle) box.

The Max Incidence Angle filter was initially designed to compare the incidence direction of the laser (which is roughly the laser sensor orientation) to the estimated normal of the segregated points. For 3D laser features (Laser Auto Cone, Cylinder, Plane, Sphere, Surface Point and Constructed Extracted Cone, Cylinder, Plane, Sphere, Surface Point), the filter now compares the estimated normal of the pointcloud point to the nominal normal of the feature, which greatly improves the results. 2D laser features remain unchanged, using the legacy incidence angle filter method.

For details on the **Filters** area, see the "Filters" topic in the PC-DMIS Laser documentation.

9. In the **Filters** area, if you want to filter out the noise in your data, select the **Noise Reduction** check box and use the **Noise Reduction Threshold** slider to set the level of noise reduction you want to apply.

10. In the **Filters** area, you can set the minimum distance a point can be from any other point before PC-DMIS discards it. If the distance between a point and any of its neighboring points is less than this value, the point is discarded. To do this, select the **Points Distance** check box and set a value in the box.

    Based on the parameters that you specified in the dialog box, PC-DMIS does an analysis of the candidate points and returns (or extracts) the extracted constructed surface and projects it to the surface.

11. In the **Visualisation** section, PC-DMIS provides these options to perform the described function:

    Visualisation Tools On/Off - This button toggles the display of the colored visualisation tools. For more information, see "Understanding the Visualisation Tools".

    Show/Hide segregated points - This button toggles the display of the points that the software passes to the feature extractor engine based on the current settings.

    Show/Hide measured points - This button toggles the display of the measured points. It remains greyed out until you click **Test** or **Create**. For more information, see the "Show Measured Points" topic in the PC-DMIS Core documentation.

    
    - The **Analysis** area allows you to determine how each measured hit/point is displayed. For more information, see the “Analysis Area” topic in the PC-DMIS Core documentation.

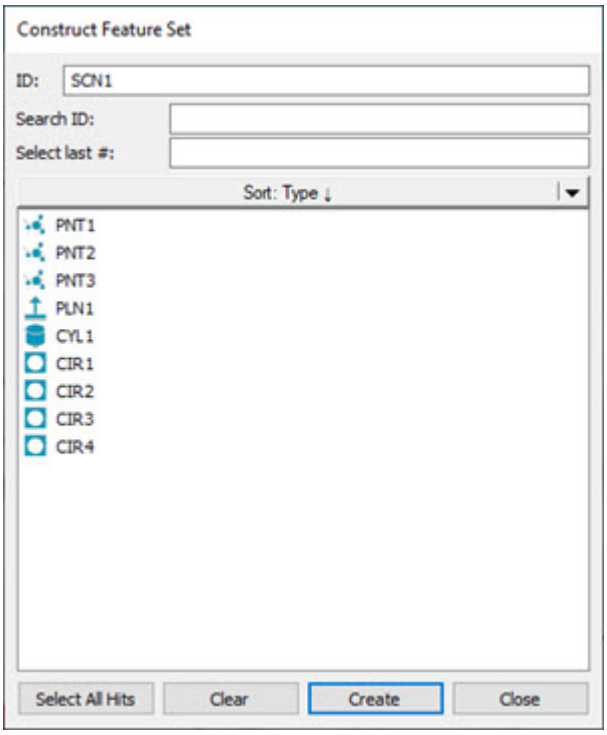
12. Click the **Test** button to test a feature's creation and preview its dimensional data before you create it. PC-DMIS performs a measurement using the current parameters. You can change the parameters and click **Test** repeatedly until you have an acceptable measurement. Then, when you click **Create**, the software converts the temporary feature into a normal feature in the measurement routine.

13. Click the **Create** button. Based on the parameters that you specified in the dialog box, PC-DMIS does an analysis of the candidate points and returns (or extracts) each measured point and projects them to the surface.

    PC-DMIS creates the command in the Edit window:

```
SRF1 =FEAT/SURFACE,THEO_THICKNESS=0,MAX DISTANCE=1
      CAD OFFSET=2,STITCH SURFACES=YES,REMOVE POINTS
WITH NORMALS
      OUTSIDE=OFF
      NOISE REDUCTION=OFF,DISTANCE=OFF
```

Constructing a Set of Features



Construct Feature Set Dialog Box

The **Set** menu command allows you to construct a set of features. You can do this by selecting (or keying in) all the features to be used in the set. When you click the **Create** button, PC-DMIS averages all of the input centroids and displays a set marker along with the new ID for the set.

If you select inappropriate feature types, PC-DMIS displays this message on the Status bar:

"Cannot construct [feature]. Combination of input features not accepted."

To construct a feature set:

1. Access the **Construct Feature Set** dialog box (**Insert | Feature | Constructed | Set**).
2. Select the features you want in your feature set. Optionally, if you click the **Select All Hits** button, PC-DMIS allows you to create the constructed Feature Set from the individual hits of the input features instead of their centroids. For details, see the "Using the Select All Hits Button to Construct a Feature Set" in the PC-DMIS Core documentation.
3. Click the **Create** button. The new feature set is given a feature ID and is placed in the Graphic Display window.

The Edit window command line for a sample Surface Construction would read:

```
 feature_name=FEAT/SET,TOG1,
THEO/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,
ACTL/x_cord,y_cord,z_cord,i_vec,j_vec,k_vec,
CONSTR/TOG2,feat_1, feat_2, feat_3...
```

TOG1= POLR or RECT

TOG2 = SET

The first three lines that display in the Edit window are the same for constructed sets. The fourth line is slightly different, according to the number of features used in the set.

The next few topics cover uses for feature sets in PC-DMIS and how to use feature hits to create a feature set.

Profile Error from a Set

If you are using CAD data, you can construct a set from measured points on a surface. When you ask for the PROFILE of the feature set, PC-DMIS reports the zone between the minimum normal to surface error and the maximum normal to surface error. (See "Dimensioning Surface or Line Profile" in the "Using Legacy Dimensions" chapter for more information.)

Average Values from a Set

When you make a set from input features, PC-DMIS averages the X, Y, and Z values of the input features. For example, the set can be used to get the average Z value of a series of measured points.

Using a Range of Hits from a Scan as Inputs

You can use a range of hits from an existing scan for your feature set inputs instead of selecting individual features.

To do this:

1. Access the **Construct Feature Set** dialog box (**Insert | Feature | Constructed | Set**).
2. Select a scan to use as the input.
3. Click **OK**. The command appears in the Edit window.
4. Place the Edit window into Command Mode.
5. Navigate to the feature set command in the Edit window.
6. Select the scan ID on the CONSTR/SET command line.
7. Modify the scan ID to take a range of hits, using a syntax like this:

   ```
   <ID>.HIT<STARTHIT>..<ENDHIT>
   ```

   <ID> - Specifies the ID of the scan.

   <STARTHIT> - Number that specifies the beginning hit in the range of hits.

   <ENDHIT> - Number that specifies the ending hit in the range of hits.

For example, the following code shows a constructed set using hits 1 through 10 of a scan named SCN1 for its input features.

```
SET1=FEAT/SET,RECT
THEO/2.2953,3.7467,0.95,0,0,1
ACTL/2.2953,3.7467,0.95,0,0,1
CONSTR/SET,BASIC,SCN1.HIT[1..10],,
```

You can use an actual expression (similar to the input code) to assign the X values of the first five features of the constructed set into an array. For example, the following code would assign just the X values of the first five hits to variable V2 and then display the values in an operator comment.

```
ASSIGN/V2=SET1.HIT[1..5].X
COMMENT/OPER,YES,V2 is:
,V2
```

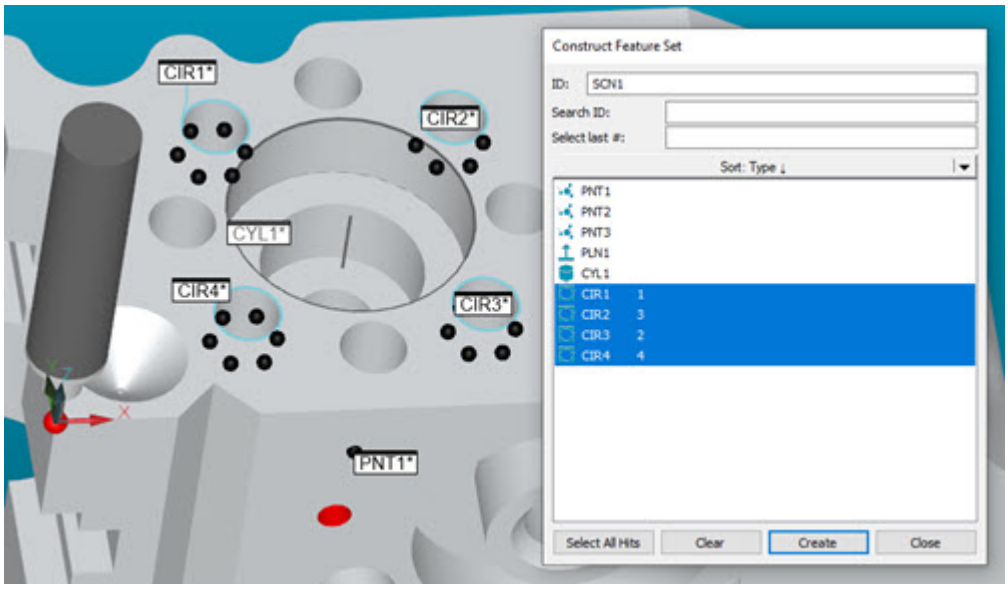
For information on using expressions to return a range of hits as an array, see the "Hit Arrays" topic in the "Using Expressions and Variables" chapter.

Using the Select All Hits Button to Construct a Feature Set

If you click the **Select All Hits** button, PC-DMIS allows you to create the constructed Feature Set from the individual hits of the input features instead of their centroids.

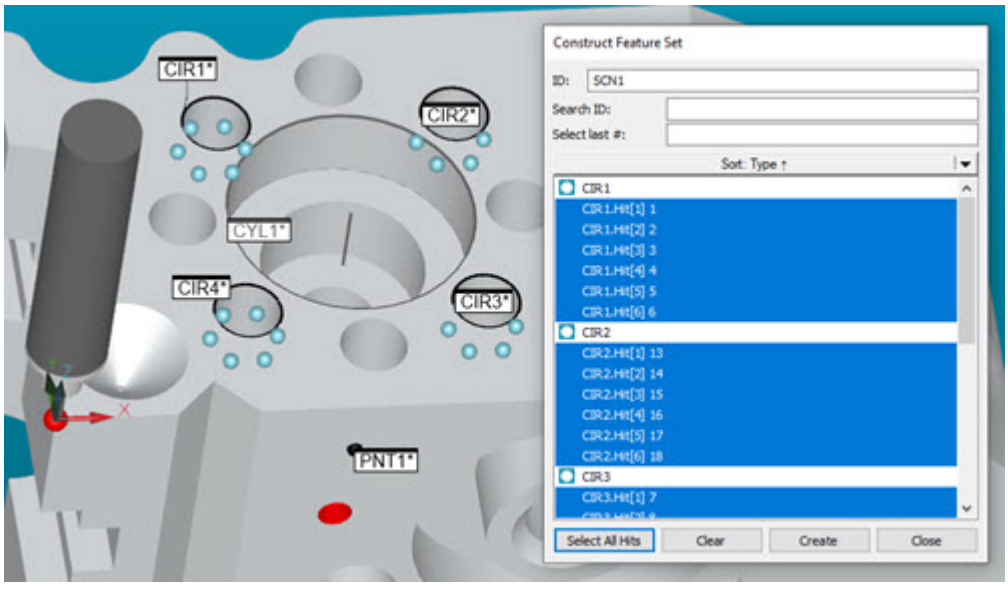
To do this:

1. From the **Feature** list, select the feature or features that you want to use to create the constructed Feature Set.



Example showing the selected features prior to clicking the Select All Hits button

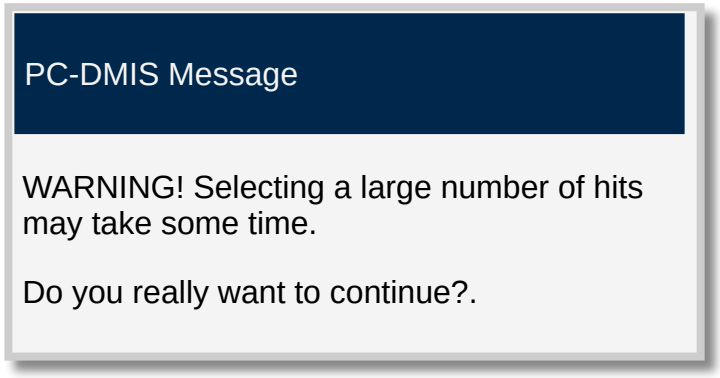
2. Click the **Select All Hits** button to display all the components that comprise the selected features.



Display of items that make up the constructed Feature Set are highlighted in the dialog box and in the Graphic Display window

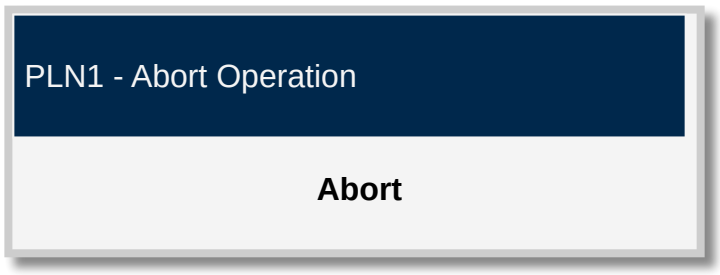
PC-DMIS displays and highlights all the components of the selected feature (or features) in the **Feature** list of the dialog box. You can select or de-select any of the features or feature components shown in the list to include or exclude them.

If there are a large number of points involved (about 10,000 or more), PC-DMIS shows a message asking if you are sure you want to proceed as this may take some time to complete.



Click **Yes** to proceed, click **No** to abort the process. You can select the **Don't ask me again** check box to prevent this message from recurring.

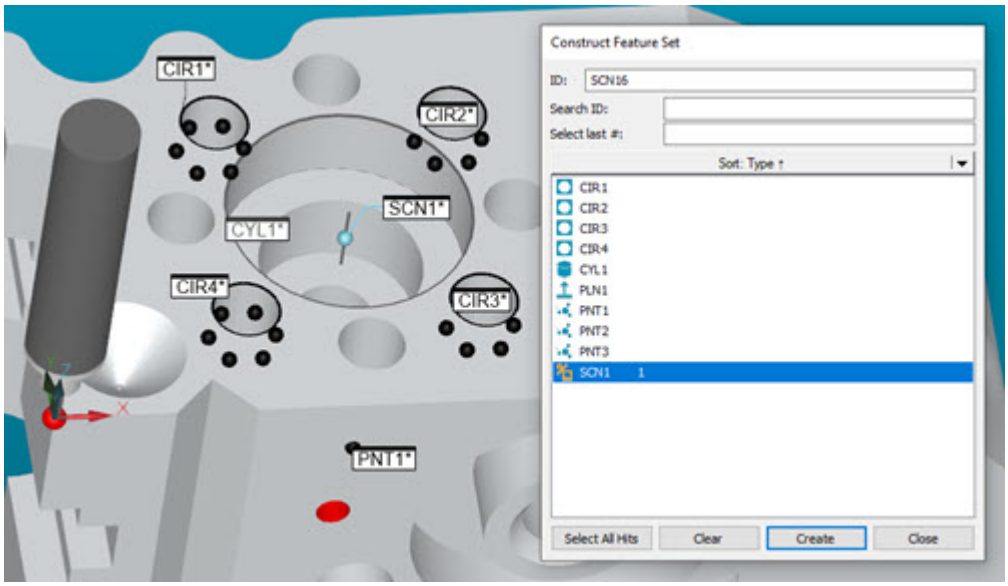
If you click **Yes**, another message is shown similar to the one shown below to let you know that PC-DMIS is generating the features from the hit points.



Once all the constructed features are created, the message disappears.

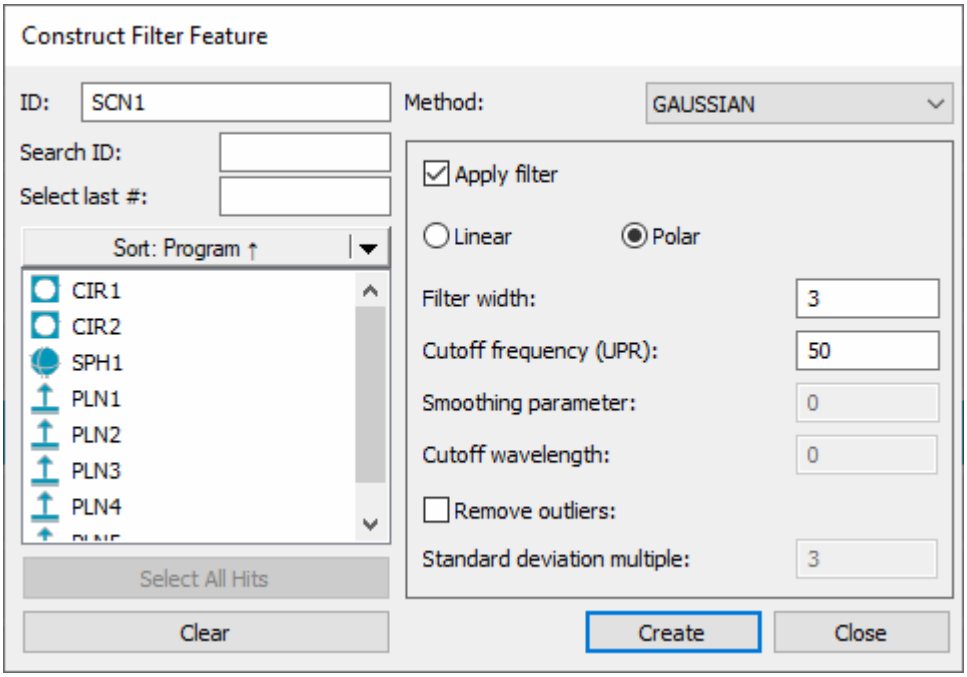
You can click the **Abort** button at any time to stop the process. Any features created up to this point are listed in the **Feature list** area of the dialog box.

3. Click the **Create** button to create the constructed Feature Set based on the final features and feature components that you selected.



Constructed Feature Set created based on selected items from the Feature list

Constructing a Filter Set



Construct Filter Feature Dialog Box

This command allows you to construct a filter set from a scan, certain constructed features, or another filter set. To do this, select (or key in) the input feature, the type of filter (method) desired, and the parameters to be used with the filter. When you click the **Create** button, PC-DMIS applies the filter routine to the data in the input feature and displays a set marker along with the new ID for the set.

This command is typically used to smooth ball center data from a scan. PC-DMIS applies a lowpass Gaussian or another lowpass filter to smooth the data.

If you select inappropriate feature types, PC-DMIS displays an error message that says it cannot construct the feature.

To construct a filter set:

1. Open the **Construct Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**).
2. Select an input for the filter set.
3. Select either the **Polar** or **Linear** option to smooth circle or linear data, respectively.
4. Select the type of filter from the **Method** list.
5. Type in values for any of the filter parameters.

6. If you want to remove outliers before filtering, select the **Outlier Removal** check box and the **Standard Deviation Multiple** check box.
7. Click the **Create** button.

The Edit window command line for this option would read:

```
CONSTR/SET/FILTER,TOG1,TOG2,feat_1,
VAL1,VAL2,OUTLIER_REMOVAL/TOG3,VAL3
```

For example:

```
CONSTR/SET,FILTER,GAUSSIAN,POLAR,SCN1,
WIDTH=3,UPR =50,OUTLIER_REMOVAL/ON,3
```

TOG1 = `ISO_16610_GAUSSIAN / SPLINE / UNIFORM / TRIANGLE / CYLINDRICAL / GAUSSIAN`

TOG2 = `POLAR / LINEAR`

Feat_1 = This is the input feature for this filter.

VAL1 = Filter width.

VAL2 = Cutoff frequency in undulations per revolution (UPR).

TOG3 = This value switches between ON or OFF. It determines if outliers should be removed before filtering.

VAL3 = Standard deviation multiplier. If *TOG3* is ON then all the points in the input that have more than this number of standard deviations from the least squares substitute feature (for example, circle, or line) will be removed before filtering.

Linear option

The **Linear** option in the **Construct Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**) enables you to filter the data in a feature that is not a circular scan. The deviations affected in this case are perpendicular to the workplane.

For the linear filters, the number of points in the filter set may be less than the number of input points. PC-DMIS removes points at both ends for which not enough data (to the left or right) is available. To compute a valid output point, see "Filter Width box".

Polar option

The **Polar** option in the **Construct Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**) enables you to apply a filter to data in a circular scan. PC-DMIS assumes that the data is periodic (meaning it forms one complete, closed circle). The deviations affected in this case are radial deviations.

Apply Filter Check Box

The **Apply filter** check box in the **Construct Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**) allows you to construct the feature set independent of whether or not the filtering is applied to the data. Use this check box to choose to remove outliers, for example, but not filter the data.

Method List

The **Method** list allows you to select from the following filter types:

- ISO_16610_GAUSSIAN
- SPLINE
- UNIFORM
- TRIANGLE
- CYLINDRICAL
- GAUSSIAN

If you select GAUSSIAN, UNIFORM, or TRIANGLE then the workplane is critical. For these three filter types, the following applies:

- If you select the **Linear** option, the filtering occurs normal (i.e., perpendicular) to the workplane.
- If you select **Polar** option, then the filtering occurs in a radial direction within the workplane.

ISO_16610_Gaussian

Starting with PC-DMIS 2025.1, the **ISO_16610_GAUSSIAN** filter option is available. This filter option is intended to supercede the **GAUSSIAN** filter option. The older version of the **GAUSSIAN** filter option was written in accordance with ISO 11562:1996 which was later cancelled and replaced by ISO 16610-21:2011. PC-DMIS retains this older **GAUSSIAN** filter option for migration purposes. Starting with PC-DMIS version 2025.1, we recommend that you select the **ISO_16610_GAUSSIAN** filter option when you create new measurement routines. You can not back-save measurement routines that use the newer **ISO_16610_GAUSSIAN** filter option to versions of PC-DMIS earlier than 2025.1.

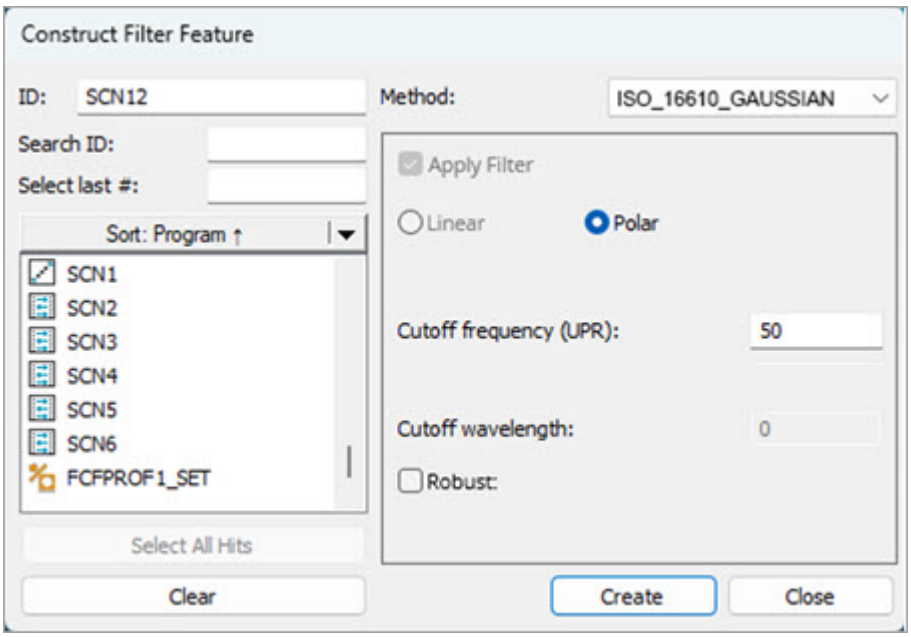
The newer **ISO_16610_GAUSSIAN** filter option combines concepts from these standards in the ISO 16610 series:

- ISO 16610-21
- ISO 16610-28
- ISO 16610-31
- ISO 16610-61
- ISO 16610-68 (not published yet)
- ISO 16610-71

This combination allows the following capabilities that were not previously available:

- You can now filter any kind of surface, not just 2D lines and 2D circles.
- Outlier handling is now standards compliant.
- Points can be irregularly spaced.
- Points are not required to be in any kind of order.
- Both linear and areal datasets are acceptable.

You can access the newer **ISO_16610_GAUSSIAN** filter option from the **Constructed Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**). This newer version of the filter smooths your data by applying a Gaussian lowpass filter to it according to the ISO 16610 collection of standards.

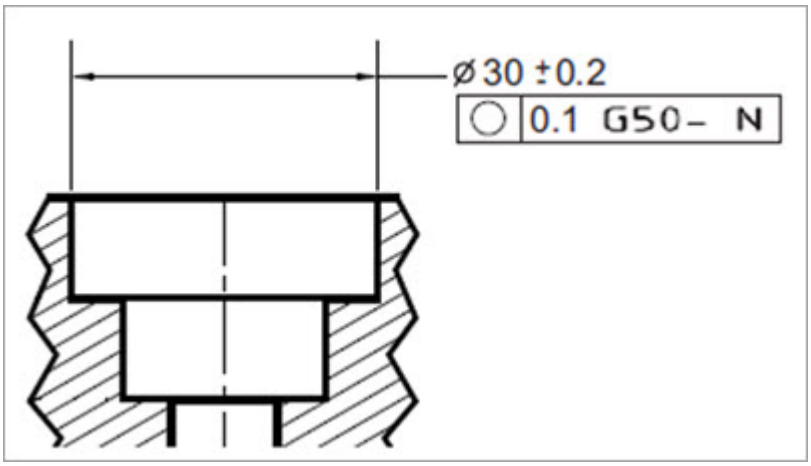


Construct Filter Feature dialog box showing the ISO_16610_GAUSSIAN filter method selected

The **Apply Filter** option is always active for this filter type. It is grayed out so it can't be deselected.

You can either type a **Cutoff frequency** (Polar) or **Cutoff wavelength** (Linear) to control the amount of smoothing.

The following example shows how the **Cutoff frequency** or **Cutoff wavelength** might be defined on the print.



In this example, a roundness specification applies relative to the minimum circumscribed reference feature (N), after the application of a Gaussian longwave pass filter with a cutoff value of 50 UPR (G50). To satisfy this requirement in PC-DMIS, you should:

- Gather surface data with a sufficient point density to satisfy the filter requirements (see "Points to Note"). You could use:
  - An Auto Cylinder with the adaptive concentric circle scan strategy, or
  - A series of linear closed or basic circle scans, or

- Extract the data from a pointcloud using a laser Auto Cylinder or a Constructed Extracted Cylinder

> Multiple individual scans must be combined into a constructed feature set before filtering.

- Construct an ISO_16610_GAUSSIAN filter set from the cylinder's hits. Set the filter type to **Polar** and type 50 in the **UPR** box. Decide whether to apply the **Robust** option or not. In most cases, Hexagon recommends that you apply this option.
- Construct a BFRE Cylinder using the ISO_16610_GAUSSIAN filter feature as the input.
- Create an ISO 1101 Geometric Tolerance Circularity command for your constructed BFRE Cylinder. Type 0.1 for the tolerance and select **N** from the **Reference Feature Association** list.

The title block might show a general filter requirement ISO 1101 TF:G0,8-x50. This means that for all tolerance features (TF), an ISO_16610_GAUSSIAN filter with a cutoff wavelength of 0.8 should be applied to all open profiles (Linear) and a 50 UPR frequency should be applied to all closed profiles (Polar). For more information, refer to ISO 1101:2017 section 8.6.

In some cases, neither the print nor the corporate standards define the critical wavelength. This is an error, because prints need to clarify the dividing line (the critical wavelength) between form error and surface texture. However, real prints often have errors, so it is helpful to have several rules of thumb to aid inspection engineers who need to select a useful critical wavelength when none is specified.

- For round features like circles and cylinders, 50 UPR is a common choice.
- When you use a contact sensor, it often makes sense to choose a critical wavelength equal to the probe diameter.
- For closed features like ellipses and slots, it often makes sense to choose a critical wavelength equal to the circumference divided by 100.
- For open features like planes and freeform surfaces, it often makes sense to choose a critical wavelength equal to the length of the feature divided by 100.

Robust

Unlike other filter types, rather than removing outliers, ISO 16610-31 and ISO 16610-71 allow the filter to be applied in a way that makes it robust to the effects of outliers. For more information, refer to ISO-16610-31 ("Robust profile filters: Gaussian regression filters") and ISO-16610-71 ("Robust areal filters: Gaussian regression filters").

The Robust check box is a simple On/Off toggle that determines whether to make the filter robust to outliers or not. No points are removed.

Points to Note

Gaussian filtering does not work well unless every point has a reasonable number of neighbors: at least four. The neighbors of a point are defined to be all points within a radius equal to the cutoff wavelength. In some cases, scans do not have enough point density, either for individual areas or for the whole scan. This results in the filter performing poorly, such as not filtering out sensor noise, surface texture, outliers, etc. In extreme cases, if a point has no neighbors, the filter does nothing for that point.

You can use the following formulas as guides.

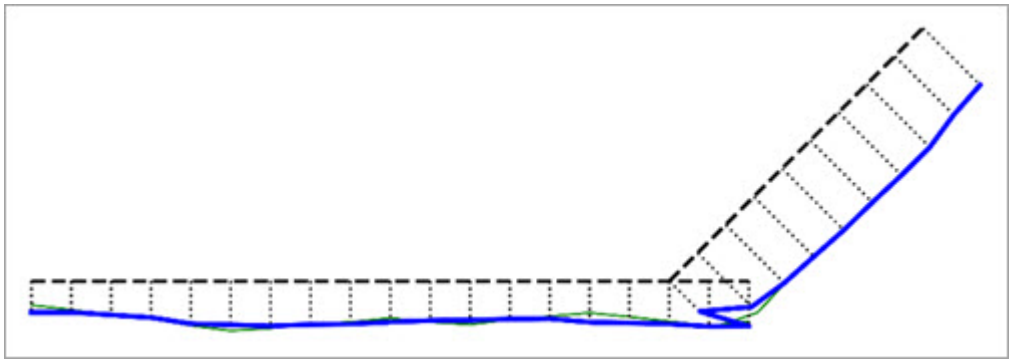
Minimum Number of Points = 5 / Cutoff Wavelength (mm)

*Minimum Number of Points = (5 * UPR) / (π * Diameter (mm))*

Gaussian filtering can also be sensitive to location errors as described in the examples below. These examples show that when PC-DMIS detects a surface that exhibits a kink, sharp corner, or tight radius, it provides a SENSITIVITY_FACTOR to indicate how much the filter has been affected.

Example 1 - Surface Exhibits a Kink

In this example, the two CAD surfaces overlap slightly, causing a kink in the scan path. This results in inconsistent vectors that cross over each other as the scan path goes back on itself.



----- Nominal Surface

_____ Measured Points

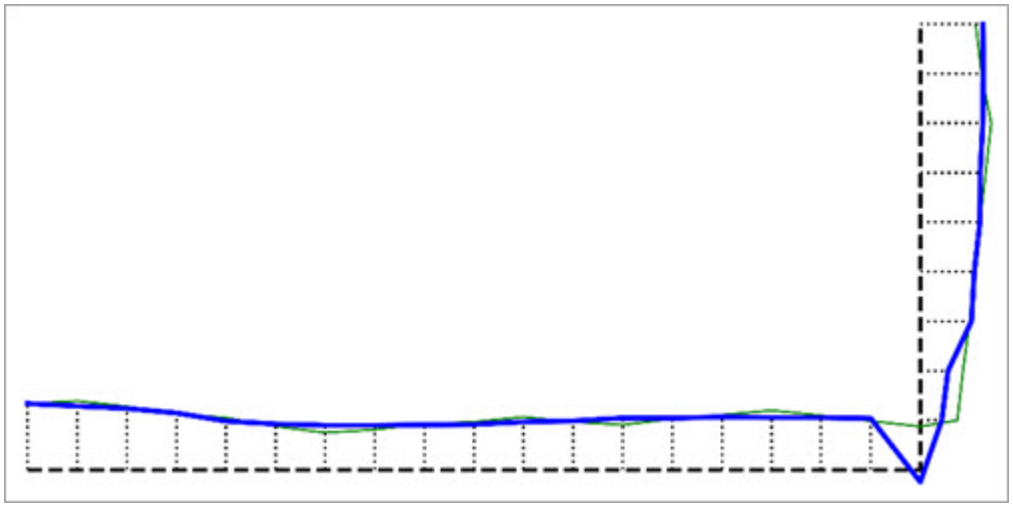
••••• Filtered Deviations

_____ Filtered Points

To fix this problem, adjust the scan path or point density to ensure the nominal vectors remain continuous near boundaries between CAD elements.

Example 2 - Surface Exhibits a Sharp Corner

In this example, the scan is off location while also going around a sharp corner. This results in significant distortion being introduced when attempting to filter.



----- Nominal Surface

_____ Measured Points

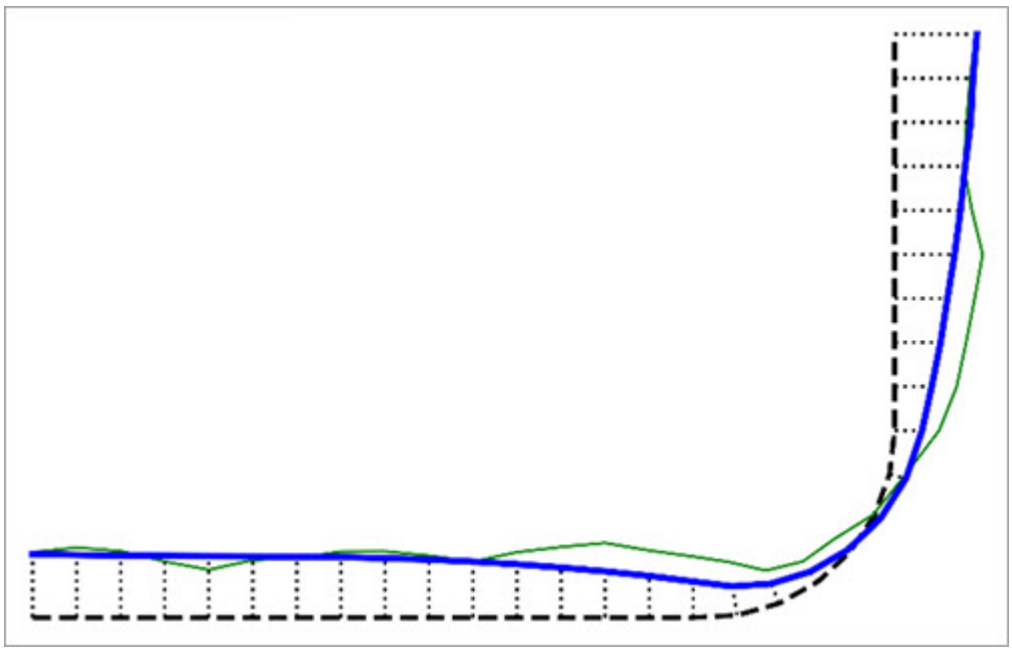
••••• Filtered Deviations

_____ Filtered Points

To fix this problem, avoid measuring near sharp corners. Maybe consider breaking the scan up into two separate scans, one for each edge.

Example 3 - Surface Exhibits a Tight Radius

In this example, the scan is off location while the critical wavelength is larger than the tight radius. This causes distortions near the radius.



----- Nominal Surface

_____ Measured Points

••••• Filtered Deviations

_____ Filtered Points

To fix this problem, ensure the critical wavelength is comparable to, or smaller than any tight radii.

The following is an example of a warning message that PC-DMIS might show when you create an ISO_16610_GAUSSIAN filter command and it detects any of these situations:

- The sensitivity factor exceeds 0.3.
- One or more points are found to have no neighbors.
- The number of points with less than four neighbors exceeds 2 + 0.01 * N, where N is the number of input points.

PC-DMIS

The filter output is sensitive to location errors by a factor of X.X which means the surface exhibits some kind of kink, sharp corner, or tight radius. To fix the problem, (1) ensure the nominal vectors remain continuous near boundaries between CAD elements, (2) avoid

measuring near sharp corners, and (3) ensure the critical wavelength is much less than any tight radii.

The following is an example of a warning message that PC-DMIS might show if it detects insufficient point density:

PC-DMIS

Warning: The point density is insufficient for the specified critical wavelength. There are 7 points with no neighbors, and 280 points with less than four neighbors.

These warnings are not triggered during execution. Instead, this command provides a number of feedback parameters to aid troubleshooting. With each execution, PC-DMIS stores the information in the Edit window command (visible in Command Mode), and is non-editable:

- **Sensitivity Factor** - This represents the proportion of the total error that this filter adds on top of ISO-16610-21 and ISO-16610-28 as a result of location errors in the input data.
- **Points With No Neighbors** - This is the number of points with no neighboring points.
- **Less Than 4 Neighbors** - This is the number of points with less than four neighboring points.

While PC-DMIS displays a warning during command creation, it does not prevent you from executing a constructed **ISO_16610_Gaussian** filter command based on this feedback. It does make the values available via GETTEXT expressions if you wish to add your own logic to test for undesirable results. The example below shows you how to do this.

```
NEW_UPR50_ROB_ON=FEAT/SET,CARTESIAN
    THEO/<-0.027007,-0.000578,-2>,<0,0,1>
    ACTL/<-0.027374,-0.00068,-1.999392>,<0,0,1>
    CONSTR/SET,FILTER,ISO_16610 GAUSSIAN,POLAR,ADP_CIRCLE,
    FILTER/ON,UPR=400,ROBUST/ON

SENSITIVITY_FACTOR=0.000005,POINTS_WITH_NO_NEIGHBORS=0,LESS_
THAN_4_NEIGHBORS=507
    ASSIGN/V1=GETCOMMAND("Constructed Filter Set", "UP",1)
    ASSIGN/FILTER_VALUE=GETTEXT("DVALUE_1",1,V1)
    ASSIGN/NO_NEIGHBORS=GETTEXT("DVALUE_1",2,V1)
    ASSIGN/LESS_NEIGHBORS=GETTEXT("DVALUE_1",3,V1)

    COMMENT/REPT,
    "FILTER_VALUE = " +FILTER_VALUE
    "NO NEIGHBORS = " +NO_NEIGHBORS
    "LESS_NEIGHBORS = " +LESS_NEIGHBORS
```

In rare cases, you might encounter an error during execution of your measurement routine similar to this one:

Construction Error

Math failed for SCN86: There are more than 100 million connections between points and their neighbors. This can be interpreted as the product of the number of points and the average number of connections between points. Please reduce the number of points or reduce the wavelength.

This can happen when you have both a very high point density and a large wavelength which would lead to unacceptable performance delays (extremely long calculation times of several minutes). For these cases, PC-DMIS is unable to execute the command, and the SENSITIVITY_FACTOR displays as an “Error” in the Edit window as shown in this code snippet:

```
SCN86=  =FEAT/SET, CARTISIAN
         THEO/<0,0,0>,<0,0,-1>
         ACTL/<0,0,0>,<0,0,-1>
         CONSTR/SET,FILTER,ISO_16610 GAUSSIAN,LINEAR,CYL1,
         FILTER/ON,WAVELENGTH=16,ROBUST/ON
         SENSITIVITY_FACTOR=Error,POINTS_WITH_NO_NEIGHBORS=0
,LESS_THAN_4_NEIGHBORS=0
```

To continue, you either need to reduce the feature’s point density or reduce the filter command’s wavelength.

Spline

The **Spline** filter option in the **Construct Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**) allows you to smooth the data by fitting a smoothing spline to it. The Smoothing Parameter value controls the amount of smoothing. However, if you want to use the "optimal" value computed by *Generalized Cross-Validation* (GCV) technique, you should set this value to 0. The Spline filter option is a 3D filtering option. This means deviations in all directions perpendicular to the line are affected.

The spline filter fits a spline approximation to the data and resamples it. This way, it smooths the data in all directions, not just radially or perpendicularly to the workplane. The fitted spline is a *natural smoothing spline*. It has a parameter that mediates between interpolating the data - trying to pass through every data point, which would retain all of the oscillations - and approximating the data with a successively smoother spline, in the sense that the oscillations are damped. The two limits of the smoothing parameter yield an interpolator (with all of the original oscillations) and a straight line. A zero value for the spline filter results in a spline that (asymptotically) minimizes the expected mean square error between it and the underlying, unknown, curve. You should usually use the zero value since this removes the noise yet leaves the underlying shape reasonably intact.

Math Information: Since the range of interest for the actual (internal) smoothing parameter lambda usually involves small values, the **Construct Filter Feature** dialog box accepts

```
-log10(lambda).
```

So, instead of `1-e-6`, you just type 6. You get more smoothing for smaller values of the smoothing parameter. For example, a value of 5 for the spline filter would give you more smoothing than a value of 6.

Uniform

The **Uniform** filter option in the **Construct Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**) filters the data by averaging all the points in a moving window. You can specify the width of the window through either the **Smoothing parameter** or the **Filter width** value.

If the **Filter width** value is `m`, then the window is `2m * delta` wide, where `delta` is the point spacing.

Triangle

The **Triangle** filter option in the **Construct Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**) filters the data by a weighted moving average of all the points in a moving window. The weights are determined by a triangle function with the peak in the middle of the window. You can specify the width of the window through either the **Smoothing parameter** or the **Filter width** value.

If the **Filter width** is *m* then the window is `2m·* delta` wide, where `delta` is the point spacing.

Cylindrical

The **Cylindrical** filter option in the **Construct Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**) filters data in a spiral scan or a circular scan that spans more or less than a full circle. The deviations in this case are radial. As PC-DMIS does not consider the data to be periodic (meaning it does not form a complete, closed circle), a number of points equal to the filter width at the beginning and at the end of the scan are absent from the filter set.

GAUSSIAN

The GAUSSIAN filter option is the most widely used filter option.

Starting with PC-DMIS 2025.1, the **ISO_16610_GAUSSIAN** filter option is available. This filter option is intended to supercede the **GAUSSIAN** filter option. The older version of the **GAUSSIAN** filter option was written in accordance with ISO 11562:1996 which was later cancelled and replaced by ISO 16610-21:2011. PC-DMIS retains this older **GAUSSIAN** filter option for migration purposes. Starting with PC-DMIS version 2025.1, we recommend that you select the **ISO_16610_GAUSSIAN** filter option when you create new measurement routines. You can not back-save measurement routines that use the newer **ISO_16610_GAUSSIAN** filter option to versions of PC-DMIS earlier than 2025.1.

You can access the newer **ISO_16610_GAUSSIAN** filter option from the **Constructed Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**). This newer version of the filter smooths your data by applying a Gaussian lowpass filter to it according to the ISO 16610 collection of standards.

The **GAUSSIAN** filter option in the **Construct Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**) enables you to smooth the data by applying a Linear or Polar Gaussian lowpass filter to it according to the ISO 11562 standard. The **Cutoff wavelength**, **Cutoff frequency**, or **Filter width** value controls the amount of smoothing.

For the polar Gaussian filter, the data should be a *complete* circle scan, with radial deviations. A partial circle scan will not work correctly with this filter. The appropriate filter for a partial circle scan is the cylindrical filter discussed below.

For the linear Gaussian filter, the data should nominally lie in a plane with the deviations perpendicular to the plane. For this filter, the cutoff wavelength is in units of length. The following paragraphs describe how a linear Gauss filter functions:

- It estimates the point spacing delta as the average distance between the X and Y coordinates of the 3D points. These should be evenly spaced and coplanar. It will smooth the Z coordinates.
- If the smoothing parameter is

`m = filter width`
(i.e., the smoothed value is at the center of `2m+1` points used in a weighted average, starting at point `m`), then the cutoff wavelength `lambda` is computed as:

`lambda = m * delta / const`
(where `const` is a numerical constant.)

- If the input parameter is `lambda = cutoff wavelength`, then the filter width `m` is computed as:

  `m = lambda * const / delta` (actually, the next higher integer value).

So, the cutoff wavelength has the same units as the point spacing, but the filter width is a pure number.

Filter Width box

The **Filter width** value in the **Construct Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**) is an optional smoothing parameter for all of the filter types except the Spline filter. The value in this box determines the number of data points used for filtering to the right and to the left of each smoothed data point. For example, if the Filter Width value is `m` then the window is `2m * delta` wide, where `delta` is the point spacing. The default value for this parameter is 3.

The value you type can be zero or any positive value.

- If there's no value at all (or if the value is zero), either the **Cutoff frequency** or the **Cutoff wavelength** value will be used to set the amount of smoothing.
- If either the **Cutoff frequency** or the **Cutoff wavelength** value is any non-zero, positive value, then the filter width corresponding to the cutoff frequency entered is displayed.
- If **Filter width** and the **Cutoff frequency** or **Cutoff wavelength** don't have values (or are zero), PC-DMIS will not filter the data.

The **Filter width** value also determines how many points will be absent from the filter set when doing *linear* filtering. PC-DMIS removes those points that don't have enough data to the right or left to fill up the data window.

A lowpass filter, one that filters out high frequency noise but transmits the lower frequency form and waviness, works by replacing the value at a data point by a weighted average of the values at a sequence of its neighbors.

For the *Gauss* filter, for instance, the **Filter width** specifies how many points to the left and right of a point are included in the weighted average.

The weights (which are positive and add up to 1) are values of a Gaussian distribution function (also known as a Bell Curve).

If the **Filter width** is equal to `m`, then the smoothed point is at the center of `2m+1` points used in the weighted average.

If the data is periodic, then the points wrap around and there are always enough points to the left and right of a point to compute this average. This is the case for a *Polar* filter. But for a *Linear* filter, the first and last `m` points do not have enough neighbors to compute the full weighted average, so these points are left out of the filtered dataset.

Cutoff Wavelength box

The **Cutoff wavelength** value in the **Construct Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**) determines the wavelength of the oscillations in the data below which the amplitudes of the oscillations are reduced when you apply a *linear* Gaussian filter.

Cutoff Frequency box

The **Cutoff frequency** value in the **Construct Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**) determines the number of "undulations per revolution" (or UPR) in the circle data above which the amplitudes of the oscillations in the data are reduced when you apply a *polar* Gaussian filter or a cylindrical filter.

Smoothing Parameter box

The **Smoothing parameter** value in the **Construct Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**) determines the degree of smoothing applied to the data for the spline, uniform, and triangle filters.

- *For the spline filter*, it is best to set this value to 0 to indicate that the value computed via GCV should be used. The computed value then replaces the 0 in the Edit window.
- *For uniform and triangle filters*, the smoothing parameter represents one-half of the width of the window used in the (weighted) moving average.

Remove Outliers check box

If you select the **Remove outliers** check box in the **Construct Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**), PC-DMIS attempts to remove all points a given number of standard deviations from the substitute feature (usually a circle or a line). You specify the number of standard deviations in the **Standard deviation multiple** box. See the "Standard Deviation Multiple box".

Outlier removal behaves similar to filtering:

- If you select the **Linear** option, outlier removal is based on the 3D distance from the point in question to the line (best fit line through the data).
- If you select the **Polar** option, outlier removal occurs in the radial direction (parallel to the workplane).

Standard Deviation Multiple box

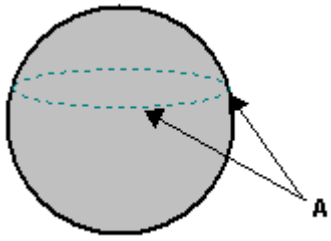
The **Standard deviation multiple** value in the **Construct Filter Feature** dialog box (**Insert | Feature | Constructed | Filter**) determines the number of standard deviations from the substitute (least squares) feature beyond which points are identified as outliers. The default value is 3.

Constructing an Adjusted Filter

The **Adjust Filter** construction type lets you adjust scan data that was gathered while scanning around these standard geometric features:

- Sphere
- Cone
- Cylinder

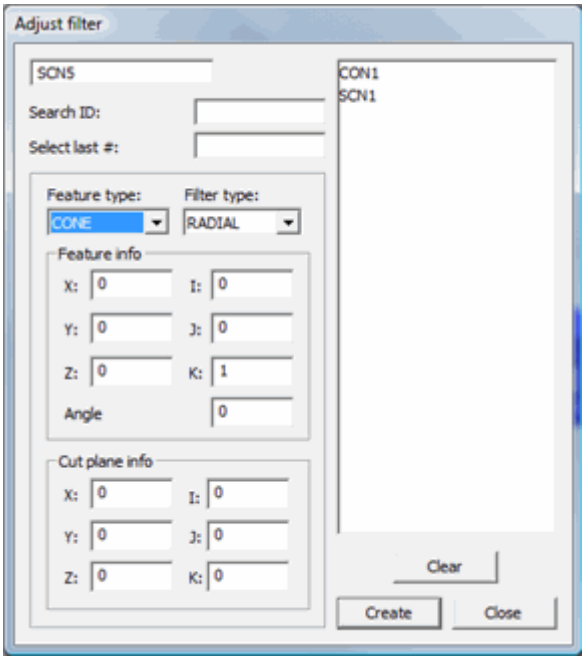
Generally, you perform these scans using an analog probe, such as an SP600. If you imagine a scan around the top quarter of a sphere, for example, you would ideally get points that lie within a plane that cuts through the sphere, like this:



A - Scan Path

However, in reality, as the probe scans around the sphere, it is physically impossible for all the points to remain inside the cut plane due to a natural rise and fall floating motion of the CMM.

The **Adjust Filter** construction can take the pre-existing scanned points and, using the known mathematical properties of the feature, better compensate the points gathered during the measurement process, adjusting them to lie more within the cut plane. You use the **Adjust filter** dialog box to do this. To access this dialog box, select **Insert | Feature | Constructed | Adjust Filter**.



Adjust filter Dialog Box

The dialog has these options:

Feature Type
This defines the primitive (simple geometric feature) being scanned. You can only select **Sphere**, **Cone**, or **Cylinder**.

Filter Type
This defines the type of filter to use, either **Axial** or **Radial** (applies to Cone and Cylinder feature only - see step 4 below).

Feature Info
This lets you define the information about the feature.

XYZ - The feature's nominal position.
IJK - The feature's normal vector.
Radius/Angle - This sets the Radius of the Sphere or Cylinder or the angle of the Cone.

Cut Plane Info
This area defines the location and vector of the cut plane.

XYZ - Location of the Cut Plane
IJK - Vector of the Cut Plane

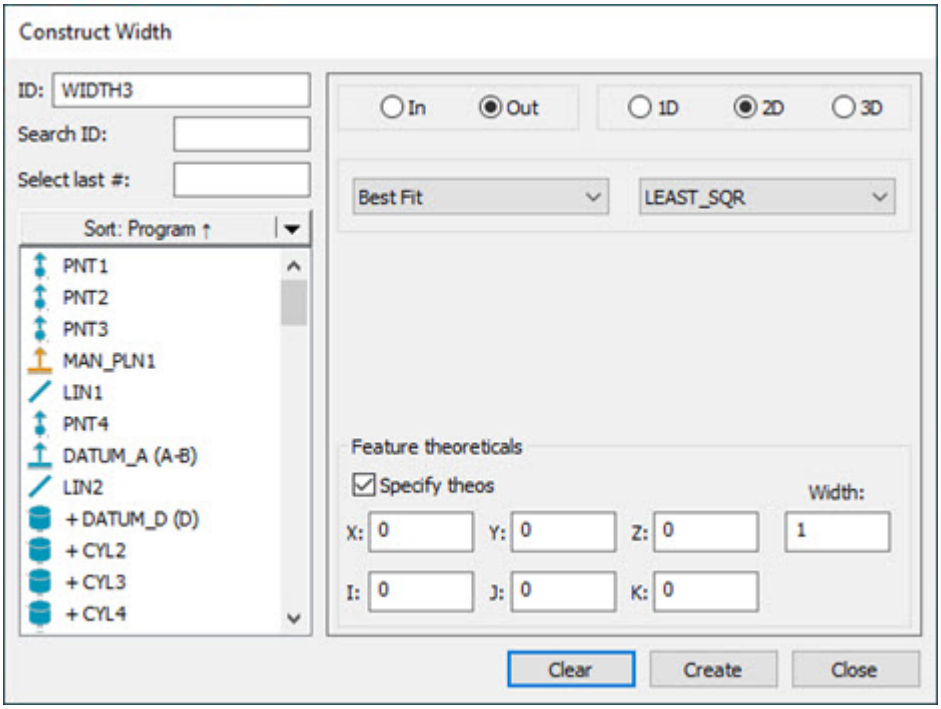
To Adjust Scan Data

To correctly adjust the data in the scan, you need to give enough information to mathematically define the feature.

1. Select the actual sphere, cone, or cylinder feature from the list of features in the **Adjust filter** dialog box.
2. Select a pre-existing scan feature from the list. Generally, your scanned feature is a pre-existing linear closed scan. The scan must be of a sphere, cone, or cylinder.
3. Choose the feature type you scanned with the selected scan from the **Feature Type** list.
4. From the **Filter Type** list, choose the correct filter type for a Cone or Cylinder feature. The filter indicates how to compensate the data.
    - If you are scanning perpendicular to the axis of the Cylinder or Cone, choose the **Radial** filter. This defines the circle that is used to adjust the points.
    - If you are scanning parallel to the feature's axis, choose the **Axial** filter. This defines a line that is used to adjust the points.
5. Define the feature's nominal XYZ location by typing the values in the **XYZ** boxes.
6. Define the feature's normal vector by typing the values in the **IJK** boxes.
7. Define the feature's size by typing a value in the **Radius** or **Angle** box.
8. In the **Cut Plane Info** area, define the scan's cut plane. Once you specify all the nominal information for the scanned feature, you can create the construction.
9. Click **Create**. All the points are projected into the cut plane along the features theoretical definition (taking into account the known geometry) rather than a straight projection along the features normal vector.

Constructing a Width Feature

You can construct a Width feature from two opposing sides of a notch, tab, or other similar surfaces. The Width feature is useful to the GD&T standard which requires the width as a datum or considered feature in Geometric Tolerance dimensions. For more information on Geometric Tolerance dimensions, see "Using Geometric Tolerances".



Construct Width Dialog Box

Width constructions require two input features, one feature for each opposing side of the notch or tab.

PC-DMIS supports the following Width constructions:

- **1D** - This construction is between two opposing points.
- **2D** - This construction is between two opposing lines.
- **3D** - This construction is between two opposing planes.

PC-DMIS considers the Width feature as an outer (OUT) feature when the opposing planes, lines, or points come from a tab-like geometric feature. PC-DMIS considers the feature as an inner (IN) feature when the opposing planes, lines, or points are measured from a notch-like geometric feature.

The vector of the Width feature points from the first selected feature perpendicular to the second feature.

To construct a Width Feature

1. Measure the required two features (two points, two lines, or two planes) on the opposing sides of a notch, tab, or other two opposing surfaces. These are the two features to use when you construct the width.
2. Open the **Construct Width** dialog box in one of these two ways:
   - Select **Insert | Feature | Constructed | Width**.
   - From the **Construction** toolbar, click the **Width** button.
3. Select **1D**, **2D**, or **3D**.
   - If your input features are two points, select **1D**.
   - If your input features are two lines, select **2D**.
   - If your input features are two planes, select **3D**.
4. From the **Feature** list, select the two input features for the construction.
5. Select **In** or **Out**:
   - If the Width feature contains material between the two opposing sides, like a tab, it's an outer feature. Select **Out**.
   - If the Width feature does not contain material between the two opposing sides (like a notch), it's an inner feature. Select **In**.
6. From the **Fitting** list, for **2D** or **3D**, select the type of fitting algorithm to use: **Best Fit** or **Best Fit Recomp**.
7. From the **Math Algorithm** list, for **2D** or **3D**, select the Best Fit math algorithm to use. The available options are:
   - Maximum Inscribed (**MAX_INSC**)
   - Minimum Circumscribed (**MIN_CIRCSC**)
   - Least Square (**LEAST_SQR**)

   For more information, see "Best Fit Type" under "Constructing a Best Fit or Best Fit Recompensate Circle".
8. If you want to define the theoretical width information, mark **Specify theos** and then type the theoretical centroid in the **X**,**Y**, and **Z** boxes. Next, type the theoretical vector in the **I**, **J**, and **K** boxes. Finally, type the width between the two sides in the **Width** box.
9. Click **Create** to insert the Width feature into the measurement routine.

The Edit window command line for the width construction shows:

```
feature_name=FEAT/WIDTH,TOG1,TOG2,TOG3,TOG4
THEO/<x_cord,y_cord,z_cord,i_vec,j_vec,k_vec>,length
ACTL/<x_cord,y_cord,z_cord,i_vec,j_vec,k_vec>,length
CONSTR/TOG5,TOG6,feat1,feat2
```

TOG1 = CARTESIAN or POLAR.

TOG2 = IN or OUT. This is for display only; you cannot use the Edit window to edit this.

TOG3 = MAX_INSC / LEAST_SQR / MIN_CIRCSC. These only apply to **2D** or **3D**.

TOG4 = YES or NO. These are user-defined theoretical values.

TOG5 = The constructed feature type.

TOG6 = BEST FIT / BEST FIT RECOMP. These only apply to **2D** or **3D**.

Notes

You can use a **3D** width as a primary, secondary, or tertiary datum, or as any referenced feature in an alignment. You can use a **2D** width as a secondary or tertiary datum, or as a “rotate to” feature or final “translate to” feature in an alignment. You can use a **1D** width as a tertiary datum or as a final “translate to” feature in an alignment.

If you create a Location dimension of the constructed Width feature, the X, Y, and Z axes represent the midpoint of the Width feature. The L axis represents the length of the Width feature.

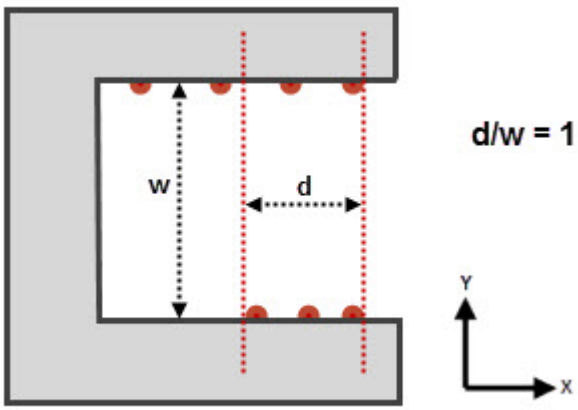
To calculate a Width feature in **2D** or **3D**, the hit locations on the two opposing features must have enough overlap. To calculate a Width feature in **1D**, the hit locations on the two opposing features must be close to opposed.

When PC-DMIS calculates a Minimum Circumscribed or Maximum Inscribed Width feature in **2D** or **3D**, if **d** is the overlap distance and **w** is the width distance (as shown in the figure below), the recommended overlap ratio should be:

d/w = 1 or more

If a large overlap ratio is not feasible due to the physical structure of the part, use the Least Square method for the Width calculation instead.

For example, in this top-down view of a part, **d** represents the amount of distance between the two sets of hits where overlap occurs on the two sides, and **w** represents the Width feature's distance between the two sides. Suppose d = 1.5 and w = 3. The overlap ratio of d/w is .5. The recommended ratio is 1. So, there may not be enough overlap for the Minimum Circumscribed or Maximum Inscribed fitting algorithms. In such a case, use the Least Squares algorithm instead:



w
d
d/w = 1
Y
X

Creating Generic Features

Creating Generic Features: Introduction

This chapter covers the ability to add generic features into your measurement routine and create point features at the probe's current position.

Generic features are often used to control the measured and theoretical values of a specific feature in order to perform calculations that PC-DMIS's constructed features don't currently support. For example, suppose you want to create the shortest line between two lines (3D) that don't intersect. PC-DMIS doesn't have that construction option. However, you can do the math yourself using the PC-DMIS Expression language and then assign the theoretical and measured values of a generic line to the appropriate values. In this way, you can create your own construction.

This section contains these major topics:

- Description of Generic Features
- Purpose of Generic Features

Description of Generic Features

Usually, when PC-DMIS measures features on your part, it guesses the correct feature type depending on the number of hits taken and the inherent feature type available on the imported CAD model itself.

PC-DMIS does not guess generic features. Instead, the user inserts and creates them.

Purpose of Generic Features

Generic features are used to hold and transform values. You can use these values to create new constructed features or modify existing features via the CALCULATION command.

For information on how to create new constructed features, see the "Constructing New Features from Existing Features" chapter.

Generic Feature Command Format

All generic features have XYZ and IJK values. They may have ANGLE, DIAMETER, RADIUS, or DISTANCE values depending on the type assigned to the feature.

The **Nominal / Measured Values** toggle button indicates the values that are used in the generic feature.

The command line in the Edit window (a cone is shown) is as follows:

```
feature_name        =GENERIC/TOG1,TOG2,  TOG3, TOG4
                     NOM/XYZ,x_cord,y_cord,z_cord
                     MEAS/XYZ,x_cord,y_cord,z_cord
                     NOM/IJK,i_cord,j_cord,k_cord
                     MEAS/IJK,i_cord,j_cord,k_cord
                     [RADIUS/radius] | [DIAMETER/diameter]
                     [ANGLE/ang]
                     [DISTANCE/dist]
```

TOG1 =POINT, PLANE, LINE, CIRCLE, SPHERE, CYLINDER, CONE, SLOT, or NONE

TOG2 = This indicates whether the generic feature is alignment dependent or independent.

TOG3 = This indicates whether the feature uses Polar or Rectangular coordinates.

TOG4 = This indicates whether the feature is an IN (hole) or OUT (stud) feature.

[ ] = The options shown in brackets are discretionary and are available based on the type assigned to the feature by TOG1. RADIUS and DIAMETER are mutually exclusive representations for the value represented as the radius or the diameter.

Creating a Generic Feature

While it is entirely possible to type the word `GENERIC` and press Tab in the Edit window in Command Mode to create a generic feature, PC-DMIS provides an easier way to create new generic features. The **Construct Generic Feature** dialog box (**Insert | Feature | Generic**) provides a more intuitive way to create new generic features.

To Add a Generic Feature

To add a generic feature:

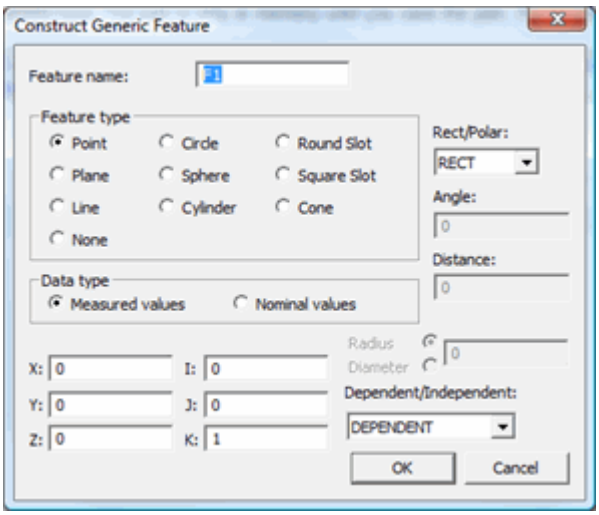
1. Place your cursor in a new line of the Edit window.
2. Access the **Construct Generic Feature** dialog box by one of the following:
    - Select **Insert | Feature | Generic**.
    - Type GENERIC in the Edit window in Command Mode.

- Select Generic Feature from the list that appears in Summary Mode after you select **Add Command**.

3. Make the changes you desire.

4. Click the **OK** button to create the feature. PC-DMIS saves the generic feature and update the information for the feature in the Edit window and the Graphic Display window.

Description of the Construct Generic Feature Dialog Box



Construct Generic Feature Dialog Box

Use this dialog box to create new features. To open this dialog box, select **Insert | Feature | Generic**.

The topics below describe the options that are available on this dialog box.

Limited CAD Selection

With the **Construct Generic Feature** dialog box open, you do have some very limited wireframe CAD selection capabilities. This is limited to selecting points and lines. For more advanced CAD selection requirements, you would need to use PC-DMIS's Auto Feature or Constructed Feature capability.

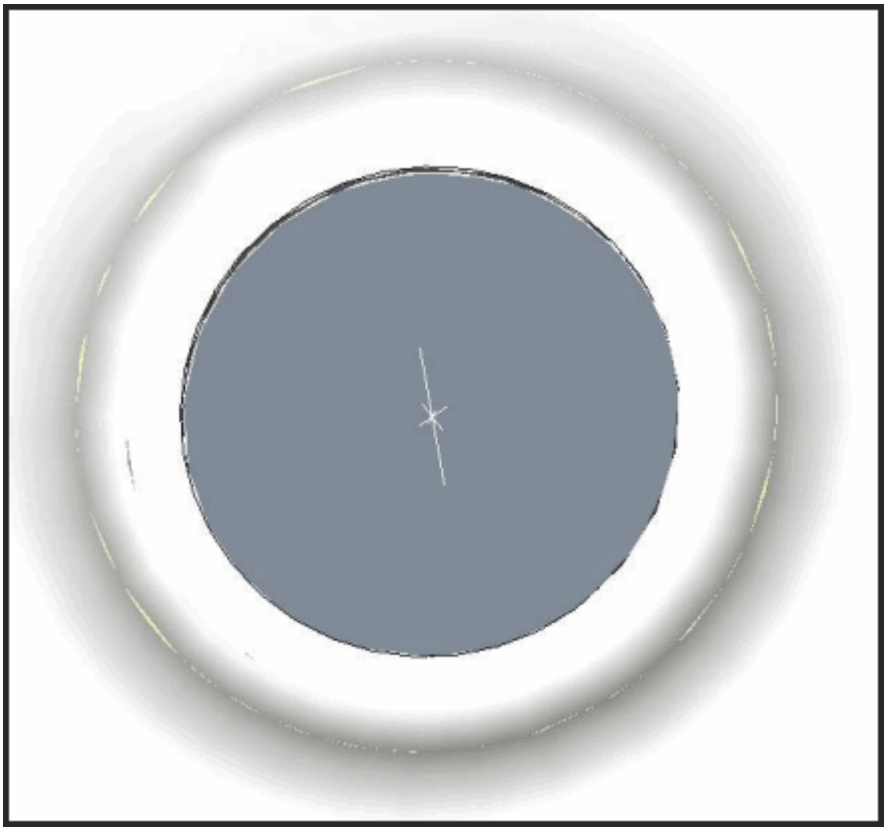
- If you select a point, PC-DMIS fills in both the nominal and measured values into the dialog box for that feature.

- If you select a line, then the IJK information is inserted for both nominal values and measured values.

PC-DMIS ignores any other type of wireframe entity that you select.

For example, in this top-down image of a circle feature seen below, you will notice a white cross and line in the center of the circle. The cross and line are CAD elements of a point and line, respectively, that are created within the CAD system and imported as part of the

CAD file into PC-DMIS. You would select either the line or the cross (not the actual circle feature) to have its data input into the dialog box.



Example showing a wireframe point and line element at the center of a Circle feature.

Feature Type

The **Feature type** area in the **Construct Generic Feature** dialog box (**Insert | Feature | Generic**) enables you to create these generic feature types:

- Point
- Plane
- Line
- Circle
- Sphere
- Cylinder
- Round Slot
- Square Slot
- Cone
- None

PC-DMIS disables or enables other areas and options in this dialog box based on the type of feature that you select.

Data Type

The **Data type** area in the **Construct Generic Feature** dialog box (**Insert | Feature | Generic**) enables you to determine the values of the generic feature that are affected by the changes you make in the dialog box. The choices include **Measured values** and **Nominal values**.

XYZ Boxes

The **X**, **Y**, and **Z** boxes in the **Construct Generic Feature** dialog box (**Insert | Feature | Generic**) enable you to determine the X, Y, and Z positions for the generic feature.

IJK Boxes

The **I**, **J**, and **K** boxes in the **Construct Generic Feature** dialog box (**Insert | Feature | Generic**) enable you to determine the vector for the generic feature.

Alignment Dependent Generic Feature

Alignment dependent generic features (**Insert | Feature | Generic**) have values that depend on the alignment from which they are referenced. They change so that they are always relative to the current alignment. Their location is constant in 3D space.

For an example in 2D, suppose 0,0 is your machine origin. An alignment is set up that locates the origin at 5,5. Now, an alignment dependent feature is defined after the alignment with the values of 2 for x and 2 for y. Relative to the alignment, its values are 2 and 2. Relative to the origin, its values are 7 and 7. No matter what alignment the numbers are given relative to, the point will always be located at 7,7 relative to the true origin.

Alignment Independent Generic Feature

Independent generic features (**Insert | Feature | Generic**) have values that remain the same, regardless of which alignment they are referenced from (therefore considered "independent"). Their location in 3D space changes as the alignment changes.

For an example in 2D, consider the same example of 2,2 (as shown in the Alignment Dependent example above) but this time with an alignment independent generic feature. If you ask for the x and y values relative to the alignment, the object will report 2,2. If you ask for its values relative to the origin, the object will still report 2,2. The set 2,2 relative to the alignment is located at 7,7 relative to the true origin. The set 2,2 relative to the origin is exactly that: 2,2. Thus, the point seems to move in 2D space.

The independent option was added so that a generic feature named XAXIS, for example, could always be used as an input feature to a construction or a datum to a dimension, and it would always have the values of 1,0,0 independent of the current alignment.

Polar/Rect

The **Polar/Rect** list in the **Construct Generic Feature** dialog box (**Insert | Feature | Generic**) enables you to pick the type of coordinate system that is used in the generic feature. You can select either POLAR or RECT.

Feature Name

The **Feature name** box in the **Construct Generic Feature** dialog box (**Insert | Feature | Generic**) enables you to name your feature. This is the ID that appears on the Feature ID label and inside the Edit window.

Radius and Diameter

The **Radius** and **Diameter** options in the **Construct Generic Feature** dialog box (**Insert | Feature | Generic**) enable you to define either a radius or a diameter for a circular feature. Select either **Radius** or **Diameter** and then type a value in the box.

Angle

The **Angle** box in the **Construct Generic Feature** dialog box (**Insert | Feature | Generic**) enables you to define the angle of a Cone. This box also becomes available if you selected **None** in the **Feature type** area.

Distance

The **Distance** box in the **Construct Generic Feature** dialog box (**Insert | Feature | Generic**) enables you to define the height or length of any generic features that have a length or height.

Creating a ReadPoint from the Probe's Position

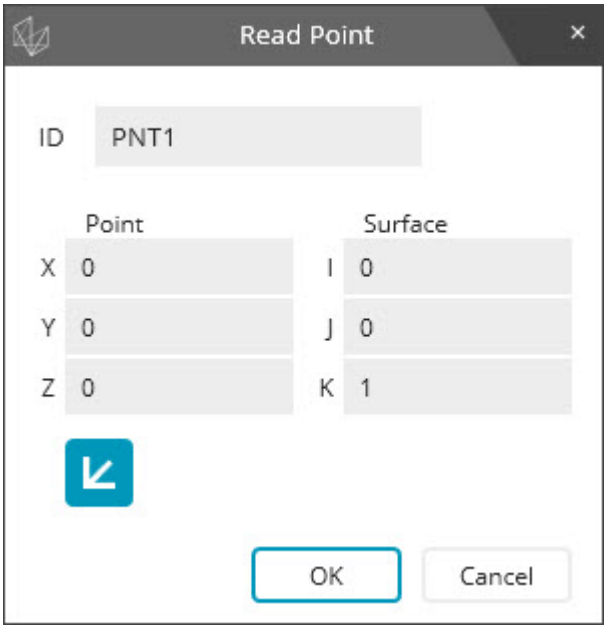
The **Insert | Feature | Read Point** inserts a point in the Edit window at the read in position. This tells PC-DMIS to read the probe's current position.

The following syntax illustrates what's inserted into the Edit window.

```
ID =FEAT/ POINT, TOG1
THEO / x, y, z, i, j, k
ACTL / x, y, z, i, j, k
READPOINT/
```

READPOINT - Identifies this feature as a read point created from the probe's position.

If you press F9 on this command, PC-DMIS displays the **Read Point** dialog box.



Read Point Dialog Box

ID - This box displays the Feature ID.

Point (X, Y, Z) - This box displays the X, Y, Z location for the constructed point.

Surface (I, J, K) - This box displays the I, J, K approach vector of the probe.

- The **Cartesian/Polar** icon switches the display of the X, Y, and Z values between the Cartesian and Polar coordinate systems. The **XYZ** labels display **RAH** when you switch to Polar.

For example:

```
PNT1 =FEAT/POINT,CARTESIAN
THEO/<7.4982,2.0111,0.95>,<0,0,1>
ACTL/<7.4982,2.0111,0.95>,<0,0,1>
READPOINT/
```

If you execute this type of point feature in Offline mode, and the feature follows a `MODE/MANUAL` command, the software copies the theoretical vector and position to the measured vector and position; otherwise, the value comes from the current probe position.

Creating and Using Alignments

Creating and Using Alignments: Introduction

Once you have activated a tip and measured features, you can create a coordinate system (or alignment). PC-DMIS provides you with a variety of tools to create and manage coordinate systems. To access the tools that allow you to work with alignments, select the desired menu options available from the **Insert | Alignment** submenu.

The major topics in this chapter describe how to use these tools to effectively create and manage alignments in your measurement routine. These topics include:

- Alignment Overview
- Alignment Command Format
- Description of the Alignment Utilities Dialog Box
- Creating a 3-2-1 Alignment
- About QuickAlign
- Creating an Iterative Alignment
- Creating a Best Fit Alignment
- Saving an Alignment
- Recalling an Existing Alignment
- Using an Alignment Inside Loops or Branches
- Equating an Alignment
- Equating CAD to Measured Part Data
- Performing a Leapfrog Operation
- Changing Alignment Nominal Values
- Updating Dependent Commands When the Alignment Changes

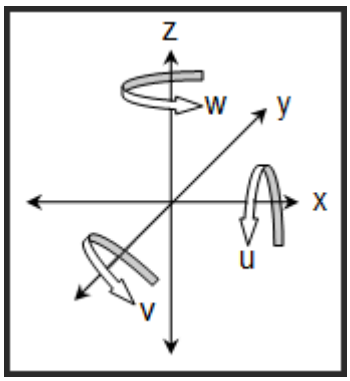
Bundle Alignments

If you have a Leica laser Tracker configuration, you can also perform a Bundle alignment. This special type of alignment is discussed in the PC-DMIS Portable documentation.

Alignment Overview

An alignment allows you to define your part's location and orientation in 3D space. It allows your measuring machine to know where the part is located. A part without any alignment has six degrees of freedom:

- Three degrees of rotation (about the X, Y, and Z axes)
- Three degrees of translation (origin in X, Y, and Z axes)



Example showing the six degrees of freedom in 3D space (X, Y, Z, U, V, and W).

Datum Reference Frame

A Datum Reference Frame (DRF) constrains the six degrees of freedom, fixing the part in 3D space.

A part alignment represents the DRF specified on the drawing. The primary, secondary, and tertiary datums define the DRF and identify the features to measure and use to create the alignment.

- The three degrees of rotation are constrained by the I, J, K vector(s) of the datum feature(s).
- The three degrees of translation are constrained by the X,Y,Z location(s) of the datum feature(s).

LEVEL

Constrains two degrees of rotation such that the leveled axis matches the vector of the selected feature.

This will always be the primary datum and must be a 3D feature with a vector.

Typical Features: Plane, Cylinder, Cone, or a constructed 3D feature.

ROTATE

Constrains one degree of rotation about the leveled axis such that the rotated axis matches the vector of the selected feature.

This will always be the secondary or tertiary datum and must be a 2D or 3D feature with a vector.

Typical Features: Plane, Line, Cylinder, Cone, or a constructed 2D/3D feature.

You can also select any two-point type features to simulate a line that can be used to rotate. These can be two points, two circles, two spheres, or a combination thereof. The direction of the simulated line is based on the order of the selected features.

ORIGIN

Constrains three degrees of translation (origin) in X, Y, and Z-axis.

This sets the origin on primary, secondary, and tertiary datums or as per drawing requirements.

Typical Features: Any feature.

Alignment Tips:

- LEVEL first, ROTATE second, and then set the ORIGIN for the X, Y, and Z axes. **Never Rotate before Leveling!**
- Always LEVEL before measuring 2D features (lines and circles).
- Always LEVEL and ROTATE before measuring points (measured point in X, Y or Z-axis)
- There is no limit on the number of alignments saved in a measurement routine.
- You can use the SAVE ALIGNMENT command to save an alignment to a file. This is typically done to create a fully automated measurement routine dependent on a holding fixture for the part.

1. Create a measurement routine that establishes an alignment on a fixture, and then save the alignment to a file.
2. Create a measurement routine, RECALL the alignment file at the beginning of the measurement routine and set it to run in DCC Mode before measuring the first feature.
3. During measurement routine execution, the CMM pauses, prompts the operator to load part, then automatically measures the part (no manual alignment).

- **Right Hand Rule of Rotation** - Point your right hand's thumb in the positive direction of the axis you are rotating about (+X, +Y, or +Z). The direction your hand naturally

curls is the positive rotation about that axis. Negative rotation is the opposite direction.

Alignment Command Format

All alignments appear in the following format in the Edit window in Command Mode. There will be slight variations that are explained more thoroughly in the following sections.

A typical alignment is shown in this pseudo-code snippet:

```
A1=ALIGNMENT/START, RECALL:,LIST=YES/NO
   ALIGNMENT/LEVEL,'feature_name'
   ALIGNMENT/ROTATE,XPLUS,TO,feat_name,ABOUT,ZPLUS
   ALIGNMENT/TRANS,XAXIS,feature_name
   ALIGNMENT/TRANS,YAXIS,feature_name
   ALIGNMENT/TRANS,ZAXIS,feature_name
ALIGNMENT/END
```

For a list of field rules for alignment commands, see "Conventions"

Descriptions of the alignment commands are available at these locations:

- For the Start command, see "Start Alignment Command".
- For the End command, see "End Alignment Command".
- For the Recall option, see "Recalling an Existing Alignment".
- For the Level command, see "Level".
- For the Rotate command, see "Rotate".
- For the Translate command, see "Origin".

Start Alignment Command

The line that starts the alignment is:

```
ALIGN_ID=ALIGNMENT/START,RECALL:ID, LIST=YES/NO
```

Changeable fields:

Align_ID
This is the ID that the alignment will be stored as. The operator assigns the ID. PC-DMIS assigns a default name if you do not specify an ID. Example: A1.

ID
ID is a previous internal alignment that will be recalled to start a new alignment. Note that you can also use the USE_ACTIVE_ALIGNMENT keyword in this field to cause PC-DMIS to use the active alignment instead of recalling a stored alignment. This is useful when you use alignments with looping and conditional branching. See the "Using an Alignment Inside Loops or Branches" topic.

You can use the USE_PART_SETUP keyword in this field to cause PC-DMIS to use the transformation defined in the **Part setup** area of the **Part/Machine** tab in the **Setup Options** dialog box. This was handled by leaving the ID field blank in versions prior to version 2012. See the "Setup Options: Part/Machine tab" topic in the "Setting Your Preferences" chapter.

LIST
Setting this field to YES or NO lets you determine whether or not PC-DMIS should display the alignment ID in the **Alignments** list on the **Settings** toolbar for later insertion in the measurement routine. The default setting is YES. Setting this field to NO is useful if you have a lot of temporary alignments, and you don't want to list all of them in the **Alignments** list on the **Settings** toolbar.

End Alignment Command

The Edit window command line for this option reads:

```
ALIGNMENT/END
```

There are no changeable fields in this command. You must use this command whenever you use the `ALIGNMENT/START` command.

Adding Lines

To add a line, do the following:

1. Place the cursor in the desired location and press the Enter key.
2. Type the word ALIGNMENT.
3. Press the Tab key.

PC-DMIS adds the new line depending on where the cursor is located:

- If the cursor is in the middle of a command, PC-DMIS creates a new line below the current line.
- If the cursor is placed at the beginning of a command line, PC-DMIS places the new line above the current cursor position.

The first new line always displays the minor command: LEVEL. To easily change this, enter a new command. Additional lines that you create after the initial line display the most recent command.

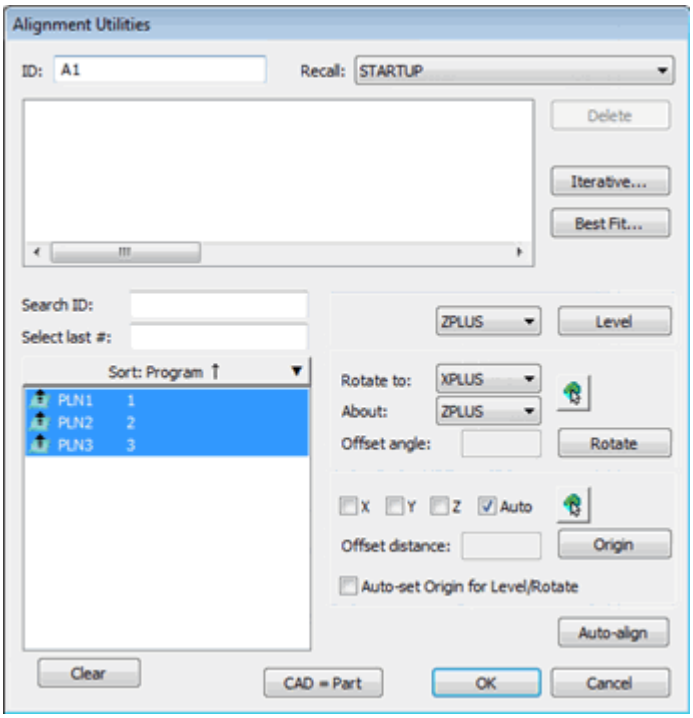
Deleting Lines

To delete a blank line, press the Down Arrow or Enter key. The line may also be highlighted and deleted. (See "Command Mode Keyboard Functions" in the "Using the Edit Window" chapter.)

Conventions

- All alignment text commands are in a macro type format with a start command and an end command.
- The `ALIGNMENT/START` command is always the first line, and the `ALIGNMENT/END` command is the last line of the alignment statement.
- All alignment function sub-commands must be inside the start and end commands. The supported sub-command types are:
    - ALIGNMENT/LEVEL
    - ALIGNMENT/ROTATE
    - ALIGNMENT/ROTATE_CIRCLE
    - ALIGNMENT/ROTATE_OFFSET
    - ALIGNMENT/TRANS
    - ALIGNMENT/TRANS_OFFSET
    - ALIGNMENT/ITERATE
    - ALIGNMENT/BF3D
    - ALIGNMENT/BF2D
    - ALIGNMENT/BFUSER
- In each "ALIGNMENT/" command (except "START" and "END"), the second field allows you to change from one choice to another. All of the other operator-dependent fields then change to represent the field that is currently active.

Description of the Alignment Utilities Dialog Box

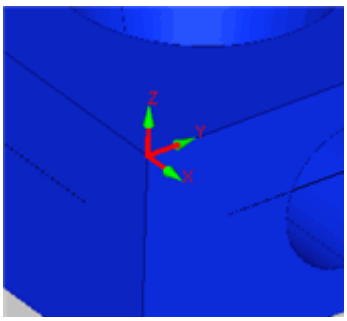


Alignment Utilities Dialog Box

When you select **Insert | Alignment | New** (or press F9 on an existing alignment command), PC-DMIS displays the **Alignment Utilities** dialog box. This dialog box provides a way for you to construct an alignment from the features that have been measured up to that point in the measurement routine.

An alignment is not complete until you select the **OK** button and PC-DMIS updates the **Active Alignment List** box.

As long as the **Alignment Utilities** dialog box remains open, PC-DMIS indicates any remaining unconstrained degrees of freedom by causing the XYZ origin symbol (or alignment trihedron) to continually rotate about and translate in the direction of those unconstrained axes in the Graphic Display window. Once the alignment is completely constrained, PC-DMIS then displays the trihedron in a fixed location and orientation that represent the alignment position:



Example showing an alignment trihedron.

ID box

This box defines the identification for the current alignment. If you are creating a new alignment, the alignment ID will default to a new name. To change the ID, type a new value in this box and press TAB.

Recall list

The **Recall** list contains all the internal alignments that have been defined in the measurement routine prior to this alignment. The alignment selected from this **Recall** list acts as the start condition of the current alignment.

If you are creating a new alignment, the **Recall** list displays the alignment active at the cursor's current location in the Edit window. If you have not defined any alignment, or if the cursor location is before any defined alignments in the Edit window, PC-DMIS selects the STARTUP command as the recalled alignment.

You can recall any available alignment listed in the **Recall** list. Only alignments created prior to the current cursor's position and certain predefined special cases are available for selection from that list.

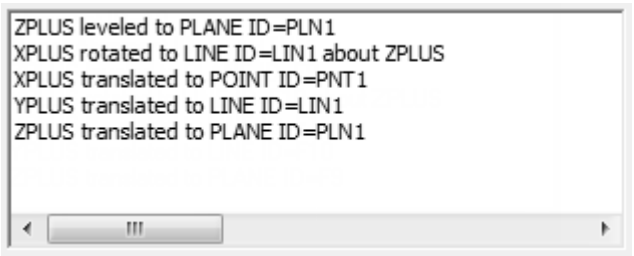
These special cases include:

STARTUP - You can recall the STARTUP alignment automatically defined at the start of the measurement routine.

USE_ACTIVE_ALIGNMENT - See the "ID" description in the "Start Alignment Command" topic for more information.

USE_PART_SETUP - See the "ID" description in the "Start Alignment Command" topic for more information.

Alignment Sub-Command list



This list displays a summary of each of the sub-commands that make up the current alignment block. This summary includes information such as the type of alignment sub-command, axis direction, and feature or features used by the sub-command to perform its rotation and/or translation.

Editing a Sub-Command

While you can edit any existing Level, Rotate, or Origin alignment sub-command inside the Summary Mode or Command Mode of the Edit window, you can also edit an existing sub-command by clicking on its entry in the sub-command list and making the needed change. Once you select an item, the appropriate area of the **Alignment Utilities** dialog box becomes available to edit. After you've edited the item, click the related sub-command button (**Level**, **Rotate**, or **Origin**) to modify the alignment.

For example, if you wanted to modify the feature to which the alignment was leveled, you would select the "leveled to" item in the list. PC-DMIS will display the current feature used for the leveling portion of the alignment, and then it would make the **Level** button available.

Simply select the new feature and axis, and click **Level**. PC-DMIS updates the **Alignment Sub-Command** list to reflect your changes.

To deselect an item from the **Alignment Sub-Command** list, click on that item a second time, or press the ESC key on the keyboard.

Delete

The **Delete** button deletes the currently-selected sub-command from the **Alignment Sub-Command** list.

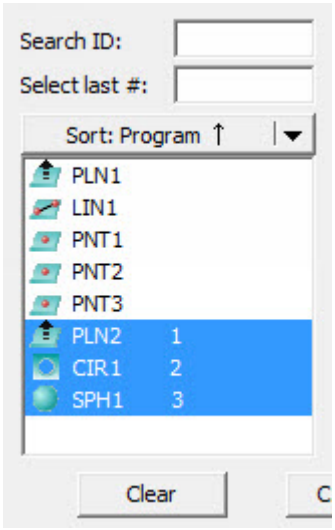
Best Fit

The **Best Fit** button opens the **Best Fit** dialog box. Use this dialog box to create or edit Best Fit alignments. See the "Creating a Best Fit Alignment" topic.

Iterative

The **Iterative** button opens the **Iterative Alignment** dialog box. Use this dialog box to create and edit Iterative alignments. See the "Creating an Iterative Alignment" topic.

Available features list



The **Available features** area displays all the available features in your measurement routine that exist above the current cursor location. These are the features available to your current alignment command.

You can also use the Graphical Hit Selection method to select inputs to your alignment. For details, see "Graphical Hit Selection Method".

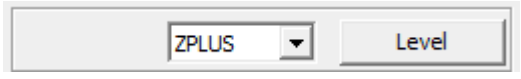
For a full description, see "Feature List box" under "Dialog Box Description" in the "Navigating the User Interface" chapter.

The **Search ID** filters the list of features by the specified ID. Type the ID string, and press the Tab key.

The **Select last #** box selects the final 'N' features in the list, where 'N' is the number you type. Type the number of features to select, and press the Tab key.

The **Clear** button clears the current feature selections from the list.

Level



The **Level** area establishes the orientation of the normal axis of the current workplane.

To choose a feature to "level" to:

1. Select the feature to be used from the **Feature List** box.
2. Choose the axis to level to from the drop-down list.
3. Click the **Level** button.

The **Level** button only becomes active if you first select a feature from the feature list or an existing level sub-command (`ALIGNMENT/LEVEL`). If you select an existing level sub-command, it will be modified to use the new feature selection; otherwise, a new level sub-command will be created using the selected feature.

You may also specify the axis to be used in establishing the orientation by selecting it from the drop-down list. The available options are:

ZPLUS

XPLUS

YPLUS

ZMINUS

XMINUS

YMINUS

After you click the **Level** button, the **Alignment Utilities** dialog box changes the **About** list next to the **Rotate** button to automatically match the **Level** button's axis direction.

The Edit window command line for this option reads:

```
ALIGNMENT/LEVEL,ZPLUS,'feat_id'
```

Changeable fields:

"ZPLUS"

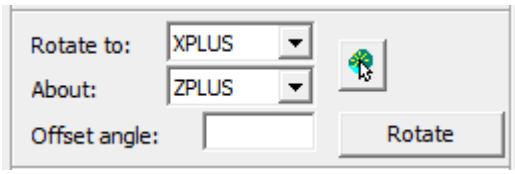
This is a field that allows you to switch between the ZPLUS, XPLUS, YPLUS, ZMINUS, XMINUS, and YMINUS fields in the Edit window. This field represents the direction of the specified axis that the feature is leveled to.

"feat_id"

The alignment levels to the specified feature.

Example: PLANE1.

Rotate



The **Rotate** area rotates the alignment to be parallel to a selected feature by a specific manual offset angle or by an angle defined from a picked CAD surface or edge.

PC-DMIS rotates the **Rotate to** axis around the alignment origin, about the specified alignment axis (**About** axis). The **Rotate** to and **About** axes cannot be the same axis.

The available options are:

ZPLUS

XPLUS

YPLUS

ZMINUS

XMINUS

YMINUS

Rotate to a Feature

To rotate to a measured feature:

1. Select the proper reference feature from the **Feature List** box in the **Alignment Utilities** dialog box.
2. Specify the axis to rotate to in the **Rotate to** list.
3. Specify the axis to rotate about in the **About** list.
4. Click the **Rotate** button.

The **Rotate** button only becomes active if you first select a feature from the feature list or select an existing rotate sub-command (`ALIGNMENT/ROTATE`). If you select an existing rotate sub-command, it is modified to use the new feature selection **Rotate to** axis and **Rotate About** axis; otherwise, PC-DMIS creates a new rotate sub-command using the selected feature and axis settings.

The Edit window command line for this option reads:
`ALIGNMENT/ROTATE,XPLUS,to,'feat_id',about,ZPLUS`

Changeable fields:

"XPLUS","ZPLUS"

This is a toggle field that allows you to toggle between these fields in the Edit window:

ZPLUS

XPLUS

YPLUS

ZMINUS

XMINUS

YMINUS

PC-DMIS sets this axis parallel to the specified input feature. It then rotates about the second axis.

"feat_id"

The alignment rotates parallel to the specified feature. Example: LINE1.

Rotate to a Line between Two Circles

To rotate to the line between two circles, select two circles in the **Available Features** list instead of a single feature and then continue with the "Rotate to a Feature" procedure described above.

The Edit window command line for this option reads:

```
ALIGNMENT/ROTATE_CIRCLE,ID, ID
```

Changeable fields: "ID"

This is one of the two ids to which to rotate.

Rotate by a Manual Offset Angle

The **Offset angle** box allows you to rotate the alignment by a specified angle about a selected axis.

To rotate by an offset:

1. Select the axis to rotate about from the **About** list.
2. Type the desired angle in the **Offset angle** box.
3. Click the **Rotate** button.

The **Rotate** button becomes active once you type a value in the **Offset angle** box or select an existing rotate offset sub-command (`ALIGNMENT/ROTATE_OFFSET`). If you select an existing rotate offset sub-command, it is modified to use the new **Offset angle** value; otherwise, a new rotate offset sub-command is created.

If you click **Rotate**, and you have a feature selected and a value entered in the **Offset angle** box, the software creates these two sub-commands:

- First, it creates a `ROTATE` command to the selected feature.
- Second, it creates a `ROTATE_OFFSET` command with a value from the **Offset angle** box.

The Edit window command line for this option reads:
`ALIGNMENT/ROTATE_OFFSET,'numeric_value',ABOUT,'AXIS'`

Changeable field: "numeric_value"

This is the value PC-DMIS rotates the alignment by in degrees of angle (for example; -14.36). The rotation is about the axis, perpendicular to the active workplane. The rotation is clockwise if the angle is negative and counter clockwise if the angle is positive.

Changeable field: "axis"

This is the axis about which PC-DMIS rotates the alignment.

If you don't select a feature, and you type in a rotation **Offset angle** value, PC-DMIS follows the right-hand rule of rotation. PC-DMIS follows the convention to treat both the negative and positive axes as positive. This means PC-DMIS always rotates about the XPLUS, YPLUS, or YPLUS axis. It does this even if you select **XMINUS**, **YMINUS**, or **ZMINUS**. Positive offset angle values go in the positive direction (counter-clockwise), and negative values go in the negative direction (clockwise). The software enables the **Rotate to** list when you select a feature that controls an axis that matches the vector of the selected feature.

Rotate by a Picked CAD Surface or Edge

To rotate the alignment by an offset angle by means of picking a surface or edge on the CAD model:

1. From the **Rotate to** list, select the axis to which you want the alignment to rotate.
2. From the **About** list, select the axis about which you want the alignment to rotate.
3. Click the **Pick in CAD** icon .

4. PC-DMIS enters a special CAD-selection mode where it disable the other dialog box controls until you either select a surface or edge from the CAD model, or you click the icon again to cancel this mode.

5. Once in this CAD-selection mode, click on the desired CAD model's surface or edge in the Graphic Display window to define the alignment rotation offset angle.

6. If the initial CAD selection does not define a valid rotation direction, PC-DMIS waits for a second CAD model selection and uses that with the first picked item to define the rotation direction.

PC-DMIS supports picking planar features, axial features (cylinders, cones, and lines), and point-type features (spheres, arcs, and ellipses).

For a given CAD feature selection, the following apply:

- If you pick a planar feature, PC-DMIS uses the plane's normal as the rotation direction.

- If you pick an axial feature, PC-DMIS uses the feature axis as the rotation direction. If the feature axis is parallel to the selected **About** axis, you must select a second feature to define the rotation direction perpendicular to the axis.

- If you pick a point-type feature, you must select a second feature to define the rotation direction.

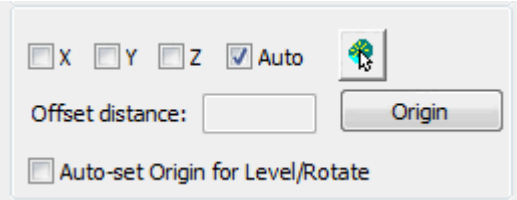
- If you picked two axial features to define the rotation direction, the axes of the two features must be parallel.

- If the picked item cannot be used to define an offset angle, PC-DMIS displays an error message and then lets you pick a different feature or cancel the CAD-selection mode.

- If the resulting angle is 0, PC-DMIS does not create an offset sub-command.

The Edit window command line for this option is identical to the "Rotate by a Manual Offset Angle" case described above.

Origin



The **Origin** area moves the alignment origin to a specific feature location, by a specific manual offset distance, or by a distance defined from a picked CAD surface or Edge.

Move to a Feature

To move the alignment origin to a feature:

1. Select the feature to move to.
2. Select the appropriate check box or check boxes (**X**, **Y**, **Z**, or **Auto**) to choose the alignment axis direction or directions to move the origin.
3. Click the **Origin** button. The **Auto** check box chooses the axes to move based on the feature type, the orientation of the feature, and the workplane.

The Edit window command line for this option reads:

```
ALIGNMENT/TRANS,ZAXIS,'feat_id'
```

Changeable fields:

"ZAXIS"

This is Edit window field that allows you to switch between the fields *ZAXIS, XAXIS, and YAXIS*. This field represents the axis that PC-DMIS moves the origin along to match the input 'feat_id'.

"feat_id"

This is the feature that the alignment sets the origin to, along the given axis. Example: CIRCLE1.

Move by a Manual Offset Distance

To move the origin by a manually-specified offset distance:

1. Select the appropriate check box or check boxes (**X**, **Y**, **Z**, or **Auto**) to choose the alignment axis direction or directions to move the origin.
2. Type the desired value in the **Offset distance** box.
3. Click the **Origin** button.

When you click **Origin**, if you have a feature selected, and you have a value entered in the **Offset distance** box, the software creates two sets of sub-commands:

- First, it creates a set of `TRANS` commands to translate to the selected feature, based on the selection state of the **X**, **Y**, **Z**, and **Auto** check boxes.
- Second, it creates a set of corresponding `TRANS_OFFSET` commands using the value from the **Offset distance** box.

The Edit window command line for this option reads:

```
ALIGNMENT/TRANS_OFFSET,ZAXIS,'numeric_value'
```

Changeable fields:

"ZAXIS"

This Edit window field allows you to switch between the fields ZAXIS, XAXIS, and YAXIS. This field represents the axis along which the origin moves. The distance moved is based on the 'numeric_value'.

"numeric_value"

This is the value by which the alignment is offset (for example, 5.12). A positive value moves along the defined axis in the positive direction. A negative value moves in the negative direction.

Move by a Picked CAD Surface or Edge

To move the origin by an offset by means of picking a surface or edge on the CAD model:

1. Select the appropriate check box or check boxes (**X**, **Y**, **Z**, or **Auto**) to choose the alignment axis direction or directions to move the origin.
2. Click the **Pick in CAD** icon .
3. PC-DMIS enters a special CAD-selection mode where it disables the other dialog box controls until you either select a surface or edge from the CAD model or you click the button again to cancel this mode.
4. Once in this CAD-selection mode, click on the desired CAD model's surface or edge in the Graphic Display window to move the alignment to the picked item.

PC-DMIS supports picking planar features, axial features (cylinders, cones, lines), and point-type features (spheres, arcs, ellipses).

For a given CAD feature and set of alignment axis directions:

- If there is a unique solution point between the CAD feature and the specified alignment axis directions, PC-DMIS moves the alignment to that point as allowed by the selected alignment axes (such as a single alignment axis and a planar feature).

- If there is more than a single solution point, PC-DMIS moves the alignment to the solution point nearest the current alignment location as allowed by the selected alignment axes (such as two alignment axes and a planar feature intersecting at a line).
- Marking the **Auto** check box behaves the same as selecting **X**, **Y** and **Z**.
- If PC-DMIS cannot use the selected CAD entity to define an offset, it displays an error message and then lets you pick a different feature or cancel the CAD-selection mode.
- If the resulting offset distance for a specific alignment direction is 0.0, no corresponding offset sub-command is created for that direction.

The Edit window command line for this option is identical to the "Move by a Manual Offset Distance" case described above.

Auto-Set Origin for Level/Rotate

The **Auto-set Origin for Level/Rotate** check box works together with the **Level** and **Rotate** buttons. If it is selected when you select a feature and click **Level** or **Rotate**, PC-DMIS uses the same feature used to define the level or rotate sub-command to automatically create one or more translate origin commands. If there are two features selected (for a rotate command), PC-DMIS only uses the first feature. The translation commands are based on the current **X**, **Y**, **Z**, or **Auto** settings in the **Origin** area.

Auto-align

The **Auto-align** button uses the currently-selected features to automatically create the alignment sub-commands. The **Auto-align** button is active only when you select exactly one, two, or three features from the list of available features, and there are no sub-commands currently defined for the alignment. Auto-align uses the same algorithms as QuickAlign. Auto-align supports all valid combinations of features selected.

For more information on QuickAlign, see "About QuickAlign".

CAD = Part

The **CAD = Part** (CAD Equals Part) button moves and orients the part origin defined by the alignment so that it is equal to the CAD origin. You should use this option after a created alignment places the part origin and orientation at the same location as the CAD origin and orientation. This can make it simpler to use the CAD data to help inspect the part by displaying the measured data directly on top of the CAD data.

To set the CAD equal to the part:

1. Measure features on the part or fixture.
2. Use the alignment options to create an alignment.
3. Select the **CAD = Part** button. After the **CAD = Part** button is selected for a part, the **Operation | Graphic Display Window** | **CAD Equals Part** menu item will be selected.

The **CAD = Part** button is only available if the alignment is at the very end of the measurement routine. If there are other commands after the alignment, PC-DMIS hides the button.

Creating a 3-2-1 Alignment

The information presented here describes the steps you'll need to take to create a standard 3-2-1 alignment.

Click this icon from the **Wizards** toolbar to access PC-DMIS's 3-2-1 Alignment Wizard.

Step 1: Measure the Alignment Features

The first thing you will need to do is measure the features used to create the 3-2-1 alignment. A 3-2-1 alignment uses three standard feature types for its creation. The numbers 3, 2, and 1 refer to the minimum number of hits you need to take on in order to measure these features.

- **Measure a Plane.** The first feature is the *leveling* feature and should be a *plane* composed of *three* hits. PC-DMIS will level the part to this feature. This defines the origin and direction of the first axis (usually the Z axis).
- **Measure a Line.** The second feature is the *rotation* feature and should be a *line* composed of *two* hits. PC-DMIS will rotate the part to this feature, orienting the second axis. The second hit of this feature should be in the positive direction of the axis, relative to your first hit. This feature defines the direction of the second axis (usually the X axis) and the origin of the third axis (usually the Y axis).
- **Measure a Point.** The third and final feature is the *origin* feature composed of just *one* hit. Since PC-DMIS creates the origin for this axis from your first two features, the third point merely establishes the origin of the entire alignment. PC-DMIS will translate the part to this feature, making it the X=0, Y=0, and Z=0 location.

Once you've measured the necessary features, you're ready to create your alignment.

Step 2: Level, Rotate, and Translate to the Features

This step uses the **Alignment Utilities** dialog box (**Insert | Alignment | New**) to level, rotate, and translate your part to the features measured in the previous step.

1. Access the **Alignment Utilities** dialog box (**Insert | Alignment | New**). Notice that the **Feature** list shows all the possible features that can be used to level, rotate, or translate the part.

2. From the **Feature** list, click on the *plane feature* you created in the previous step. Once PC-DMIS selects the feature, select the axis to which PC-DMIS should level the part, and then click the **Level** button. PC-DMIS will display a line of text inside the **Alignment Utilities** dialog box informing you of the feature and axis to be used in the leveling process.

3. From the **Feature** list, click on the *line feature* you created in the previous step. Once PC-DMIS selects the feature, select what axis to rotate to and what axis to rotate about, and then click the **Rotate** button. Again, PC-DMIS displays the feature and axis to be used for the rotation process.

4. From the **Feature** list, click on the *point feature* you created in the previous step. Once PC-DMIS selects the feature, select the appropriate axis check box to determine which axis (or axes) you want to move to this origin feature, and click the **Origin** button.

Alternately, you can select all three of the features from the **Feature** list and click the **Auto Align** button to have PC-DMIS automatically level to the first feature selected, rotate to the second feature selected, and translate the axes to the third feature selected.

Now you're ready to complete the alignment creation process.

Step 3: Completing the Alignment

To complete the alignment:

1. Ensure that the information in the **Alignment Utilities** dialog box (**Insert | Alignment | New**) is correct.

2. When you're ready, click the **OK** button. PC-DMIS closes the dialog box. If this new alignment differs from the existing alignment, PC-DMIS displays a prompt asking if you want to update affected commands in the Edit window to use the new alignment (see "Updating Commands in Learn Mode" in the "Updating Dependent Commands When the Alignment Changes" topic). If the alignment doesn't change (or the change

is too small to matter), PC-DMIS simply inserts the alignment without displaying the prompt or updating any commands.

3. PC-DMIS inserts the commands for the alignment into the Edit window, and graphically shows the alignment on the CAD model inside the Graphic Display window.

4. You can edit the alignment's code at any time by using the techniques described in the "Using the Edit Window" chapter.

About QuickAlign

QuickAlign is designed so you can create alignments from the Edit window with a single click of a toolbar icon. You can select valid combinations of one, two, or three features to create an automatic alignment. QuickAlign is based on datum precedence principles as described in the GD&T ASME Y14.5.1M standard.

The alignment is based on certain rules described in the topics below. There is no dialog box for this functionality. The alignment is automatically created directly in the Edit window in both the Summary Mode and Command Mode.

Using QuickAlign

Measure the alignment features you want to use in the QuickAlign.

From the **QuickMeasure** or **Alignment** toolbar, click the **QuickAlign** icon , or select the **Insert | Alignment | QuickAlign** menu item.

If no other user-defined alignment command exists, PC-DMIS automatically selects the features and creates the alignment depending on whether the measurement routine is in Startup mode or Standard mode.

QuickAlign creates the alignment based on:

- Feature type
- Selection order
- Feature positions relative to each other

QuickAlign constrains the degrees of freedom (DOF) as explained below:

- The first feature constrains all available DOF possible for that feature type.
- If two or more features are selected, the second feature constrains all available unconstrained DOF possible for that feature type.

- If three features are selected, the third feature constrains as many remaining unconstrained DOF possible for that feature type.
- QuickAlign aligns the machine axes closest to the theoretical axis of the features that determine the LEVEL and ROTATE.
- QuickAlign supports all valid cases of feature combinations for creating an alignment.

PC-DMIS displays the DOF that are controlled by the alignment on the Status bar.

For more information on constraining degrees of freedom, see the "Alignment Overview" topic.

QuickAlign in Startup Mode

When you first create a measurement routine, it contains a `STARTUP` command with a default alignment. For QuickAlign, the measurement routine is considered to be in "Startup mode" if it does not have any user-defined alignment commands.

If it is in Startup mode, the following apply:

- You do not need to select any features to create the alignment but you can if you desire.
- If you don't select features, QuickAlign uses up to the last three features in the measurement routine to automate the initial alignment creation.
- If you do select features, QuickAlign uses the features in the selected order. For more information on feature selection, see the "QuickAlign Feature Selection" topic.
- It recalls the STARTUP alignment automatically if the alignment constrains all six DOF. The STARTUP alignment is the default empty alignment at the start of every measurement routine. This means that the software adds no extra features to the dependency list.
- QuickAlign creates the initial manual alignment by "backfilling" partial alignments for level and rotation where applicable. For information on backfilling, see the "Alignment Backfilling for QuickAlign" topic.
- QuickAlign creates DCC features and a DCC alignment if the following conditions are met:
    - The Machine type supports DCC Mode.
    - The alignment constrains all six degrees of freedom (DOF).
    - The measurement routine is in Manual Mode.

  For more information, on DCC alignment creation, see the "DCC Alignment Creation for QuickAlign" topic.

You can have non-feature commands, like dimensions, assignments, and so on, in-between the features used for the alignment.

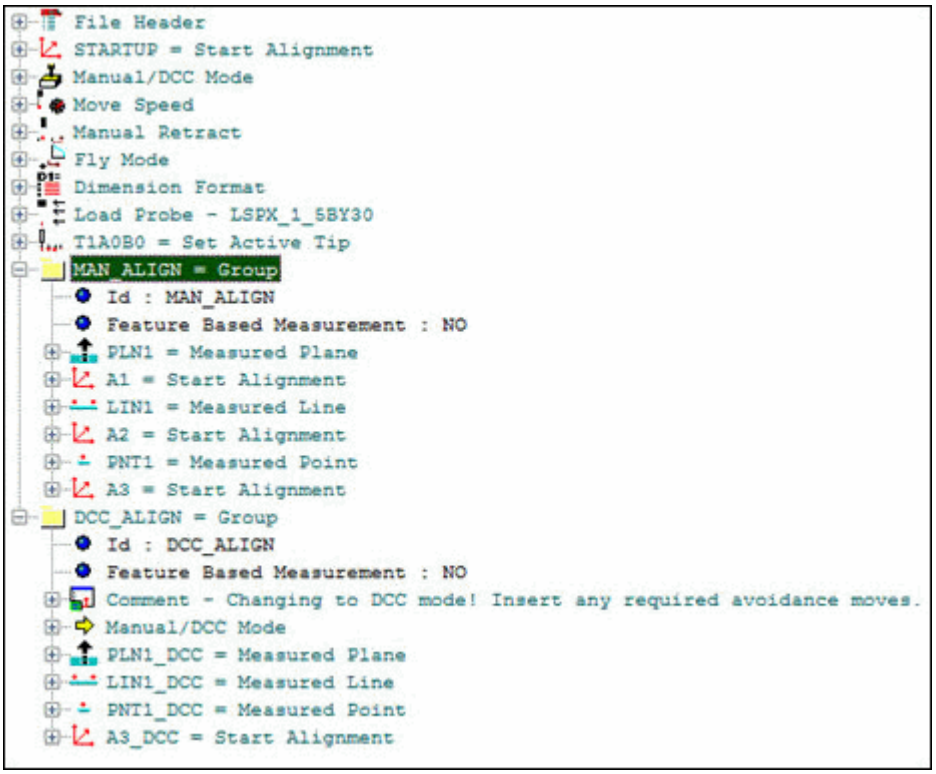
An Example

Measure a plane, line, and a point.

From the QuickMeasure or Alignment toolbar, click the **QuickAlign** icon , or select the **Insert | Alignment | QuickAlign** menu item.

QuickAlign searches up from the end of the measurement routine and collects the three newest features to use in the alignment.

It then uses the collected features to automatically generate fully constrained manual and DCC alignments.



Clearance moves or other move points are not generated. To avoid collision during probe motion, be sure to activate the ClearanceCube or insert `MOVE/POINT` commands as needed. QuickAlign does insert an Operator comment (`COMMENT/OPER`) to remind the operator to add all needed clearance avoidance commands.

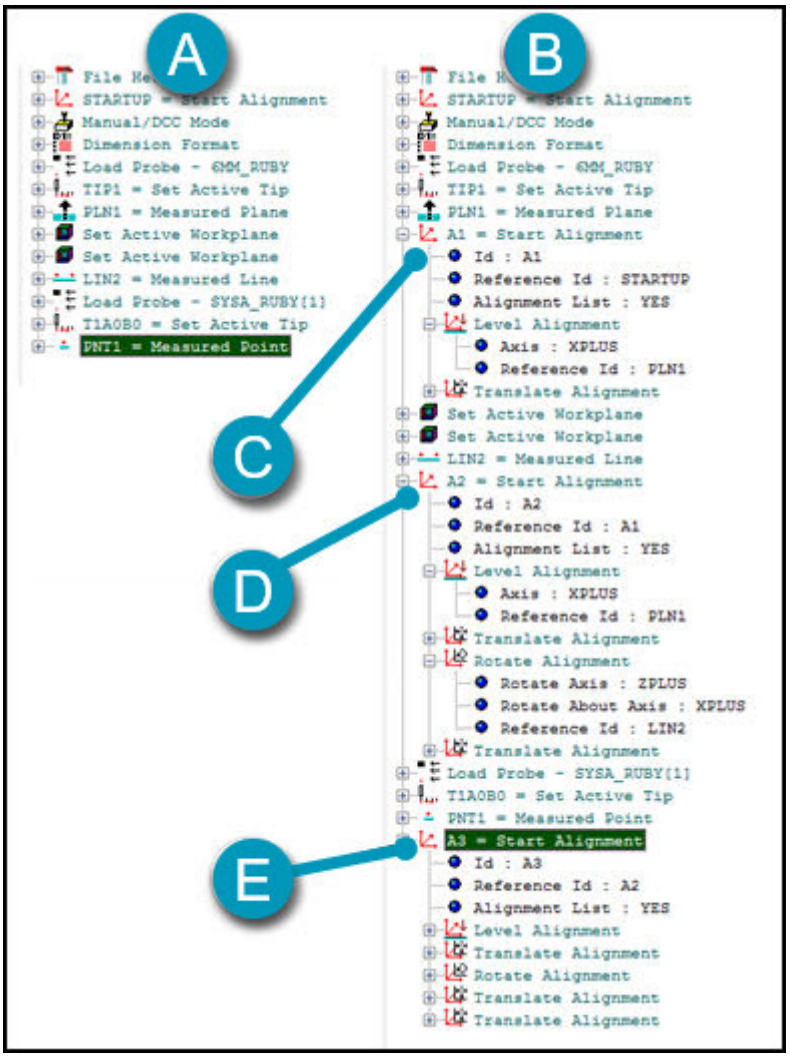
Alignment Backfilling for QuickAlign

"Backfilling" means QuickAlign looks back in the measurement routine and creates partial alignments as required in order to accurately handle probe compensation of any non-3D feature.

Back-filling occurs if these conditions are met:

- The measurement routine is in startup mode and therefore doesn't have a user-defined alignment.
- One or more selected features for the QuickAlign operation is a 2D feature, such as a line, circle, or point.
- A feature before the selected 2D feature exists that controls two degrees of rotation (LEVEL).

An Example



A. Measurement Routine before QuickAlign

B. Measurement Routine after QuickAlign

C. Back-filled alignment after PLN1

D. Back-filled alignment after LIN2

E. Final, fully constrained alignment

DCC Alignment Creation for QuickAlign

For measuring machines capable of DCC operation, QuickAlign can automatically define a DCC alignment by duplicating the features and rough manual alignment commands in DCC Mode in order to get a more accurate alignment.

DCC alignment creation can occur if these conditions are all met:

- PC-DMIS is in startup mode.
- PC-DMIS is connected to a DCC-enabled machine.
- The measurement routine is in Manual Mode.
- The features you choose for the alignment fully constrain the six degrees of freedom.

How the DCC QuickAlign Functionality Works

The QuickAlign DCC functionality does the following:

- Adds an operator comment command (`COMMENT/OPER`), to remind the operator to add all needed collision avoidance commands.
- Adds a mode command to change to DCC Mode (`MODE/DCC`).
- Copies all the feature commands used for the manual alignment, along with any feature commands they depend on, and pastes them using the same name as their original feature names, appended with "_DCC".
- If the manual features are Auto features and the probe type used is a scanning probe and the **Use Scanning Strategies for Quick Align** check box, from the **General** tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**) is marked then the DCC Mode features are created using the scanning strategy defined in the Measurement Strategy Editor (MSE). Make sure that a measurement strategy is defined and selected in the Measurement Strategy Editor.
- Generates a DCC alignment command after each DCC feature that is a copy of one of the original manual features used to define the final manual alignment. The original manual feature is replaced with its DCC copy in the new DCC alignment. The resulting DCC alignment commands constrain all six DOF. Each generated DCC alignment command is named based on the last manual alignment name appended with _DCC1, _DCC2, and so on (for example, if A3 is the name of your manual alignment, and two DCC commands are generated from that alignment, they appear as A3_DCC1 and A3_DCC2).

- Recalls the STARTUP alignment automatically if the alignment constrains all six DOF. The STARTUP alignment is the default empty alignment at the start of every measurement routine. This means no extra features are added to the dependency list.
- Ensures that all constructed features in DCC Mode are constructed using features measured in DCC Mode.
- Creates an alignment using QuickAlign with features similar to a manual alignment but is measured and constructed in DCC Mode.
- Combines the manual alignments and their associated feature commands into a `GROUP` command named "MAN ALIGN".
- Combines DCC alignment and its associated features into a `GROUP` command named "DCC ALIGN".

H. Final DCC alignments

QuickAlign in Standard Mode

If one or more user-defined alignments already exist in the measurement routine, the measurement routine is considered to be in "Standard mode".

In standard mode, the following apply:

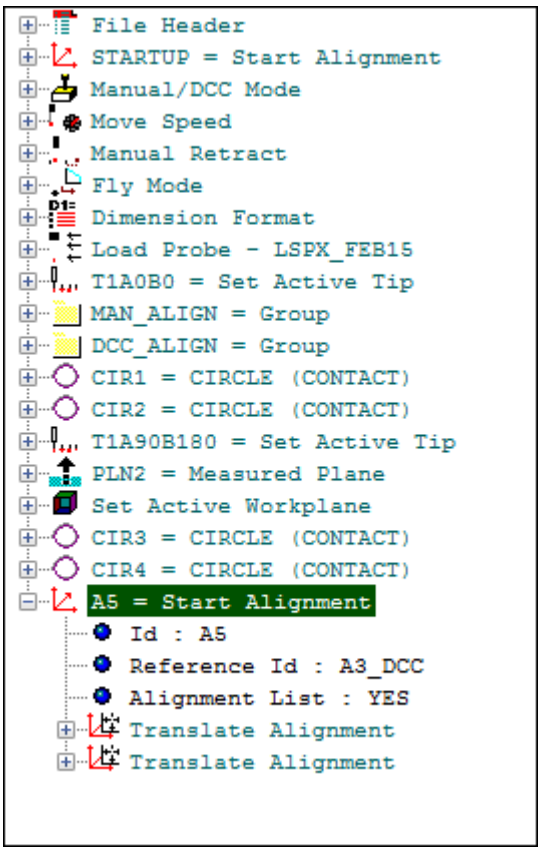
- QuickAlign does not backfill partial alignments.
- QuickAlign does not automatically create a DCC alignment.
- If you don't select features, only the last feature is used to create the alignment.
- To create an alignment with more than just one feature, you must select the features from the Edit window.
- The alignment is added at the end of the measurement routine.
- The alignment is created based on the same principles as described in the "QuickAlign in Startup Mode" topic.

An Example

Measure some features.

From the **QuickMeasure** or **Alignment** toolbar, click the **QuickAlign** icon , or select the **Insert | Alignment | QuickAlign** menu item.

QuickAlign automatically uses the last feature in the measurement routine to constrain all possible degrees of freedom for that feature type.



QuickAlign Feature Selection

You can tell QuickAlign to use features by selecting them from the Edit window. QuickAlign uses these features in the order you select them and creates the alignment.

To select multiple features in the Edit window:

1. Press and hold Ctrl.
2. From the Edit window, click on each feature to use in the alignment. The selected features are highlighted as you select them.
3. From the QuickMeasure or Alignment toolbar, click the **QuickAlign** icon , or select the **Insert | Alignment | QuickAlign** menu item.
4. QuickAlign uses the selected features to create an alignment at the *end of the measurement routine*.

Be sure to select the features in the correct precedence order. If you select more than three features, PC-DMIS disables QuickAlign.

An Example

```
STARTUP    =ALIGNMENT/START,RECALL:USE_PART_SETUP,LIST=YES
            ALIGNMENT/END
            MODE/MANUAL
            MOVESPEED/ 100
            MANRETRACT/20
            FLY/ON,3
            FORMAT/TEXT,OPTIONS, ,HEADINGS,SYMBOLS, ;NOM,TOL,MEAS,DEV,OUTTOL, ,
            LOADPROBE/LSPX_1_5BY30
            TIP/T1A0B0, SHANKIJK=0, 0, 1, ANGLE=0
PLN1       =FEAT/PLANE,CARTESIAN,TRIANGLE
            THEO/<143.01173,44.01082,0>,<0,0,1>
            ACTL/<143.01173,44.01082,0>,<0,0,1>
            MEAS/PLANE,4
            HIT/BASIC,NORMAL,<91.87123,101.06849,0>,<0,0,1>,<91.87123,101.06849,0>,USE THEO=YES
            HIT/BASIC,NORMAL,<227.24958,65.06429,0>,<0,0,1>,<227.24958,65.06429,0>,USE THEO=YES
            HIT/BASIC,NORMAL,<164.84462,3.97514,0>,<0,0,1>,<164.84462,3.97514,0>,USE THEO=YES
            HIT/BASIC,NORMAL,<88.08148,5.93537,0>,<0,0,1>,<88.08148,5.93537,0>,USE THEO=YES
            ENDMEAS/
LIN1       =FEAT/LINE,CARTESIAN,UNBOUNDED
            THEO/<46.81872,0,-7.89217>,<1,0,0>

            HIT/BASIC,NORMAL,<0,24.27247,-27.85998>,<-1,0,0>,<0,24.27247,-27.85998>,USE THEO=YES
            ENDMEAS/
PNT1       =FEAT/POINT,CARTESIAN,NO
            THEO/<0,0,-17.4833>,<1,0,0>
            ACTL/<0,0,-17.4833>,<1,0,0>
            CONSTR/POINT,INT,LIN1,LIN2
                        END OF MEASUREMENT FOR
```

QuickAlign Error Messages

If the set of feature commands does not form a valid alignment, the alignment is not created. In addition, PC-DMIS shows one or more of these error messages:

- "Unsupported feature combination!" - This message means the selected combination of features does not define a well-formed alignment.
- "<FEATURE> is invalid!" - This message means the feature represented by <FEATURE> has errors in its definition; this usually occurs with a line measured on a surface where the line's line direction vector and the surface's normal vector are not perpendicular.
- "<FEATURE> is not valid as the alignment second feature!" - This message means the feature represented by <FEATURE> cannot be used as the second feature in the alignment, due to its vector direction or its origin location.
- "<FEATURE> is not valid as the alignment third feature!" - This message means the feature represented by <FEATURE> cannot be used as the third feature in the alignment, due to its vector direction or its origin location.
- "Alignment error!" - This message indicates a general QuickAlign or Auto-align error.

If PC-DMIS creates the alignment, but it has problems with its degrees of freedom, PC-DMIS shows one of the following warning messages:

- "<FEATURE> is not used. All DOFs constrained by first two features." - This message means that all six degrees of freedom (DOF) are already constrained by first two features used to define the alignment; so the third feature isn't used to constrain any of the DOF.
- "Not all 6 DOFs constrained" - This message means that the three features used to define the alignment, do not constrain the six DOF, even though PC-DMIS creates a valid alignment.

- QuickAlign determines if an axial feature is in a given plane by checking if the vector of the feature (such as a circle, cylinder, cone, or line) is within +/- 5 degrees of the axis or vector of the primary feature.
- QuickAlign determines if an axial feature can be used for rotation by checking if it is more than 45 degrees from the primary feature vector.

Degrees of Freedom for Features in QuickAlign

The Auto-align algorithms are based on GD&T datum precedence principles and the native degrees of freedom (DOF) of each feature type.

DOF of Supported Features

The supported features are grouped into the following six DOF-based cases, detailed in this table:

DOF Case	Feature Types	DOF Constraints
Planar	Planes, 3D Widths	R1 R2 T3
Axial	Cylinder, 3D lines, Cones*	R1 R2 T1 T2
2D Line	Lines (on a surface), 2D Widths	R1 T2
1D Point	Vector Points, Round Slots*, Square Slots*	T1
2D Points	Circles, Ellipses*, Edge Points, Angle Points	T1 T2
3D Points	Spheres, Corner Points	T1, T2, T3

* These features are treated differently in the QuickAlign algorithm:

- Cone features are treated as cylinders.
- Ellipses are treated as circles.
- Slot features (both round and square) are treated as one-dimensional vector points with their surface normal vector pointing in the direction of the slot width.

Table Key:

R1 - Rotation DOF about the first coordinate axis

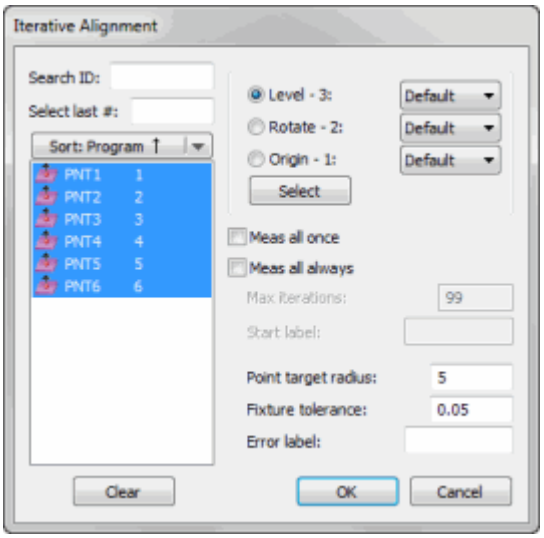
R2 - Rotation DOF about the second coordinate axis

T1 - Translation DOF in first coordinate axis direction

T2 - Translation DOF in the second coordinate axis direction

T3 - Translation DOF in the third coordinate axis direction

Creating an Iterative Alignment



Iterative Alignment Dialog Box

When you click the **Iterative** button from the **Alignment Utilities** dialog box (**Insert | Alignment | New**), PC-DMIS displays the **Iterative Alignment** dialog box. This dialog box provides a way for you to three-dimensionally "best fit" the measured data to the nominal points (or surfaces, if available).

The resulting iterative alignment coordinate system origin is approximately located at and oriented with the CAD coordinate system, even if the set of features used is located and oriented somewhere very different. This is much like an automotive system, in the sense that all the features on all the parts of the automobile's body are defined in terms of a single global coordinate system, even if they are physically located or oriented far away from that coordinate system. The CAD coordinate system serves the same function for the iterative alignment as the car body's global coordinate system.

An iterative alignment requires at least three features to be measured. Certain feature types, such as points and lines, have poor three dimensional locations. If one of these types of features is selected, additional features are needed to provide accurate measured data.

- The first set of features establishes the orientation of the normal axis of the current workplane by fitting a plane through the feature centroids. At least three features must be used in this section (LEVEL - 3 +).
- The next set of features rotates the defined axis of the workplane to the features, fitting a line through the features. At least two features need to be used in this section (ROTATE - 2 +).
  If no features have been marked, the alignment will use features from the LEVEL section. (The two features used from the LEVEL section are the second and third from last feature.)
- The last set of features translates the part origin to a specific location (SET ORIGIN - 1).

  If no features have been marked, the alignment will use the last feature from the LEVEL section.

Understanding Iterative Alignments

To properly create your iterative alignment, first consider the information presented here; these topics will help you to understand important aspects of iterative alignments.

Iterative Alignment Command Format

The Edit window command line for this option reads:

```
ALIGNMENT/ITERATE,'feat_id'
, PNT TARGET RAD=n, START LABEL=label, FIXTURE TOL = n,
ERROR LABEL=label
MEAS ALL FEAT=NO/ALWAYS/ONCE,
MAX ITERATIONS = n
LEVEL AXIS =axis, ROTATE AXIS=axis, ORIGIN AXIS=axis
LEVEL = id, id, id,...
ROTATE = id, id,...
ORIGIN = id,...
```

Changeable field: "feat_id"
These are the features that are used to do the iterative alignment. Currently, you must select at least three different features for the calibration. If features support a datum axis in more than one direction, such as circles or slots, you can specify them in more than one datum axis. For example, you can use a circle to both establish the

level axis as well as the rotation axis. Typically, you can only use measured points (including vector and surface points) to establish one datum axis.

PNT TARGET RAD = This option specifies the target radius value for the measured point features used in the alignment. See "Point Target Radius" for complete information.

START LABEL = PC-DMIS starts at the label specified here when remeasuring alignment features. You must set `MEAS ALL FEAT` to `ALWAYS` for this to work. See "Start Label" for complete information.

FIXTURE TOL = This is the tolerance that PC-DMIS uses to compare measured alignment features to their theoretical values. See "Fixture Tolerance" for complete information.

ERROR LABEL = PC-DMIS goes to the label specified here when the fixture tolerance level is exceeded. If you don't define a label, PC-DMIS generates an error message showing the amount of error on each of the input features. See "Error Label" for complete information.

LEVEL AXIS = PC-DMIS uses the **LEVEL** input features to set the orientation and origin of the axis specified here. See "Level" for complete information.

ROTATE AXIS = PC-DMIS uses the **ROTATE** input features to set the rotation of the axis specified here about the level axis. The origin of the axis specified here is also set by PC-DMIS using the **ROTATE** input features. See "Rotate" for complete information.

ORIGIN AXIS = PC-DMIS uses the **ORIGIN** input features to set the origin of the axis specified here. See "Origin" for complete information.

MEASURE ALL FEATURES = This option either re-measures the input features or automatically re-executes a portion of the measurement routine in DCC Mode. There are three possible settings for this option:

- `NO` - See "Point Target Radius" for complete information.
- `ONCE` - See "Meas All Once" for complete information.
- `ALWAYS` - See "Meas All Always" for complete information.

MAX ITERATIONS = This option determines the maximum number of iterations that PC-DMIS performs for this iterative alignment. PC-DMIS only uses this value if the **Meas All Always** check box is selected.

Iterative Alignment Rules

There are some general rules when doing an iterative alignment:

PC-DMIS needs both the measured values and theoretical values for each of the elements in the sets. The normal vectors for the first set of elements must be approximately parallel. The one exception to this rule is if only three features are being used in the set.

If measured points (VECTOR, EDGE, or SURFACE) are being used, then all three sets of elements are needed (three features to Level, two features to Rotate, and one feature to Set Origin) to define the alignment. Any feature type can be used, but three-dimensional elements are better defined elements and therefore improve the accuracy. Some of the possible 3D elements are sheet metal circle, slot, cylinder, sphere, or a corner point.

The sheet metal circle, slot, or cylinder needs at least three sample hits.

The difficulty of using measured points lies in not knowing where to take the measurement until after the alignment. This poses a problem as the points must be measured before the alignment. Three dimensional elements, by definition for this use, are elements that can be measured precisely the first time.

Further, if measured points (VECTORS, EDGE, or SURFACE) are being used, the features in the ROTATE set must have normal vectors that are approximately perpendicular to the vectors of the features in the LEVEL set. The features in the ORIGIN set must have a normal vector that is approximately perpendicular to both the vectors from the LEVEL set and the ROTATE set.

If measured points (VECTORS, EDGE or SURFACE) are being used as part of the set, PC-DMIS may ask that they be re-measured if they were taken too far from the nominal location. PC-DMIS first "best fits" the measured data to the nominal data. Next, PC-DMIS checks to see how far off each measured point is. If the distance is greater than the amount specified in the **Point Target Radius** box, PC-DMIS will request that the point be re-measured. PC-DMIS in effect puts a cylindrical tolerance zone around the theoretical location of each vector, surface, or edge point. The radius of this tolerance zone is the point tolerance specified in the dialog. PC-DMIS will continue to re-measure point features until all the measured points fall into 'tolerance'. The tolerance zone only affects measured points.

A special capability of PC-DMIS allows the center point of a slot to slide up or down the axis as needed. For this reason, an iterative alignment cannot converge when a slot is used as part of the ORIGIN set. It is possible to use a slot as part of the ORIGIN set by first constructing a point from the slot and then using that constructed point in the ORIGIN set.

A slot is not recommended as part of the ORIGIN set of an iterative alignment.

Type of Feature used:	Minimum # of Features needed:	
Circle	3 circles:	This method uses 3 DCC circles for the alignment.
Line	This feature type is not recommended.	
Point	6 points:	The points are used as a 3-2-1 alignment.
Slot	This feature type is not recommended as part of the ORIGIN set.	
Sphere	3 spheres:	This method uses 3 spheres for the alignment.

To Create an Iterative Alignment

Click this icon from the **Wizards** toolbar to access PC-DMIS's Iterative Alignment Wizard.

To create an iterative alignment:

1. Access the **Alignment Utilities** dialog box (**Insert | Alignment | New**).
2. Click the **Iterative** button. The **Iterative Alignment** dialog box appears. You will use this dialog box to create the iterative alignment. See "Description of the Iterative Alignment Dialog Box" if you need information about the dialog box.
3. From the **Feature List** box, select the first set of features (at least three features) to be used in establishing the orientation of the normal axis on the current workplane.
4. Verify that the **Level** option is selected.
5. Click the **Select** button.
6. Select with the mouse the second set of features (at least two features) to be used in the rotation process.
7. Verify that the **Rotate** option is selected.

8. Click the **Select** button.
9. Select the final set of features (at least one feature) that indicate the desired location of the part origin. (The same features may be used in more than one process.)
10. Verify that the **Origin** option is selected.
11. Click the **Select** button.
12. Click the **OK** button. The **Iterative Alignment** dialog box closes.
13. Click the **OK** button on the **Alignment Utilities** dialog box to complete the alignment. The dialog box closes. If this new alignment differs from the existing alignment, PC-DMIS will display a prompt asking if you want to update affected commands in the Edit window to use the new alignment (see "Updating Commands in Learn Mode" in the "Updating Dependent Commands When the Alignment Changes" topic). If the alignment doesn't change (or the change is too small to matter), PC-DMIS simply inserts the alignment without displaying the prompt or updating any commands.

Selecting the **Level**, **Rotation**, or **Origin** options after they've already been assigned features will display the indicated input features for that option.

After this process is complete, PC-DMIS will three-dimensionally "best fit" the measured data and display the new alignment in the Graphic Display window and in the Edit window. See the "Iterative Alignment Command Format".

Description of the Iterative Alignment Dialog Box

The following describes the items included in the **Iterative Alignment** dialog box (**Insert | Alignment | New | Iterative** button).

Level

The **Level - 3** option in the **Iterative Alignment** dialog box (**Insert | Alignment | New | Iterative** button) is used in conjunction with at least three features selected from the **Feature List** box. This set of features establishes the orientation of the normal axis of the current workplane by fitting a plane through the feature centroids.

At least three features must be used to level.

Rotate

The **Rotate - 2** option in the **Iterative Alignment** dialog box (**Insert | Alignment | New | Iterative** button) is used in conjunction with at least two features selected from the **Feature List** box. This set of features rotates the defined axis of the workplane to the features, fitting a line through the features.

At least two features need to be used to rotate.

If no features have been marked, the alignment uses features from the LEVEL section. (The two features used from the LEVEL section are the second and third from last feature.)

Origin

The **Origin - 1** option in the **Iterative Alignment** dialog box (**Insert | Alignment | New | Iterative** button) is used in conjunction with one feature selected from the **Feature List** box. This feature set translates (or moves) the part origin to a specific location

One feature must be used to set the origin.

If no features have been marked, the alignment uses the last feature from the LEVEL section.

Select

The **Select** button in the **Iterative Alignment** dialog box (**Insert | Alignment | New | Iterative** button) enables you to use selected features from the **Feature List** box to perform the Leveling, Rotating, and translating (or moving) to the Origin operations for an iterative alignment.

Meas All Once

If you select the **Meas All Once** check box in the **Iterative Alignment** dialog box (**Insert | Alignment | New | Iterative** button):

- PC-DMIS remeasures all the input features at least once in DCC Mode.

- The input features are measured in the order specified by the iterative alignment command in the Edit window.
- PC-DMIS displays which feature is about to be measured in a message box.
- Before accepting the move, ensure that the probe can reach the indicated feature(s) without colliding with the part.
- Stored moves found before or after each feature are *not* executed.
- After all the features have been measured at least once, PC-DMIS continues to remeasure the features for measured point types of features and those points that missed their **Point Target Radius** target (see "Point Target Radius").

Since their location never changes, PC-DMIS only measures circles once while in this mode.

Meas All Always

If you select the **Meas All Always** check box in the **Iterative Alignment** dialog box (**Insert | Alignment | New | Iterative** button), PC-DMIS remeasures (or re-executes) a portion of the current measurement routine at least once in DCC Mode. The portion that is re-executed depends on the Start Label (for information, see "Start Label"):

With a Start Label

If you provide a start label, PC-DMIS re-executes in DCC Mode from that defined label to the `ALIGNMENT/START` command that contains the currently executing iterative alignment command.

Without a Start Label

If you don't provide a start label, the following occurs:

- PC-DMIS begins the DCC re-execution from the first feature measured in the measurement routine that is used by the iterative alignment command.
- If the first feature has any stored move points preceding it then PC-DMIS also executes those move points.
- PC-DMIS continues the re-execution of the measurement routine commands until the last measured feature used by the iterative alignment command.
- PC-DMIS does not execute any stored moves after this command.
- Once the re-execution finishes, PC-DMIS recalculates the alignment and tests any measured input points to see if they are all within the tolerance radius specified in the **Point Target Radius** value.

- If they are all in the target radius, the re-execution does not need to continue, and PC-DMIS considers the iterative alignment command complete.
- If any points missed the target area, the same portion of the measurement routine is re-executed as described above.

Move Points and Meas All Always During First Execution

A move point contains an XYZ value to which the probe moves during execution. If you mark **Meas All Always** but PC-DMIS is in Manual Mode then during the measurement routine execution of the iterative alignment, PC-DMIS redefines all the move point locations to be relative to the iterative alignment's coordinate system in which they are executed. This only happens once, on the very first execution of the iterative alignment. If you later add additional move points and then re-execute the iterative alignment, the new move points are also redefined to be relative to the iterative alignment, similar to the other move points.

Point Target Radius

Use the **Point Target Radius** box in the **Iterative Alignment** dialog box (**Insert | Alignment | New | Iterative** button) to specify the target radius tolerance for measured point features used as inputs in the alignment. Measured input points include the following:

- Measured Points (MEAS/POINT)
- Auto Vector Point (AUTO/VECTOR)
- Auto Edge Point (AUTO/EDGE)
- Auto Surface Point (AUTO/SURFACE)
- Auto Angle Point (AUTO/ANGLE)

While you can usually see the location needed to measure a circle on a part easily enough, determining the exact location to measure a point on the surface isn't easily done. Without any visual indicators to tell you where to measure the point, it is difficult to manually measure the point in an exact spot. The **Point Target Radius** specifies an imaginary tolerance zone (or target) the size of the radius, around each point. This allows you to take a manual hit anywhere within the indicated tolerance when you execute the measurement routine. If the measured point does not fall within this zone, PC-DMIS re-measures the point in DCC Mode.

PC-DMIS attempts to re-measure the input features based on the selected check boxes in the **Iterative Alignment** dialog box (see "Meas All Once" and "Meas All Always").

If you don’t select either the **Meas All Always** or **Meas All Once** check box (or if you manually set `MEASURE ALL FEAT=NO` in the Edit window),

- PC-DMIS tries to calculate an alignment transform so that the measured datums match the theoretical datums, and then it checks to see if any measured input points missed their targets. If so, only these features are re-measured in DCC Mode.
- PC-DMIS displays a dialog box indicating the feature that is about to be measured. This lets you ensure that the probe can reach the desired feature without colliding with the part.
- Once all point features are in target, PC-DMIS considers the iterative alignment command complete.
- If there are any measured point features that missed their targets, PC-DMIS continues to re-measure these features until they are in target.

Be careful not to set the **Point Target Radius** value too small (for example 50 microns). Many CMMs are unable to accurately position the probe to touch each measured point on a minuscule target. A better choice is a tolerance of about .5 millimeters. If the re-measurement continues indefinitely, increase the value.

Fixture Tolerance

The **Fixture Tolerance** box in the **Iterative Alignment** dialog box (**Insert | Alignment | New | Iterative** button) enables you to type a fitting tolerance value against which PC-DMIS compares feature elements making up the iterative alignment to their theoretical values.

If after fitting the measurement values to the theoretical values, one or more of the input features have an error along their assigned datum axis that exceeds this tolerance value, PC-DMIS automatically goes to the error label (if one exists). See "Error Label".

If you don't provide an error label, PC-DMIS displays an error message showing the errors along each of the datums. You will have the choice to accept the datum as it is and continue with the rest of the measurement routine, or to cancel the measurement routine execution.

PC-DMIS can only use the fixture tolerance value if you used more than the minimum number of points needed to create the feature. For example, if you are measuring a plane, the minimum number of points needed for that plane is usually three points. However, if you wanted to use the fixture tolerance value, you would need to measure at least four points. If you use only three points, then only one solution exists, and PC-DMIS cannot adjust or re-iterate.

Max Iterations

This box in the **Iterative Alignment** dialog box (**Insert | Alignment | New | Iterative** button) determines the maximum number of repetitions that PC-DMIS performs when creating the iterative alignment. PC-DMIS only uses this value if the Meas All Always check box is selected.

Start Label

The **Start Label** box in the **Iterative Alignment** dialog box (**Insert | Alignment | New | Iterative** button) allows you to define a label that PC-DMIS execution moves to when remeasuring iterative alignment features. It remains disabled until you mark the **Meas All Always** check box.

For information on how the **Start Label** works with **Meas All Always** during execution, see the "Meas All Always" topic.

For more information on labels, see "Using Labels" in the "Branching by Using Flow Control" chapter.

Error Label

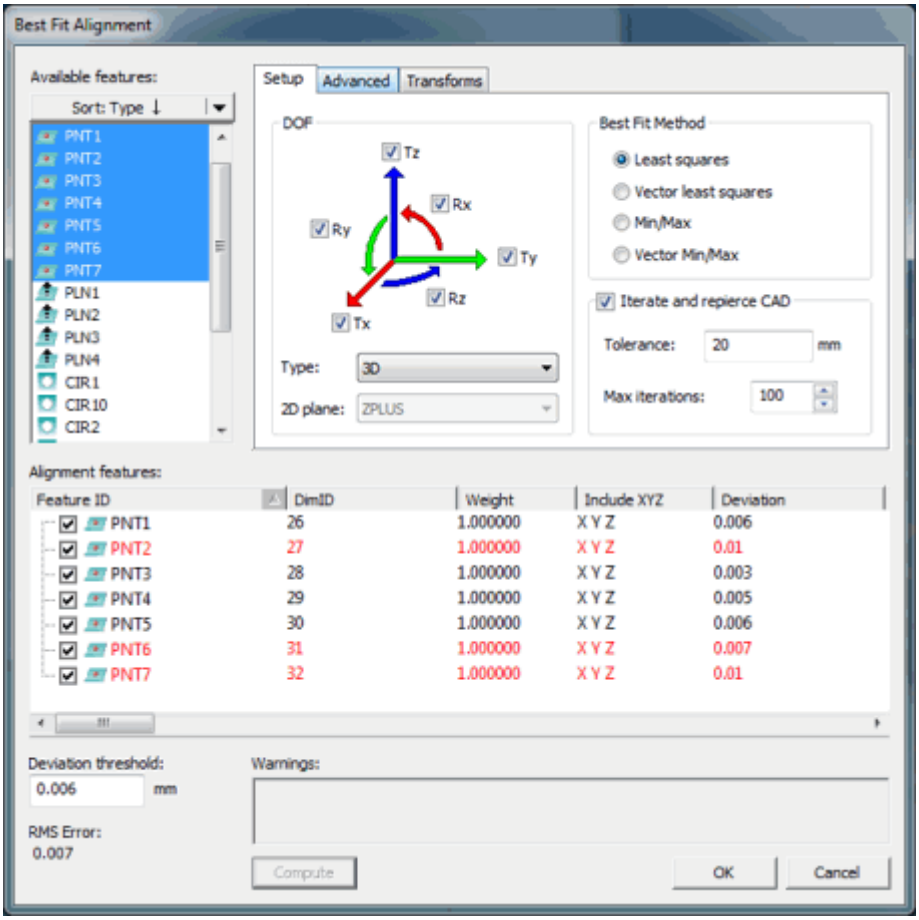
Use the **Error Label** box in the **Iterative Alignment** dialog box (**Insert | Alignment | New | Iterative** button) to define a label that the measurement routine flow will go to if the error in matching the measured level, rotate, and origin datum features to their corresponding theoretical features exceeds the fixture tolerance level in the **Fixture Tolerance** box.

If you supply the minimum number of inputs for each of the datum axes (three for the **Level** datum, two for the **Rotate** datum, and one for the **Origin** datum), PC-DMIS can fit the input feature measurement value to its theoretical values without errors. In this case PC-DMIS doesn't really need the fixture tolerance. If you supply more than the minimum number of inputs for any of the defined datums, then either part or fixture errors may make it impossible to fit the measurement values to the theoretical values with less error then the supplied fixture tolerance.

If you don't define an error label, PC-DMIS will generate an error message displaying the amount of error for each of the datum features, giving you the option to cancel or continue execution with the datums as they are.

To create a label, see "Using Labels" in the "Branching by Using Flow Control" chapter.

Creating a Best Fit Alignment



Best Fit Alignment Dialog Box

When you click the **Best Fit** button in the **Alignment Utilities** dialog box (**Insert | Alignment | New**), PC-DMIS displays the **Best Fit Alignment** dialog box. This dialog box provides a way for you to "best fit" the measured data to the nominal points. With the exception of the **Vector** method, which requires at least two points, you need at least one point feature to create a best fit alignment.

To Create a Best Fit Alignment

To create a Best Fit alignment:

1. Access the **Alignment Utilities** dialog box (**Insert | Alignment | New**).
2. Click the **Best Fit** button to open the **Best Fit Alignment** dialog box. You can use the dialog box to create the Best Fit alignment. For details on the **Best Fit Alignment** dialog box, see the "Description of the Best Fit Alignment Dialog Box" topic in the PC-DMIS Core documentation.
3. From the **Available features** list, select the features that you want to use. PC-DMIS shows the selected features in the **Alignment features** list box.

4. To define the orientation and degrees of freedom of the alignment, select either the **2D**, **3D** or **User Defined** options from the **Type** list. For a 2D alignment, select the correct active plane from the **2D Plane** list.

5. From the **Best Fit Method** area, select the best fit type.

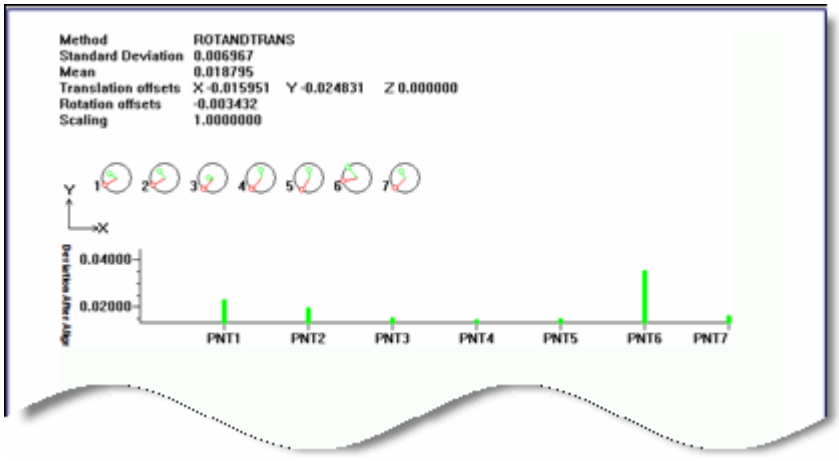
6. To edit the weights of the features, double-click its weight value in the **Alignment features** list. The weight value cell turns into an inline edit field. Edit the value, and then return or click outside the cell to finalize the change.

7. To set the point of rotation about a given feature, select the feature from the **Input List**, and then click the **Set** button in the **Rotate About** area of the **Advanced** tab. Alternately, you can enter a value into the **Theoretical** and **Measured** boxes in the **Rotate About** area of the dialog box.

8. Click the **OK** button to close the **Best Fit Alignment** dialog box.

9. Click the **OK** button on the **Alignment Utilities** dialog box. The dialog box closes. If this new alignment differs from the existing alignment, PC-DMIS displays a prompt asking if you want to update affected commands in the Edit window to use the new alignment (see "Updating Commands in Learn Mode" in the "Updating Dependent Commands When the Alignment Changes" topic). If the alignment doesn't change (or the change is too small to matter), PC-DMIS simply inserts the alignment without displaying the prompt or updating any commands. Following the execution of the measurement routine, PC-DMIS displays a 3D Alignment Best Fit Graphical Analysis in the Report window.

Example of a Best Fit Alignment's Graphical Analysis in the Report Window



Example of a Best Fit alignment graphical analysis in the Report Window.

This graphical analysis of the 3D Best Fit alignment displays this information in the Report window:

- **Header** - This contains various values used in the Best Fit alignment: Method, Standard Deviation, Mean, Translation offsets, Rotation offsets, Max iterations, Iterations.

- **Vertical Axis** - This shows the amount of deviation before and after the alignment.

  Red bars on bar graphs or red dots on circle graphs represent the deviation, the 3D distance between the actual and the theoretical, *before* the Best Fit alignment.

  Green bars on bar graphs or green dots on circle graphs represent the deviation, the 3D distance between the actual and the theoretical, *after* the Best Fit alignment.

- **Horizontal Axis** - This displays the IDs of the points used in the alignment.

Note that 3D alignments only use the bar graph.

Understanding Best Fit Alignments

A Best Fit alignment is an alignment that causes a set of measured points or a set of actual feature centroids to match, as closely as possible to its nominal location or theoretical counterpart. In certain cases, it is also possible for a Best Fit alignment to optimally match a set of points to a CAD curve or surface.

To understand the different Best Fit Alignment methods, see "The Best Fit Alignment Methods".

About Exclusions

For 2D Vector Best Fit Alignments - Features with vector directions that are perpendicular to the 2D best-fit plane are excluded from the alignment calculation.

For All Best Fit Alignments - Features that are skipped during measurement routine execution are excluded from the alignment calculation.

If all features of the alignment are excluded, PC-DMIS displays an error message. If this occurs during execution, PC-DMIS pauses the execution and gives you the option of canceling execution. You can check the **Best Fit Alignment** dialog box (**Insert | Alignment | New | Best Fit** button) to see if any of the alignment's features were excluded due to invalid vectors or because they were skipped during execution.

The Best Fit Alignment Methods

This topic covers the available Best Fit Alignment solution methods when you define a Best Fit Alignment.

The Best Fit Alignment minimizes deviations between measured point data and nominal point data. The features you use in the alignment require correct nominal values in their THEO fields.

The alignment methods below minimize the deviations in different ways:

Method 1: Least Squares Fit

Command Mode: LEAST_SQR

Description: The Least Squares algorithm aligns the two point sets. It does this by transforming the measured points in such a way that it minimizes the sum of the squared distances (between matching measured and nominal points). This is the same as minimizing the average squared error. To understand how the Least Squares alignment works, visualize a spring (of initial length zero) between each measured point and its nominal counterpart. As the distance between the two points increases, the springs stretch. The point set's final position when you release it and let the springs act is the solution to the Least Squares alignment problem.

When to Use It: Use Least Squares to reverse engineer parts and to troubleshoot manufacturing processes, when aligning to feature centers. These feature centers come from regular features such as circles or cylinders.

Least Squares is the most common best fit type because it produces very repeatable results. Least Squares is also used to troubleshoot the manufacturing process, because it gives a better representation of all the point data, rather than just the most extreme points (see the Min Max description below). Least Squares is not ideal for complex surfaces where data is a set of points with unique vectors. In that case, a Vector Least Squares fit is a better option.

Other Info: This is the default. Least Squares works with 2D, 3D, and **User Defined** best fit alignments.

Algorithm: The least squares algorithm minimizes the sum of the squared lengths of the deviations, meaning it minimizes the following mathematical function:

$$\mathcal{L}_{\text{least squares}} = \sum_i w_i \|\mathbf{d}_i\|^2,$$

where w_i are the weights.

Method 2: Vector Least Squares Fit

Command Mode: VECTOR_LST_SQR

Description: The Vector Least Squares fit is a kind of Least Squares fit, except that it projects the error vectors onto the nominal vectors. It then uses these projected distances in the Least Squares fit. A vector fit type allows points to "slide" along the surface but discourages them from pulling away from the surface. All errors are along the nominal vectors.

When to Use It: Use Vector Least Squares to reverse engineer parts and to troubleshoot manufacturing processes, when aligning to surfaces. These surfaces might be regular features, such as circles or cylinders, or they might be irregular complex surfaces. The surface may be represented as a set of points with unique vectors.

For instance, suppose the points are on the surface of a car hood. In this case, motion along the surface is not as important as motion perpendicular to the surface. Therefore, we use a vector fit to only measure deviations perpendicular to the surface.

Other Info: This is also known as Projected Least Squares. Vector Least Squares works with standard 2D and 3D best fit alignments, not **User Defined** best fit alignments.

Suppose you have a nominal point of 1,1,1 with a vector of 0,0,1, with measured values of 4,2,0.95. With this fit, the software adjusts the measured data to 1,1,0.95, and snaps it to the vector of 0,0,1.

Algorithm: The vector least squares algorithm minimizes the sum of the squared projected deviations, where the deviations are projected onto the nominal vectors $\mathbf{v}_i$, meaning it minimizes the following function:

$$\mathcal{L}_{\text{vector least squares}} = \sum_i w_i (\mathbf{d}_i \cdot \mathbf{v}_i)^2.$$

Method 3: Min Max Fit

Command Mode: MIN_MAX

Description: A Min Max fit minimizes the maximum error (the largest distance) among the features being fit.

When to Use It: Use Min Max to evaluate Position tolerances according to the ASME and ISO standards, when tolerancing feature centers. These feature centers come from regular features, such as circles or cylinders.

The Min Max algorithm applies simultaneous diametric tolerance zones to the feature centers. Min Max fit types comply with ASME Y14.5 and ISO 1101.

Min Max fits are very sensitive to measurement uncertainty. A single bad feature can affect the alignment results drastically.

The recommended input feature types for Min Max fits to evaluate position tolerances are circles, spheres, cylinders, and cones. Min Max is not ideal for complex surfaces where data is a set of points with unique vectors. In that case, a Vector Min Max fit is a better option.

Other Info: Min Max works with 2D and 3D best fit alignments, not **User Defined** best fit alignments.

Algorithm: The Min Max algorithm minimizes the maximum deviation length, meaning it minimizes the following function:

$$\mathcal{L}_{\text{min-max}} = \max_i \, w_i \, \|\mathbf{d}_i\| \, .$$

Method 4: Vector Min Max Fit

Command Mode: VECTOR_MIN_MAX

Description: The Vector Min Max fit is a kind of Min Max fit, except that it projects the error vectors onto the nominal vectors. It then uses these projected distances in the Min Max fit.

A vector fit type allows points to "slide" along the surface but discourages them from pulling away from the surface. All errors are along the nominal vectors. A Min Max fit minimizes the maximum deviation (the largest distance) among the features being fit.

When to Use it: Use Vector Min Max to evaluate Profile tolerances according to the ASME and ISO standards, when tolerancing surfaces. These surfaces might be regular features such as circles or cylinders or they might be irregular complex surfaces. Such surfaces include parts like blades and airfoils. The surface may be represented as a set of points with unique vectors.

For instance, suppose the points are on the surface of a car hood. In this case, motion along the surface is not as important as motion perpendicular to the surface. Therefore, we use a vector fit to only measure deviations perpendicular to the surface.

Make sure there is a good initial alignment of the machine to the part. Min Max fit types comply with ASME Y14.5 and ISO 1101.

Other Info: Vector Min Max works with 2D and 3D best fit alignments, not **User Defined** best fit alignments.

Algorithm: The Vector Min Max algorithm minimizes the maximum projected deviation, so it minimizes the function:

$$\mathcal{L}_{\text{vector min-max}} = \max_i \, w_i \, |\mathbf{d}_i \cdot \mathbf{v}_i| \, .$$

2D Best Fit Command Line Format

The Edit window command line for the Best Fit 2D option reads:

```
ALIGNMENT/BF2D,TOG1,TOG2,CREATE WEIGHTS=NO,TOG3,USE
SCALING=YES,n1,n2,n3,n4,n5

ITERATEANDREPIERCECAD=YES,TOLERANCE=n6,MAX ITERATIONS=n7,

CENTER OF ROTATION,MEAS_X,MEAS_Y,MEAS_Z,THEO_X,THEO_Y,THEO_Z

SHOWALLINPUTS=YES,SHOWALLPARAMS=YES

ID=
```

Available Fields:

"**TOG1**" This field allows you to switch between the available workplanes. The current workplane should be displayed.

"**TOG2**" This field allows you to switch between the available types of best fits: **LEAST_SQR**, **VECTOR_LST_SQR**, **MIN_MAX**, **VECTOR_MIN_MAX**. For information on Best Fit alignment methods, see the "The Best Fit Alignment Methods" topic in the PC-DMIS Core documentation.

CREATE WEIGHTS= This option lets you determine whether or not PC-DMIS creates weights for the features used in the best fit alignment. Available options are **YES** or **NO**. The created weights correspond to tolerances on the features used in the alignment. For information on feature weight, see the "Feature Weights" topic in the PC-DMIS Core documentation.

"**TOG3**" This field determines the degrees of freedom for the 2D alignment. Available options are: **ROTONLY** (rotation only), **ROTANDTRANS** (rotation and translation), and **TRANSONLY** (translation only).

USE SCALING = This option is available if TOG2 is set to LEAST_SQR. If set to **YES**, PC-DMIS computes a transformation (rotation and translation) and a scale factor to optimally match nominal data to the scaled measured data. For information on the **Use Scaling** check box, see the "Description of the Best Fit Alignment Dialog Box" topic in the PC-DMIS Core documentation.

n1,n2,n3= Translation in X,Y,Z

n4= The angle offset value.

n5= This is the scale factor. It only appears if **USE SCALING** is set to **YES**.

ITERATEANDREPIERCECAD= If set to **YES**, PC-DMIS will perform an Iterative Best Fit alignment by piercing the CAD geometry and adjusting the feature nominals with each iteration, using TOLERANCE= and ITERATIONS= values to control the result. If set to **NO**, PC-DMIS does a single best fit alignment. For information on the **Use Scaling** check box,

see the "Description of the Best Fit Alignment Dialog Box" topic in PC-DMIS Core documentation.

TOLERANCE=**n6**. This is the tolerance value for performing an iterate and repierce cad operation. This only appears if **ITERATEANDREPIERCECAD** is set to **YES**.

ITERATIONS=n7. This is the maximum number of times the best fit alignment algorithm iterates when performing an iterate and repierce cad operation. This only appears if **ITERATEANDREPIERCECAD** is set to **YES**.

CENTER OF ROTATION This field and the measured and theoretical XYZ values associated with it, represent the center of rotation. They only appear if ROTONLY or ROTANDTRANS is used for the TOG2 field. MEAS_X, MEAS_Y, and MEAS_Z are the X,Y,Z values for the measured center of rotation. THEO_X, THEO_Y, and THEO_Z are the theoretical X,Y,Z values for the theoretical center of rotation.

SHOWALLINPUTS= This option lets you determine whether or not the alignment code block displays the feature inputs used to create the alignment. Available options are **YES** or **NO**.

SHOWALLPARAMS= This option lets you determine whether or not the alignment code block displays all the parameters for the feature inputs. Available options are **YES** or **NO**.

If set to **YES**, then PC-DMIS displays this information for each input feature: Feature ID, Feature Type, Dimension ID, Feature Weight, Feature Use.

For example, it might look something like this:

```
ID = CIR2,Circles,LOC12,2.000000,YES
```

If set to **NO**, then PC-DMIS displays only the ID of the input feature:

```
ID = CIR2
```

ID= Each line began with "ID=" represents an input feature used in the alignment.

3D Best Fit Command Line Format

The Edit window command line for the Best Fit 3D option reads:

```
ALIGNMENT/BF3D,TOG1,CREATE WEIGHTS=YES,TOG2,USE
SCALING=YES,n1,n2,n3,n4,n5,n6,n7

ITERATEANDREPIERCECAD=YES,TOLERANCE=n8,MAX ITERATIONS=n9,

CENTER OF ROTATION,MEAS_X,MEAS_Y,MEAS_Z,THEO_X,THEO_Y,THEO_Z

SHOWALLINPUTS=YES,SHOWALLPARAMS=YES

ID=
```

Available Fields:

"**TOG1**" This field allows you to switch between the available types of best fits.

"**TOG2**" This field allows you to switch between the available types of constraints for the 3D alignment. Available options are: **ROTONLY** (rotation only), **ROTANDTRANS** (rotation and translation), and **TRANSONLY** (translation only).

n1,n2,n3 - Translation in X,Y,Z

n4 - Rotation in the XY plane

n5 - Rotation in YZ plane

n6 - Rotation in ZX plane

Note that the values for translation and rotation are relative to the current active alignment, and the angles are always in degrees.

USE SCALING= This option is available if TOG2 is set to LEAST_SQR. If set to **YES**, PC-DMIS computes a transformation (rotation and translation) and a scale factor to optimally match nominal data to the scaled measured data. See "Description of the Best Fit Alignment Dialog Box" where the **Use Scaling** check box is discussed.

n7= This is the scale factor. It only appears if USE SCALING is set to YES.

If seven number values are visible then the seventh number is the scale factor.

CENTER OF ROTATION This field and the measured and theoretical XYZ values associated with it, represent the center of rotation. They only appear if ROTONLY or ROTANDTRANS is used for the TOG2 field. MEAS_X, MEAS_Y, and MEAS_Z are the X,Y,Z values for the measured center of rotation. THEO_X, THEO_Y, and THEO_Z are the theoretical X,Y,Z values for the theoretical center of rotation.

ITERATEANDREPIERCECAD= If set to **YES**, PC-DMIS will perform an Iterative Best Fit alignment by piercing the CAD geometry and adjusting the feature nominals with each iteration, using TOLERANCE= and ITERATIONS= values to control the result. If set to **NO**, PC-DMIS does a single best fit alignment. See "Description of the Best Fit Alignment Dialog Box" where the **Use Scaling** check box is discussed.

TOLERANCE=n8. This is the tolerance value for performing an iterate and repierce cad operation. This only appears if **ITERATEANDREPIERCECAD** is set to **YES**.

ITERATIONS=n9. This is the maximum number of times the best fit alignment algorithm iterates when performing an iterate and repierce cad operation. This only appears if **ITERATEANDREPIERCECAD** is set to **YES**.

SHOWALLINPUTS= This option lets you determine whether or not the alignment code block displays the feature inputs used to create the alignment. Available options are **YES** or **NO**.

SHOWALLPARAMS= This option lets you determine whether or not the alignment code block displays all the parameters for the feature inputs. Available options are **YES** or **NO**.

If set to **YES**, then PC-DMIS displays this information for each input feature: Feature ID, Feature Type, Dimension ID, Feature Weight, Feature Use.

For example, it might look something like this:

```
ID = CIR2,Circles,LOC12,2.000000,YES
```

If set to **NO**, then PC-DMIS displays only the ID of the input feature, like this:

```
ID = CIR2
```

ID= Each line that starts with "**ID=**" represents an input feature used in the alignment.

Best Fit Alignment Types

You can have Best Fit Alignments solve 2D, 3D, or custom user-defined degrees of freedom.

(For a user-defined approach, in the **Type** list of the **Best Fit Alignment** dialog box, select **User Defined**).

Some important differences between these best fit alignment types are:

- A 2D Best Fit alignment requires an initial alignment to establish the 2D plane. The alignment is created in the workplane defined by the current active alignment.
- A 3D Best Fit alignment uses the raw (machine) data and correlates it to the theoretical values. It does not require a previous alignment, but if the degrees of freedom are set to rotation-only and a rotation center is not explicitly defined, it uses the origin of the current active alignment as the rotation center.
- In most cases, a user-defined Best Fit alignment requires a previous alignment in order to reliably establish the XYZ directions for the custom degrees of freedom.

Constraints for Best Fit Alignments

There are also constraints that can be applied to the Best Fit alignments.

Constraints for 2D and 3D Best Fit Alignments

1. **Rotate and Translate** (default) - This allows the alignment full flexibility while correlating the machine data to the theoretical values.

2. **Rotate Only** - This option restricts the alignment to rotation only, without applying any translations of the rotation center. If no rotation center is defined, the part coordinate system origin (0,0,0) is used as the rotation center.

3. **Translate Only** - This option restricts the alignment to translation only, without applying any rotations.

Constraints for User-Defined Best Fit Alignments

The user-defined Best Fit alignment allows any degree-of-freedom combination other than cases with two rotations (zero, one, and three rotations are allowed). It does not support defining a rotation center. For relevant degree-of-freedom combinations, it uses the part coordinate system origin (0,0,0) as the rotation center.

Feature Weights

The purpose of weights is to aid in simultaneous evaluation of Position or Profile tolerances.

You can specify feature weights, or you can have PC-DMIS automatically generate feature weights based on the tolerances' values.

Specified Weights

Each feature used as an input has an associated weight. The default value for these weights is 1. You can modify the weights in the Edit window (**View | Edit Window**) or in the **Best Fit Alignment** dialog box (**Insert | Alignment | New | Best Fit** button). The values of these weights affect the resulting alignment. The larger the weight of a particular feature, the more the resulting alignment will attempt to match the measured value of that feature to its theoretical value. This association allows you to assign priorities to the features in the alignment. If the weights of all the input features are equal, then the features will be treated equally *regardless* of the value of the weight.

You can edit any of the weights by selecting the feature in the **Alignment features** list and double-clicking the specific weight value. Edit the value as needed and then click outside the field to set the new value. The new value will then be assigned to that feature and used during the calculations.

Weights may also be assigned to each feature based on its associated dimension. If there is no associated dimension, it will be assigned a default tolerance. Assign the weights by clicking the **Set** button. A composite weight for the feature is then computed by multiplying the user-defined weights with the tolerance weights.

Tolerance-Generated Weights

For tolerance-based weights, a Min_Max fit reduces the percentage of the available tolerance that each feature uses. The Least Squares fit reduces the "average" amount of tolerance that all features use.

Because the generated weights are reciprocals of the tolerances, a feature with a relatively small weight (or lower priority) corresponds to a large tolerance zone. This gives it more freedom to move without affecting the other features. A feature with a relatively large weight (or small tolerance zone) gets a high priority in the alignment process.

Using Weights for Simultaneous Evaluation

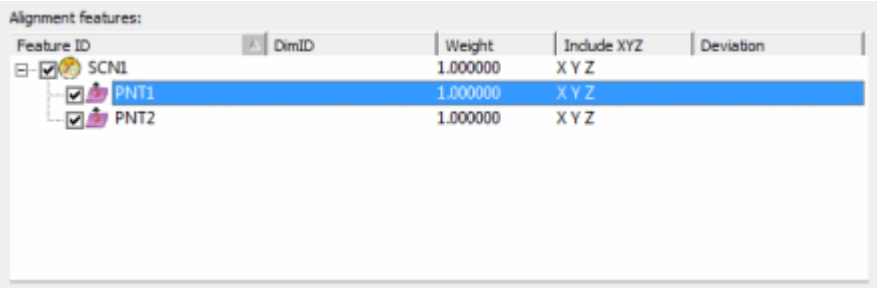
1. Create some dimensions with the appropriate tolerances. Choose "no fit" for these dimensions. Do not include these dimensions in the report. These dimensions are for-reference-only. These are only present to inform the best-fit alignment what the tolerances are.

2. Create a best-fit alignment that automatically creates weights on the toleranced features. The best-fit alignment takes into account the tolerance sizes and any applicable bonus as it creates the weights.

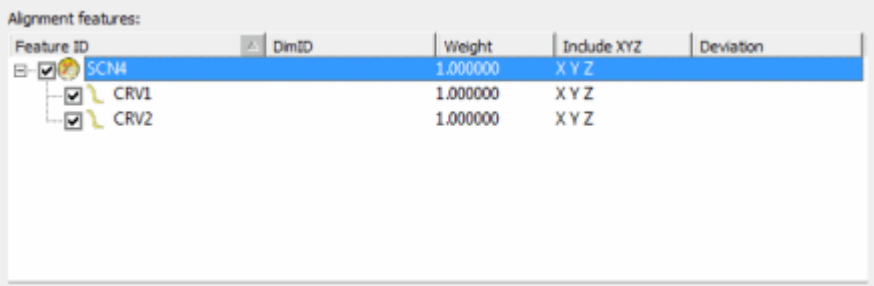
3. Create a second set of dimensions with the appropriate tolerances, using the weighted best-fit alignment. Include these dimensions in the report.

Constructed Feature Sets and Curves as Best Fit Alignment Inputs

When using a constructed feature set or a constructed curve as inputs to the Best Fit alignment, a plus (+) sign will appear next to the feature ID in the **Alignment features** list box in the **Best Fit Alignment** dialog box (**Insert | Alignment | New | Best Fit** button). When you click on the plus (+) sign once, the features that make up that set or curve will be displayed. Initially the weights for each feature will be the same as its parent feature (the original set or curve).



Example of the Alignment features list box showing features in a set.



Example of the Alignment features list box showing features in a curve.

You can edit the weight for each child feature of the set or curve by double-clicking the current weight value and entering the new value as necessary. To change the weight of all of the features in the set or curve, edit the weight on the feature set or the curve itself. That weight will be transferred to all of its children.

Scans as Best Fit Alignment Inputs

When working with a scan, there is one extra component than when working with a feature set. Scans are composed of basic scans. Each basic scan is composed of individual points. When clicking a plus (+) sign next to a scan, it will expose all of the basic scans associated with it. A plus (+) sign will appear next to each basic scan. By clicking the plus (+) sign next to each basic scan, it will expose all of the individual points associated with the basic scan. The weight for each point can be edited, the weight of the basic scan (and all of its points) can be edited, or the weight of the scan itself can be edited.

Tagged Features in a Feature Set or Scan

Also, you can tag individual members within a feature set so that they are not used. To tag a member of a set to not be used in the best fit alignment, clear the check box to the left of the feature in the **Alignment features** list box in the **Best Fit Alignment** dialog box (**Insert | Alignment | New | Best Fit** button). If a check box for a basic scan is cleared, it and all of its associated points will *not* be used in the calculations.

Alignment Center of Rotation

For 2D and 3D Best Fit alignments, you can specify a center of rotation in one of two ways:

- Method 1: Select a feature from the **Alignment features** list in the **Best Fit Alignment** dialog box (**Insert | Alignment | New | Best Fit** button). Next, click the **Set** button. The theoretical and measured values are automatically entered into the appropriate boxes in the **Rotate About** area.
- Method 2: If a specific coordinate is desired, manually provide the values by typing the XYZ coordinate into the **Theoretical** and **Measured** boxes in the **Best Fit Alignment** dialog box. The number values must be in an X,Y,Z comma-delimited format in order to be valid. The values must be entered in terms of part coordinates with regards to the active alignment trihedron.

If you do not specify a center of rotation, PC-DMIS uses the part coordinate system origin (0,0,0) as the rotation center.

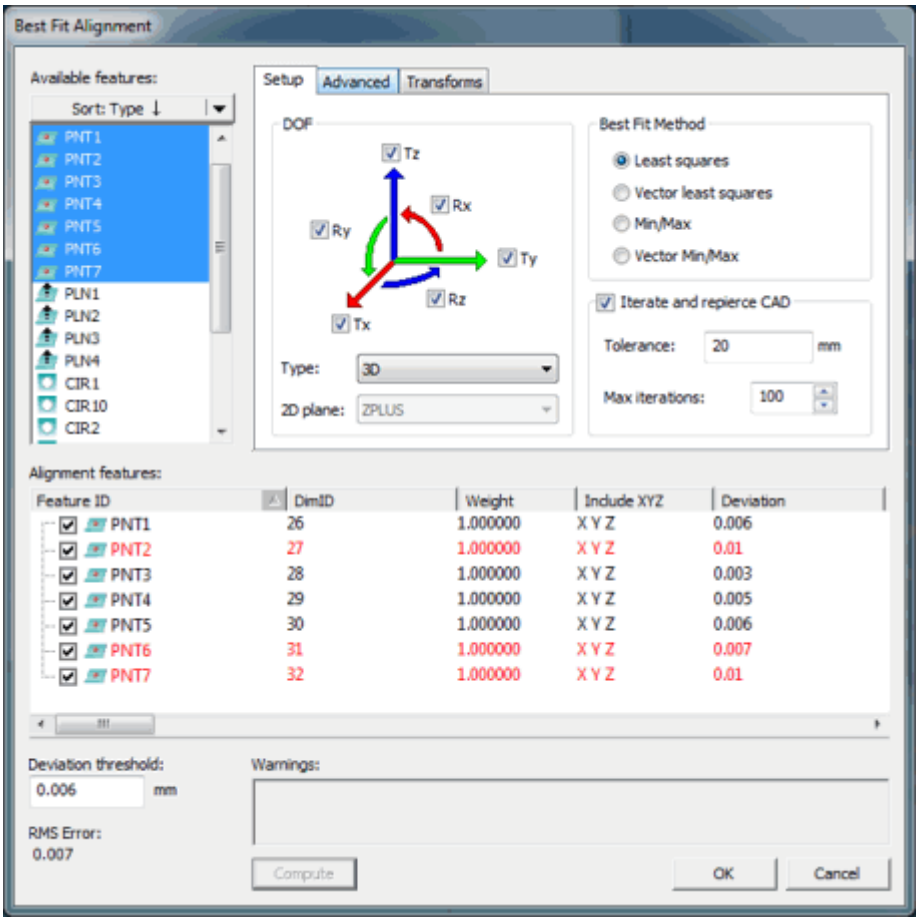
For user-defined Best Fit alignments, you cannot specify the rotation center. In this case, the part coordinate system origin (0,0,0) is always used for degree-of-freedom combinations where a rotation center is relevant.

Point Set to CAD Alignments

By default, PC-DMIS matches the measured points in your best fit alignment to the original nominal point set. However, by enabling **Iterate and Repierce CAD** (see the **Iterate and Repierce CAD** area discussed in "Description of the Best Fit Alignment Dialog Box"), you can have the best fit alignment match the measured points to CAD curves or surfaces instead. In this case, after the first best fit alignment is computed, updated nominal points on the CAD curve or surface, corresponding to the transformed measured points, are calculated. This process is repeated until convergence takes place. This alignment method changes the theoretical values of the points.

If the re-pierce operation fails for all of the measured points included in the Best Fit alignment, PC-DMIS will display an error message in the Warnings area and abort the alignment calculation.

Description of the Best Fit Alignment Dialog Box



Best Fit Alignment Dialog Box

The following features appear on all of the tabs in the **Best Fit Alignment** dialog box (**Insert | Alignment | New | Best Fit** button):

Available features list
The **Available features** list contains a list of all the features in your measurement routine before the alignment. For a full description, see "Dialog Box Description" and "Feature List box".

Alignment features list
The **Alignment features** area lists the features selected for the best fit calculation from the **Available features** list. You can sort each column by clicking on the column header. The check box to the left of each feature ID enables or disables the feature in the best fit calculation. If marked, the feature is used in the calculation; otherwise, it isn't.

If you select the **Pause during execution** check box (discussed below), the alignment is automatically reset to include all features in the best fit calculation during measurement routine execution.

If a calculated deviation is above the **Deviation threshold** value, the text for that feature is displayed in red.

You can modify weights by double-clicking the specific **Weight** factor for the feature in the **Alignment Features** list.

You can determine which axes are included in the calculation by double-clicking the specific item in the **Include XYZ** column for the feature. This displays the **Include XYZ** dialog box. Marking an axis includes the axis in the calculation. Clearing an axis excludes it.

> You cannot change the **Weight** and **Include XYZ** settings of a scan's hits independent of their parent scan feature. Each hit uses the **Weight** and **Include XYZ** settings of its parent scan.

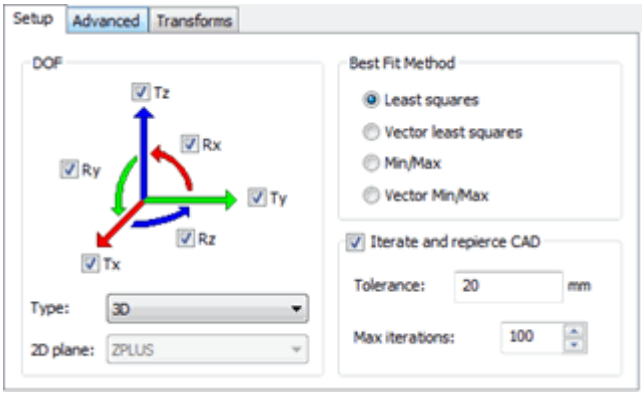
Deviation threshold box
The **Deviation threshold** sets the maximum acceptable value for the calculated deviation value. If a calculated deviation is above this threshold value, the text for that feature is displayed in red in the **Alignment features** area. The measurement units are the same as those defined in your system settings.

RMS Error
This displays the **RMS Error** value from the most recent alignment calculation.

Warnings area
The **Warnings** area displays any error messages from the most recent alignment calculation.

Compute button
The **Compute** button updates the best fit alignment calculation using the current features and settings.

Setup Tab



Setup Tab

The **Setup** tab contains the most common settings for defining a best fit alignment. The following features are specific to this tab:

DOF (Degree of Freedom) area

DOF Check Boxes

The **Tx**, **Ty**, **Tz**, **Rx**, **Ry**, and **Rz** check boxes define which of the six degrees of freedom (rotation about X, Y, or Z axis, and translation in the X, Y, or Z direction) to include in the alignment. As the degrees of freedom are modified, the value of the **Type** list (**2D**, **3D**, **3D No Rotation**, and so on) is automatically updated according to the current settings. If the current combination of degrees of freedom does not match any of the pre-defined cases, the type is set to **User Defined**. Conversely, as the type is changed, the check boxes are updated to match.

Type

The **3D** option causes the resulting alignment to be a 3D alignment that is both Translated and Rotated.

The **3D No Translation** option causes the resulting alignment to be a 3D alignment that is Rotated but not Translated.

The **3D No Rotation** option causes the resulting alignment to be a 3D alignment that is Translated but not Rotated.

The **2D** option causes the resulting alignment to be a 2D alignment that is both Translated and Rotated in the selected 2D plane.

The **2D No Translation** option causes the resulting alignment to be a 2D alignment that is Rotated but not Translated in the selected 2D plane.

The **2D No Rotation** option causes the resulting alignment to be a 2D alignment that is Translated but not Rotated in the selected 2D plane.

2D Plane

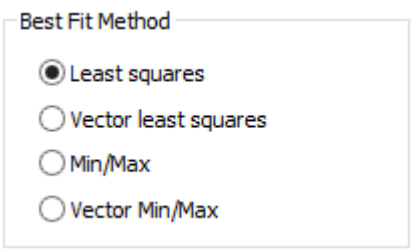
The **2D Plane** list sets the plane in which to calculate a 2D alignment.

If **Type** is set to **User Defined**, PC-DMIS automatically selects the Least squares option in the **Best Fit Method** area. The **2D plane** list on this tab and the **Rotate About** options on the **Advanced** tab are then unavailable.

The **2D Plane** list is available only if you choose one of the 2D options from the **Type** list. Available options are ZPLUS, XPLUS, YPLUS, ZMINUS, XMINUS, and YMINUS.

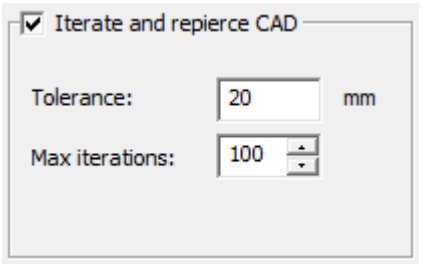
The coordinate image dynamically updates based on the marked vector or coordinate check boxes.

Best Fit Method area



The **Best Fit Method** area contains several methods that you can use to compute the best fit alignment. For information on these methods, see "The Best Fit Alignment Methods".

Iterate and repierce CAD area



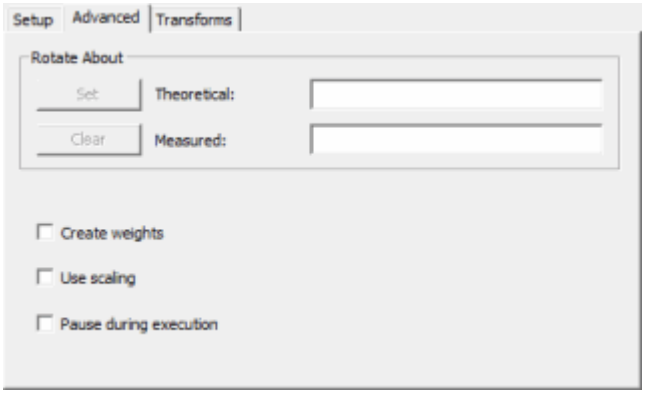
Iterate and repierce CAD - If you select this check box, PC-DMIS performs an Iterative Best Fit alignment after you click **OK**. This pierces the CAD geometry and adjusts the feature nominals with each iteration using Tolerance and Max iterations to control the result. If this check box is cleared, PC-DMIS does a single Best Fit alignment.

Tolerance - Type a tolerance value. PC-DMIS uses this tolerance when searching for CAD surfaces to pierce. The measurement units for the tolerance is the same as those used by the measurement routine. The new nominal point becomes the CAD point closest to the actual feature, provided it is within this tolerance. If no CAD surface is found within this distance from the actual feature, then that feature is ignored in subsequent iterations.

Max iterations - This determines the maximum number of times the best fit alignment algorithm iterates.

If the repierce operation fails for all of the features included in the Best Fit alignment, PC-DMIS displays an error message in the **Warnings** area and aborts the alignment calculation.

Advanced Tab



Advanced Tab

The **Advanced** tab contains specialized settings for several less-common conditions. The following are features specific to this tab:

Rotate About area
This area has two boxes that define the theoretical and measured center of rotation. You can click **Set** to automatically populate these fields with X, Y, and Z values from the feature selected in the **Alignment features** list, or you can manually type your own X, Y, and Z values.

The **Theoretical** box contains the *theoretical* center of rotation for 2D and 3D best fit alignments.

This **Measured** box contains the *measured* center of rotation for 2D and 3D best fit alignments.

The **Clear** button clears both fields.

Use scaling check box

The **Use scaling** check box becomes available for 2D or 3D alignments when you select the **Least squares** method. It is not available for alignments with specified constraints.

When you use scaling, PC-DMIS computes a transformation (rotation and translation) and a scale factor that optimally matches the nominal data to the scaled measured data. The scaled alignment also scales all of the measured data and subsequent measured features in the measurement routine, multiplying it by the computed scale factor.

Once scaling has been applied to the measured data and features in a measurement routine, it cannot be undone. Only mark **Use scaling** on in a single alignment in the measurement routine.

You may find this useful, for example, in compensating for expansion or contraction of a part due to temperature.

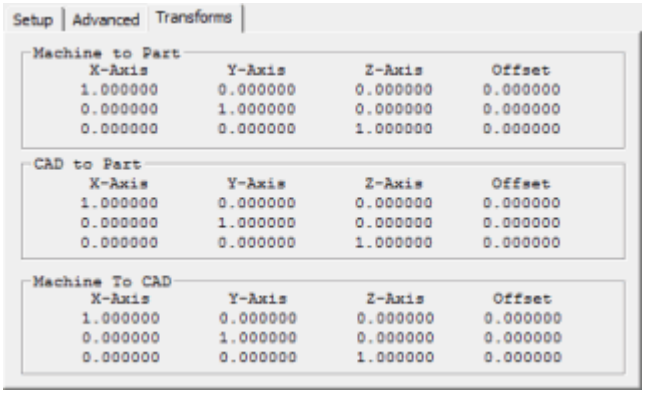
Create weights check box
If you select this check box, the software scales the values in the **Weights** column located in the **Alignment features** list by the tolerance values of the dimensions that control each feature.

If you clear this check box, the dimension tolerances are not factored into the calculation. Only the weights you defined are included.

Pause during execution check box
If you select this check box, the software causes the measurement routine to pause execution and display the **Best Fit Alignment** dialog box. This allows you to examine the magnitude of the error in the alignment solution, identify any features or scan hits that are bad, eliminate them from the alignment, recalculate, and then repeat that process until you are satisfied with the alignment. When you click **OK**, measurement routine execution resumes.

> This option is only available for portable measurement devices. For non-portable machine types, it is hidden and ignored during measurement routine execution.

Transforms Tab



Transforms Tab

The **Transforms** tab displays the alignment transforms from the most recent best fit alignment calculations. These transforms represent the cumulative state of the measurement routine up to and including this best fit alignment. The following sections are specific to this tab:

Machine to Part area - Displays the calculated Machine to Part transform values.

CAD to Part area - Displays the calculated CAD to Part transform values.

Machine to CAD area - Displays the calculated Machine to CAD transform values.

Saving an Alignment

To save the current alignment in an external file that can be recalled by a different measurement routine, select **Insert | Alignment | Save**. It also inserts a `SAVE/ALIGNMENT` command into the Edit window.

The topics presented here describe the **Save Alignment As** dialog box and how to save the alignment so that you can use it in other measurement routines.

Description

- The **Save in** list and other familiar folder controls let you navigate to the directory to which you will be saving the alignment.
- **File name** - Enables you to name the file of the alignment you are saving. By default, the file name is based off of the **Active Alignment** box when the dialog box opens.
- **Save as type** - Shows all the .aln files in the current directory. Only those files with the alignment extension (*.aln) will be shown.
- **Active Alignment** - Defines the alignment name that will be saved to the external alignment file. The alignment saved is the current (or active) alignment in use based on the current insertion point in the Edit window.
    - If the active alignment is from an `ALIGNMENT/START` command, it will display the alignment's name.
    - If it is from a `RECALL/ALIGNMENT, EXTERNAL` command, it will display the external filename without the ".aln" extension.
    - If it is from a `RECALL/ALIGNMENT, INTERNAL` command, it will display the name of the recalled internal alignment plus ':INTERNAL'.
- **Inches** or **Millimeters** - Sets the alignment to be saved with this type of measurement unit.
- **Machine to Parts** - Stores only the machines to parts transformation matrix.
- **Both** - Stores both the CAD to parts transformation matrix and the machine to parts transformation matrix.

To Save an Alignment

Note that you only need to save the alignment using the following procedure if the alignment is going to be recalled into a *different* measurement routine. All alignments are automatically saved when used within a measurement routine.

To save an alignment:

1. Select **Insert | Alignment | Save**. The **Save Alignment As** dialog appears.
2. Type an alignment name (maximum ten characters) in the **File name** box.
3. Select either the **Inches** or **Millimeters** option to save the alignment as either inches or millimeters, respectively. The default unit of measurement for any alignment will be the same unit of measurement used by the measurement routine for which the alignment was created. To use an alignment in a different measurement routine, it is not necessary that the alignment's units of measurement be saved in the units type of the new measurement routine. The alignment will automatically convert to the same units as the new measurement routine (For information on recalling an alignment, see "Recalling an Existing Alignment").
4. Select either the **Machine to Parts** or **Both** option. Select **Both** to store both the machine-to-parts and the CAD-to-parts transformation matrices. Select **Machine to Parts** to store only the machine-to-parts transformation.
5. Click the **Save** button.

You must provide a file name in order to save. The only file name extension permitted is ".aln". If you don't type a valid name for the alignment file, clicking **Save** will not close the dialog box.

The alignment can be saved to any directory. However, to use the saved alignment file in a measurement routine, it must be saved the same directory as the measurement routine or in the user-specified **Recall Directory**.

Whether you choose the **Machine to Parts** option or the **Both** option depends on the following:

- If the part alignment origin matches the CAD origin, then it is not necessary to include the CAD to Part transform. Either option will work.
- If the part alignment origin differs from the CAD origin in either location or orientation, it is necessary to include the CAD to Part transform. Choose **Both**.
- If the measurement routine does not include a CAD model, there is no need to include the CAD

The Edit window command line for this option reads:

```
SAVE /ALIGNMENT,filename, TOG1
```

TOG1

This toggle field switches between `BOTH` and `MACHINETOPARTS`. Select `BOTH` to store both the machine to parts and the CAD to parts transformation matrices. Select `MACHINETOPARTS` to store only the machine to parts transformation.

Editing the Save/Alignment Command

You can edit the `SAVE/ALIGNMENT` command by placing the mouse on the command line and pressing F9. The **Save Alignment As** dialog box opens. You can use this dialog box to edit all the settings for the alignment (file name, units, saved transformation matrix) and then save the changes as a new or existing alignment file. Once you make your changes, and click **Save**, PC-DMIS saves the alignment file and applies the changes to the Edit window's `SAVE/ALIGNMENT` command.

See the "Saving an Alignment" topic for a description of the dialog box.

Recalling an Existing Alignment

The **Insert | Alignment | Recall** menu option recalls an alignment that was previously created in the current measurement routine (Internal Alignment) or saved from another measurement routine (External Alignment). You can also recall an alignment using the **Alignments** list on the **Settings** toolbar. For information, see the "Settings Toolbar" topic.

> **!** You must save alignments (.aln) in the same folder as your measurement routine (.prg), or in a sub-folder where you saved your measurement routine. If not, you must use the **Search Path** dialog box (**Edit | Preferences | Set Search Path**) to specify where to recall your alignments.

For example, if you save your measurement routine in the "C:\Users\Public\Documents\Hexagon\PC-DMIS\2021.2" folder, and you save your alignment in "C:\Users\Public\Documents\Hexagon\PC-DMIS\2021.2\folder1\folder2", you can use this command in the Edit window to recall the alignment:

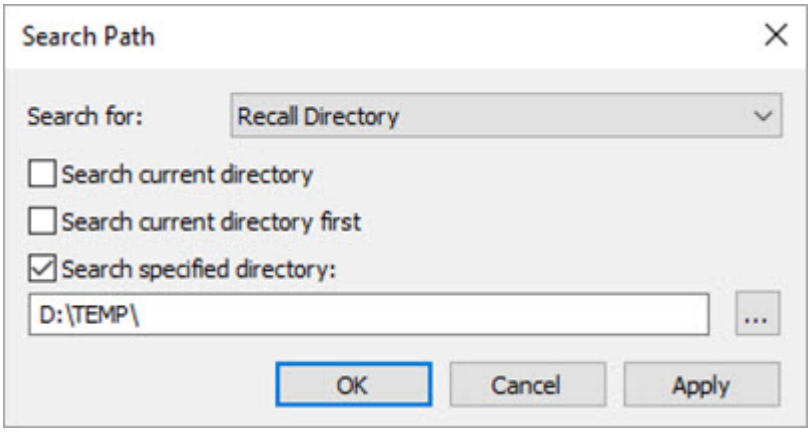
```
RECALL/ALIGNMENT,EXTERNAL,FOLDER1/FOLDER2/A1
```

However, if you save your measurement routine in a different drive, such as "D:\TEMP\folder1", you must define the recall path in the **Search Path** dialog box (**Edit | Preferences | Set Search Path**).

To do this:

1. Open the **Search Path** dialog box.
2. From the **Search for** list, select **Recall Directory**.
3. Select the **Search specified directory** check box.
4. Enter the folder location you want PC-DMIS to search in to recall your files.
5. Click **Apply** and then **OK** to set the recall location and close the **Search Path** dialog box.

For this example, the **Search Path** dialog box will look like this:



Search Path Dialog Box

You can now use this command in the Edit window to recall the alignment:

```
RECALL/ALIGNMENT,EXTERNAL,A1
```

PC-DMIS uses the path you set for the **Recall Directory** option in the **Search Path** dialog box for an A1 alignment.

Even if you save your alignment in a new sub-folder to the location you defined, PC-DMIS can locate the alignment. For example, you can create the folder "D:\TEMP\folder1". Because this is a sub-folder of the path defined in the **Search Path** dialog box, you can use this command successfully without making any further changes in the dialog box:

```
RECALL/ALIGNMENT,EXTERNAL,FOLDER1/A1
```

You can only insert the command outside an alignment block.

*The Alignment Block is the block of text in the Edit window that defines the alignment. It consists of the **ALIGNMENT/START** command and ends with the **ALIGNMENT/END** command.*

The **Recall** list in the **Alignment Utilities** dialog box (**Insert | Alignment | New**) also enables you to recall an existing alignment, but it only enables you to recall alignments previously created in that measurement routine (internal alignments).

Before an alignment can be recalled to another measurement routine, you must save it to a folder with the **Insert | Alignment | Save** menu option. For information on how to do this, see "Saving an Alignment".

If the alignment you want to recall has different units of measurement than the current measurement routine, its measurement units are automatically converted to the units of measurement of the current measurement routine.

All recall external alignment commands re-load their external alignment file when the measurement routine is first opened. During this process, if the new alignment transforms differ from the existing alignment, PC-DMIS displays a prompt asking if you want to update affected commands in the Edit window to use the new alignment. For more information, see "Updating Commands When Loading a Measurement Routine" in the "Updating Dependent Commands When the Alignment Changes" topic.

To Recall an Alignment

To recall an alignment using the **Recall** menu or **Alignment Utilities** dialog box:

1. To access the **Select Alignment** dialog box, select **Insert | Alignment | Recall**; or access the **Alignment Utilities** dialog box (**Insert | Alignment | New**) and select an alignment from the **Recall** list.
2. Type the 15 character (or less) saved alignment ID or use the list to select the desired alignment.
3. Click **OK** to insert the recall command into the Edit window (`RECALL/ALIGNMENT`).

To recall an alignment using the **Settings** toolbar (**View | Toolbar | Settings**):

1. Use the **Alignments** list in the **Settings** toolbar and select the desired alignment.
2. PC-DMIS inserts the recall command into the Edit window (`RECALL/ALIGNMENT`).

Recall Alignment Command Line Format

The Edit window command line for this option reads:

```
RECALL/ALIGNMENT, INTERNAL, 'align_id'

RECALL/ALIGNMENT, EXTERNAL, FILE_NAME
```

This command does not need to be bounded by the `ALIGNMENT/START` or `ALIGNMENT/END` commands.

Code Used to Recall an Internal Alignment

```
RECALL/ALIGNMENT, INTERNAL, 'align_id'
```

align_id

This is the internal alignment that will be recalled from within the current measurement routine.

Example:

```
RECALL/ALIGNMENT, INTERNAL, A1
```

Code Used to Recall an External Alignment

```
RECALL/ALIGNMENT, EXTERNAL, FILE_NAME
```

`FILE_NAME`

This is the file name used for the saved external alignment, minus the .aln extension. If you type a non-existent filename, PC-DMIS will display a warning message letting you know that it could not find the alignment.

Example:

```
RECALL/ALIGNMENT, EXTERNAL, FIXTURE1
```

Using an Alignment Inside Loops or Branches

PC-DMIS facilitates changing alignments inside a measurement routine that uses looping or conditional branching by using the `USE_ACTIVE_ALIGNMENT` keyword following the `RECALL:` text within your `ALIGNMENT/START` command. This keyword lets you recall the active alignment.

If you have an alignment command inside a loop, and the loop uses offsets, you *must* define all axes for that alignment. Additionally, the alignment inside the loop must use features measured inside the loop.

The `USE_ACTIVE_ALIGNMENT` keyword also displays the name of the active alignment within parentheses. So, if the active alignment was A3 during the last execution, the keyword shows the following after execution:

```
USE_ACTIVE_ALIGNMENT(A3)
```

PC-DMIS uses the active alignment name for different purposes depending on whether PC-DMIS is in learn or in execute mode.

- *In learn mode*, changing the alignment name in parentheses does not have any bearing on the actual active alignment used or displayed during execution. In learn mode this name is merely used as a tool for you to visualize different scenarios that may occur during execution. You can visualize what may occur by changing the

active alignment in parentheses and watching the trihedron move to that alignment's coordinate system in the Graphic Display window.

- *In execute mode*, PC-DMIS determines which alignment is active based on the last executed alignment. This is dependent on any branching and looping that occurred during execution. After execution, the actual alignment which was active during the last execution is displayed in parentheses.

Also, the alignment name in parentheses is now saved with the measurement routine. When opening a measurement routine created prior to PC-DMIS 2010 MR2, the information that appears in parentheses is dynamically populated by PC-DMIS as it searched for alignments above the alignment with the `USE_ACTIVE_ALIGNMENT` setting. This happens regardless of commands that may affect measurement routine flow during execution, such as looping or branching commands.

Measurement Routines that have been imported from a DMIS file into PC-DMIS do not support the functionality of showing the alignment name in parentheses, even if you save the file as a new measurement routine.

USE_ACTIVE_ALIGNMENT Example

If you look at the `ALIGNMENT/START` command line in Command Mode, you'll see that the field immediately following the `RECALL:` text tells the measurement routine to use a stored starting alignment first. In the following example, alignment D_1 starts with the alignment from D_0 and then executes a 45 degree rotation about ZPLUS:

```
D_1=ALIGNMENT/START,RECALL:D_0, LIST= YES
ALIGNMENT/ROTATE_OFFSET,45.0,ABOUT,ZPLUS
ALIGNMENT/END
```

However, if you use the `USE_ACTIVE_ALIGNMENT` keyword instead, you can cause PC-DMIS to rotate 45 degrees from the active alignment:

```
D_1=ALIGNMENT/START,RECALL:
USE_ACTIVE_ALIGNMENT(D_0), LIST= YES
ALIGNMENT/ROTATE_OFFSET,45.0,ABOUT,ZPLUS
ALIGNMENT/END
```

When you use this keyword for an alignment inside a loop:

- The *first time* through the loop the active alignment will be the last executed alignment preceding the loop.
- Additional times through the loop the active alignment will be itself and will rotate a further 45 degrees from the previous time through the loop.

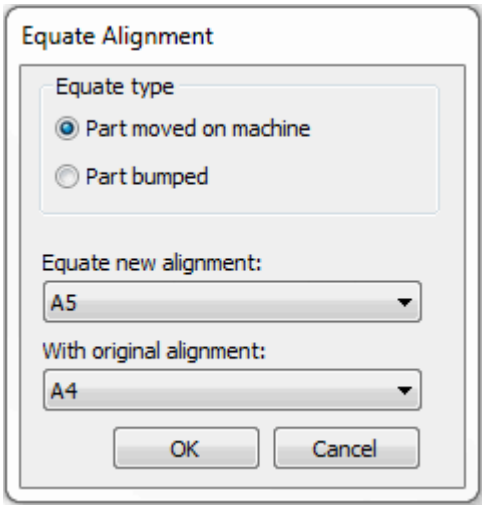
For information on looping, see the "Creating Generic Loops" topic in the "Branching by Using Flow Control" chapter.

Preferences that Affect USE_ACTIVE_ALIGNMENT

When you use the `USE_ACTIVE_ALIGNMENT` keyword, you should generally deselect the **Reset global settings when branching** check box and select the **Treat theo values as if stored in part coordinates** check box on the **General** tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**).

See the "Setting Your Preferences" chapter for information on specifying setup preferences.

Equating an Alignment

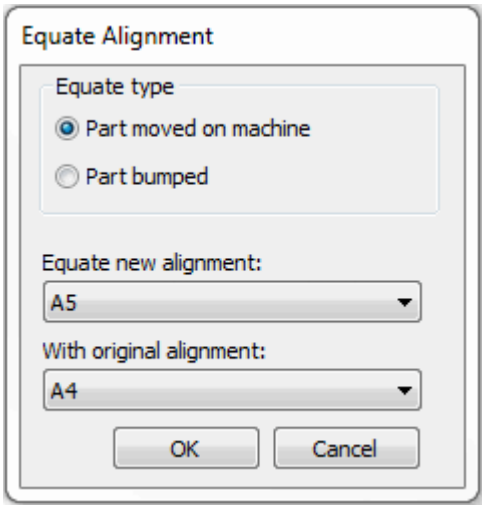


Equate Alignment Dialog Box

The **Insert | Alignment | Equate** option provides the means to:

- Change the position or orientation of a part while retaining previous dimensional information.
- Re-align the part and save previously measured data if the part is accidentally bumped or moved during the inspection process.

To Change a Part's Position and Orientation



Equate Alignment Dialog Box - Part moved on machine Option

For Equate Alignment to function properly:

- The features referenced in your new alignment must be measured after you move your part.
- Those features must reside in the measurement routine below the commands that are executed in the part's original position and orientation (including the original alignment).
- You should reference all of the features for your new alignment in a single alignment block.
- The new alignment should be fully constrained.

This command works with both regular alignment blocks (`START_ALIGN/ END_ALIGN` pairs) and external recalled alignments. The external alignment must be recalled using the `RECALL/ALIGNMENT, EXTERNAL` command before it becomes available for use in the dialog box.

Equate new alignment:

This list allows you to select the *new alignment* you are equating with your original created alignment.

With original alignment

This list allows you to select the *previously created original alignment* to which you are equating the new alignment.

For example, to measure a dimension that references features on two sides of the part that are not accessible from a single part orientation:

1. Measure the alignment features on the first side of the part.

2. Create the original (fully-constrained) alignment.
3. Measure all required features that can be reached from the first orientation of the part.
4. Move the part to its new position.
5. Switch to Manual Mode.
6. Recall the startup alignment (Machine Coordinate System).
7. From CAD or the print values, program the new alignment features in Manual Mode and in DCC Mode.

   > The origin must be the same, and the axis must be in the same direction as the axis of the alignment to which you are equating. It is easiest to understand this if you imagine that the original origin and axes' arrows are glued onto the part before moving it. The new alignment places the origin and axes' arrows in the same position with respect to the part.

8. Select the **Insert | Alignment | Equate** menu option. The **Equate Alignment** dialog box appears.
9. In the **Equate Type** area, select **Part moved on machine**. Note that when editing an existing Equate alignment command, the **Equate Type** area is disabled.
10. In the **Equate new alignment** list, select the *new alignment*.
11. In the **With original alignment** list, select the *original alignment*.
12. Click the **OK** button to insert the new `EQUATE` alignment command into the measurement routine. The CAD model won't move relative to the alignment axes, but the measured values will move once PC-DMIS executes the equate alignment.

The Edit window command line for this option reads:

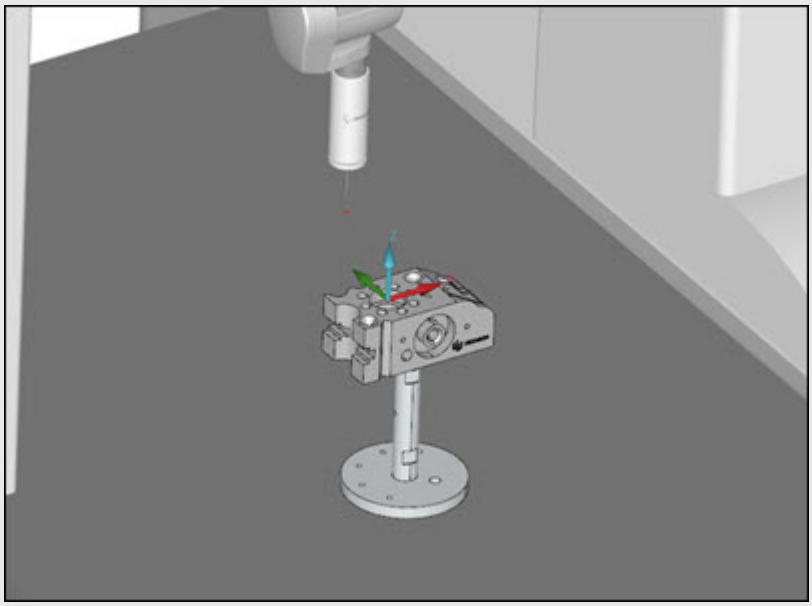
```
EQUATE/"name1"TO ALIGNMENT,"name2"
```

Note about Clearance Planes

After equating the new alignment, any existing clearance planes continue to use the same "relative" plane from the previous alignment. This means after you have moved your part, you should define new clearance planes to avoid incorrect clearance plane moves.

Example:

In this setup, we want to measure all features in the X-, X+, Y-, Y+, and Z+ planes. The features in the Z- direction are not accessible which requires a second setup.

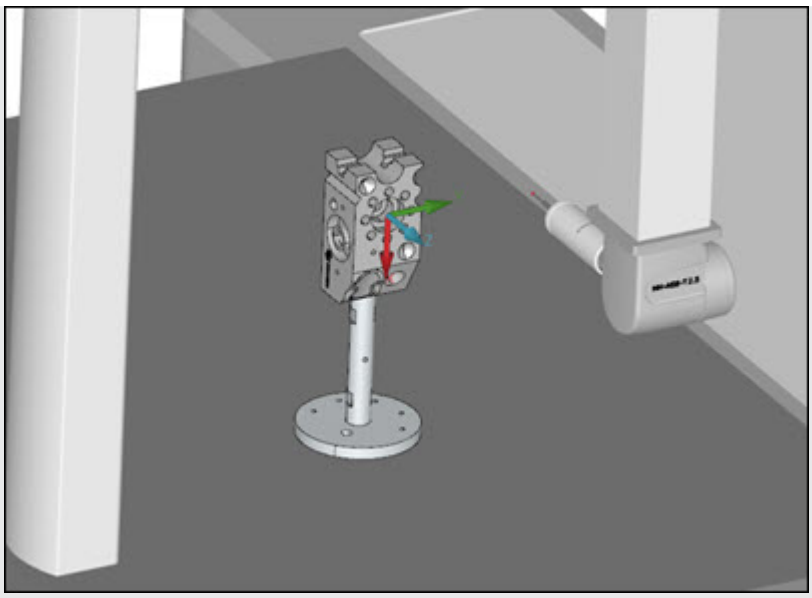


Example setup #1

1. To begin, create the measurement routine with a manual and DCC alignment, and then measure all the accessible features.
2. When you need to relocate the part, make note of the coordinate system and the orientation of the axes. You must replicate this in the second setup.

   Before you switch to the second setup, remember to switch to Manual Mode and recall the startup alignment (step 5 above).

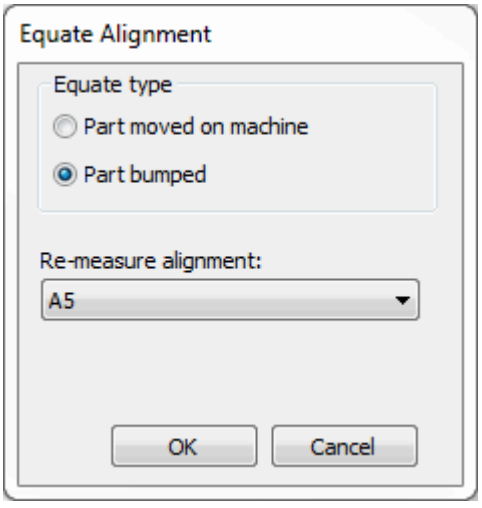
3. Add your manual and DCC alignments. For the best accuracy, take the measurements in the same location as in the first setup.
4. Measure all the features in the Z- plane.



Example setup #2

5. To relate the Z- features with the other planes, equate the alignments. For details on how to equate an alignment, see "Equating an Alignment" in the PC-DMIS Core documentation.

To Recover after Accidentally Moving a Part



Equate Alignment Dialog Box - Part bumped Option

For this operation to function properly, the alignment should be fully constrained.

This command only works with regular alignment blocks (`START_ALIGN/ END_ALIGN` pairs).

Re-measure alignment

This list allows you to select the *existing alignment* to remeasure to update all the machine coordinates of the commands in the measurement routine.

If a part has been moved accidentally, do the following:

1. Select the **Insert | Alignment | Equate** menu option to open the **Equate Alignment** dialog box.
2. In the **Equate Type** area, select **Part bumped**.
3. In the **Re-measure alignment** list, select the ID of the alignment you need to remeasure.
4. Click **OK** to begin the remeasure process.
5. Re-measure the alignment features. When this finishes, all dimensional and feature information are translated to the new position of the part. The CAD model does not move relative to the alignment axes, but the measured values are updated.

If you use this option, PC-DMIS does not insert a new command in the Edit window.

Equating CAD to Measured Part Data

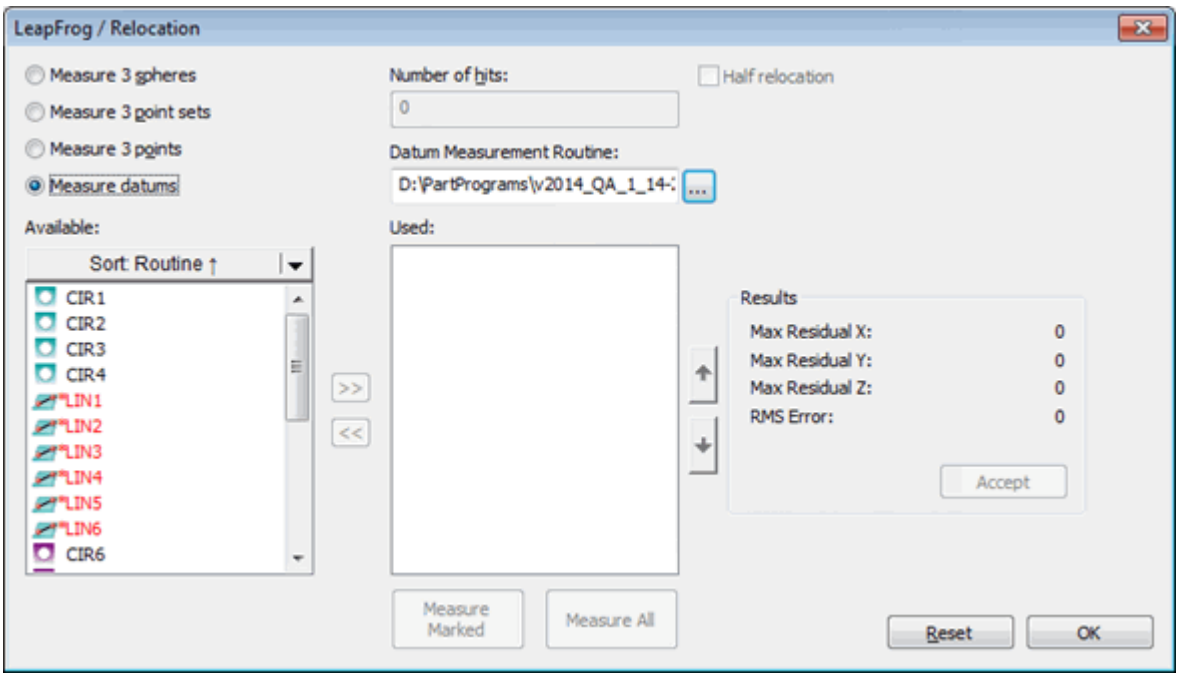
The **Operation | Graphic Display window | CAD Equals Part** menu option (or the **CAD = Part** button in the **Alignment Utilities** dialog box) links CAD data to the measured data. This option is only available after a created alignment places the part origin/orientation at the same location as the CAD origin/orientation. PC-DMIS offers the CAD EQUALS PART option in two areas (also see "CAD Equals Part" within the **Alignment** option). Select this option and PC-DMIS will display the measured data on top of the CAD data. It will use the CAD data to help inspect the part.

Once the CAD Equals Part option has been used on a measurement routine, the CAD Equals Part menu option will be selected.

Performing a Leapfrog Operation

PC-DMIS does not support Leapfrog and Bundle Alignment commands used in the same measurement routine.

Select **Insert | Alignment | Leapfrog** to display the **LeapFrog / Relocation** dialog box. This menu option is disabled in Offline mode. You must be connected to a physical and supported portable machine.



LeapFrog / Relocation Dialog Box

The **LeapFrog / Relocation** dialog box allows you to move supported portable machines in order to measure parts that are too large for your CMM. You should be aware of machine accuracy limitations before using this method.

Currently, supported machines include Faro, Romer, and Garda.

Your PC-DMIS license needs to be programmed to support your portable machine.

The basis for Leapfrog is to measure a series of features, and then after moving the machine, re-measure the same features in the same order. This creates a transformation and makes the machine behave as if it were in the same coordinate system before the move.

Prior to PC-DMIS version 4.2, Leapfrog transformation information was stored in a separate file and was thereby independent of all measurement routines. This meant the Leapfrog was still active in newly-created measurement routines and you had to remove it by clicking the **Reset** button on the **Leapfrog / Relocation** dialog box. In version 4.2 and later, however, this has changed. Leapfrog transformation information is now stored with the measurement routine that used the Leapfrog operation; you no longer have to remove the Leapfrog from new measurement routines.

PC-DMIS enters a Leapfrog command into the Edit window when you click the **Accept** button.

The command line in the Edit window is:

```
LEAPFROG/TOG1, NUM, TOG2
```

TOG1: This first parameter in the Leapfrog command is a toggle field that relates to the different types of measurement options that are available in the dialog box. These include:

1. SPHERES (**Measure 3 Spheres** option)
2. PSETS (**Measure 3 Point Sets** option)
3. POINTS (**Measure 3 Points** option)
4. DATUMS (**Measure Datums** option)

There is also an OFF value for this parameter, in which case the other two parameters do not appear. The OFF value turns off Leapfrog translation.

NUM: This second parameter in the Leapfrog command is the number of hits you want to take. This corresponds to the **Hits** box in the **LeapFrog / Relocation** dialog box.

TOG2: This last parameter in the Leapfrog command is a toggle field that you can use to switch between either a FULL or a PARTIAL Leapfrog. This parameter corresponds to the **Half relocation** option in the dialog box.

When this command executes, PC-DMIS prompts you to take your hits. After all the hits are taken, a Leapfrog translation is in effect.

Measure Options

The **Measure** options in the **LeapFrog / Relocation** dialog box (**Insert | Alignment | Leapfrog**) enable you to select the method that PC-DMIS uses to perform the translation comparison.

- The **Measure 3 Spheres** option tells PC-DMIS to use spheres as the features for translation comparison. This method uses the center of each measured sphere.
- The **Measure 3 Point Sets** option tells PC-DMIS to use the centroid of a set of points. It is recommended that you use the bottom of an inverted cone with a hard probe. This method is slightly more accurate than the spheres method and much quicker for the operator. For information on how to create point sets, see the "Creating Measured Feature Sets" topic in the "Creating Measured Features" chapter.
- The **Measure 3 Points** option tells PC-DMIS to use only three points and is the least accurate of the three methods.
- The **Measure Datums** option tells PC-DMIS to use existing datum features from a measurement routine of your choice. Because the datum features are already assumed to have been measured in your existing measurement routine, you only need to measure them after relocating your machine.

Number of Hits

The **Number of Hits** box in the **LeapFrog / Relocation** dialog box (**Insert | Alignment | Leapfrog**) enables you to specify the number of hits you wish to use for each feature. Of course, this will not be used in the point method.

Half Relocation

The **Half Relocation** check box in the **LeapFrog / Relocation** dialog box (**Insert | Alignment | Leapfrog**) lets you determine whether or not PC-DMIS performs a FULL RELOCATION (FULL LEAPFROG) operation (if not selected) or performs a PARTIAL RELOCATION (PARTIAL LEAPFROG) operation (if selected).

Relocation refers to moving the portable measuring machine to a new location.

- Doing a full relocation (clearing this check box) means you would need to measure something before you move the portable machine and then re-measure some or all of those items after moving the machine. Remeasuring allows PC-DMIS to determine the new location of the machine.
- A half relocation (selecting this check box) means you move the portable machine first and then measure the datum features.

Datum Measurement Routine

This area in the **LeapFrog / Relocation** dialog box (**Insert | Alignment | Leapfrog**) enables you to specify the measurement routine file to use as the datum program file. This box becomes enabled when you click the **Measure Datum Features** option. You can type the full pathway to the measurement routine (.PRG) file, or you can use the **Browse** button to navigate through your directory structure and select one that way.

Once you select a file, the features available for use in the Leapfrog operation appear in the **Available** list.

Available and Used Lists

The **Available** and **Used** lists in the **LeapFrog / Relocation** dialog box (**Insert | Alignment | Leapfrog**) display, respectively, datum features that are available for use or datum features that you have chosen to use in the Leapfrog operation.

Available List

When you select a measurement routine file to use in the **Datum Program File** area, the available features from that file appear in the sortable **Available** list. You can then assign features to the current Leapfrog operation by selecting them and then clicking the **>>>** button. More information on the Feature list section can be found in the

Used List

Assigned features that appear in the **Used** list will be measured when you click the **Measure Marked** or **Measure All** buttons in the order that they appear in the **Used** list. You can remove them from the **Used** list by clicking the **<<<** button. You can change a feature's order of execution by selecting a feature clicking the up or down arrow buttons.

Measure Marked

The **Measure Marked** button in the **LeapFrog / Relocation** dialog box (**Insert | Alignment | Leapfrog**) only functions when you use the **Measure datums** option. It allows you to measure any selected features from the **Used** list. PC-DMIS will use these features in the Leapfrog operation. When you click this button, PC-DMIS displays the **Execution** dialog box, prompting you to measure the selected features once you have moved the CMM, not before.

The results box will display the 3D distance between the features taken before the move and after the move of the CMM. If you find the results unsatisfactory then you may re-measure the last set of features again as the button will now read **Re-measure**.

After you move the CMM, there is not a way to revert to the previous alignment. If the Leapfrog results are unsatisfactory after the **Re-measure** process, you must reset the Leapfrog and restart the entire part inspection process by executing the measurement routine from the initial alignment. The physical limitation of using a single CMM device makes this condition possible for all relocation methods. *You should take great care during the execution of any relocation procedure.*

Measure All

Similar to Measure Marked, the **Measure All** button in the **LeapFrog / Relocation** dialog box (**Insert | Alignment | Leapfrog**) also opens the **Execution** dialog box.

- If you are using **Measure 3 Spheres**, **Measure 3 Point Sets**, or **Measure 3 Points**, then this dialog box will first prompt you to measure the three features before prompting you to move the CMM. After moving the machine, you will be prompted to re-measure the same features in the same order.
- If you are using **Measure Datums**, then the **Execution** dialog box prompts you to measure all the datum features once you have moved the CMM, not before.

The results box will display the 3D distance between the features taken before the move and after the move of the CMM. If you find the results unsatisfactory then you may re-measure the last set of features again as the button will now read **Re-measure**.

If the re-measure process proves unsatisfactory, then you must reset the leapfrog and start again from the beginning. This is a problem with all leapfrog systems and should be remembered.

Results area

The **Results** area in the **LeapFrog / Relocation** dialog box (**Insert | Alignment | Leapfrog**) shows the deviations between the machine's first position and its subsequent position(s) by displaying the 3D distance between the features taken before the move and after the move of the CMM.

Accept

Once you have a filled out the **Leapfrog / Relocation** dialog box, you must click the **Accept** button from the **Results** area before PC-DMIS uses the leapfrog transformation. Click **Accept** to add the `LEAPFROG` command to the measurement routine. If you don't click the **Accept** button but click the X in the upper-right corner or click **OK** first, the constructed leapfrog translation is lost.

Reset

The **Reset** button in the **LeapFrog / Relocation** dialog box (**Insert | Alignment | Leapfrog**) removes any translation by adding a `LEAPFROG/OFF` command into the Edit window.

OK

Clicking **OK** in the **LeapFrog / Relocation** dialog box (**Insert | Alignment | Leapfrog**) closes the dialog box. If you click this button before you click the **Accept** button, the dialog box will close without inserting the LEAPFROG command.

Changing Alignment Nominal Values

If you modify an alignment feature's theoretical values during execute mode, PC-DMIS changes the CAD to Parts alignment. This means that features in your measurement routine that come after the alignment, and are measured relative to the alignment features, shift by the amount of the changed theoretical values.

If you select the **Ignore CAD to Part** check box on the **General** tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**), the CAD to Parts alignment does not change when your alignment feature theoretical values change. PC-DMIS measures the features

below the alignment in their same position. See "Ignore CAD to Part" in the "Setting Your Preferences" chapter.

You cannot use the **Ignore CAD to Part** functionality if you use Position dimensions in your measurement routine.

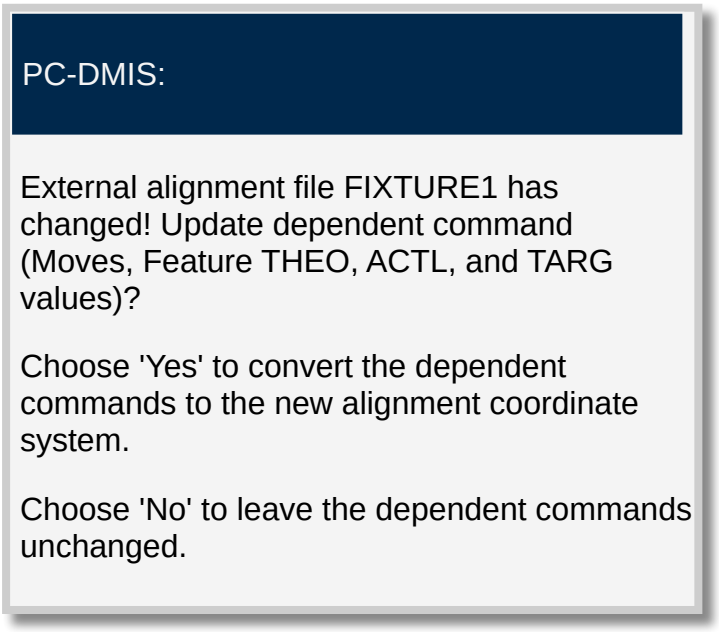
You can also control how PC-DMIS handles your features' nominal values when you update an alignment's theoretical values with the `UpdateBelowChangedAlignmentDuringExecution` entry in the PC-DMIS Settings Editor. For additional information, see the "Modifying Setting Entries" appendix.

Updating Dependent Commands When the Alignment Changes

An alignment consists of two transforms:

1. Machine origin to Part origin (termed "Machine-to-Part")
2. CAD origin to Part origin (termed "CAD-to-Part")

If you modify either of the transforms, PC-DMIS displays a Yes/No message similar to the following, letting you choose how the commands dependent on the alignment are updated:



You can choose to convert the dependent commands to the new alignment coordinate system or to leave the dependent commands unchanged.

The text in the message indicates what types of commands and command values the software updates for each alignment change.

Different commands and command values may change depending on the transform change. This table lists the commands and command values that are updated after a transform change:

	Transform Change		
	Machine-to-Part	**Cad-to-Part**	**Both**
Commands and command values that may update after a changed transform:	• Move commands • Feature command ACTL	• Feature command THEO • Feature command TARG	• Move commands • Feature command THEO • Feature command ACTL • Feature command TARG

In the following two general scenarios, you need to decide how to update the commands in the measurement routine in response to an alignment change:

1. When you load a measurement routine that recalls an external alignment file. See "Updating Commands When Loading a Measurement Routine " below.
2. When you add a new alignment or modify or delete an existing alignment while in Learn mode. See "Updating Commands While in Learn Mode" below.

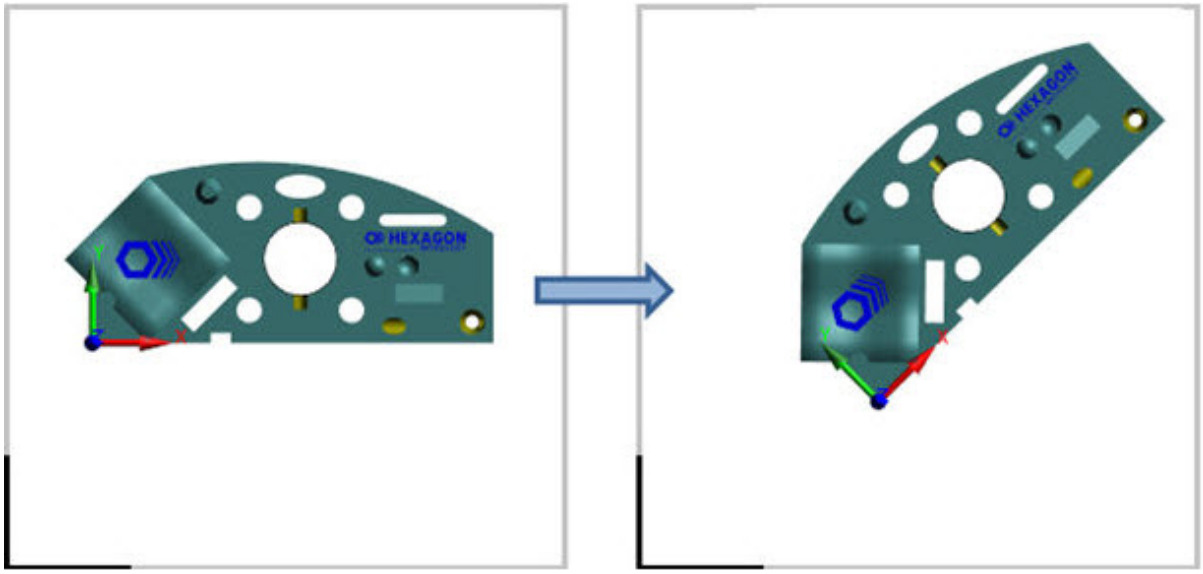
Updating Commands When Loading a Measurement Routine

A measurement routine that includes `RECALL/ALIGNMENT, EXTERNAL` commands attempts to re-load the referenced external alignment files each time the measurement routine opens.

The correct answer to the question "Update dependent commands?" depends on *why* the external alignment file has changed. Consider these reasons:

- **The Alignment file changed because you moved the part on the CMM** - In this case, the theoretical and actual values of the commands dependent on that alignment need to remain fixed, relative to the part (see the figure below). The Machine-to-Part transform is modified. It's possible that the Cad-to-Part transform is also modified, but that is not very common. Choose **No** at the Yes/No message so

the values of the dependent commands do not change. The position and orientation of the part can then change while retaining the previous dimensional information, similar to equating an alignment. *This is the most common scenario*.



Example of part movement on the CMM.

- **The Alignment file changed because you made small adjustments to the alignment to see how it affects the measured results, without actually re-measuring the part** - In this case, the values of the dependent commands must be updated to the new alignment coordinate system. The Machine-to-Part transform is modified, but the Cad-to-Part transform has not changed.

  This usually requires the `SAVE/ALIGNMENT` command be configured to only include the Machine-to-Part transform, not both transforms.

  Choose **Yes** at the Yes/No message.

- **The Alignment file changed because you moved the alignment origin to a new location on the part, but you did not move the part itself** - For example, you changed the level, rotate, and/or locate features to different features. In this case, theoretical and actual values of the commands dependent on that alignment must be updated to the new alignment coordinate system. The Cad-to-Part transform has been modified, but the Machine-to-Part transform has not changed.

  This requires the `SAVE/ALIGNMENT` command to be configured to include both transforms.

  Choose **Yes** at the Yes/No message so that the measured data does not shift away from the CAD geometry. *This is not a common scenario.*

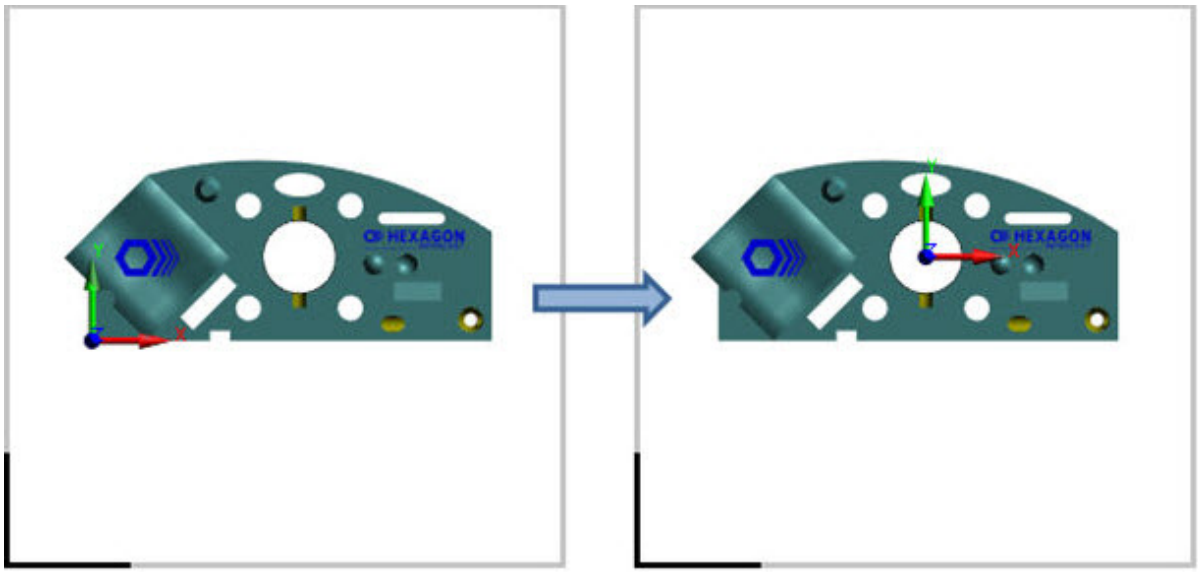
When loading a measurement routine that recalls an external alignment, if the external alignment file transforms have been modified since the measurement routine was last saved, by default, PC-DMIS does not display the dialog box, asking to update the dependent commands. Instead, it automatically answers No to that question. You can control this behavior with the `UpdateExtAlignmentDepCommandsDuringFileOpen` entry. For information on how to modify values for entries, see "Modifying Setting Entries".

Updating Commands While in Learn Mode

When you edit a measurement routine in Learn mode, if changes are made that modify or delete an existing alignment command or create a new one, PC-DMIS asks if you want to update the commands dependent on that alignment.

The correct answer to the question "Update dependent commands?" depends on why the alignment definition has changed. Consider these reasons:

- **The alignment definition changed because you moved the alignment command origin to a new location on the part** - For example, you changed the level, rotate, and/or locate features to different features. In this case, the theoretical and actual values of the commands dependent on that alignment command need to be updated to the new alignment coordinate system (see the figure below). Both transforms have been modified.



Example showing the alignment movement on the part.

Choose **Yes** at the Yes/No message so that the measured data does not shift away from the CAD geometry. *This is a common scenario.*

- **The alignment is from a command that recalls an external alignment (RECALL/ALIGNMENT, EXTERNAL), and you changed the file reference to a different external alignment file that represents the part at a different location on the CMM** - In this case, the theoretical and actual values of the commands dependent on the alignment remain fixed relative to the part. The Machine-to-Part transform has been modified, but the Cad-to-Part transform needs to remain the same.

Choose **No** at the Yes/No message so that the values of the dependent commands are not changed. *This is a less-common scenario*. It allows the position and orientation of the part to change while retaining the previous dimensional information, similar to equating an alignment.

Using Gages

This section of the documentation provides information on the PC-DMIS gages.

PC-DMIS gages are quick-check tools designed to measure various system and feature characteristics.

2D Radius Gage

The 2D Radius Gage function is a quick-check tool that you can use to measure the radii on a pointcloud or mesh cross section.

You can create a 2D Radius Gage graphically on a cross section in the 2D Slide Show view.

For details, see "2D Radius Gage Overview" in the PC-DMIS Laser documentation.

Caliper Gage

The Caliper is a quick-check tool that works similar to a physical caliper. It provides a local two-point size check on the Pointcloud (COP), Mesh, or COPOPER (such as the COPSELECT, COPCLEAN or COPFILTER) object. The Caliper shows the measured length along the selected axis or direction.

For details, see "Caliper Overview" in the PC-DMIS Laser documentation.

Temperature Gage

For the temperature gage, see "Temperature Gage" under Setting Your Preferences.

Thickness Gage

The Thickness Gage command calculates and reports a 2D thickness and gage position.

The Thickness Gage command requires a primary and a secondary feature since PC-DMIS determines the thickness by piercing the secondary feature normal to a primary feature gage point. When you create a Thickness Gage command, the software only shows the valid features to select from in the **Thickness Gage** dialog box.

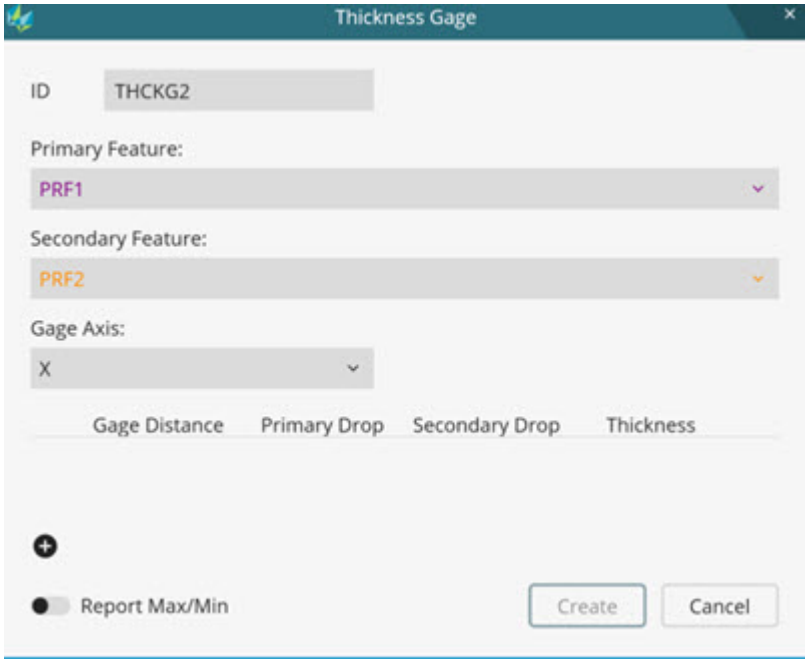
The Thickness Gage command only supports these feature types:

- Thickness Scan
- Linear Scan
- Profile 2D

You can use the Linear scan and the Profile 2D in any combination. However, you can only use the Thickness scan by itself since it contains data for two surfaces.

To create a Thickness Gage command:

1. Create your primary and secondary features.
2. Select **Insert | Gage | Thickness** to open the **Thickness Gage** dialog box.



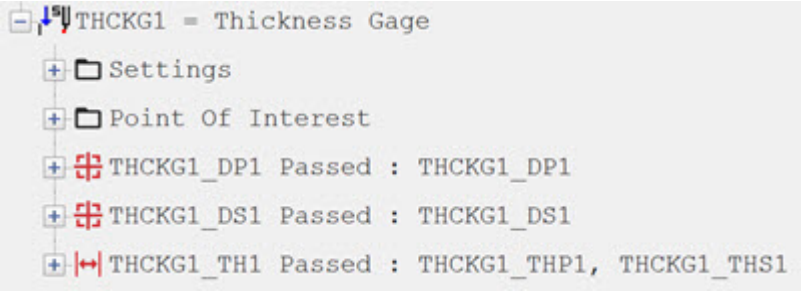
Thickness Gage Dialog Box

You can also access the **Thickness Gage** dialog box from the **QuickMeasure** toolbar (**View | Toolbars | QuickMeasure**). Click the **Gage** drop-down arrow, and then click the **Thickness Gage** button.

3. Select the primary and secondary features from the respective **Primary Feature** and **Secondary Feature** lists. The software populates the list items based on the surface or cut vector of the current alignment.
4. Select the **Gage Axis** and define your Point of Interest (POI). For details, see "Point of Interest (POI) Definition and Reporting".

5. To add the Thickness Gage to your report, click the **Report Max/Min** button.
6. Click **Create** to create the Thickness Gage.

Once you create the Thickness Gage command, the software adds the selected dimensions for the command in the Edit window:



Example of the Thickness Gage command in the Edit window

PC-DMIS considers the dimensions created by the Thickness Gage command to be internal dimensions to the command. Because of this, you cannot delete or cut and paste them in the Edit window.

You can press the F9 key while your cursor is over the internal dimension to display the **Thickness Gage** dialog box.

PC-DMIS considers the features generated by the Thickness Gage command to be internal commands. Because of this, you can use them in Alignments, Constructions, Dimensions and Assignments.

Point of Interest (POI) Definition and Reporting

Once you select the Gage Axis, you can define the Point of Interest (POI).

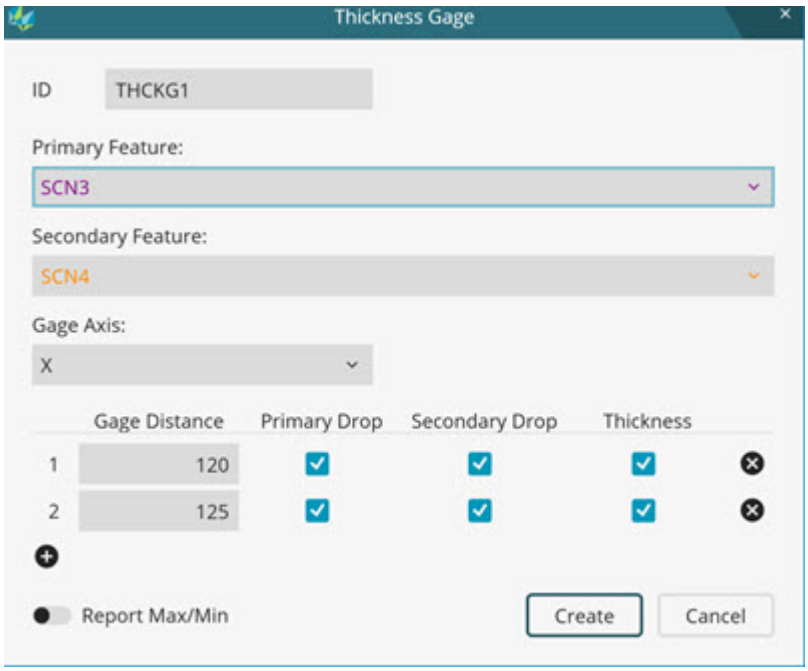
There are two methods to define the POI.

Method 1:

In the **Thickness Gage** dialog box, from the CAD View in the Graphic Display window, click the primary feature. The software completes the Gage Distance value based on the mouse-click position on the CAD.

Method 2:

In the **Thickness Gage** dialog box, click the **Add** button and then enter a value.



Once you define a POI, PC-DMIS creates these commands:

THCKG1_DP1 (Drop Point Primary) - This is the nominal pierce value and the actual primary curve value at the Gage Distance.

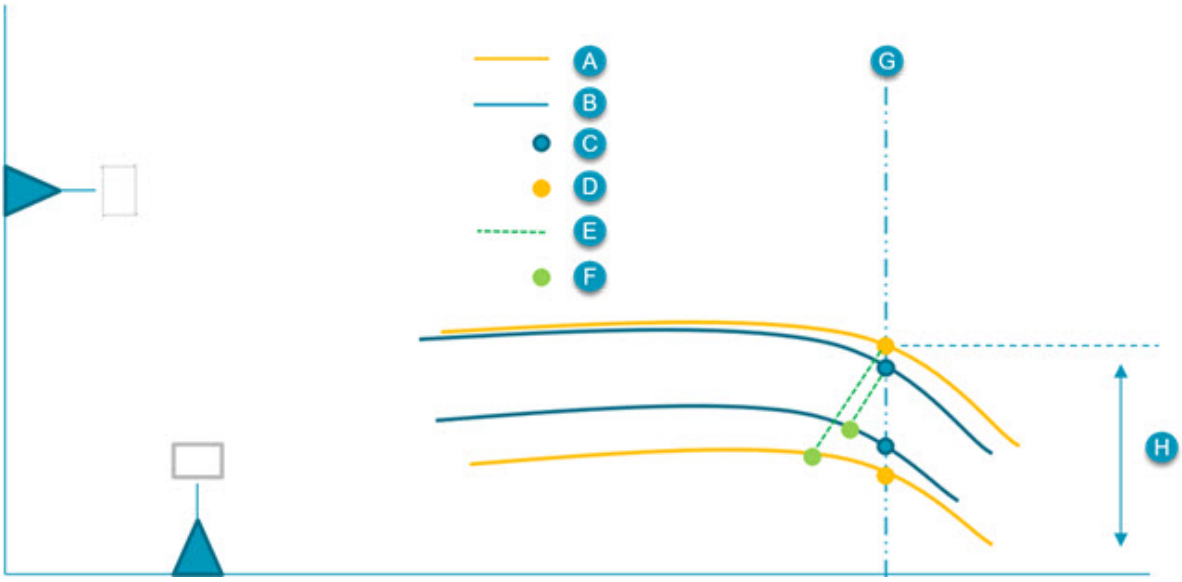
THCKG1_DS1 (Drop Point Secondary) - This is the nominal pierce value and actual secondary curve value at the Gage Distance.

THCKG1_THP1 (Thickness Point of THCKG1_DP1) - This is a duplicate point of THCKG1_DP1.

THCKG1_THS1 (Thickness Point Secondary) - This is the nominal pierce value and actual secondary curve value normal to THCKG1_THP1.

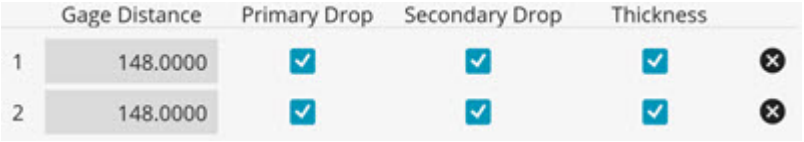
To report the thickness and gage position, the Thickness Gage command uses a Gage Axis method:

- If the input features are in the XY plane (Z is constant), the Gage Axis option is XY.
- If the input features are in the YZ plane (X is constant), the Gage Axis option is YZ.
- If the input features are in the XZ plane (Y is constant), the Gage Axis option is XZ.

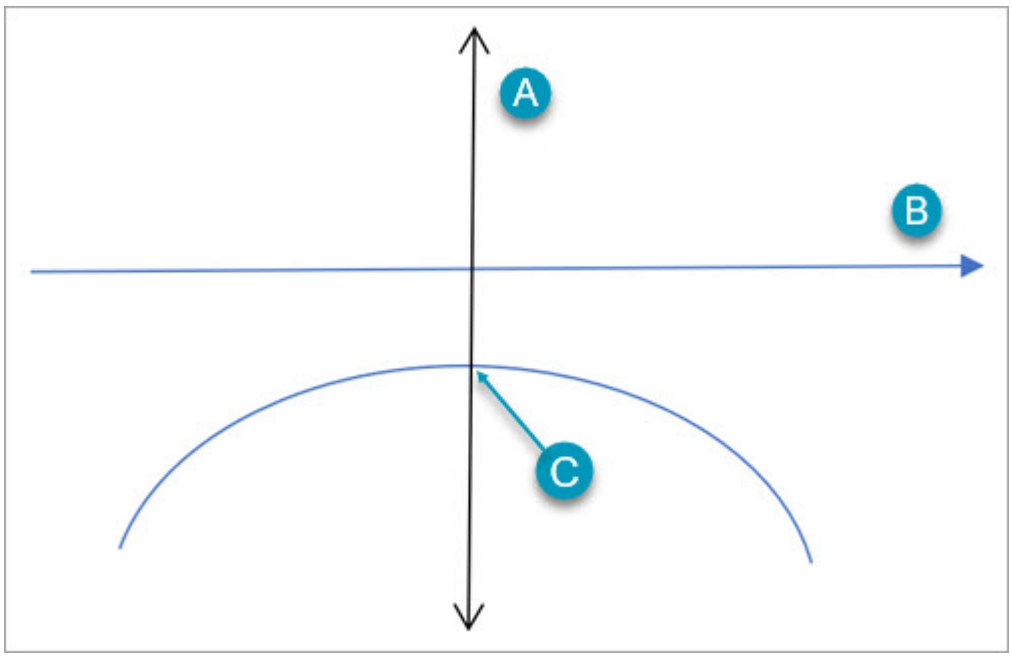


A - Actual
B - Nominal
C - Nominal Drop Point XYZIJK
D - Actual Drop Point XYZIJK
E - Normal to Top Curve
F - Thickness Point XYZIJK
G - Gage Distance
H - Drop

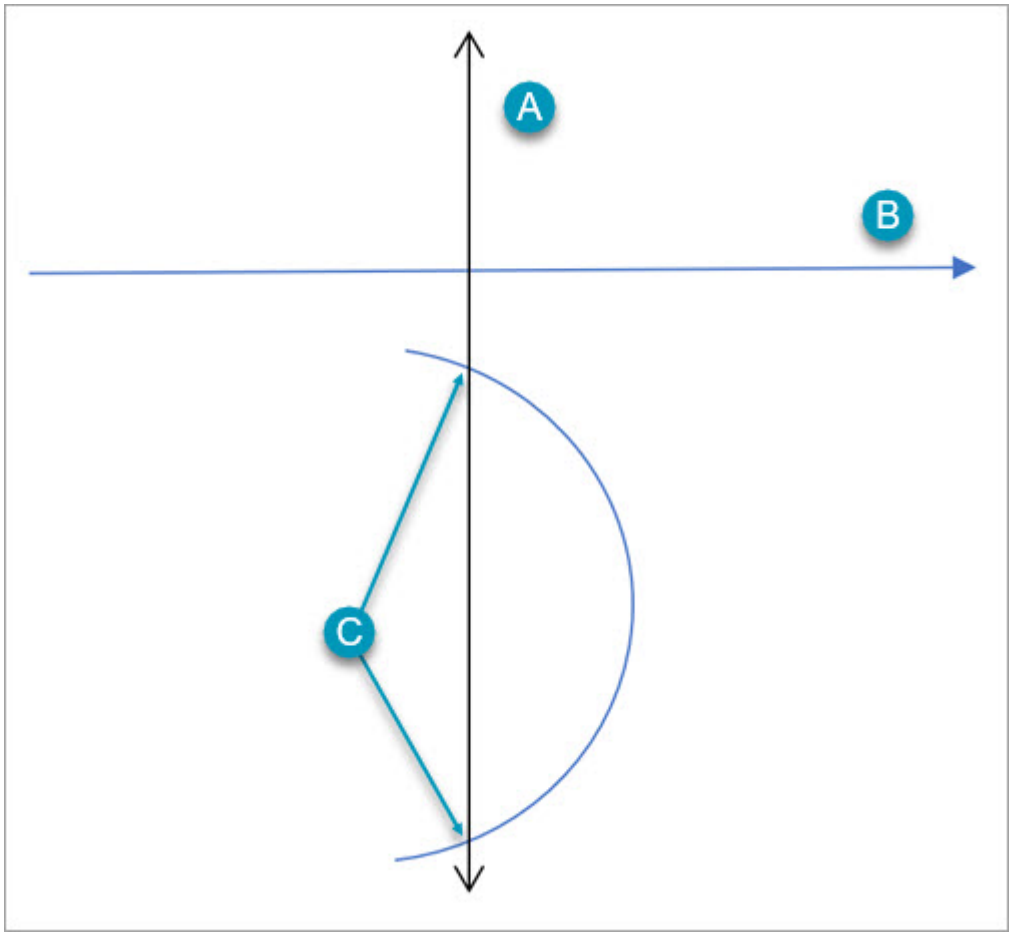
You can determine which dimensions to report with the **Primary Drop**, **Secondary Drop**, and **Thickness** check boxes.



You must use simple curves to create a POI. A simple curve is a curve that has only one intersection along any line normal to the gage axis as shown here:



A - Vector normal to the gage axis
B - Gage Axis
C - Single intersection point along the line normal to the gage axis
Example of a simple curve



A - Vector normal to the gage axis
B - Gage Axis
C - Multiple intersection points along the line normal to the gage axis

Example of a non-simple curve

When you manually enter the gage distance value or click the CAD to create a POI, if the primary or secondary curve is not simple, PC-DMIS displays an error message and does not create a POI.

PC-DMIS

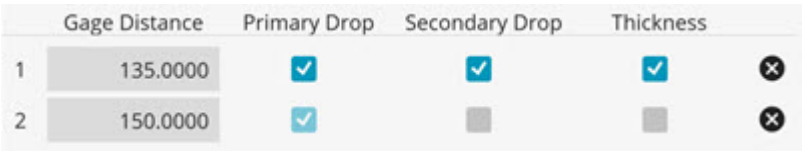
The features and gage axis represents an unsupported shape. Features with curves which have multiple intersections along any line normal to the gage axis are not supported.

The primary curve nominal data must also be smooth relative to the thickness. When you enter the **Gage Distance** value, or click the CAD to create a POI, if the primary curve is not smooth enough, PC-DMIS displays an error message and does not create a POI.

PC-DMIS

The nominals are not smooth enough to calculate thickness curve.

If a Drop Point or Thickness Point cannot be found on the secondary curve, the software disables the relevant options in the **Thickness Gage** dialog box.



If PC-DMIS cannot detect a POI, it displays this message:

PC-DMIS

No point of interest found at this gage distance.

You can add the maximum and minimum thickness values between the primary and secondary features into your report.

Using Legacy Dimensions

Using Legacy Dimensions: Introduction

Once you measure or construct your features, you can generate the inspection report. The first step in preparing a report is to calculate dimensions according to specific requirements. While this chapter covers PC-DMIS's legacy dimensions, understanding the information here may help you to create the newer Geometric Tolerance dimensions discussed in the "Using Geometric Tolerances" chapter.

You can calculate dimensions immediately after you complete a measurement or later in the measurement routine. PC-DMIS displays the result of each dimensioning operation in the Report window.

See the "Printing Dimensions to the Inspection Report" section of the PC-DMIS Core documentation for general information on how to modify the Edit window report.

PC-DMIS also allows you to specify nominal values, modify the output format, and/or print out the results of the calculations.

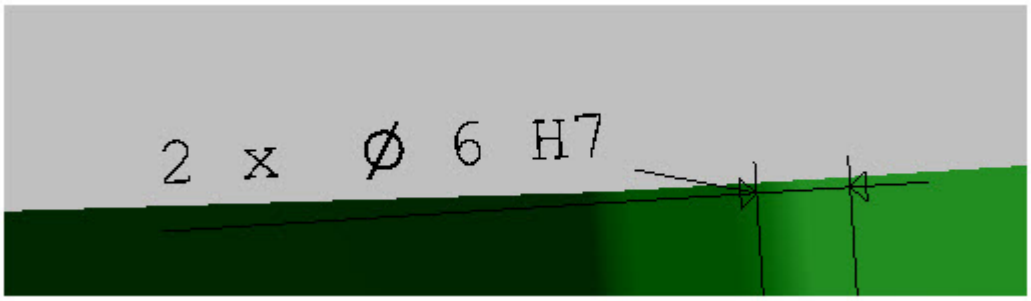
- To change the nominal or tolerance values displayed in the Edit window, click on the value to be changed and type in a new one.
- To show or hide nominals or tolerance fields in the Edit window, change the selected check boxes in the **Dimension Output Format** area of the **Dimension** tab in the **Parameters** dialog box (**Edit | Preferences | Parameters**). See the "Parameter Settings: Dimension tab" topic in the "Setting your Preferences" chapter.
- To change the measured values of a feature (for example, to get the radius of a circle to print out), see the "Modifying Report and Motion Parameters" topic in the "Setting your Preferences" chapter.

To dimension a feature, select the **Insert | Dimension** submenu from the menu bar, or access the **Dimension** toolbar and then select the desired dimension. This chapter covers the legacy dimensions found in the **Dimension** submenu.

You can toggle between using legacy dimensions and the newer Geometric Tolerance commands from the **Insert | Dimension | Use Legacy Dimensions** menu.

ISO Dimension Tolerances

ISO tolerances have an alphanumeric label instead of normal plus and minus tolerance values. The labels appear as "H7", "h7", or "G9", for example, as shown below.



Example of ISO tolerances in a PC-DMIS graphic

The following is based on the ISO Standard 286-1, ISO system of limits and fits.

The letter ("H", "h", "g", etc.) indicates the tolerance class. It is case-sensitive: capital letters indicate holes or other internal shapes, while lower-case letters indicate stems or other external shapes.

The number indicates the grade of the tolerance.

For more detailed information on ISO dimension and tolerance standards, visit the ISO website.

Reporting Dimensions for Measured Points

PC-DMIS has a flag in the basic hit now that stores whether the probe has a shank vector. If it does not, then all three axes are displayed rather than just one. This value is also serialized because when a measurement routine is read in, global_active_probe is not valid and the flag using that mechanism cannot be checked or set.

Dimension Command Format

All dimensioned features appear in the following format. There will be slight variations that are explained more thoroughly in the following sections.

PC-DMIS displays dimensions that aren't linked to any features with the color you have defined for out-of-tolerance text.

For example, the Edit window displays dimensions as:

```
 dimension_name = TYPE OF DIMENSION,feat_1 UNITS=IN,$
GRAPH=OFF TEXT=OFF MULT=1.00 OUTPUT=BOTH
```

AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
x	8.0000	0.1000	0.1000	8.0000	8.5000	7.5000	0.0000	0.0000
y	3.0000	0.1000	0.1000	3.0000	3.5000	2.5000	0.0000	0.0000
z	0.4947	0.1000	0.1000	0.4947	0.1428	0.8466	0.0000	0.0000
d	1.0000	0.1000	0.1000	1.0000	1.0000	1.0000	0.0000	0.0000
v	0.0000	0.5938	0.8046	-	-	-	-	-

```
END OF DIMENSION dimension_name (for LOCATION only)
```

See "Conventions" for field rules.

TYPE OF DIMENSION: denotes the dimension type. This field cannot be changed except by changing the name of the feature.

feat_1: name of feature to be dimensioned. This is a user editable field.

All nominal and tolerance values in a dimension are editable. To edit the nominal and tolerance values:

1. Move to the desired cell by pressing the TAB key, or double-click on the field using the left mouse button.
2. Type in the desired value.
3. Press the TAB key again or click outside of the dimension.

Press the ENTER key to add a line. (See "Dimensioning Location".)

Adding Lines

To create an additional line within the location dimension, do the following:

1. Place the cursor in the desired location.
2. Press the Enter key.
3. Type in the desired axis (X, Y, Z, D, R, A, V, T, L, S, H, M, PR, PA, PD).
4. Press the Tab or Enter key.

PC-DMIS then displays the values for the added axis. PC-DMIS adds the new line depending on where the cursor is located. If the cursor is in the middle of a command, a new line is created below the current line. If the cursor is placed at the beginning of a command line**,** PC-DMIS creates the new line above the current cursor position.

Deleting Lines

To delete a single axis within a location dimension, highlight the desired axis and then press the Backspace or Delete key. (See "Command Mode Keyboard Functions" in the "Using the Edit Window" chapter.)

Editing Lines

When the *tolerances* of a dimension are edited in the Edit window, a dialog box appears asking if you want to carry the changed tolerances forward to any of the same dimension types. If the response is Yes, PC-DMIS will search from that point forward in the measurement routine to copy the tolerances into any dimensions that were of the same type and had the same original tolerances.

When the *nominals* of a dimension are edited in the Edit window, a dialog box appears asking if you also want to carry the changed nominals back to the dimension’s feature. If the response is **Yes**, PC-DMIS will change the feature nominals to the new nominal values.

Conventions

The **Dimension** tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**) enables you to define parameters for the displayed dimensions.

- All angles can be represented 1-5 places to the right of the decimal. The actual number displayed is determined by the parameters set in the **Dimension** tab.
- All lengths, distances (x_cord, y_cord, z_cord, diam, height, length, etc.), and vectors (i_vec, j_vec, k_vec) in the dimensions are represented 1-5 places to the right of the decimal. The actual nominal that will be displayed is determined by the parameters set in the **Dimension** tab.

For information on the **Dimension** tab, see the "Setup Options: Dimension tab" topic in the "Setting your Preferences" chapter.

Accessing the Dialog Box

To access the corresponding dimension dialog box from which an Edit window's dimension was created:

1. Make sure the Edit window is open (**View | Edit Window)**.

2. In the Edit window, click on the dimension.
3. Press F9 to show the dimension dialog box for that dimension.

With this dialog box, you can make any desired changes to the existing dimension. When you click the **Create** button, PC-DMIS then applies the changes to the command in the Edit window.

Printing Dimensions to the Inspection Report

You can easily generate dimensions inside the Edit window, which, in turn, will generate these dimensions inside your inspection report.

To Automatically Create Dimensions in the Edit Window

To have PC-DMIS automatically create dimensions in the Edit window:

1. Access the Edit window (**View | Edit Window**).
2. Place the cursor where you want the dimension information to appear.
3. Type the appropriate keyword.

   OR

1. Select **Edit | Preferences | Setup** to access the **Setup Options** dialog box.
2. Select the **Dimension** tab.
3. Select the **Auto Create Dimension** option.
4. Select any other options.
5. Click the **OK** button.

The next time you measure a feature an automatic dimension will be created and inserted into the Edit window.

To Modify the Dimension Prior to Printing

In many cases, you must modify the nominals, tolerances, or output format before you print the results.

To change the nominals or tolerances from the Edit window:

1. Access the Edit window and place it in Command Mode (**View | Edit Window**).

2. Click on the dimension in the Edit window.
3. Press the Tab key to move to the value you want to change.
4. Type a new value.

To edit the nominals or tolerances using the dimension's dialog box:

1. Click on the dimension in the Edit window.
2. Press F9 to access its dialog box.
3. Change the necessary values.
4. Click the **Create** button.

To change the contents of the dimension report, access the **Dimension** tab in the **Parameter Settings** dialog box (**Edit | Preferences | Parameters**) (see "Parameter Settings: Dimension tab" in the "Setting your Preferences" chapter) and modify the dimension information that PC-DMIS should display.

The "Analysis Settings" section of each dimension's dialog box enables you to display the dimension printout in a format suitable for close examination.

Displaying Dimensions in RTF and PDF Files

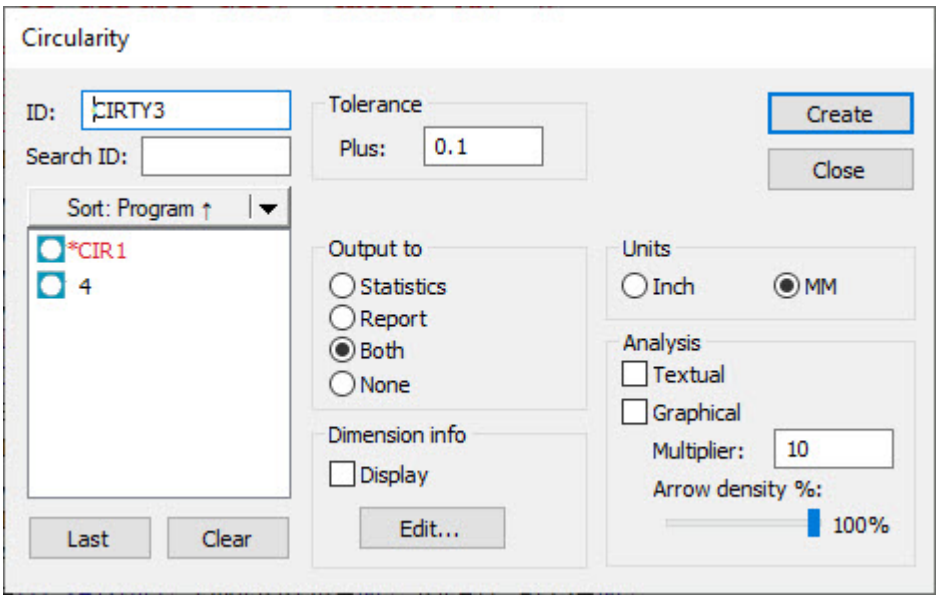
You can send the inspection report with its dimensions to an external RTF (Rich Text Format) or PDF (Portable Document Format) file by selecting the output options in the **Output Configuration** dialog box (**File | Printing | Report Window Print**) for the Edit window. See "Printing from the Inspection Report" in the "Using Basic File Options" chapter.

Be aware that because of formatting limitations between the RTF and PDF outputs, dimensions are displayed somewhat differently in the two files.

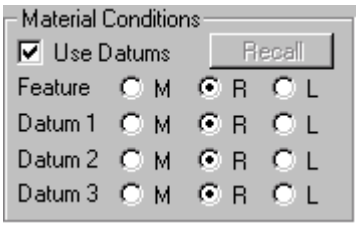
- *In RTF files*, dimensions are printed with a light border around the header, a blue background color, and the dimension symbol.
- *In PDF files*, dimensions are printed without a border, there is no background color, and no dimension symbol. Dimensions are printed with a left margin.

Common Dimension Dialog Box Options

Several dialog box options are common to many of the **Dimension** dialog boxes (**Insert | Dimension**).



Material Conditions



The **Material Conditions** area for a dimensioned feature (**Insert | Dimension**) contains the following tolerancing methods:

Option Button	Stands for	Description
M	MMC	Maximum material condition applied to either the feature or a datum.
R	RFS	Regardless of feature size applied to either the feature or a datum.
L	LMC	Least material condition applied to either the feature or a datum.

You can select material condition modifiers for Position, Parallelism, and Perpendicularity dimensions.

Be aware that for position dimensions, selecting the **Use Datums** check box causes the XYZ output values to use the alignment of the datums.

Recall Button

The **Recall** button in the **Material Conditions** area for a dimensioned feature (**Insert | Dimension**) enables you to select the same datums used in a previous similar dimension. This button remains unavailable for selection until you select a feature to dimension from the Feature list.

For example, suppose you used four circles, as your datums in a previous Position dimension. You can tell PC-DMIS to use these same circles as your features by selecting the feature to dimension from the **Feature** list, and clicking the **Recall** button. PC-DMIS will then select the datums from the **Feature** list.

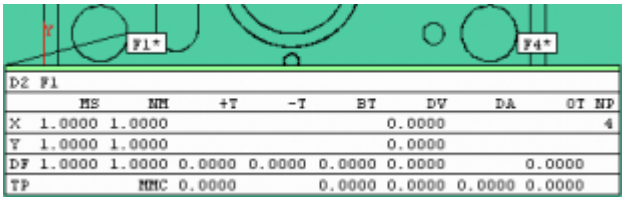
Display Dimension Information

The **Display** check box for a dimensioned feature (**Insert | Dimension**) creates a DIMINFO command in the Edit window after the dimension. This command will show all dimension information in the Graphic Display window next to the feature selected in the **Feature List** box. This DIMINFO command will also display the same dimension axes that are available in the Edit window for that particular dimension.

To use the **Display** option:

1. Select the **Display** check box.
2. Select the feature to dimension.
3. Click the **Create** button.

Dimension information then appears in the Graphic Display window.

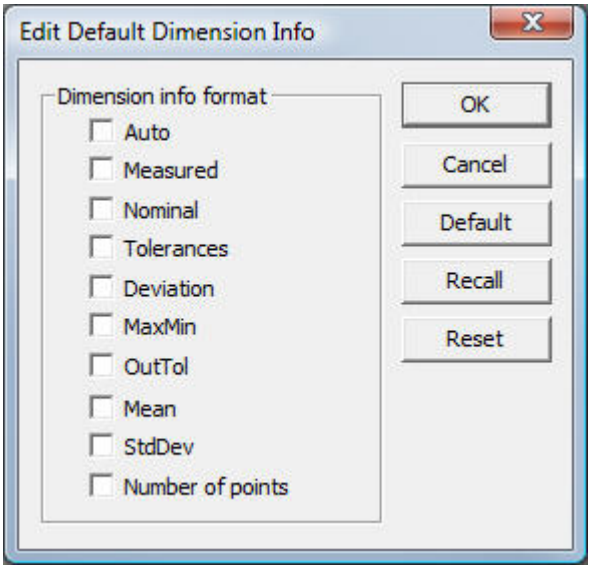


Example of the dimensional data in the Graphic Display window.

For more in-depth information on DIMINFO boxes and on rules that govern their creation, see "Inserting Dimension Info Boxes" in the "Inserting Report Commands" chapter.

Edit Default Dimension Info

The **Edit** button for a dimensioned feature (**Insert | Dimension**) displays the **Edit Default Dimension Info** dialog box.



Edit Default Dimension Info Dialog Box

These check boxes determine the type of information to display in the Graphic Display window for each dimension. The available check boxes are:

Auto
This check box automatically displays the following information: Measured, Nominal, Tolerances, Deviation, MaxMin, OutTol.

Measured
This check box displays the actual measured dimensions.

Nominal
This check box displays the theoretical values for the dimension.

Tolerances
This check box displays the acceptable tolerance levels either greater than or less than the nominal.

Deviation
This check box displays the deviation of the measured value from the nominal.

MaxMin
This check box displays the maximum and minimum deviation values from the points that make up the dimension. While can mark this for any dimension, it only makes sense for Line Profile and Surface Profile dimensions. For an example of this, see

the "Parameter Settings: Dimension tab" topic of the "Setting Your Preferences" chapter.

OutTol
This check box displays how far out of tolerance the measured value is from the nominal and tolerance values.

Mean
This check box displays the average of all the deviations for the dimension.

StdDev
This check box displays the standard deviation of all the deviations for the dimension

Number of Points
This check box displays the number of points used to measure the feature of the dimension.

For more in depth information on editing dimensions and on rules governing their creation, see "Inserting Dimension Info Boxes" in the "Inserting Report Commands" chapter. The following five buttons: **OK**, **Cancel**, **Default**, **Recall,** and **Reset** all deal with the **Edit Default Dimension Info** dialog box.

Reset Button

The **Reset** button for a dimensioned feature clears any selected check boxes in the **Edit Default Dimension Info** dialog box (**Insert | Dimension | Edit** button) and selects the **Auto** check box.

The **Reset** button completes the descriptions of the buttons found in the **Edit Default Dimension Info** dialog box. The following buttons and sections finish describing other common functions found among the various dimension dialog boxes.

Units

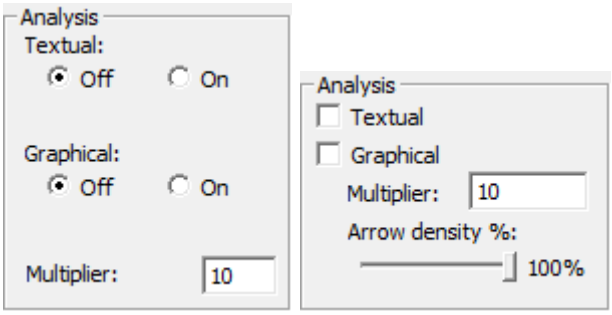
The **Units** area for a dimensioned feature (**Insert | Dimension**) enables you to choose between the following two options:

- Inch = Inches
- MM = Millimeters

When you create a dimension (either legacy or Geometric Tolerance) for the first time, PC-DMIS uses the measurement unit of the current measurement routine. Thereafter, PC-

DMIS recalls what you selected on your last created dimension when you next open a dimension or the **Geometric Tolerance** dialog box.

Analysis Settings



Analysis area for Location and Position dimensions (left) and all other dimensions (right).

The **Analysis** area for a dimensioned feature (**Insert | Dimension**) enables you to set the dimensional output analysis format to textual, graphical, or both when viewing a dimension's deviations.

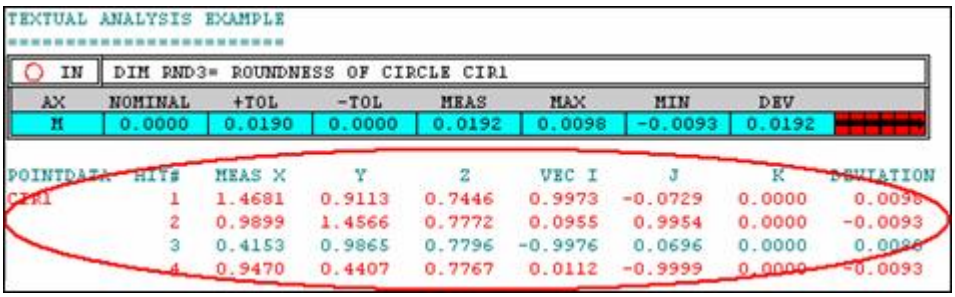
Unique to Location and Position dimensions, the **Analysis** area allows you to analyze not only a feature's location, but a feature's *form* as well.

> Use caution when interpreting a Location or Position dimension's graphical data along with its integrated form dimension. Analysis tolerance lines sometimes overlap, which makes it difficult to distinguish them.

Textual

When you select the **Textual** check box (or the **On** option for Location and Position dimensions) for a dimensioned feature (**Insert | Dimension**), PC-DMIS will print out the following in the inspection report for each individual hit used in the dimension:

- Measured X, Y, and Z values
- Measured I, J, and K values
- Deviation of each individual hit
- "MAX" or "MIN" marker at the end of the line whenever the hit produces either a maximum or minimum deviation.



TEXTUAL ANALYSIS EXAMPLE

IN | DIM RND3= ROUNDNESS OF CIRCLE CIR1

AX	NOMINAL	+TOL	-TOL	MEAS	MAX	MIN	DEV
M	0.0000	0.0190	0.0000	0.0192	0.0098	-0.0093	0.0192

POINTDATA	HIT#	MEAS X	Y	Z	VEC I	J	K	DEVIATION
CIR1	1	1.4681	0.9113	0.7446	0.9973	-0.0729	0.0000	0.0098
	2	0.9899	1.4566	0.7772	0.0955	0.9954	0.0000	-0.0093
	3	0.4153	0.9865	0.7796	-0.9976	0.0696	0.0000	0.0086
	4	0.9470	0.4407	0.7767	0.0112	-0.9999	0.0000	-0.0093

Example of a textual analysis report.

Graphical

When you select the **Graphical** check box (or the **On** option for Location and Position dimensions) for a dimensioned feature (**Insert | Dimension**), the software provides a graphical view of the dimension in the Graphic Display window.

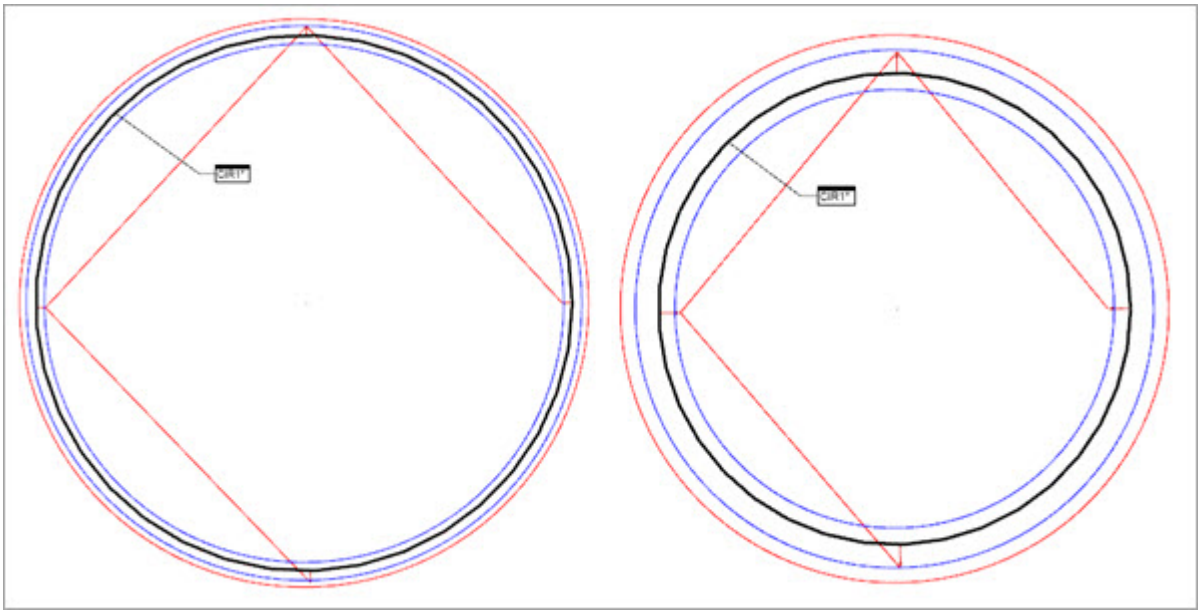
In that window, PC-DMIS displays the deviation of each dimension's individual probe hit as individual-colored arrows. These arrows, with their colors and directions, indicate the relative size of the deviation, as well as its direction.

For the Position, Concentricity, and Coaxiality dimensions, PC-DMIS shows the position of a feature with one or more arrows. For Symmetry dimensions of width features, PC-DMIS shows the points that make up the center plane.

Command line in the Edit window:

```
...GRAPH=BOTH TEXT=OFF MULT=10.00
```

Consider this example:



Example of a Location Dimension using Graphical Analysis with a multiplier of 10 (on the left) and 25 (on the right)

The Location example above contains various colored lines, arrows, and circles. The following items describe the colored elements in the example and what they mean:

Black Circle = Shows the nominal circle.

Red Circle = Shows the measured, out-of-tolerance circle.

Blue Circles = Show the tolerance bands.

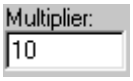
Colored Lines = Show the lines between hits.

Colored Arrows = Show the hits themselves (the tip of the arrow), the relative size of the deviation for each hit (by the colored arrow), and in the deviation direction (the direction the arrow points).

The colors from the example above are the default dimension colors. They correspond to the colors on the Dimension Colors window. For information, see "Editing Dimension Colors" in the "Editing the CAD Display" chapter.

For information on using the **Textual** check box to display dimension information for textual analysis, see the example in the "Textual" topic.

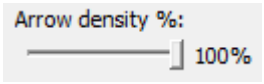
Multiplier



The **Multiplier** box for a dimensioned feature (**Insert | Dimension**) is a scaling factor that magnifies the deviation arrows and tolerance zone by the value typed for the graphical analysis mode. If you type a 2.0 value, PC-DMIS will scale the arrows two times the calculated deviation for each feature hit.

This changes the arrow's size for viewing purposes only. It does not affect the size of the deviation in the text printout in any way.

Arrow Density



This option for a dimensioned feature (**Insert | Dimension**) lets you set the percentage of dimension arrows, representing individual points, that are displayed in the Graphic Display window when graphical analysis is used on a dimension. This limits the amount of arrows drawn for these supported legacy dimensions: circularity, cylindricity, flatness, straightness, profile, and runout.

Both Option (for Position and Location)

- **Textual**: Selecting **Both** for a dimensioned feature (**Insert | Dimension**) displays deviations for both the location *and the form* axes in the inspection report.
- **Graphical:** Selecting **Both** displays tolerancing lines for both a feature's location dimension *and the integrated form dimension*, possibly overlapping one another.

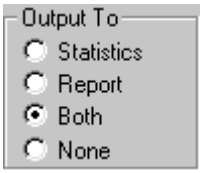
Form Option (for Position and Location)

With the **Form** option for a dimensioned feature (**Insert | Dimension**), you can analyze dimensional information for a feature's location *and* a feature's form at the same time.

You must select the **Form** check box in the **Axes** area of the dialog box to use the **Analysis** area to report on a feature's form. See "Default Axes" for additional information.

Selecting **Form** acts as if you automatically selected the **Both** option as well, since *both* a graphical and a textual analysis are generated.

Output To



Dimension output for a dimensioned feature (**Insert | Dimension**) can be printed to either the inspection report or to statistical files used by statistics software, to both of these, or to none at all. This is controlled through the **Output To** area of the dialog box, which contains these options:

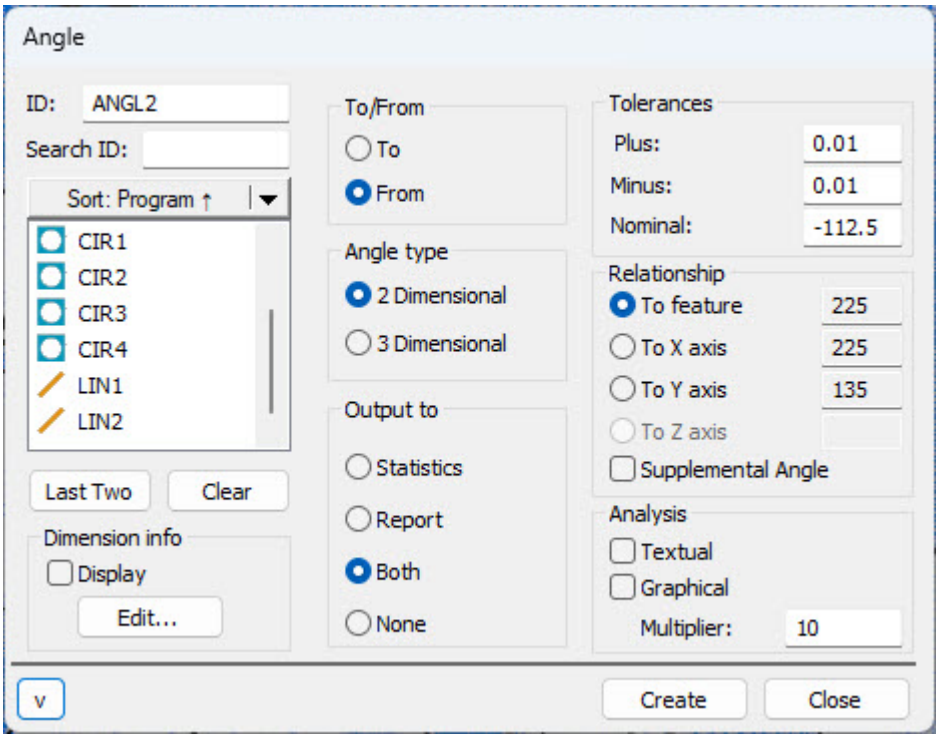
- **Statistics** - sends output to statistical files
- **Report** - sends output to inspection report
- **Both** - sends output to both inspection report and statistical files
- **None** - doesn't send dimension output anywhere

Upon the dimension's execution, the output will go to the inspection report, the stats file, both of these, or none of them (depending on the selection).

Note that if either the **Stats** option or the **Both** option is selected, a preceding `STATS/ON` command must exist inside the Edit window for this dimension to be sent to the stats file.

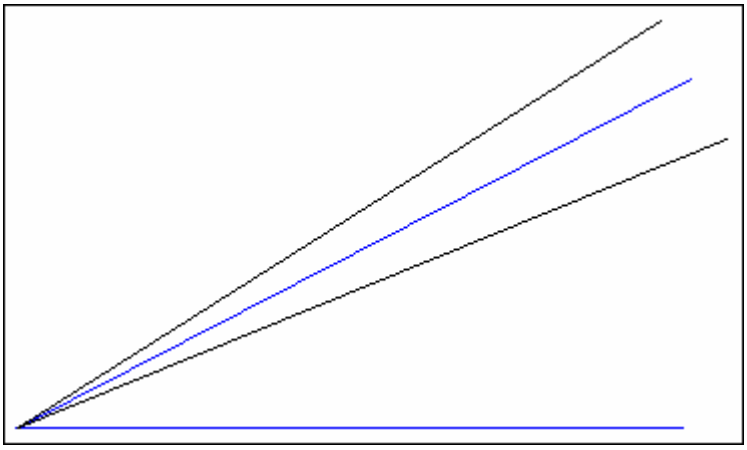
Dimensioning Angle

If you load a measurement routine from PC-DMIS version 3.7 or earlier, PC-DMIS displays a message to inform you that the way Angle dimensions were calculated has changed and that all Angle dimensions in the measurement routine were updated.



Dimension Angle Dialog Box

The **Insert | Dimension | Angle** menu option calculates the angle between a selected feature and either a second selected feature or a coordinate axis.



Example showing the measured angle (blue) and the angularity tolerance band (black).

For a 2D angle type, PC-DMIS projects the vectors onto the current workplane. It calculates the angle from the first feature to the second feature or axis.

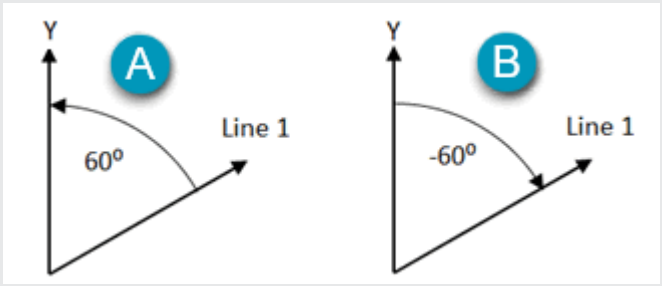
PC-DMIS gives a positive angle if it calculates the angle in a counterclockwise direction. It gives a negative angle if it calculates the angle in a clockwise direction.

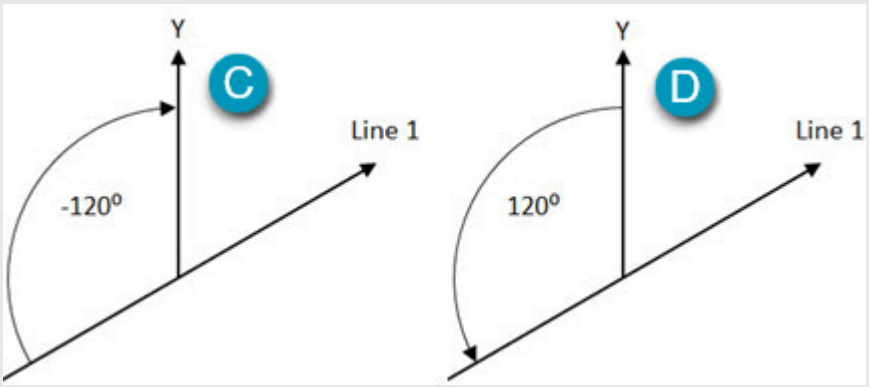
The **To** and **From** options determine the direction of the calculation and the resulting sign (positive or negative):

- If you select **To**, PC-DMIS calculates the angle from feature 1 to feature 2 (or the selected axis).
- If you select **From**, PC-DMIS calculates the angle to feature 1 from feature 2 (or the selected axis).

By default, PC-DMIS uses the angle from feature 1 to feature 2 (or the selected axis). If you want the supplemental angle (180 degrees - angle), mark the **Supplemental Angle** box.

Consider the following examples:





Example A - From line feature (Line 1) to the Y axis (**To** option)

Example B - To line feature (Line 1) from the Y axis (**From** option)

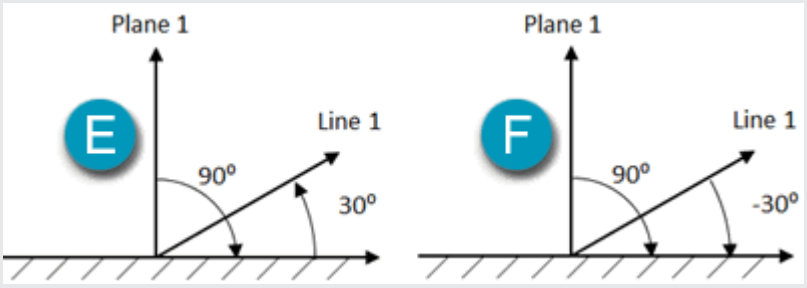
Example C - From line feature (Line 1) to the Y axis (**To** option with **Supplemental Angle**)

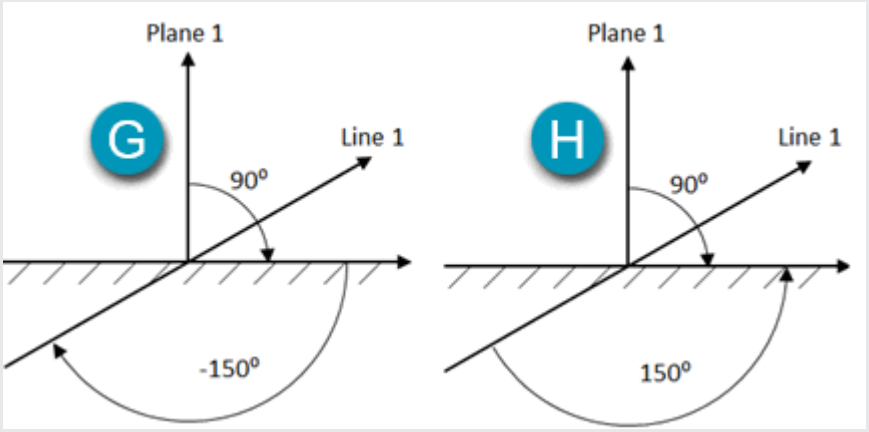
Example D - To line feature (Line 1) from the Y axis (**From** option with **Supplemental Angle**)

If you select one of these features (or feature types), PC-DMIS rotates the surface normal vector 90 degrees clockwise to represent a vector along the surface:

- Plane
- 2D feature with width
- 3D feature with width

Consider the following examples:





Example E - From plane feature with normal vector (Plane 1) to line feature (Line 1) (**To** option)

Example F - To plane feature with normal vector (Plane 1) from line feature (Line 1) (**From** option)

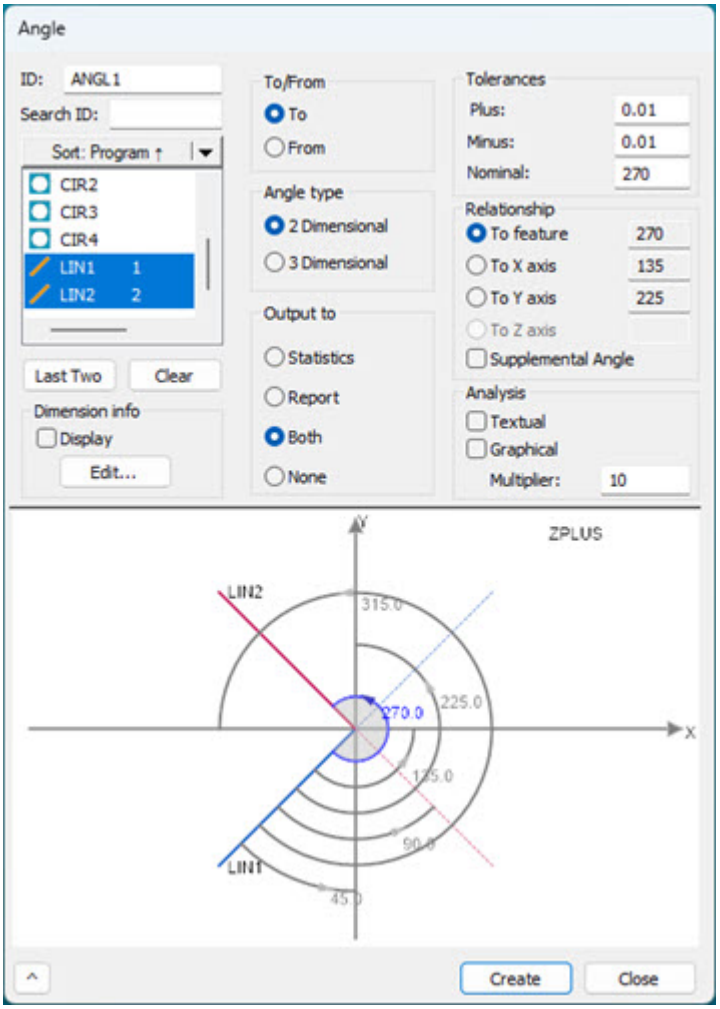
Example G - From plane feature with normal vector (Plane 1) to line feature (Line 1) (**To** option with **Supplemental Angle**)

Example H - To plane feature with normal vector (Plane 1) from line feature (Line 1) (**From** option with **Supplemental Angle**)

Angle Visualization

You can use the Angle Visualization function to view the possible angles associated with the **To/From** and **Angle type** (2D or 3D) relationship.

To do this, click the **Expand** button in the lower-left corner of the **Angle** dialog box to show the **Angle Visualization** area.



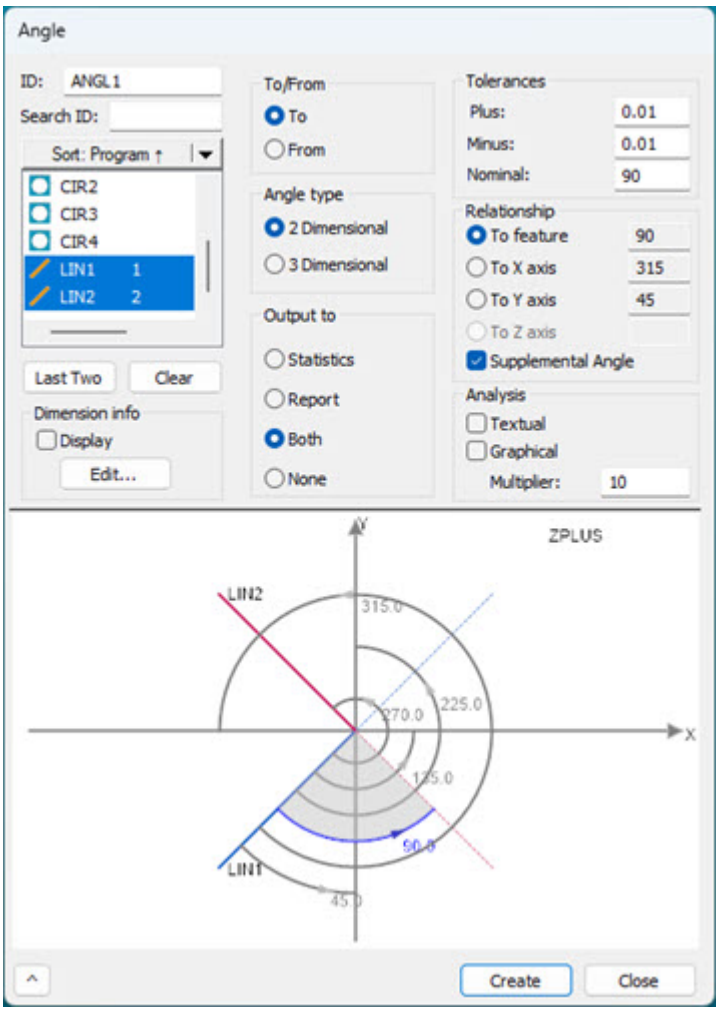
Example of the Angle dialog box for a 2D angle showing the Angle Visualization area.

For 2D angles, PC-DMIS draws the coordinate axes in the active workplane. In the image above, this is the ZPLUS workplane as shown in the upper-right of the Angle Visualization area.

PC-DMIS highlights the current selection in blue with a shadow to show the sweep angle.

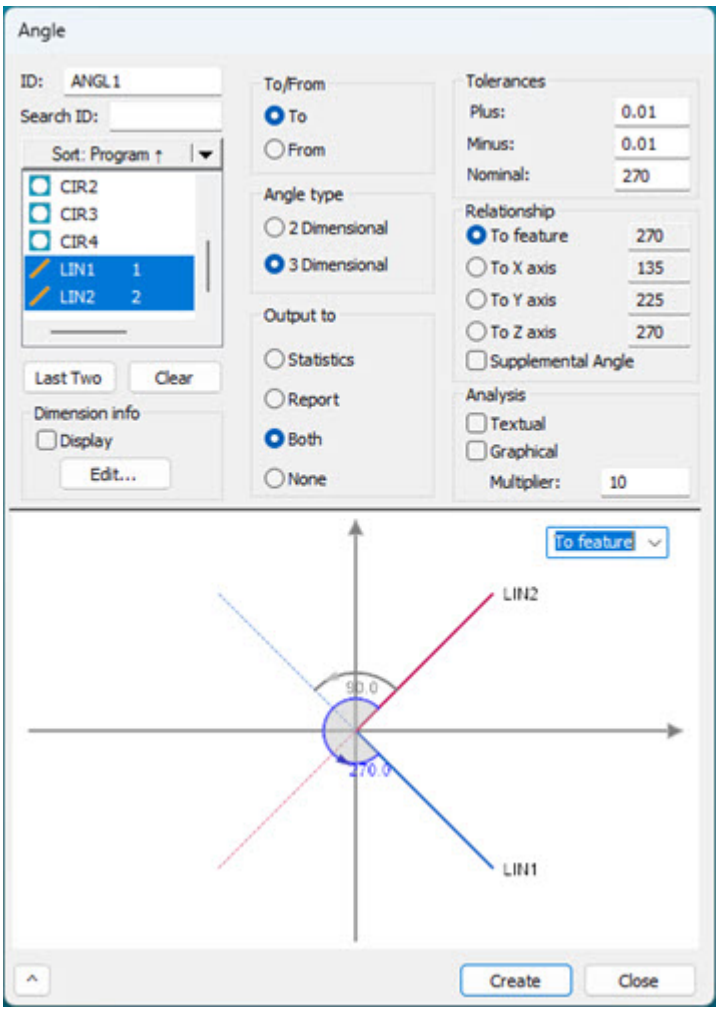
You can click any of the angles to view their properties. When you do, PC-DMIS dynamically:

- Updates the values for the selected angle in the **Tolerances** area
- Selects the appropriate **Relationship** option related to the angle and updates the values for that angle in the **Relationship** boxes
- Auto-selects the **Supplemental Angle** check box if applicable



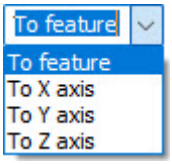
Example showing the updated properties when you select a different angle.

For 3D angles, PC-DMIS draws the references in the projection plane and shows the angles of the selected relationship.



Example of the Angle dialog box for a 3D angle showing the Angle Visualization area.

The projection plane varies with different input features. Select an option from the **Relationship** area or from the **Relationship** list to change the angle's view and properties.



Relationship List

You can also click a different angle sweep in the **Angle Visualization** area to view the properties for that angle.

Click the **Collapse** button to hide the **Angle Visualization** area.

To Dimension the Angle Between Two Features:

1. Select **Insert | Dimension | Angle** from the submenu. The **Angle** dialog box appears.
2. Select the feature or features to dimension from the **Feature List** box.

3. Type the plus tolerance value in the **Plus** box.
4. Type the minus tolerance value in the **Minus** box.
5. Type the nominal angle in the **Nominal** box.
6. Select either the **2 Dimensional** or **3 Dimensional** option in order to specify the angle type.
7. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both**, or **None** option.
8. Select the **To Feature**, **To X Axis** , **To Y Axis**, or **To Z Axis** option to determine the relationship that defines the angle.
9. To change the sign of the angle and direction of the calculation, select the **From** option.
10. To switch to the supplemental angle (180 degrees - angle), mark the **Supplemental Angle** check box.
11. If you don't use a CAD model, and you have not set the theoretical vectors of the feature, you may need to edit the nominal angle.
12. Select the desired analysis options by selecting the **Textual** check box or the **Graphical** check box. If the Graphical check box was selected, type the multiplier value in the Multiplier box.
13. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format you would like displayed in the Graphic Display window.
14. Click the **Create** button.

The dimension will appear in the Edit window with this information:

```
dimension_name = 2D_ANGLE,FROM feat_1,TO feat_2,
```

or

```
dimension_name = 3D_ANGLE,FROM feat_1,TO feat_2
```

AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
A	5.0000	0.0100	0.0100	5.0000	0.0000	0.0000	0.0000	0.0000

Editing Degrees, Minutes, and Seconds Values

When manually editing the Angle's nominal or tolerance value in the Edit window, and the angle value is displayed in Degrees, Minutes, and Seconds, you need to type a comma between each value. For example, if you wanted 100°33'51" as your Nominal angle value,

you would need to type 100,33,51 in the Nominal field and then press the Tab key for PC-DMIS to accept that value.

To determine whether or not PC-DMIS displays Angle in Degrees, Minutes, and Seconds, use the `AngleDegMinSec` entry in the **Option** section of the PC-DMIS Settings Editor. A value of 1 uses this format, while 0 uses the standard decimal value format.

Tolerances for Angle Dimensions

The **Tolerances** area in the **Angle** dialog box (**Insert | Dimension | Angle**) enables you to type plus and minus tolerances along the plus and minus directions.

Plus Tolerance

The **Plus** box in the **Angle** dialog box (**Insert | Dimension | Angle**) enables you to enter a tolerance value along the plus direction. This means that any profile that measures more than your nominal or theoretical profile can still be a valid measurement as long as it falls within the tolerance range specified.

PC-DMIS also allows a negative-upper tolerance (or a minus tolerance in the positive range). This is done by entering in a minus sign before the value in the **Plus** box.

Minus Tolerance

The **Minus** box in the **Angle** dialog box (**Insert | Dimension | Angle**) enables you to enter a tolerance value along the minus direction. This means that any profile that measures less than your nominal or theoretical profile can still be a valid measurement as long as it falls within the tolerance range specified.

PC-DMIS allows positive-lower tolerances (or a positive tolerance in the negative range). This is done by typing a minus sign before the value in the **Minus** box.

Nominal for Angle Between

Nominal values for Angle dimensions aren't always based on CAD data or measured data. Often you will obtain them from a hard copy printout, you can use the **Nominal** box in the **Angle** dialog box (**Insert | Dimension | Angle**) to enter the nominal angle value from the printout.

Angle Type

The **Angle type** area in the **Angle** dialog box (**Insert | Dimension | Angle**) determines whether or not the angle is 2 or 3 dimensional.

2 Dimensional Angle Type

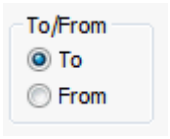
The **2 Dimensional** option in the **Angle** dialog box (**Insert | Dimension | Angle**) calculates the two-dimensional angle between features.

3 Dimensional Angle Type

The **3 Dimensional** option in the **Angle** dialog box (**Insert | Dimension | Angle**) calculates the three-dimensional angle between features. If only one feature is selected, the angle is calculated between the current workplane and the selected feature.

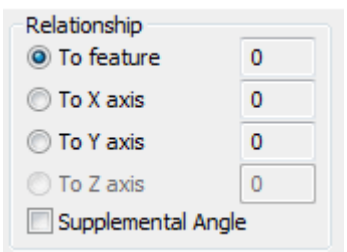
See "Dimensioning Angle" above for instructions on converting the quadrant of the reported angle.

Relationship for Angle Dimensions



The **To/From** area in the **Angle** dialog box (**Insert | Dimension | Angle**) determines the direction of the angle calculation and the resulting sign (positive or negative).

- If you select **To**, PC-DMIS calculates the angle from feature 1 to feature 2 (or selected axis). This also changes the options in the **Relationship** area begin with "To".
- If you select **From**, PC-DMIS calculates the angle to feature 1 from feature 2 (or selected axis). This also changes the options in the **Relationship** area begin with "From".



The **Relationship** area determines whether the Angle dimension can calculate the angle between two features, or between one feature and a particular axis: X axis, Y axis, and Z axis. As soon as you select at least one feature for the Angle dimension, PC-DMIS fills in the boxes next to the option buttons with the computed nominal angle values.

To feature / From feature
Select the **To feature** option if you are measuring the angle between two features. The second feature will be the datum feature.

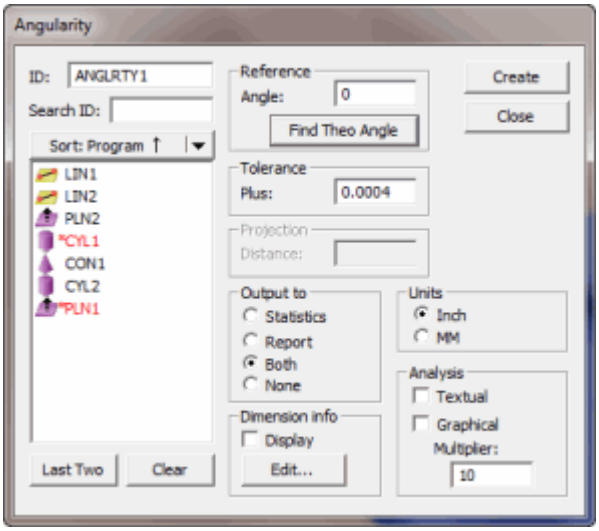
To X axis / From X axis
Select the **To X axis** check box if you are measuring the angle between a feature and the X axis.

To Y axis / From Y axis
Select the **To Y axis** check box if you are measuring the angle between a feature and the Y axis.

To Z axis / From Z axis
Select the **To Z axis** check box if you are measuring the angle between a feature and the Z axis.

Supplemental Angle
By default, PC-DMIS uses the angle from feature 1 to feature 2 (or the selected axis). If you want to use the supplemental angle (180 degrees - angle), mark the **Supplemental Angle** check box.

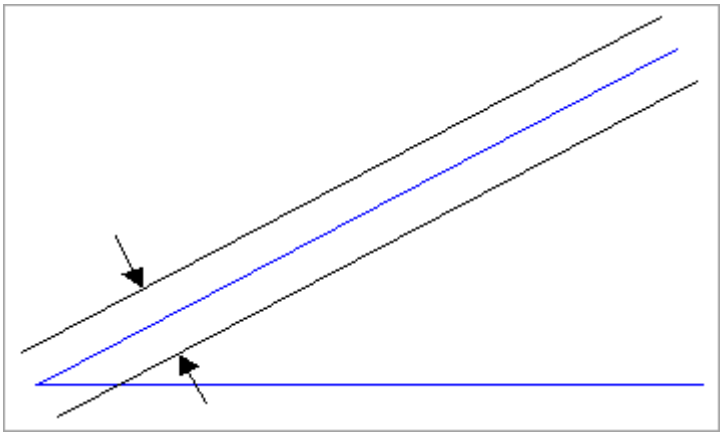
Dimensioning Angularity



Dimension Angularity Dialog Box

The **Insert | Dimension | Angularity** menu option computes the angularity error of a plane or line to a datum plane or line. (If only one feature is selected or entered, PC-DMIS uses the current workplane as the datum.)

Similar to perpendicularity or parallelism, the Angularity dimension allows you to specify an angle that isn't 90 degrees (perpendicularity) or 0 degrees (parallelism). For example, if you specify a 45-degree angle, PC-DMIS creates a tolerance band at 45 degrees and checks that the hits are within that tolerance band.



Example showing the measured angle (blue) and the angularity tolerance band (black) with two parallel lines or planes.

To Compute the Angularity Error by Using the Angularity Option

1. Select **Insert | Dimension | Angularity** from the submenu. The **Angularity** dialog box appears.
2. Type the nominal angle from the datum in the **Angle** box.
3. Select or type the plane or line, feature, and datum.
4. Type the plus tolerance value in the **Plus** box.
5. Type the projection distance in the **Distance** box.
6. Select either **Inch** or **MM** in the **Units** area.
7. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both**, or **None** option.
8. Select the optional **Display** check box if you want to view dimension information in the Graphic Display window.
9. Select either **Form Only** or **Form and Location** in the **Control Options** area of the dialog box.
10. Select the desired analysis options by selecting the **Textual** check box or the **Graphical** check box. If the **Graphical** check box was selected, type the multiplier value in the **Multiplier** box.

11. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format you would like displayed in the Graphic Display window.

12. Click the **Create** button.

The dimension appears in the Edit window with this information:

```
dimension_name = ANGULARITY FROM feat_1 TO feat_2
EXTENDLENGTH=n ANG=n UNITS=MM/IN

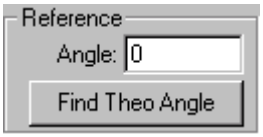
GRAPH=ON/OFF TEXT=ON/OFF MULT=n OUTPUT=NONE/BOTH/STATS/
REPORT
```

AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
M	0.0000	0.0100	0.0100	5.0000	0.0000	0.0000	0.0000	0.0000

feat_2: LINE or PLANE.

PC-DMIS then computes the angularity error and displays it in the current dimension window.

Reference Angle



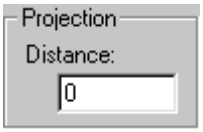
The **Angle** box in the **Angularity** dialog box (**Insert | Dimension | Angularity**) enables you to type the nominal angle from the datum feature. This is the angle between the two features. PC-DMIS then calculates the deviation of one feature from the angle.

Clicking the **Find Theo Angle** button calculates the nominal reference angle you should use from the theoretical values of the selected features. This makes it so you don't have to go and look up the angle in the Edit window.

Plus Tolerance for Angularity Dimensions

The **Plus** box in the **Angularity** dialog box (**Insert | Dimension | Angularity**) enables you to type a tolerance value along the plus direction. This means that any angularity error that differs from your nominal or theoretical angularity error can still be a valid measurement as long as it falls within the tolerance range specified.

Projected Distance for Angularity Dimensions

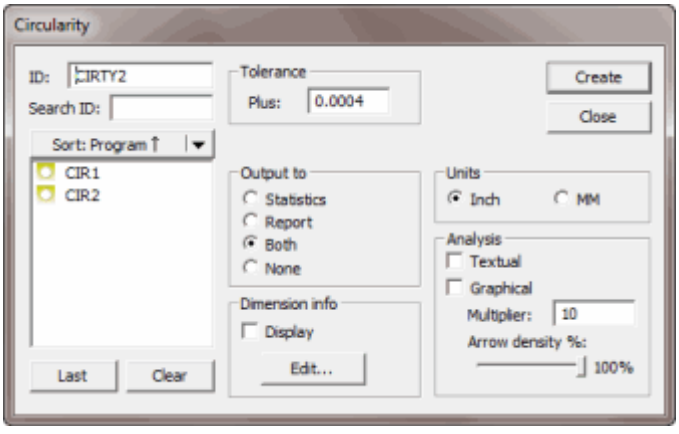


PC-DMIS allows you to project a reference distance. This option in the **Angularity** dialog box (**Insert | Dimension | Angularity**) is used with line features to calculate the angularity dimension.

For these features, the points used for the angularity calculation are the end point of the axis and a point projected from this end point along the feature axis.

The distance between these two points is the referenced distance. For other features, this distance has no effect on the dimension. This option is useful when the dimension needs to be calculated a certain distance along the feature.

Dimensioning Circularity



Dimension Circularity Dialog Box

One hit, plus the feature's minimum hit requirement is necessary to determine the roundness of that feature. Additional hits provide a better representation of the roundness of the entire feature.

The **Insert | Dimension | Circularity** menu option determines the roundness of a circle, sphericity of a sphere, or the conicity of a cone. This dimension type is considered one sided, meaning a single positive value tolerance is applied.

To Dimension a Feature Using the CIRCULARITY Option

1. Select **Insert | Dimension | Circularity** from the submenu. PC-DMIS opens the **Circularity** dialog box.
2. Select the feature(s) to dimension from the **Feature List** box.
3. Type the plus tolerance value in the **Plus** box.
4. Select either **Inch** or **MM** in the **Units** section.
5. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both**, or **None** option.
6. Select the optional **Display** check box if you want to view dimension information in the Graphic Display window.
7. Select the desired Analysis options by marking the **Textual** check box or the **Graphical** check box. If you selected the Graphical check box, type the Multiplier value in the **Multiplier** box.
8. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format you would like displayed in the Graphic Display window.
9. Click the **Create** button.

PC-DMIS shows the dimension in the Edit window with this information:

```
dimension_name = CIRCULARITY,OF feat_1
```

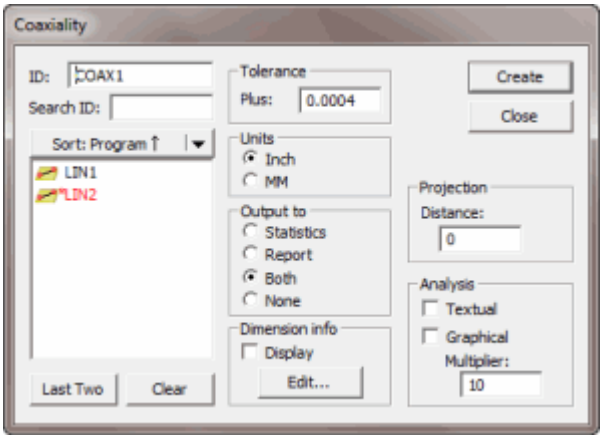
AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
M	0.0000	0.0100	0.0100	5.0000	0.0000	0.0000	0.0000	0.0000

Plus Tolerance for Circularity Dimensions

The **Plus** box in the **Circularity** dialog box (**Insert | Dimension | Circularity**) enables you to enter a tolerance value along the plus direction. This means that any roundness that differs from your nominal or theoretical roundness can still be a valid measurement as long as it falls within the tolerance range specified.

For information on how PC-DMIS reports tolerance zones for form dimensions, see "Reported Tolerance Zones for Form Dimensions" in the "Reporting Measurement Results" chapter.

Dimensioning Coaxiality



Dimension Coaxiality Dialog Box

The **Insert | Dimension | Coaxiality** menu option calculates the coaxiality of a cylinder, cone, or line with a datum feature. The second feature that is entered is always the datum feature, and may be a cylinder, cone, line, or circle. If only one feature is selected, and you click **Create**, PC-DMIS will clear the list box and display a message informing you that it needs a second feature.

This dimension type is considered one sided, meaning a single positive value tolerance is applied.

To Dimension a Feature Using the COAXIALITY Option:

1. Select **Insert | Dimension | Coaxiality** from the submenu. The **Coaxiality** dialog box appears.
2. Select the feature(s) to dimension from the **Feature List** box.
3. Type the plus tolerance value in the **Plus** box.
4. Select either **Inch** or **MM** in the **Units** area.
5. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both**, or **None** options.
6. Select the optional **Display** check box if you want to view dimension information in the Graphic Display window.
7. Select the desired Analysis options by selecting one or both of the check boxes. If the **Graphical** check box was selected, enter the Multiplier value in the **Multiplier** box.
8. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format you would like displayed in the Graphic Display window.

9. Click the **Create** button.

The dimension appears in the Edit window with this information:

```
dimension_name = COAXIALITY,FROM feat_1,TO feat_2
```

or

```
dimension_name = COAXIALITY,FROM feat_1,TO THE ORIGIN
```

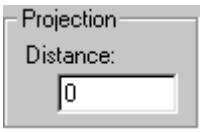
AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
M	0.0000	0.0100	0.0100	2.0000	0.0000	0.0000	0.0000	0.0000

After the dimension is created, the dialog box remains open. If desired, use your **Edit** button at this time to edit aspects of your dimension's information. See "Edit Default Dimension Info".

Plus Tolerance for Coaxiality Dimensions

This **Plus** box in the **Coaxiality** dialog box (**Insert | Dimension | Coaxiality**) enables you to enter a tolerance value along the plus direction. This means that any coaxiality that differs from your nominal or theoretical coaxiality can still be a valid measurement as long as it falls within the tolerance range specified.

Projected Distance for Coaxiality



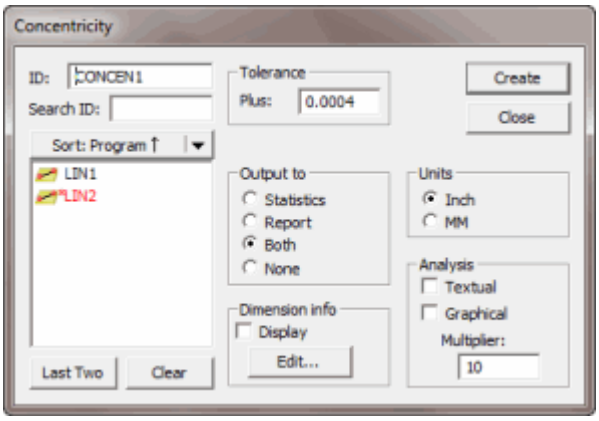
PC-DMIS allows you to type a reference distance. This option in the **Coaxiality** dialog box (**Insert | Dimension | Coaxiality**) is useful when you want to specify the points along the feature axis to be used in the coaxiality calculations. When this distance is zero, the two points used will be the endpoints of the feature's axis. When this distance is nonzero, the two points used will be the starting point of the axis, and along the axis vector the distance from the starting point.

Increasing the projected distance will magnify the error. Decreasing the distance lessens the error. For example, suppose two toothpicks lay on a table, sharing the same line and touching each other at one end. At the other end of the toothpicks, about two inches apart, the error between their centerlines might be 0.005 inches. Now imagine those toothpicks are 20 inches long, they would still touch at one end and the error would be 0.005 inches

at 2 inches away, but at 20 inches away from the first end, the toothpicks might have a 0.05 inch error.

The value you type in the **Distance** box reflects the total length of the feature.

Dimensioning Concentricity



Dimension Concentricity Dialog Box

If a sphere is selected as the first feature, the second feature must also be a sphere. PC-DMIS will then three-dimensionally calculate the concentricity between the two features.

The **Insert | Dimension | Concentricity** menu option calculates the concentricity of two circles or cylinders, cones, and spheres. The second feature that is entered is always the datum feature and may be a line feature that represents an axis. If only one feature is selected, the current workplane becomes the datum feature. This dimension type is considered one sided, meaning a single positive value tolerance is applied.

To Dimension a Feature Using the CONCENTRICITY Option

1. Select **Insert | Dimension | Concentricity** from the submenu. The **Concentricity** dialog box appears.
2. Select the feature(s) to dimension from the **Feature List** box.
3. Type the plus tolerance value in the **Plus** box.
4. Select either **Inch** or **MM** in the **Units** section.
5. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both**, or **None** option.
6. Select the optional **Display** check box if you want to view dimension information in the Graphic Display window.

7. Select the desired analysis options by selecting the **Textual** check box or the **Graphical** check box. If the **Graphical** check box was marked, type the multiplier value in the **Multiplier** box.

8. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format you would like displayed in the Graphic Display window.

9. Click the **Create** button.

The dimension appears in the Edit window with this information:

```
dimension_name = CONCENTRICITY,FROM feat_1,TO feat_2
```

or

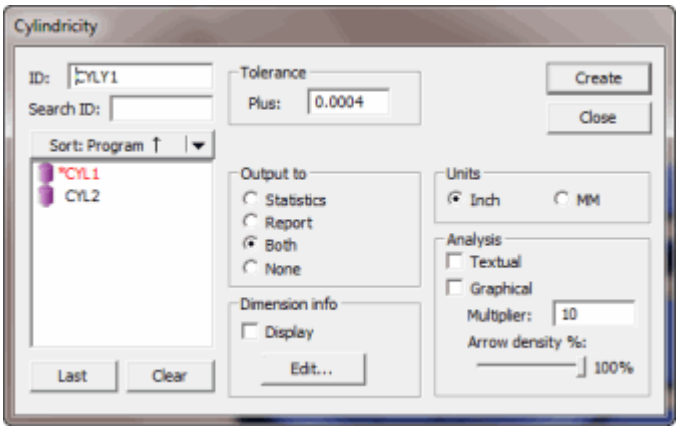
```
dimension_name = CONCENTRICITY,FROM feat_1,TO THE ORIGIN
```

AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
M	0.0000	0.0100	0.0100	2.0000	0.0000	0.0000	0.0000	0.0000

Tolerance for Concentricity Dimensions

The **Plus** box in the **Concentricity** dialog box (**Insert | Dimension | Concentricity**) enables you to enter a tolerance value along the plus direction. This means that any concentricity that differs from your nominal or theoretical concentricity can still be a valid measurement as long as it falls within the tolerance range specified.

Dimensioning Cylindricity



Dimension Cylindricity Dialog Box

The **Insert | Dimension | Cylindricity** menu option determines the cylindricity of a cylinder. This dimension type is considered one sided, meaning a single positive value tolerance is applied.

For legacy Form dimensions (Circularity, Cylindricity, Flatness, and Straightness), as well as a Location dimension's RN Line, PC-DMIS uses the feature solution to compute the dimension. By default, this is Least Squares. However, you can choose to solve the feature using Minimum Separation, Maximum Inscribed, Minimum Circumscribed, or Fixed Radius regression algorithms.

PC-DMIS computes Geometric Tolerance Form commands, on the other hand, using the Chebyshev algorithm (Min/Max) as required by the Y14.5 standard. Because of the change in calculation, PC-DMIS generally computes Geometric Tolerance Form dimension commands to a slightly smaller value than their legacy counterparts.

To Dimension a Feature Using the CYLINDRICITY Option

1. Select **Insert | Dimension | Cylindricity** from the submenu. The **Cylindricity** dialog box appears.
2. Select the feature(s) to dimension from the **Feature List** box. You can only select cylinder features.
3. Type the plus tolerance value in the **Plus** box.
4. Select either **Inch** or **MM** in the **Units** section.
5. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both**, or **None** option.
6. Select the optional **Display** check box if you want to view dimension information in the Graphic Display window.
7. Select the desired Analysis options by marking the **Textual** check box or the **Graphical** check box. If the Graphical check box was marked, type the Multiplier value in the **Multiplier** box.
8. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format you would like displayed in the Graphic Display window.
9. Click the **Create** button.

The dimension appears in the Edit window with this information:

```
dimension_name = CYLINDRICITY,OF feat_1
```

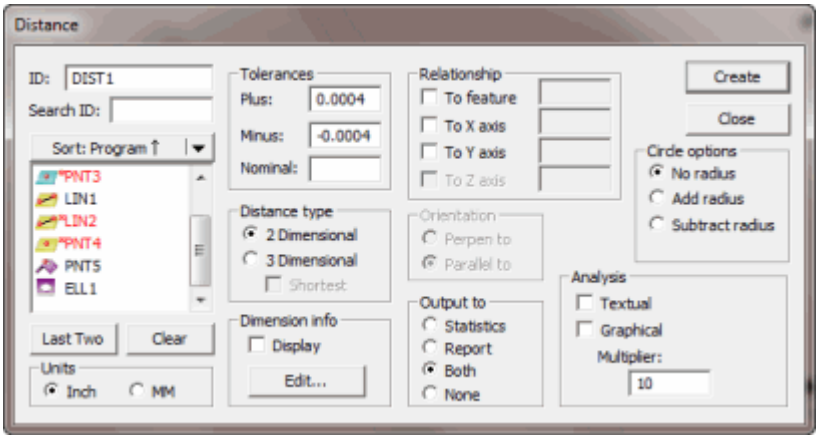
AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
M	0.0000	0.0100	0.0100	5.0000	0.0000	0.0000	0.0000	0.0000

Plus Tolerance for Cylindricity Dimensions

The **Plus** box in the **Cylindricity** dialog box (**Insert | Dimension | Cylindricity**) enables you to enter a tolerance value along the plus direction. This means that any cylindricity that differs from your nominal or theoretical cylindricity can still be a valid measurement as long as it falls within the tolerance range specified.

For information on how PC-DMIS reports tolerance zones for form dimensions, see "Reported Tolerance Zones for Form Dimensions" in the "Reporting Measurement Results" chapter.

Dimensioning Distance



Distance Dialog Box

The **Insert | Dimension | Distance** menu option calculates the distance between two features. You can select a third feature or an axis for the direction to use in the calculation.

Calculating distance is a bit more difficult to visualize than most of the other dimension calculations. The distance that is calculated between two features uses either the default or straight line method. Two-dimensional distances using a straight line will be parallel to the workplane. Three-dimensional distances using a straight line will be from centroid to centroid.

To Dimension a Distance Using the DISTANCE option:

1. Select **Insert | Dimension | Distance** from the submenu. The **Distance** dialog box appears.
2. Select the feature(s) to dimension from the **Feature List** box.
3. Type the plus tolerance value in the **Plus** box.
4. Type the minus tolerance value in the **Minus** box.
5. Select either the **2 Dimensional** or **3 Dimensional** option in order to specify the distance type.
6. Select either **Inch** or **MM** in the **Units** area.
7. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both,** or **None** option.
8. Select either the **To Feature**, **To X Axis** , **To Y Axis**, or **To Z Axis** option to determine the relationship that defines the distance.
9. Select either the **Perpen To** or the **Parallel To** radio button.
10. Select the desired analysis options by selecting the **Textual** check box or the **Graphical** check box. If the **Graphical** check box was selected, type the multiplier value in the **Multiplier** box.
11. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format you would like displayed in the Graphic Display window.
12. Click the **Create** button.

The dimension will appear in the Edit window with this information:

```
 DIM dimension_name = 2D_DISTANCE FROM feat_1 TO feat_2 TOG1 TO
TOG2, TOG3, UNITS=MM/IN,
GRAPH=ON/OFF TEXT=ON/OFF MULT=n OUTPUT=NONE/REPORT/STATS
```

or

```
 DIM dimension_name = 3D_DISTANCE FROM feat_1 TO feat_2, TOG3,
UNITS=MM/IN,
GRAPH=ON/OFF TEXT=ON/OFF MULT=n OUTPUT=NONE/REPORT/STATS
```

AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
M	5.0000	0.0100	0.0100	5.0000	0.0000	0.0000	0.0000	0.0000

TOG1 = PAR / PERP (Parallel or Perpendicular)

TOG2 = XAXIS / YAXIS / ZAXIS / feature

work plane = this field can be changed to any feature. The default is the current workplane.

TOG3= NO_RADIUS / ADD_RADIUS / SUB_RADIUS

Tolerances for Distance Dimensions

The **Tolerances** area allows you to type plus and minus tolerances for distances along the plus and minus directions.

Plus Tolerance

The **Plus** box in the **Distance** dialog box (**Insert | Dimension | Distance**) enables you to enter a tolerance value along the plus direction. This means that any angle that measures more than your nominal or theoretical angle can still be a valid angle as long as it falls within the tolerance range specified.

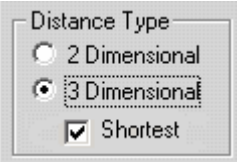
Minus Tolerance

This **Minus** box in the **Distance** dialog box (**Insert | Dimension | Distance**) enables you to enter a tolerance value along the minus direction. This means that any angle that measures less than your nominal or theoretical angle can still be a valid angle as long as it falls within the tolerance range specified.

Nominal for Distance

Nominal values for the distance between features aren't always based on CAD data or measured data. Often you will obtain them from a hard copy printout, you can use the **Nominal** box in the **Distance** dialog box (**Insert | Dimension | Distance**) to enter the nominal distance value from the printout.

General Rules for 2D and 3D Distance Dimensions



2D and 3D distance dimensions in the **Distance** dialog box (**Insert | Dimension | Distance**) apply the following rules according to the related features:

Treatment of Features

- Spheres, Points, Circles, and Sets are treated as *Points*.
- Slots, Cylinders, Cones, Lines, and 2D Widths are treated as *Lines*.
- Planes and 3D Widths are treated as Planes.

Other Rules

- If both elements are points (as defined above), PC-DMIS gives the shortest distance from point to point.
- If one element is a line (as defined above) and the other is a point, PC-DMIS gives the shortest distance between the line (or centerline) and the point.
- If both elements are lines, and the **Shortest** check box is *not selected*, PC-DMIS gives the shortest distance between the centroid of the first line to the second line. See the "Shortest check box" topic for what happens when it is selected.
- If one element is a plane and the other is a line, PC-DMIS gives the shortest distance between the centroid of the line and the plane
- If one element is a plane and the other is a point, PC-DMIS gives the shortest distance between the point and the plane.
- If both elements are planes, PC-DMIS gives the shortest distance between the centroid of the first plane to the second plane.

2D Distance

The maximum and minimum distance is the measured distance between two lines over the length of the lines.

The **2 Dimensional** option in the **Distance** dialog box (**Insert | Dimension | Distance**) calculates the two-dimensional distance between features. All features used to calculate the 2D distance are first projected into the current workplane before the distance is computed, except as noted below when you attempt to calculate the distance perpendicular to a third feature defined as a plane.

PC-DMIS computes the maximum, minimum, and average distances between the two features. If the distance is between two lines or planes, the maximum, minimum and average are computed using the measurement point data. (Verify that the distance type is set to 2 Dimensional.)

2D distances that are calculated using three features are either parallel or perpendicular to a datum feature. The datum feature can be any previously measured or constructed feature.

If the third feature is a plane and the distance is being calculated perpendicular to the datum feature, PC-DMIS ignores the current workplane.

To calculate the distance using three features:

1. Select the two features to calculate the distance.
2. Select the third (datum) feature. (Using a line for the third feature provides the best results.)
3. Verify that the correct orientation is marked.
4. Select the **To Feature** check box.
5. Click the **Create** button.

PC-DMIS calculates the distance between the first two features parallel or perpendicular to the third (datum) feature or axis.

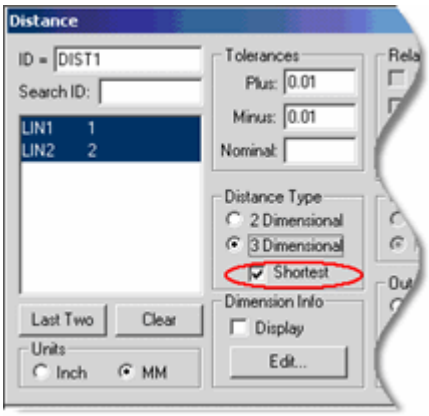
When you click **Close**, PC-DMIS closes the **Distance** dialog box without creating another dimension.

3D Distance

The **3 Dimensional** option in the **Distance** dialog box (**Insert | Dimension | Distance**) calculates the three-dimensional distance between two features.

- If one of the input features is a line, centerline, or plane, PC-DMIS computes the 3D distance normal to that feature.
- If both features are lines, centerlines, or planes the second feature is used for the datum. If both features are planes, the 3D distance is the perpendicular distance from the centroid of the first plane to the second plane; the second plane acts as the datum.
- If neither input feature is a line, centerline, or plane, PC-DMIS computes the shortest distance between the two features. (Verify that the mode is set to 3 Dimensional.)

Shortest Check Box



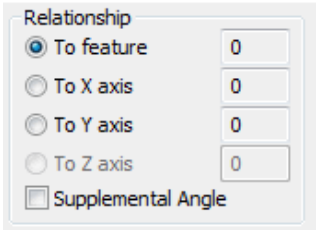
Distance Dialog Box - Shortest Check Box

The **Shortest** check box in the **Distance** dialog box (**Insert | Dimension | Distance**), when selected, calculates the true shortest 3D distance between two lines. This check box becomes enabled for selection when you choose **3 Dimensional** from the **Distance Type** area and the input features for the dimension are two lines.

By default, assuming you are working on a dimension created in version 4.3 and later, PC-DMIS automatically selects the check box when the above conditions are met. However, if you access the **Distance** dialog box for a distance dimension created prior to 4.3, the check box will not be selected by default.

- If you select the **Shortest** check box, PC-DMIS calculates the distance between two lines as the minimum distance between any point on the first line and any point on the second line. The two lines are considered to be unbounded (infinite length).
- If you do not select this check box, PC-DMIS behaves as it did prior to 4.3 and returns the shortest distance between the centroid of the first line to the second line.

Relationship for Distance Dimensions



The options in the **Relationship** area in the **Distance** dialog box (**Insert | Dimension | Distance**) enable you to specify whether the distance measured between two features will be perpendicular to or parallel to a specific axis, or perpendicular to or parallel to a selected feature:

To Feature check box

When you select the **To Feature** check box in the **Distance** dialog box (**Insert | Dimension | Distance**), the **Perpen To** and **Parallel To** options in the **Orientation** area become available for selection. These options tell PC-DMIS to compute the distance between the first selected feature and the second selected feature parallel to, or perpendicular to a certain feature.

- If only *two features* are selected from the list, PC-DMIS computes the distance between feature 1 and feature 2, parallel or perpendicular to feature 2.
- If *three features* are selected from the list, PC-DMIS computes the distance between feature 1 and feature 2, parallel or perpendicular to feature 3.

The feature used to establish the relationship should be a linear feature.

To X Axis check box

Select the **To X Axis** check box in the **Distance** dialog box (**Insert | Dimension | Distance**) if you are measuring the distance from the first selected feature to the second selected feature, perpendicular to or parallel to the X axis.

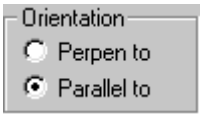
To Y Axis check box

Select the **To Y Axis** check box in the **Distance** dialog box (**Insert | Dimension | Distance**) if you are measuring the distance from the first selected feature to the second selected feature, perpendicular to or parallel to the Y axis.

To Z Axis check box

Select the **To Z Axis** check box in the **Distance** dialog box (**Insert | Dimension | Distance**) if you are measuring the distance from the first selected feature to the second selected feature, perpendicular to or parallel to the Z axis.

Orientation for Distance Dimensions



When measuring the distance between two features, you have the option of determining how the distance is to be measured by using these orientation options in the **Distance** dialog box (**Insert | Dimension | Distance**).

- Measure the distance between the first selected feature parallel or perpendicular to either the second or another selected feature.

- Measure the distance between the first selected feature and the second selected feature parallel to or perpendicular to a specific axis.

The **Perpendicular To** and the **Parallel To** options enable you to determine the orientation of the features.

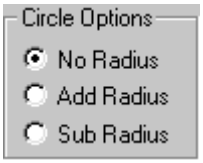
Perpendicular To

Select the **Perpendicular To** option in the **Distance** dialog box (**Insert | Dimension | Distance**) if the distance between the two features is perpendicular to either the second feature, or perpendicular to a specified axis.

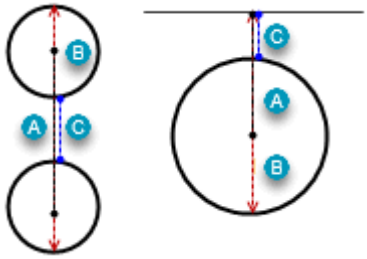
Parallel To

Select the **Parallel To** option in the **Distance** dialog box (**Insert | Dimension | Distance**) if the distance between the two features is parallel to either the second feature, or parallel to a specified axis.

Circle Options



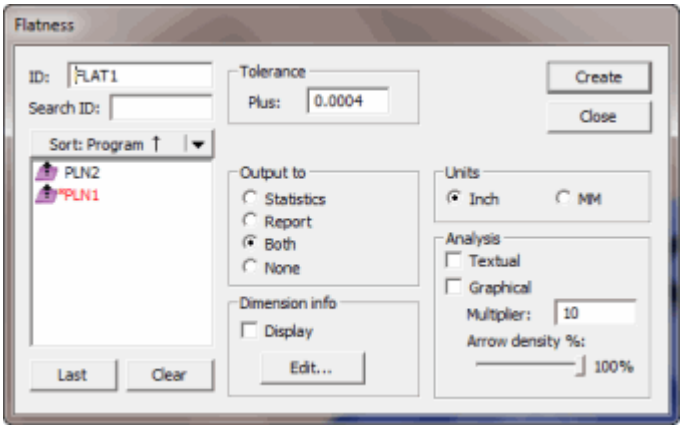
With the **Circle Options** area in the **Distance** dialog box (**Insert | Dimension | Distance**), you can use the **Add Radius** and **Subtract Radius** options to tell PC-DMIS to either add or subtract the radius of the measured feature to the total distance that is measured. The amount that is added or subtracted will always be along the same vector that calculates the distance. Only one option is available at a time.



A - Normal calculated distance between features
B - Add Radius
C - Subtract Radius

Using the **No Radius** option does not apply the radius of the feature to the distance measured.

Dimensioning Flatness



Dimension Flatness Dialog Box

A minimum of four hits are necessary to determine the flatness of a plane.

The **Insert | Dimension | Flatness** menu option determines the flatness of a plane. This dimension type is considered one sided, meaning a single positive value tolerance is applied.

For legacy Form dimensions (Circularity, Cylindricity, Flatness, and Straightness), as well as a Location dimension's RN Line, PC-DMIS uses the feature solution to compute the dimension. By default, this is Least Squares. However, you can choose to solve the feature using Minimum Separation, Maximum Inscribed, Minimum Circumscribed, or Fixed Radius regression algorithms.

PC-DMIS computes Geometric Tolerance Form commands, on the other hand, using the Chebyshev algorithm (Min/Max) as required by the Y14.5 standard. Because of the change in calculation, PC-DMIS generally computes Geometric Tolerance Form dimension commands to a slightly smaller value than their legacy counterparts.

To Dimension a Feature Using the FLATNESS Option

1. Select **Insert | Dimension | Flatness** from the submenu. The **Flatness** dialog box appears.
2. Select the feature(s) to dimension from the **Feature List** box.
3. Type the plus tolerance value in the **Plus** box.
4. Select either **Inch** or **MM** in the **Units** section.
5. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both**, or **None** option.

6. Select the optional **Display** check box if you want to view dimension information in the Graphic Display window.
7. Select the desired Analysis options by marking the **Textual** check box or the **Graphical** check box. If the **Graphical** check box was marked, type the multiplier value in the **Multiplier** box.
8. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format you would like displayed in the Graphic Display window.
9. Click the **Create** button.

The dimension appears in the Edit window with this information:

```
dimension_name = FLATNESS,OF feat_1
```

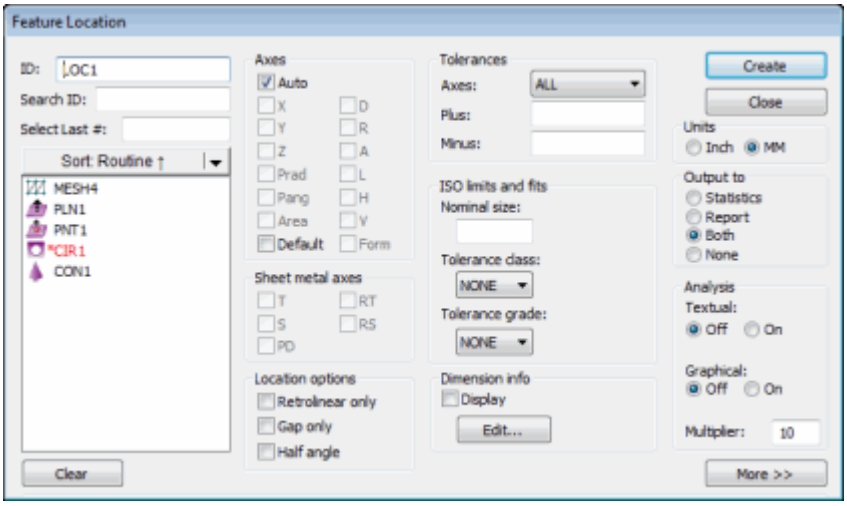
AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
M	0.0000	0.0100	0.0100	5.0000	0.0000	0.0000	0.0000	0.0000

Plus Tolerance for Flatness

The **Plus** box in the **Flatness** dialog box (**Insert | Dimension | Flatness**) enables you to enter a tolerance value along the plus direction. This means that any flatness that differs from your nominal or theoretical flatness can still be a valid measurement as long as it falls within the tolerance range specified.

For information on how PC-DMIS reports tolerance zones for form dimensions, see "Reported Tolerance Zones for Form Dimensions" in the "Reporting Measurement Results" chapter.

Dimensioning Location



Dimension Feature Location Dialog Box

The **Insert | Dimension | Location** menu option calculates the distance from the feature to the X, Y, Z origin, parallel to its respective axis. The feature's diameter, angle, and vector are also part of the calculation. This section relates only to location or coordinate dimensioning. For position dimensions, see "Dimensioning Position".

Location can be calculated using Cartesian or Polar coordinates, Position or box tolerancing.

- To switch between Cartesian and Polar coordinates, select **Pang** or **Prad** in the **Feature Location** dialog box.
- To switch between `POSITION` and `RECT` tolerancing methods, see the "Dimensioning Position" dimension option.

By default, the dialog box marks the **Auto** check box. To change the default behavior for your measurement routine, see the "Default Axes for Location Dimensions" topic.

For legacy Form dimensions (Circularity, Cylindricity, Flatness, and Straightness), as well as a Location dimension's RN Line, PC-DMIS uses the feature solution to compute the dimension. By default, this is Least Squares. However, you can choose to solve the feature using Minimum Separation, Maximum Inscribed, Minimum Circumscribed, or Fixed Radius regression algorithms.

PC-DMIS computes Geometric Tolerance Form commands, on the other hand, using the Chebyshev algorithm (Min/Max) as required by the Y14.5 standard. Because of the change in calculation, PC-DMIS generally computes Geometric Tolerance Form dimension commands to a slightly smaller value than their legacy counterparts.

To Dimension a Feature Using the LOCATION Option

1. Select **Insert | Dimension | Location** from the submenu. The **Feature Location** dialog box appears.
2. Select the desired axes from the **Axes** area. The **Auto** check box is marked as the default.

   If you mark the **Auto** check box, PC-DMIS automatically determines the default axes to display in the dimension. The default axes are based on the feature type, as shown in the table below.

   The default output format for the following features is:

   CIRCLE = X, Y, D (based on the workplane).

   CONE = X, Y, Z, A

   CYLINDER = X, Y, Z, D, L (based on the workplane).

   ELLIPSE = X, Y, Z, D, A, L

   LINE = Based on the axis that is perpendicular to the axis closest to (and the axis related to) the workplane that the line is measured in.

   PLANE = Based on the axis most closely related to the plane.

   POINT = X, Y, Z, T

   SLOT = X, Y, D, R, L (based on the workplane).

   SPHERE = X, Y, Z, D
3. Select the feature(s) to dimension from the **Feature List** box.
4. Select the axes from the **Axes** drop-down list to which you want to apply Plus and Minus tolerances.
5. Type the Plus tolerance value in the **Plus** box.
6. Type the Minus tolerance value in the **Minus** box.
7. Type the Nominal size value in the **Nominal Size** box.
8. Select a Tolerance Class from the **Tolerance Class** drop-down list.
9. Select a Tolerance Grade from the **Tolerance Grade** drop-down list.
10. Select either the **Inch** or **MM** option from the **Units** area of the dialog box.

11. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both,** or **None** option.
12. Select the desired Analysis options by selecting the **Textual** check box or the **Graphical** check box. If you select the **Graphical** check box, type the Multiplier value in the **Multiplier** box.
13. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format that you would like to display in the Graphic Display window.
14. Click the **Create** button. If you did not select any check boxes from the **Axes** area, the **Create** button is unavailable for selection.

The dimension appears in the Edit window with this information:

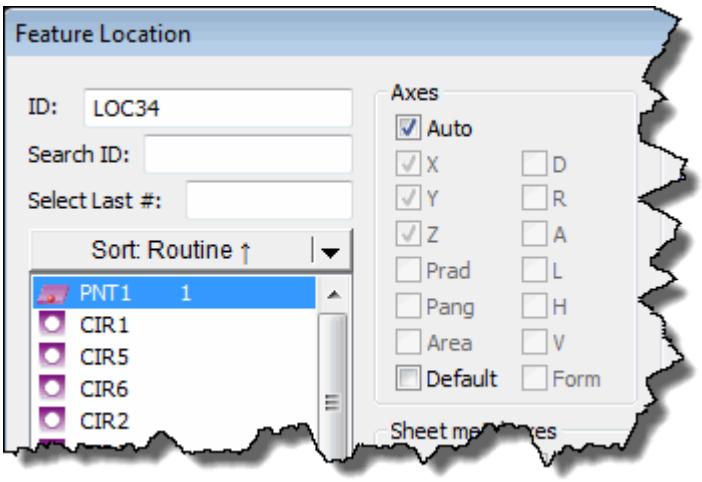
```
dimension_name = TYPE OF DIMENSION,feat_1 UNITS=IN ,$
GRAPH=OFF TEXT=OFF MULT=1.00 OUTPUT=BOTH
```

	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
x	8.0000	0.1000	0.1000	8.0000	8.5000	7.5000	0.0000	0.0000
y	3.0000	0.1000	0.1000	3.0000	3.5000	2.5000	0.0000	0.0000
z	0.4947	0.1000	0.1000	0.4947	0.1428	0.8466	0.0000	0.0000
d	1.0000	0.1000	0.1000	1.0000	1.0000	1.0000	0.0000	0.0000
v	0.0000	0.5938	0.8046	-	-	-	-	-

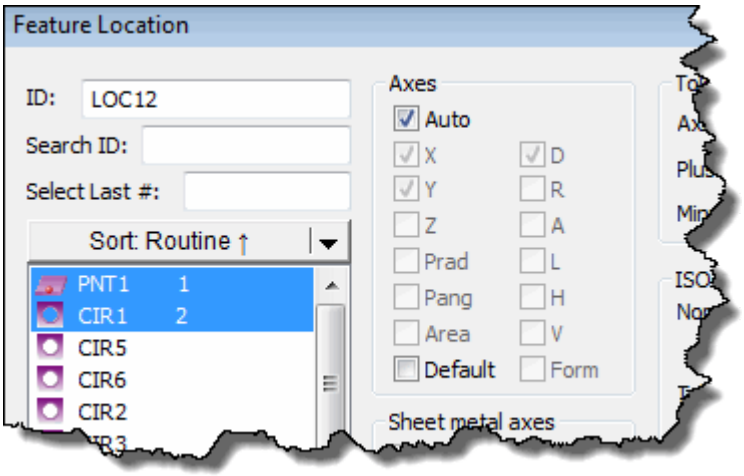
`END OF DIMENSION dimension_name` (for LOCATION only)

Default Axes for Location Dimensions

When the **Auto** check box in the **Axes** area in the **Feature Location** dialog box (**Insert | Dimension | Location**) is checked, the check boxes for the axes that appear in the dimension are selected according to the default axes of the feature type. In this case, the check boxes for those axes are not available to edit:



If you select multiple features of different types (for example a circle feature and a point feature), the **Axes** area selects the axes to use based on the last-selected feature:



By default, PC-DMIS marks the **Auto** check box. But if you want to choose your own axes, you can clear **Auto** and choose them manually. If you want to then save your selection as the new default for this routine, you can mark **Default** and create your dimension. The next time you open the **Feature Location** dialog box in that routine, PC-DMIS uses your defaults.

Changing the Default Axes

In some circumstances, it may be necessary to override the default setting. The **Default** check box remains available so that you can alter the format of the default output.

To alter the default output:

1. Select each feature to dimension.
2. Select the **Default** check box. The **Auto** check box clears, and all axes become available for selection.
3. Select the appropriate axes as needed.

X = Prints the X axis value.

Y = Prints the Y axis value.

Z = Prints the Z axis value.

Prad = Prints the Polar Radius.

Pang = Prints the Polar Angle.

Area = Prints the area of a selected Blob feature. It appears as AR in the report and in the Edit window in Command Mode.

D = Prints the Diameter value. For an ellipse, this is the minor diameter value (same as H).

R = Prints the Radius (half of the Diameter) value.

A = Prints the Angle value.

L = Prints the Length (used for cylinder, cones, slots, and ellipses). For an ellipse, L gives you the major diameter value.

H = Prints the Height (used on cones, cylinders, and ellipses). For an ellipse, H gives you the minor diameter value.

V = Prints the Vector location.

Form = Prints the feature's integrated form dimension with the location dimension.

- For a circle, cylinder, or cone feature, this is the Roundness (RN) dimension.
- For a plane feature, this is the Flatness (FL) dimension.
- For a line feature, this is the Straightness (ST) dimension.

4. Click the **Create** button.

Once the output values have been changed to something other than the default, PC-DMIS uses the new settings for all subsequent dimensions.

Resetting to the Original Axes

If you modified the default axes, but you want PC-DMIS to use the original default axes, you must reset the format to the default settings.

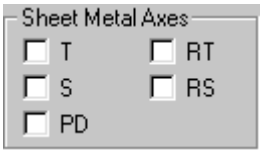
To reset the format to the default settings:

1. Select the **Default** check box.
2. Select the **Auto** check box. All of the axes check boxes become unavailable.
3. Select each feature to dimension. The original default axes are selected.

4. Click the **Create** button.

PC-DMIS automatically resets the dimension to print the default axes according to the feature type.

Sheet Metal Axes



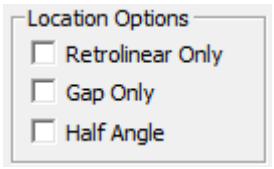
The **Sheet Metal Axes** area in the **Feature Location** dialog box (**Insert | Dimension | Location**) contains check boxes only available when sheet metal features (Auto Features) are being dimensioned.

T = prints the deviation along the approach vector (for points on curved surfaces).
S = prints the deviation along the surface vector.
RT = prints the deviation along the report vector.
RS = prints the deviation along the surface report.
PD = prints the diameter of a circle (perpendicular to the pin vector).

If a **T**, **RT**, **S**, or **RS** axis is used, none of the other location dimensions is used for the analysis (graphical or textual).

For Location dimensions of Vector Point, Surface Point, Edge Point, and Angle Point features, the default **Sheet Metal Axes** output format is **T**. Location dimensions of all the other Auto feature types do not initially have any of these axes selected.

Location Options



PC-DMIS also allows you to show these specialty axes:

- Retrolinear Only
- Gap Only
- Half Angle

These options can be selected in the **Locations Options** area in the **Feature Location** dialog box (**Insert | Dimension | Location**). All future locations of vector, surface, and

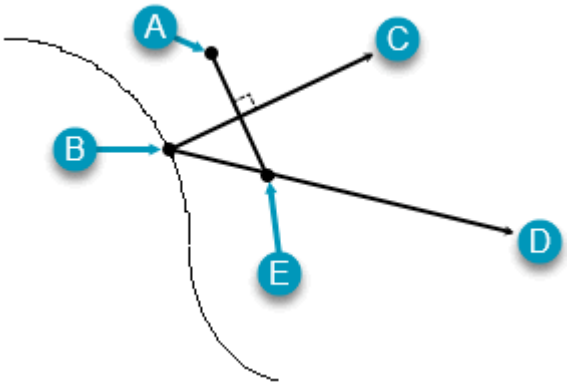
edge points within the measurement routine is printed using the appropriate specialty axes until the option is turned OFF.

Retrolinear Only for Location Dimensions

This check box is available when dimensioning vector and surface points. When the retrolinear only option has been selected for valid points, the location axes are calculated by:

- Finding the largest component of the theoretical surface normal vector (largest in x, y, or z direction).
- Projecting the measured point to this largest component vector in a manner that the projection is perpendicular to the original theoretical surface normal vector.

The location axes are then calculated from this new projected point.



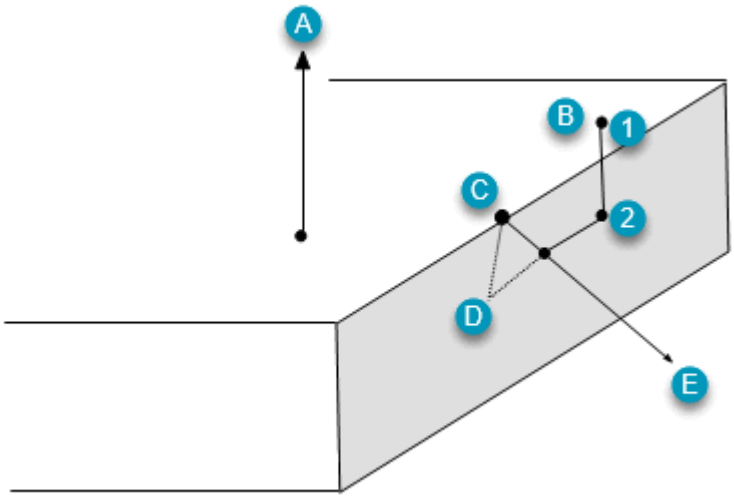
A - Actual Measured Point
B - Theoretical Point
C - Theo Surface Normal Vector
D - Largest component of the Theo Surface Normal Vector
E - Projected Point (reported point)

Gap Only for Location Dimensions

The **Gap Only** check box is available when dimensioning edge points. When you select the **Gap Only** check box, and an edge point is measured, the location axes are calculated by:

- Projecting the measured point (1) to the theoretical surface.
- Projecting this new point on to the theoretical approach vector.

Any location axes are then calculated from this new point.



A. *Theoretical Surface Normal*

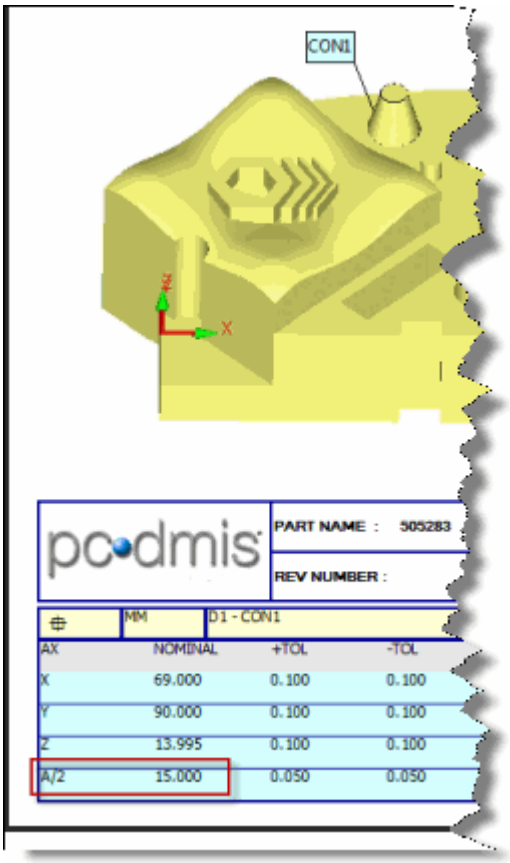
B. *Measured Point*

C. *Theo Point*

D. *Gap*

E. *Theoretical Approach Vector*

Half Angle for Location Dimensions



Example of a cone dimension with half-angle.

The **Half Angle** check box lets you display the angle axis (the **A** axis in the **Axes** area) at half its usual value. When you select this check box, the **A** axis in the **Axes** area changes to display **A/2**. In addition, the expanding grid area in the **Feature Location** dialog box and the dimension in the Edit window, Report window, and Diminfo boxes will also change to display the angle at half its value with label of A/2.

Tolerances for Location Dimensions

The **Feature Location** dialog box (**Insert | Dimension | Location**) provides you with two methods of entering Plus and / or Minus tolerances for these available axes:

ALL = All the axes and options displayed in the **Axes** drop down list in the **Tolerances** area.

X = X axis value

Y = Y axis value

Z = Z axis value

D = Diameter

R = Radius (half the Diameter)

A = Angle (for Cones)

L = Length (used for cylinders, slots, cones and ellipses)

H = Height

PR = Polar Radius

PA = Polar Angle

AR = Area (for Blob features)

T = Error along the approach vector (for points on curved surfaces)

RT = Deviation along the Report vector

S = Deviation along the Surface vector

RS = Deviation along the Surface report

PD = Diameter of a circle (perpendicular to the pin vector)

FORM = Feature's integrated form dimension.

- For a circle or cylinder feature, this is the Roundness (RN) dimension.

- For a plane feature, this is the Flatness (FL) dimension.
- For a line feature, this is the Straightness (ST) dimension.

1) Old Method - Use the Tolerances Area

The **Tolerances** area allows you to type plus and minus tolerances for each of the following axes found in the **Axes** drop-down list.

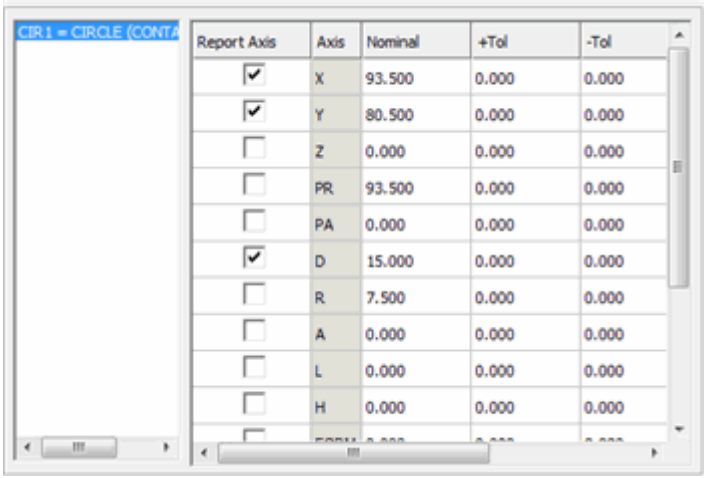
To enter in plus and minus tolerances:

1. From the **Axes** drop-down list, select the axis that you want to edit.
2. In the **Plus** box, type the plus tolerance value for the selected axis.
3. In the **Minus** box, type the Minus tolerance value for the selected axis.
4. Repeat the above steps for any axes with tolerance values.

2) New Method - Use the Expanding Grid

When you select a feature from the main feature list and click the **More>>** button from the **Feature Location** dialog box, the dialog box expands vertically to provide you with a grid. You can use this grid to type in the values to specify the tolerance and nominal values for the desired axes. In addition, an **Update Feature Nominal** column lets you update the associated feature's nominal values as desired.

PC-DMIS shows a blank grid unless you select one or more features from the dialog's main **Feature List** box.



List of Features - The list to the left of the grid's columns contains the feature or features you selected from the dialog's main **Feature List** box. When you select a feature from the

list, PC-DMIS displays the possible axes for that feature which you can then apply tolerance values.

Report Axis - This column contains check boxes for each axis. A selected check box sends that axis to the report.

Axis - This column lists available axes for the selected feature.

Nominal - This column contains nominal values. You can click each one and type a different value as needed.

+Tol / -Tol - The plus and minus tolerance columns provide fields into which you can type tolerances for the various axes used in your dimension.

Update Feature Nominal - This column lets you specify whether or not any changes you made to the nominal values should get applied not only to the dimension but to the feature as well.

Entering Positive-lower and Negative-upper Tolerances

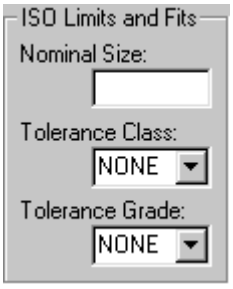
PC-DMIS allows positive-lower tolerances (or a positive tolerance in the negative range). To do this, add a minus sign before the value in the **Minus** box.

PC-DMIS also allows a negative-upper tolerance (or a minus tolerance in the positive range). This is done by entering in a minus sign before the value in the **Plus** box.

If 1.000 is entered for the nominal, .003 is entered for the plus tolerance and .001 is entered for the minus tolerance it would be interpreted as 1.000 + .003 / –.001. To get the lower tolerance to be +.001 (sign change) simply type in 1.000 (nominal), .003 (plus tol) and –.001 (minus tol) thereby achieving a tolerance range of 1.000 + .003 / + .001.

Negative lower tolerances may be displayed with a minus sign if the **Minus Tols Show Negative** option has been selected. See "Minus Tols Show Negative" in the "Setting Your Preferences" chapter.

ISO Limits and Fits



The **ISO Limits and Fits** area in the **Feature Location** dialog box (**Insert | Dimension | Location**) allows you to apply ISO standardized tolerances to the diameter of circular features. When a tolerance class and grade have been selected, PC-DMIS will look up the appropriate tolerances for the diameter of a cylinder or circle from the International Organization for Standardization's tables of Limits and Fits. These tables define the tolerances for various design classes and grades of diameters.

Although PC-DMIS allows the calculation of ISO tolerances in English (Inch) and metric (mm) units, they are only defined by ISO to be applied with metric (mm) units. Also, because these tables use various classes and grades of diameters, cylinders and circles are the only appropriate features for this option. If no nominal diameter is entered, PC-DMIS uses the feature's nominal diameter for the tolerance calculations.

Nominal Size

The **Nominal Size** box in the **Feature Location** dialog box (**Insert | Dimension | Location**) enables you to enter the nominal diameter of the feature selected.

Tolerance Class

The **Tolerance Class** list in the **Feature Location** dialog box (**Insert | Dimension | Location**) enables you to select from the following ISO Tolerance classes:

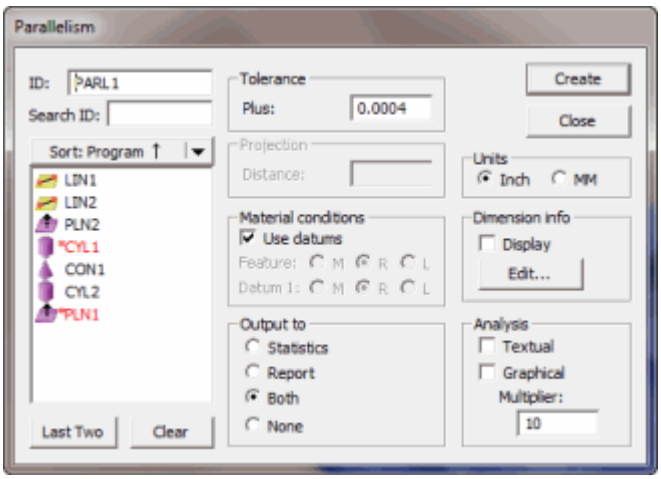
A B C CD D E EF F FG G	H J JS K M N P R S	T U V X Y Z ZA ZB ZC

Tolerance Grade

The **Tolerance Grade** list in the **Feature Location** dialog box (**Insert | Dimension | Location**) enables you to select from the following ISO Tolerance grades:

IT1	IT7	IT13
IT2	IT8	IT14
IT3	IT9	IT15
IT4	IT10	IT16
IT5	IT11	IT17
IT6	IT12	IT18

Dimensioning Parallelism



Dimension Parallelism Dialog Box

The **Insert | Dimension | Parallelism** menu option measures the parallelism between two features. The second feature is always the datum feature. When only one feature is selected, the current workplane becomes the datum feature. This dimension type is considered one sided, meaning a single positive value tolerance is applied.

The evaluation of parallelism is 3-dimensional regardless of the workplane or the feature being dimensioned.

To perform a 2-dimensional evaluation, or when you require more advanced support, (for example, when you need to reference multiple datums or you want to add the tangential plane modifier), you must use the newer Geometric Tolerance command. For details, see the "Using Geometric Tolerances" chapter of the PC-DMIS Core documentation.

To Perform a Dimension Using PARALLELISM:

1. Select **Insert | Dimension | Parallelism** from the submenu. The **Parallelism** dialog box appears.
2. Select the feature(s) to dimension from the **Feature List** box.
3. If a datum feature is desired, select the **Use Datums** check box.
4. If a datum feature is desired, select another feature in the **Feature List** box.
5. Select the appropriate **Material Condition** options for the feature(s) and datum.
6. Type the plus tolerance value in the **Plus** box.
7. Type the projection distance in the **Distance** box.
8. Select either the **Inch** or **MM** option in the **Units** area.
9. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both**, or **None** option.
10. Select the optional **Display** check box if you want to view dimension information in the Graphic Display window.
11. Select the desired analysis options by marking the **Textual** check box or the **Graphical** check box. If the **Graphical** check box was marked, enter the Multiplier value in the **Multiplier** box.
12. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format you would like displayed in the Graphic Display window.
13. Click the **Create** button.

The dimension will appear in the Edit window with this information:

```
dimension_name = PARALLELISM,OF feat_1,TOG1,TO feat_2,TOG1
```

or

```
dimension_name = PARALLELISM,OF feat_1,TOG1,
```
TO workplane

AX	NOM	+TOL	-TOL	BON	MEAS	MAX	DEV	OUT-TOL
DF	1.0000	0.0100	0.0100	0.0000	1.0000		0.0000	0.0000
D1	0.0000	0.0100	0.0100	0.0000	0.0000	0.0000	0.0000	0.0000
M	0.0000	0.0100	0.0100	0.0000	0.0000		0.0000	0.0000

TOG1= MMC / RFS / LMC

Explanation of Axes

DF is the Diameter or Width of the feature. This appears when you set LMC or MMC conditions.

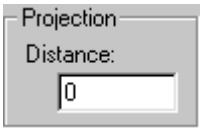
D1 is the Diameter or Width of the first datum. This appears when you set a datum feature.

M is the measured value. This always appears.

Plus Tolerance for Parallelism Dimensions

The **Plus** box in the **Parallelism** dialog box (**Insert | Dimension | Parallelism**) enables you to enter a tolerance value along the plus direction. This means that any parallelism that differs from your nominal or theoretical parallelism can still be a valid measurement as long as it falls within the tolerance range specified.

Projected Distance for Parallelism Dimensions



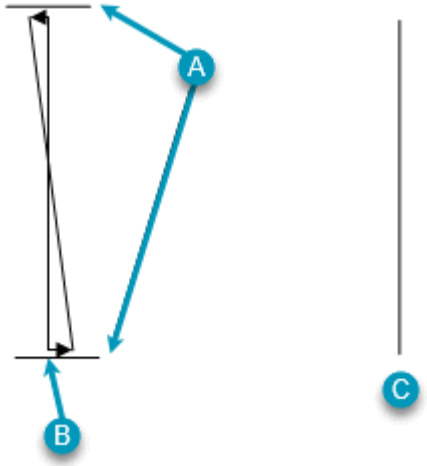
PC-DMIS allows you to type a reference distance in the **Distance** box in the **Parallelism** dialog box (**Insert | Dimension | Parallelism**). PC-DMIS uses this value with cylinder, cone, and line features to calculate the parallelism dimension.

For these features, the points used for the parallelism calculation are the end point of the axis and a point projected from this end point along the feature axis.

The distance between these two points is the referenced distance. For other features, this distance has no effect on the dimension. This option is useful when the dimension needs to be calculated a certain distance along the feature.

Understanding Parallelism's Distance Projection

Usually a parallelism dimension takes the datum line's vector, and checks the endpoints of the dimensioned feature to see if they are within tolerance as shown here:

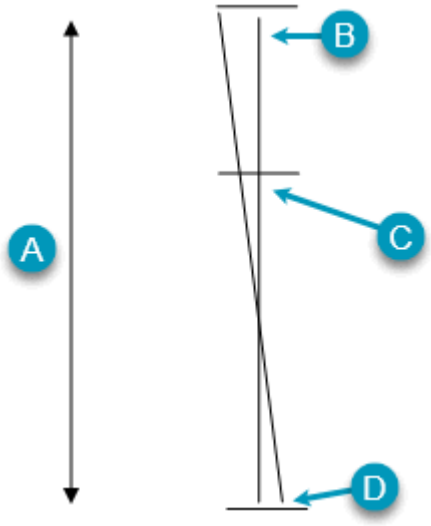


A - Tolerance width (or cylinder).
B - Datum vector positioned at measured feature.
C - Datum line.

Sometimes, however, you can't always measure right to the edge of the line, so you will need to extend the line out by a certain distance.

Since the extreme deviations are usually at the ends of the line, if you extend out the line to a distance longer than the actual length of the line you will usually get larger deviations. You can also extend the line's opposite direction by using a negative reference length.

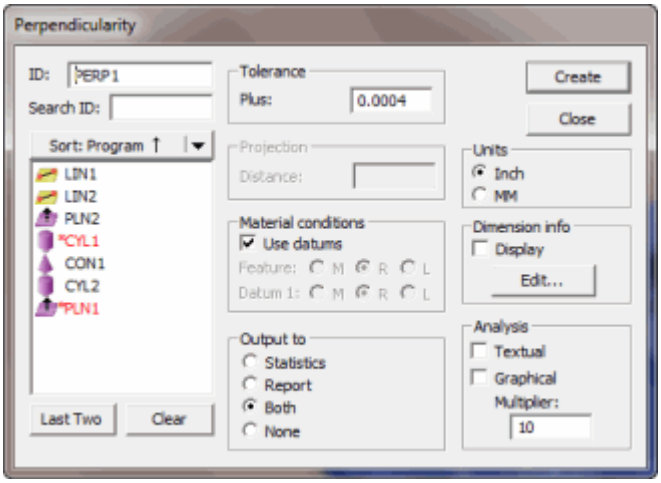
An extended line may look like this:



A - Reference Length
B - Extended point, from reference length greater than line length
C - End point of line, or reference length same as line length.
D - Start point of line, or 0.0 reference length.

You can also use the **Distance** box to specify a reference length to check the axis of a cylinder.

Dimensioning Perpendicularity



Dimension Perpendicularity Dialog Box

The **Insert | Dimension | Perpendicularity** menu option measures the perpendicularity between two features. The second feature is always the datum feature. When you select only one feature, the current workplane becomes the datum feature. This dimension type is considered one sided, meaning a single positive value tolerance is applied.

When you require more advanced support, (for example, when you need to reference multiple datums or you want to add the tangential plane modifier), you must use the newer Geometric Tolerance command. For details, see the "Using Geometric Tolerances" chapter of the PC-DMIS Core documentation.

To Dimension a Feature Using the PERPENDICULARITY Option:

1. Select **Insert | Dimension | Perpendicularity** from the submenu. The **Perpendicularity** dialog box appears.
2. Select the feature(s) to dimension from the **Feature List** box.
3. Select the appropriate **Material Condition** options for the feature(s) and datum.
4. If a datum feature is desired, select the **Use Datums** check box and select another feature in the **Feature List** box.
5. Select the appropriate **Material Condition** options for the feature(s) and datum.
6. Type the plus tolerance value in the **Plus** box.
7. Enter the projected distance in the **Distance** box.
8. Select either **Inch** or **MM** in the **Units** section.

9. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both**, or **None** option.
10. Select the optional **Display** check box if you want to view dimension information in the Graphic Display window.
11. Select the desired Analysis options by marking the **Textual** check box or the **Graphical** check box. If the **Graphical** check box was marked, type the Multiplier value in the **Multiplier** box.
12. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format you would like displayed in the Graphic Display window.
13. Click the **Create** button.

The dimension will appear in the Edit window with this information:

```
dimension_name = PERPENDICULARITY,OF feat_1,TO feat_2
```

or

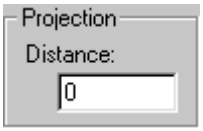
```
dimension_name = PERPENDICULARITY,OF feat_1,
```
TO workplane

AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
M	0.0000	0.0100	0.0100	5.0000	0.0000	0.0000	0.0000	0.0000

Plus Tolerance for Perpendicularity Dimensions

The **Plus** box in the **Perpendicularity** dialog box (**Insert | Dimension | Perpendicularity**) enables you to enter a tolerance value along the plus direction. This means that any perpendicularity that differs from your nominal or theoretical perpendicularity can still be a valid measurement as long as it falls within the tolerance range specified.

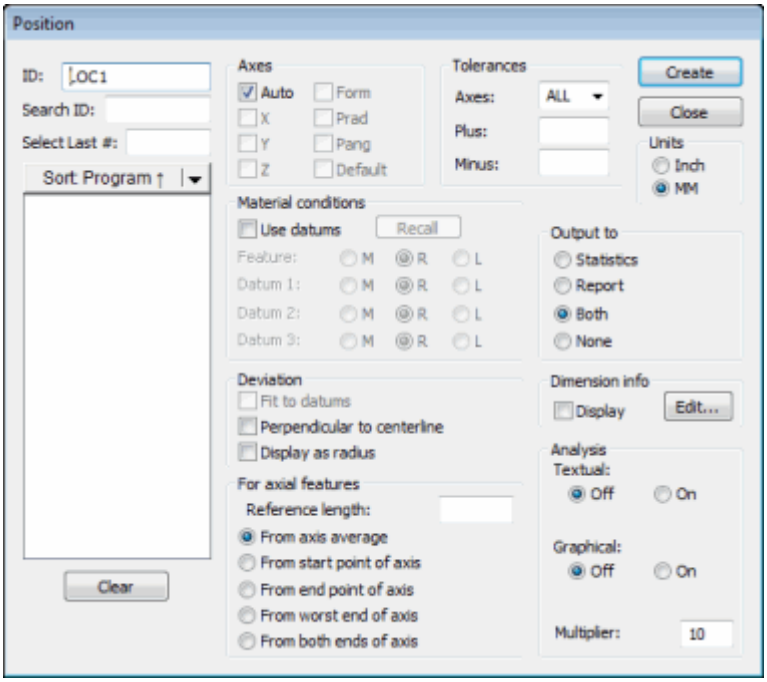
Projected Distance for Perpendicularity Dimensions



PC-DMIS allows you to type a reference distance in the **Distance** box in the **Perpendicularity** dialog box (**Insert | Dimension | Perpendicularity**). This option is

useful when the feature not only needs to be perpendicular to the datum feature, but needs to be calculated a certain distance away from the datum as well.

Dimensioning Position



Dimension Position Dialog Box

The **Insert | Dimension | Position** menu option calculates the position from the feature to the X, Y, or Z origin parallel to its respective axis. The feature's diameter, angle, and vector are also part of the calculation.

The **Position** dialog shown above is available only when the **Use Legacy Dimension** option is selected from the **Insert | Dimension** menu.

This section relates only to *Position* dimensions. Location or coordinate dimensioning is discussed in the "Dimensioning Location" section.

If datums are used, the measured and deviation XYZ values are calculated with respect to the alignment of the datums, but are displayed in the current alignment in order to interpret the values. This means that a feature reported with one position dimension can have different measured and deviation values than another position dimension if the dimensions have different or no datums defined, even if they have the same nominal values.

To Dimension a Feature Using the POSITION Option

1. Select **Insert | Dimension | Position** from the submenu. The **Position** dialog box appears.
2. Select the feature(s) to dimension from the **Feature List** box.
3. If a datum is desired, select the **Use Datums** check box. Be aware that selecting this will cause the dimension to be calculated with respect to the datums. However, the XYZ output values will be displayed with respect to the current alignment in the measurement routine.
4. Select any desired datum features from the **Feature List** box.
5. Select the appropriate options in the **Material Conditions** area to set the Material Conditions for the feature(s) and datum(s).
6. Select the appropriate check boxes from the **Deviation** area.
7. If you are dimensioning an axial feature (such as a cylinder), type a value in the **Reference Length** box and select the appropriate option from the **For Axial Features** area.
8. Select the desired axes from the **Axes** area. The software selects the **Auto** check box by default.
9. Select the axes to which you want to apply plus and minus tolerances.
10. Type the plus tolerance value in the **Plus** box.
11. Type the minus tolerance value in the **Minus** box.
12. Select either the **Inch** or **MM** option in the **Units** area.
13. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both,** or **None** option.
14. Select the desired analysis options by marking the **Textual** check box or the **Graphical** check box. If you selected the **Graphical** check box, type the Multiplier value in the **Multiplier** box.
15. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format you would like displayed in the Graphic Display window.
16. Click the **Create** button. If you did not select any check boxes from the **Axes** area, the **Create** button is not available for selection.

PC-DMIS shows the dimension in the Edit window with this information:

```
DIM dimension_name = POSITION OF FEAT_ID UNITS = IN/MM,

```

Using Datums

Although there are many different combinations of features that may be used as datums for Position dimensions, there are some general principles to follow when selecting datum features. One common scenario for designs that utilize Position dimensions is to use a circle or cylinder as the sole datum feature.

Another accepted practice is to select a set of datum features that follow 3-2-1 alignment principles. (Remember, the minimum definition for a datum is 3 datum points to describe the first datum, 2 datum points to describe the second datum and 1 datum point to describe the third datum.) This means that the selected features would be a plane, a line, and then a single point.

However, 3-2-1 alignment principles can also be used with plane/line/line, plane/line/circle, plane/cylinder/cylinder, and many other combinations.

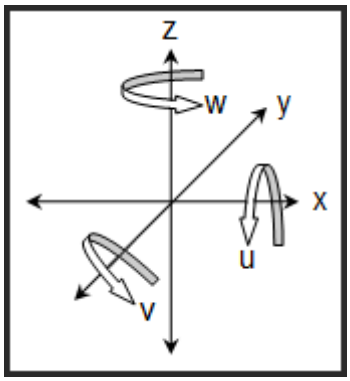
When multiple circular features have been used with the Maximum Material Condition (MMC) or Least Material Condition (LMC),

- The bonus tolerance from the TP axis will not likely be a simple addition of other bonus tolerances. This is because a best-fit calculation determines the correct bonus tolerance.
- Any circular or slot features may be measured using MMC or LMC.
- All non-circular features are measured Regardless of Feature Size (RFS).

When datum features have been selected, the Position's X,Y,Z, PA, and PR axes are calculated with respect to the alignment of the datums, but are displayed in the current alignment in order to interpret the values. Also, the datum features must be selected using the general steps discussed in this topic or else the dimension is likely to give unexpected results.

General Rules for Position Dimensions when Use Datums is Selected:

- Select all the datums specified in the feature control frame so that proper fitting is performed. The features selected for datum 1, datum 2, and datum 3 represent the Primary, Secondary, and Tertiary Datums and are used to constrain up to *six degrees of freedom* (3 degrees of translation and 3 degrees of rotation).



Example of the six degrees of freedom in 3D space (X,Y,Z,U,V, and W).

- Ensure that all Measured Feature commands (both datums and features) contain the correct nominal values (X,Y,Z,I,J,K) in the THEO field. (The fitting process references the measured feature commands to calculate datum constraints and the dimensional results.)
- The Measured Feature command and the associated Position Dimension command must come from the same alignment to ensure that the nominal values are correct and the same as what is called out as basic dimensions on the drawing. This is critical when programming without CAD as it will require editing measured feature commands (Guess Mode) to provide the correct nominal values (used for fitting).
- The datums must be mutually perpendicular to each other.
- DO NOT use the **Ignore CAD to Part** option on the **General** tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**).

For more complex datum reference frames built from combinations of non-orthogonal features or when there are modifier(s) (MMC or LMC) on the datums, we recommend that you use the Geometric Tolerance Position method of dimensioning Position. The legacy Position command with **Use Datums** selected is available for measurement routine migration.

Bonus Refinement

When calculating the bonus on a datum, if there is a previous Position dimension or orientation dimension on that datum feature, then the Position and/or orientation tolerance is added to the datum bonus to calculate the virtual size of the datum.

Using the Same Datums when Repeating Dimensions

To use the same datums from a previous Position dimension in your current Position dimension, select the Feature to dimension, and click the **Recall** button available in the **Material Conditions** area in the **Position** dialog box (**Insert | Dimension | Position**). See "Recall Button".

Examples of Use Datums with Legacy Position Dimension

The **Use Datums** option in the legacy Position command was created over 20 years ago and its behavior is based on the best interpretation of the ASME Y14.5 standard at that time. Standards continually evolve and, over the years, there have been many changes, amendments and improvements, particularly on the subject of datum fitting, bonus calculation and, more recently, full mathematical definitions for datum feature calculations.

The legacy position command does not take any of these changes into consideration and as such, does not fully comply with the requirements of any GD&T standard. It is maintained primarily to support legacy program migration and, although it can be useful for providing process information, we strongly advise using the Geometric Tolerance Position method of dimensioning instead – particularly in these cases:

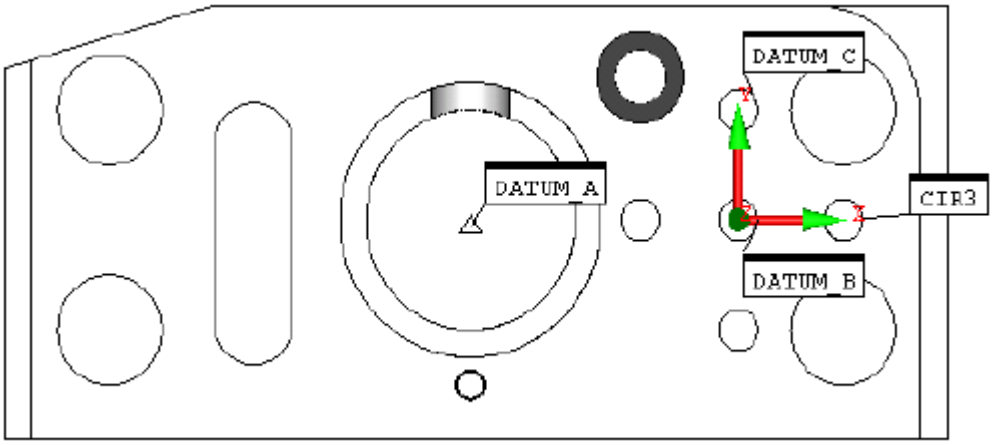
- Where there are material modifiers on datums that require PC-DMIS to perform datum shift calculations on.
- Where PC-DMIS needs to evaluate multiple position (and profile) dimensions simultaneously, since legacy dimensioning does not support simultaneous evaluations.

For details on the Geometric Tolerance Position method, see the "Position" topic in the "Using Geometric Tolerances" chapter of the PC-DMIS Core documentation.

The **Use Datums** option in the **Position** dialog box (**Insert | Dimension | Position**) enables you to perform the analysis in three ways.

- From the active alignment. See Option #1 below
- From a mathematical Virtual Hard Gage simulation (Fit to Datums: ON). See Option #2 below
- From a Datum Reference Frame simulation (Fit to Datums: OFF). See Option #3 below

These are discussed in turn. All examples reference the illustration below (Features, Datums, and Alignment):



Option #1: Use Datums: OFF

Application: Use this method when there are no modifier(s) (MMC or LMC) on the datum(s) and when checking the Position of one or multiple features (creates a single position command for each selected feature) from the currently active alignment. Bonus tolerance is only available on the feature(s).

Results: The Position of the selected feature(s) is evaluated in the active alignment. Therefore, the active alignment must be set up to reflect the specified Datum Reference Frame (DRF) before creating the Position dimension(s).

You can see the affect of setting **Use Datums** to Off in the images below:

	IN	LOC2 - CIR3					
AX	MEAS	NOMINAL	+TOL	-TOL	BONUS	DEV	OUTTOL
X	1.0030	1.0000	0	0	0	0.0030	0
Y	0.0030	0.0000	0	0	0	0.0030	0
DF	0.3760	0.3750	0.0050	0.0050	0.0060	0.0010	0.0000
TP	0	MMC	0.0100	0	0.0060	0.0085	0.0000

Option #2: Use Datums: ON and Fit to Datums: ON

Application: Use this method when:

- There are modifier(s) (MMC or LMC) on the datum(s)
- Those datums are mutually perpendicular to each other and...
- When checking the Position of a single feature (multiple features are not supported in legacy dimension mode).

Position of multiple features are supported when you use the newer Position Geometric Tolerance method of dimensioning if they meet these requirements:

- MMC/LMC is applied to the Datum feature(s)
- Simultaneous evaluations of multiple position tolerances
- The use of complex datum reference frames built from non-orthogonal features

For details on the latest Geometric Tolerance methods, see the "Using Geometric Tolerances" chapter in the PC-DMIS Core documentation.

Results: A "Virtual Hard Gage" simulation is performed mathematically by translating and rotating based on the amount of bonus tolerance from the datum(s). This results in the measured values for the feature changing by the amount of "datum shift" which simulates the jiggling of the gage. In many cases, the measured values may be the same as the nominal values when there is sufficient bonus from the datum features. When the feature is out of tolerance, no fitting occurs, and the measured values and deviations reflect the actual location of the feature such that process adjustments can be made or an engineering analysis of the nonconformance can be performed.

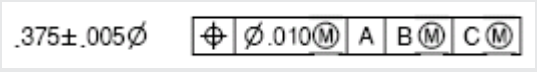
The results are representing "Pass/Fail" analysis just as a functional gage does; therefore, it is not possible to monitor for process variation or perform statistical studies.

Bonus Column: The bonus column in the report shows the calculated amount of bonus of the feature (DF) and the calculated amount of bonus of each datum feature of size (D1 primary, D2 secondary, D3 tertiary). The total bonus value is determined based on the following conditions:

Condition #1A: In-Tolerance

When sufficient bonus tolerance from the datum(s) allows datum shift such that there is no deviation from the nominal values without utilizing up to 100% of the allowable bonus from the datum(s), the total bonus amount is the sum of the bonus from the feature and the unused amount of bonus from the datum(s).

Example of Condition #1A In-Tolerance:



The measured values changed based on the allowable datum shift derived from the bonus of datums D2 and D3 (simulates a functional gage). In this case the measured values check nominal resulting in zero deviation, and the total bonus is the sum of the bonus from the feature (0.006) and the unused bonus from the datums (0.002) for a total of 0.008 bonus tolerance.

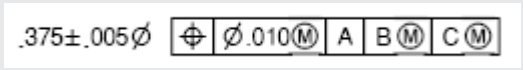
- Two degrees of freedom from bonus on D2 (0.008 bonus): translation in X and Y axis
- One degree of freedom from bonus on D3 (0.008 bonus): rotation about Z axis

⌖	IN	LOC1 - CIR3					
AX	MEAS	NOMINAL	+TOL	-TOL	BONUS	DEV	OUTTOL
X	1.0000	1.0000	0	0	0	0.0000	0
Y	0.0000	0.0000	0	0	0	0.0000	0
DF	0.3760	0.3750	0.0050	0.0050	0.0060	0.0010	0.0000
D1	0	0	0	0	0	PLANE	
D2	0.3780	0.3750	0.0050	0.0050	0.0080	CIRCLE	
D3	0.3780	0.3750	0.0050	0.0050	0.0080	CIRCLE	
TP	0	MMC	0.0100	0	0.0080	0.0000	0.0000

Condition #1B: In-Tolerance

When 100% of the bonus from the datum(s) is used then the total bonus amount is only the bonus from the feature. Typically this case would show some amount of deviation from the nominal values.

Example of Condition #1B In-Tolerance:



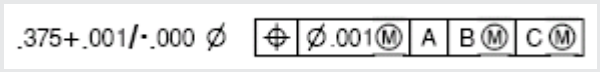
The tolerance for D2 and D3 were changed to illustrate using 100% of the bonus from the datums where there is deviation from nominal yet still an In-Tolerance condition.

	IN	LOC4 - CIR3					
AX	MEAS	NOMINAL	+TOL	-TOL	BONUS	DEV	OUTTOL
X	1.0015	1.0000	0	0	0	0.0015	0
Y	0.0000	0.0000	0	0	0	0.0000	0
DF	0.3760	0.3750	0.0050	0.0050	0.0060	0.0010	0.0000
D1	0	0	0	0	0	PLANE	
D2	0.3780	0.3750	0.0030	0.0000	0.0030	CIRCLE	
D3	0.3780	0.3750	0.0030	0.0000	0.0030	CIRCLE	
TP	0	MMC	0.0100	0	0.0060	0.0030	0.0000

Condition #2: Out of Tolerance

When there is insufficient bonus from the datum(s) to allow datum shift such that the feature is In-Tolerance, no fitting is performed, the measured values are not altered and the total bonus is only the bonus from the feature.

Example of Condition #2 Out of Tolerance:



The tolerance for the DF, D2, D3 and the TP were changed to illustrate the out of tolerance condition.

	IN	LOC3 - CIR3					
AX	MEAS	NOMINAL	+TOL	-TOL	BONUS	DEV	OUTTOL
X	1.0030	1.0000	0	0	0	0.0030	0
Y	0.0030	0.0000	0	0	0	0.0030	0
DF	0.3760	0.3750	0.0010	0.0000	0.0010	0.0010	0.0000
D1	0	0	0	0	0	PLANE	
D2	0.3780	0.3750	0.0030	0.0000	0.0030	CIRCLE	
D3	0.3780	0.3750	0.0030	0.0000	0.0030	CIRCLE	
TP	0	MMC	0.0010	0	0.0010	0.0085	0.0065

Option #3: Use Datums: ON and Fit to Datums: OFF

Application: Use this method when there are modifier(s) (MMC or LMC) on the Datum(s) and you do not want the measured data fitted (no datum shift). This option was added based on customer request to provide the ability to incorporate bonus from a Datum and still monitor for process variation (the measured values are not altered because no "datum shift" is applied).

This method is not compliant with ASME Y14.5 or ISO 1101.

Results: A "Datum Reference Frame" simulation is performed mathematically by Translating and Rotating based on the degrees of freedom constrained by the selected Datum(s). The X, Y, or Z measured values and deviations are from the active alignment and are not altered based on the bonus from the datum features (no datum shift).

Bonus Column: The bonus column in the report shows the calculated amount of bonus of the feature (DF) and the calculated amount of bonus of each datum feature of size (D1 primary, D2 secondary, D3 tertiary). The total bonus value is the sum of the bonus from the feature and the datum with the smallest amount of bonus amongst the selected datums.

Example of Condition #1 In-Tolerance:

.375±.005Ø | ⌖ | Ø.010Ⓜ | A | B Ⓜ | C Ⓜ

⌖	IN	LOC7 - CIR3					
AX	MEAS	NOMINAL	+TOL	-TOL	BONUS	DEV	OUTTOL

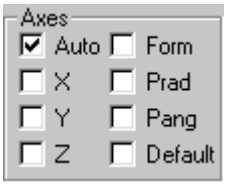
Default Axes for Position Dimensions



The **Default** check box in the **Position** dialog box (**Insert | Dimension | Position**) enables you to alter the format of the default output. When the **Auto** check box is checked, the axes that appear in the dimension are selected according to the default axes of the feature type. However, in some circumstances, it may be necessary to override the default setting. To do this, you would select the **Default** check box and any other desired axes.

To alter the output, select the desired check boxes:

Auto = Prints the default axes based on the feature type.

X = Prints the X axis value.

Y = Prints the Y axis value.

Z = Prints the Z axis value.

Form = Prints the integrated form dimension for the feature.

- For a circle or cylinder feature, this is the Roundness (RN) dimension.
- For a plane feature, this is the Flatness (FL) dimension.
- For a line feature, this is the Straightness (ST) dimension.

Pang = Prints the polar angle (PA) value.

Prad = Prints the polar radius (PR) value.

Default = Alters the format of the default output.

Once the output values have been changed to something other than the default, PC-DMIS uses the new settings for all subsequent dimensions. If you want PC-DMIS to then use the original default axes, you must reset the format to the default settings.

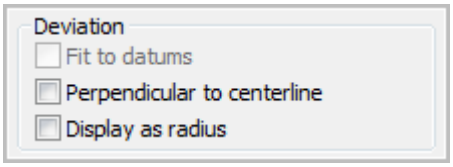
To reset the format to the default settings:

1. Select the **Auto** check box.
2. Select the **Default** check box.
3. Click the **Create** button.

PC-DMIS automatically resets the dimension to print the default axes according to the feature type.

If the **Auto** check box is marked, PC-DMIS automatically determines the default axes to print. The default output format is based on the feature type. PC-DMIS automatically determines the position of the selected feature using the documented (see box above) axis format.

Deviation



The **Deviation** area in the **Position** dialog box (**Insert | Dimension | Position**) enables you to select options that determine how you want deviations performed and how you want deviations displayed in the Edit window.

Fit to Datums

The **Fit To Datums** check box in the **Position** dialog box (**Insert | Dimension | Position**) determines whether PC-DMIS calls the fitting algorithm when datums are used.

- When selected, PC-DMIS calls the fitting algorithm when datums are specified. It reports the considered feature in the fitted position, with the total bonus being the remaining available bonus after fitting.
- When cleared, PC-DMIS analyses the Position dimension with the features in their measured position, with no fitting applied. The reported total bonus is the total available bonus from the considered feature and the datum based on the datum constraints.

For a detailed explanation of how the legacy PC-DMIS Position command behaves with different combination of Use Datums and Fit to Datums, see the "Examples of Use Datums with Legacy Position" topic in the PC-DMIS Core documentation.

Perpendicular to Centerline

The **Perpendicular to Centerline** check box in the **Position** dialog box (**Insert | Dimension | Position**) determines whether PC-DMIS calculates the deviation perpendicular to the feature's theoretical centerline or perpendicular to the direct X, Y, and Z values.

- If marked, PC-DMIS calculates the deviation perpendicular to the feature's theoretical centerline, ignoring any deviation in the direction of the centerline.

- If not marked, PC-DMIS calculates the deviation perpendicular to the X, Y, and Z values.

This check box is especially useful with sheetmetal points which may have approach vectors not oriented along the X, Y, or Z axis. This check box will allow the deviation to be found perpendicular to the approach vector.

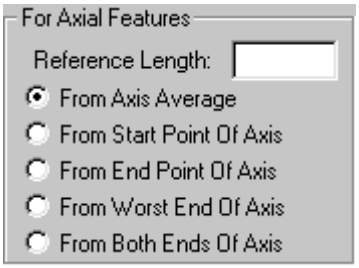
Display As Radius

The **Display As Radius** check box in the **Position** dialog box (**Insert | Dimension | Position**) determines whether or not PC-DMIS will display the radii of the features and datums instead of displaying their diameters.

- If selected, PC-DMIS displays the radii in the DF, D1, D2, D3, and TP lines and places text in the Edit window's dimension field showing whether the dimension is displaying the features' radius or diameter.
- If deselected, PC-DMIS displays the diameters as usual.

If you use this check box, be aware that it is *not* compliant with ISO standards.

Axial Features



For axial features, such as cylinders, you can specify where along the axis PC-DMIS should create the Position dimension. You can tell PC-DMIS to create the dimension at the axis' average (or centroid), at the axis' start point, at the axis' end point, at the axis' worst end (the end with the greatest deviation), or at both ends of the axis. You can also create the dimension at a specified reference length away from the selected point on the axis.

To use the reference length with a Position dimension:

1. Type the desired value in the **Reference Length** box in the **Position** dialog box (**Insert | Dimension | Position**).
2. Select one of the option buttons (**From Axis Average**, **From Start Point Of Axis**, **From End Point Of Axis**, **From Worst End Of Axis**, or **From Both Ends Of Axis**).

3. Click the **Create** button. PC-DMIS locates the selected point (or points if you've selected **From Both Ends Of Axis**) and then moves along the axis the distance of the specified reference length and creates the dimension(s) there.

   Reference Length
   The value in this box specifies the length from the selected point or axis end where PC-DMIS will create the Position dimension.

   From Axis Average
   This option tells PC-DMIS to dimension the axial feature, from the centroid (or average) of the axis.

   From Start Point of Axis
   This option tells PC-DMIS to dimension the axial feature from the Start Point of the axis.

   From End Point of Axis
   This option tells PC-DMIS to dimension the axial feature from the End Point of the axis.

   From Worst End of Axis
   This option tells PC-DMIS to dimension the axial feature from the start or end point that gives the worst-case scenario for the dimension. PC-DMIS creates the dimension at the axis end that deviates the farthest from the nominal. For example if your part contains a skewed cylinder, the start or end point along the cylinder's axis that deviates farthest from the nominal is the point that gives the worst-case scenario.

   From Both Ends of Axis
   This option tells PC-DMIS to dimension the axial feature, from both the start and end point of the axis selected. PC-DMIS creates a dimension at both ends of the axis.

Tolerances for Position Dimensions

The **Tolerances** area in the **Position** dialog box (**Insert | Dimension | Position**) enables you to type plus and minus tolerances for each axis found in the **Axes** drop-down list; it also lets you define certain material condition modifiers.

To enter in axes tolerances:

1. From the **Axes** list, select the axis that you want to apply the tolerance.

2. In the **Plus** box, enter the plus tolerance value for the selected axis.

3. In the **Minus** box, enter the minus tolerance value for the selected axis. Since the TP and FORM axes require a plus tolerance, PC-DMIS ignores the values entered for these if they are minus entries.

4. Select the materials condition modifiers from the **Materials Condition** area.

You can set tolerances for multiple axes from the list. PC-DMIS stores your defined tolerances with the selected list item. Even if you select a different item from the **Axes** list and give it different tolerances, you can switch between the available axes to view and set their individual stored tolerances.

Axes

The **Axes** list in the **Position** dialog box (**Insert | Dimension | Position**) provides you with a list of available axes to which you can apply plus and / or minus tolerances. The list contains the following:

ALL = All the axes and options displayed in the drop down list

D1 = Diameter /Width of the first datum

D2 = Diameter /Width of the second datum

D3 = Diameter /Width of the third datum

DF = Diameter /Width of the feature

LF = Length of the feature if the feature is a slot

WF = Width of the feature if the feature is a slot

LD = Length of the datum if the datum is a slot

WD = Width of the datum if the datum is a slot

TP = Position tolerance and its associated deviation

FORM = The integrated form dimension for the feature.

- For a circle or cylinder feature, this is the Roundness (RN) dimension.
- For a plane feature this is the Flatness (FL) dimension.
- For a line feature this is the Straightness (ST) dimension.

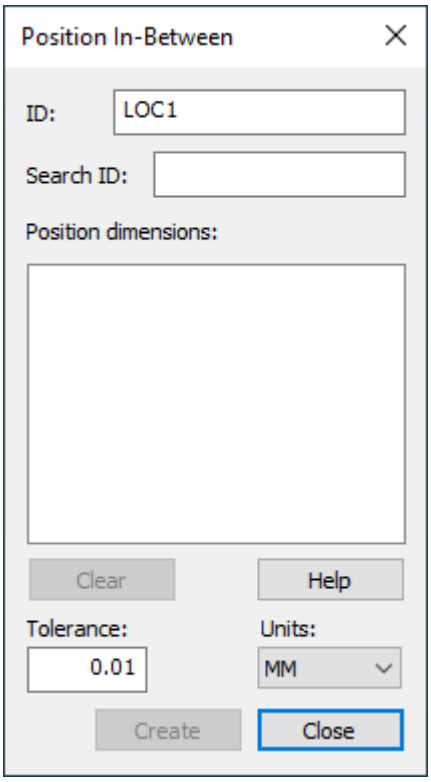
Plus

In the **Plus** box in the **Position** dialog box (**Insert | Dimension | Position**), you can enter the plus values for tolerances of the axis or axes selected from the **Axes** list.

Minus

In the **Minus** box in the **Position** dialog box (**Insert | Dimension | Position**), you can enter the minus values for tolerances of the axis or axes selected from the **Axes** list.

Dimensioning Position In-Between



Position In-Between Dialog Box

The **Insert | Dimension | Position In Between** menu option computes the in-between position deviation and deviation angle from two specified Position dimensions. This dimension is useful when you have a set of position dimensions on a pattern of holes and you want to report the position deviation and deviation angle of one hole relative to another where each individual hole of the pattern has been dimensioned with a separate position callout.

The ANSI or ISO standards do not include Position In-Between. This is a special implementation unique to PC-DMIS.

To create this dimension:

1. Access the **Position In Between** menu option to open the **Position In-Between** dialog box.

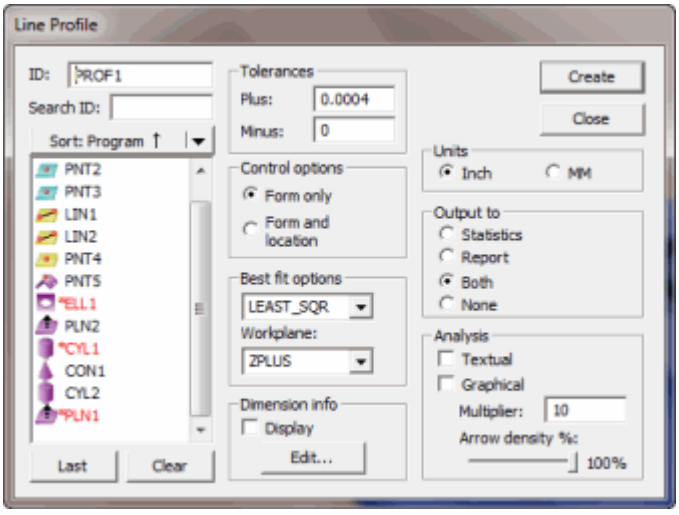
2. Select two dimensions from the **Position Dimensions** list. If you select a composite FCF Position or a multiple single-segment FCF Position (a Position with more than one segment), PC-DMIS only uses the Primary Dimension to compute the Position In-Between dimension.
3. Type a label ID for the dimension by typing in the **ID=** box.
4. Type a tolerance value for the dimension in the **Tolerance** box.
5. Select the measurement units to use from the **Units** list.
6. Click **Create**.

   The dimension appears in the Edit window with this information:

```
dimension_name = POSITION IN BETWEEN dim_1 AND dim_2,
UNITS=IN/MM
AX     NOMINAL        MEAS        +TOL        -TOL
     BONUS          DEV      DEVANG      OUTTOL
TP      0.0000      0.0000      0.0100
                            0.0000   -172.4842      0.0000
#-------
```

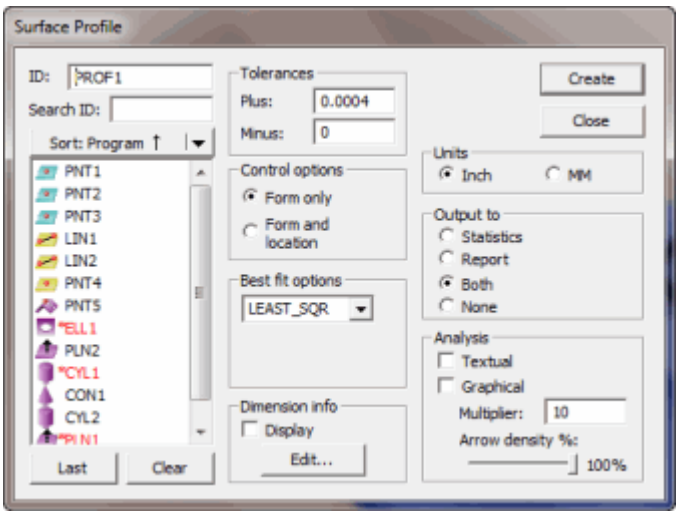
   DEV is the deviation of the In-Between dimension. DEVANG is the deviation angle of the In-Between dimension.

Dimensioning Profile - Line or Surface



Dimension Line Profile Dialog Box

The profile's **Line** menu option (**Insert | Dimension | Profile | Line**) computes the two-dimensional profile error of a curve.



Dimension Surface Profile Dialog Box

The profile's **Surface** menu option (**Insert | Dimension | Profile | Surface**) computes the three-dimensional profile error of a surface or curve feature.

You can use any type of feature for a profile scan.

For dimensioning of vision 2D Profile Auto-Features, the theoretical vectors are projected to the workplane. The deviations reported are 2D relative to this workplane rather than surface normal deviations.

By default, legacy profile form and location, reports the two-value method, as per ASME Y14.5.1 - 1994. PC-DMIS compares the MAX and MIN deviations to the +TOL and -TOL values to determine conformance.

An alternate single-value method is available from the PC-DMIS Settings Editor. From the **Option** section, you can change the `UseISOCalculations` setting to 1. This causes PC-DMIS to calculate a single MEAS value that is two times the maximum deviation. It then compares that single measured value to the +TOL. This method is in accordance with ASME Y14.5.1 - 2019.

To Dimension a Feature Using the Surface Profile Option:

1. Select **Insert | Dimension | Profile | Surface** from the submenu. The **Surface Profile** dialog box appears.
2. Select the feature(s) to dimension from the **Feature List** box. If a datum feature is selected, it must be a plane.
3. Type the plus tolerance value in the **Plus** box.

4. Type the minus tolerance value in the **Minus** box.
5. Select either **Inch** or **MM** in the **Units** area.
6. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both**, or **None** option.
7. Select the optional **Display** check box if you want to view dimension information in the Graphic Display window.
8. Select either **Form Only** or **Form and Location** in the **Control Options** area of the dialog box.
9. If you selected **Form Only**, select the **Use Best Fit** check box. This causes the dimension to use the internal best fit alignment to allow the shape to rotate or translate until it finds the best fit for the feature.
10. Select the desired analysis options by marking the **Textual** check box or the **Graphical** check box. If the **Graphical** check box was marked, type the multiplier value in the **Multiplier** box.
11. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format you would like displayed in the Graphic Display window.
    - If you've selected the **Form and Location** option earlier, be sure to select **MaxMin** check box from the **Dimension Info Format** area of the **Edit Default Dimension Info** dialog box.
    - If you've selected the **Form Only** option earlier, be sure to select the **Measured** check box from the **Dimension Info Format** area of the **Edit Default Dimension Info** dialog box.
12. Click the **Create** button.

The dimension will appear in the Edit window with this information:

```
dimension_name = PROFILE,OF feat_1
```

AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
M	5.0000	0.0100	0.0100	5.0000	0.0000	0.0000	0.0000	0.0000

Displaying Surface Profile Contour Plots

PC-DMIS allows you to display a colored surface contour plot that rests on the surface of the CAD model in the Graphic Display window when you use Patch scans or UV scans and create a profile dimension from them.

> Contour Plots are only supported for Legacy Profile of a Surface. You cannot use them with the newer Geometric Tolerances.

To do this:

1. Import a solid CAD model.
2. Select the **Edit | Graphic Display Window | View Setup** menu option to open the **View Setup** dialog box.
3. From the **View Setup** dialog box, click the **Solid** check box for one of your views and then close the dialog box.
4. From the **Graphic Modes** toolbar (**View | Toolbars | Graphic Modes**), click the **Surface Mode** icon to place PC-DMIS in Surface Mode.
5. Create a Patch or UV scan. For details on these scan types, see "Performing a Patch Advanced Scan" and "Performing a UV Advanced Scan" topics in the "Scanning" chapter of the PC-DMIS CMM documentation.
6. Select the **Edit | Graphic Display Window | Analysis Options** menu option to open the **Analysis** dialog box.
7. From the **Analysis** dialog box, select the **Show Contour Plot** option and click **OK** until you return to the main PC-DMIS screen.
8. Select the **Insert | Dimension | Profile | Surface**) menu option to open the **Surface Profile** dialog box.
9. From the **Surface Profile** dialog box, select the Patch or UV scan from the **Feature List** box.
10. In the **Analysis** area of the **Surface Profile** dialog box, select the **Graphical** check box.
11. Make any other desired changes to the **Surface Profile** dialog box.
12. Click **Create** to generate the dimension.

You can see that PC-DMIS places a colored contour plot directly onto the model surface where the scan was.

To Dimension a 2D Feature Using the Line PROFILE Option:

1. Select **Insert | Dimension | Profile | Line** from the submenu. The **Line Profile** dialog box appears.
2. Select the feature(s) to dimension from the **Feature List** box. You can select any 2D feature. If a datum feature is selected, it must be a plane.
3. Type the plus tolerance value in the **Plus** box.
4. Type the minus tolerance value in the **Minus** box.
5. Select either **Inch** or **MM** in the **Units** area.
6. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both**, or **None** option.
7. Select the optional **Display** check box if you want to view dimension information in the Graphic Display window.
8. Select either **Form Only** or **Form and Location** in the **Control Options** area of the dialog box.
9. If you selected the **Form Only** option, select the **Use Best Fit** check box. This causes the dimension to use the internal best fit alignment to allow the shape to rotate or translate until it finds the best fit for the feature.
10. If you selected the **Use Best Fit** check box, select the desired workplane to allow rotation and translation. Using the workplane restricts the alignment to be a two-dimensional alignment.
11. Select the desired analysis options by marking the **Textual** check box or the **Graphical** check box. If the **Graphical** check box was marked, type the multiplier value in the **Multiplier** box.
12. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format you would like displayed in the Graphic Display window.
    - If you've selected the **Form and Location** option earlier, be sure to select **MaxMin** check box from the **Dimension Info Format** area of the **Edit Dimension Info** dialog box.
    - If you've selected the **Form Only** option earlier, be sure to select the **Measured** check box from the **Dimension Info Format** area of the **Edit Dimension Info** dialog box.
13. Click the **Create** button.

The dimension will appear in the Edit window with this information:

```
dimension_name = PROFILE,OF feat_1
```

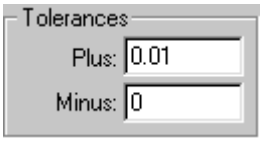
AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
M	5.0000	0.0100	0.0100	5.0000	0.0000	0.0000	0.0000	0.0000

Displaying Line Profile Contour Plots

PC-DMIS allows you to display a colored contour plot that rests on the surface of the CAD model in the Graphic Display window for linear or curve features.

For a Surface Profile, follow the instructions listed in "Displaying Surface Profile Contour Plots", and substitute the input feature with the appropriate line or curve feature (or scan).

Tolerances for Surface Profile Dimensions



This dimension type is considered either one sided, meaning a single positive value tolerance is applied, or two sided, meaning upper and lower tolerance values are applied.

- If the **Form Only** option in the **Surface Profile** dialog box (**Insert | Dimension | Profile | Surface**) has been selected, only a plus tolerance can be applied.
- If the **Form and Location** has been selected, the profile dimension can be one sided or two sided.

Plus Tolerance

The **Plus** box in the **Surface Profile** dialog box (**Insert | Dimension | Profile | Surface**) enables you to enter a tolerance value along the plus direction. This means that any profile that measures more than your nominal or theoretical profile can still be a valid measurement as long as it falls within the tolerance range specified.

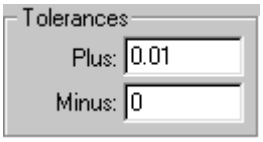
PC-DMIS also allows a negative-upper tolerance (or a minus tolerance in the positive range). This is done by entering in a minus sign before the value in the **Plus** box.

Minus Tolerance

The **Minus** box in the **Surface Profile** dialog box (**Insert | Dimension | Profile | Surface**) enables you to enter a tolerance value along the minus direction. This means that any profile that measures less than your nominal or theoretical profile can still be a valid measurement as long as it falls within the tolerance range specified.

PC-DMIS allows positive-lower tolerances (or a positive tolerance in the negative range). This is done by typing a minus sign before the value in the **Minus** box.

Tolerances for Line Profile Dimensions



This dimension type is considered either one sided, meaning a single positive value tolerance is applied, or two sided, meaning upper and lower tolerance values are applied.

- If the **Form Only** option in the **Line Profile** dialog box (**Insert | Dimension | Profile | Line**) has been selected, only a plus tolerance can be applied.
- If the **Form and Location** has been selected, the profile dimension can be one sided or two sided.

Plus Tolerance

The **Plus Tol** box enables you to enter a tolerance value along the plus direction. This means that any measurement that measures more than your nominal or theoretical measurement can still be a valid measurement as long as it falls within the tolerance range specified.

Minus Tolerance

The **Minus Tol** box enables you to enter a tolerance value along the minus direction. This means that any measurement that measures less than your nominal or theoretical measurement can still be a valid measurement as long as it falls within the tolerance range specified.

Control Options for Surface Profile Dimensions

The options in this area in the **Surface Profile** dialog box (**Insert | Dimension | Profile | Surface**) determine if a profile matches the same form, or form and location as its nominal.

Form Only

When dimensioning a profile, selecting the **Form Only** option in the **Surface Profile** dialog box (**Insert | Dimension | Profile | Surface**), you can tell PC-DMIS to only determine if a particular profile matches the same form as its nominal. This option ignores whether the location of the profile is outside of acceptable tolerances.

For a **Form Only** dimension, pay attention to the measured values in the generated dimension.

Form and Location

When dimensioning a profile, you can use the **Form and Location** option in the **Surface Profile** dialog box (**Insert | Dimension | Profile | Surface**) to determine if a particular profile matches the same form and the same location as its nominal. This differs from the **Form Only** option because the location of the profile must also be within acceptable tolerances.

For a **Form and Location** dimension, pay attention to the Max/Min values in the generated dimension.

Control Options for Line Profile Dimensions

The options in this area in the **Line Profile** dialog box (**Insert | Dimension | Profile | Line**) determine if a profile matches the same form, or form and location as its nominal.

Form Only

When dimensioning a profile, you can use the **Form Only** option in the **Line Profile** dialog box (**Insert | Dimension | Profile | Line**) to tell PC-DMIS to only determine if a particular profile matches the same form as its nominal. This option ignores whether the location of the profile is outside of acceptable tolerances.

For a **Form Only** dimension, pay attention to the measured values in the generated dimension.

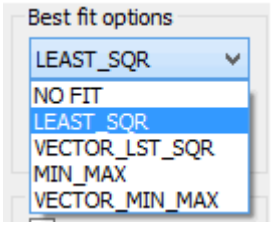
PC-DMIS 2009 and later support the Form Only Profile of a Line when the considered feature is a constructed curve based on a linear scan. The theoretical points are projected onto the theoretical curve to determine what theoretical points and vectors to use in the profile calculation.

Form and Location

When dimensioning a profile, using the **Form and Location** option in the **Line Profile** dialog box (**Insert | Dimension | Profile | Line**), you can determine if a particular profile matches the same form and the same location as its nominal. This differs from the **Form Only** option, because the location of the profile must also be within acceptable tolerances.

For a **Form and Location** dimension, pay attention to Max / Min values in the generated dimension.

Best Fit Options for Surface Profile Dimensions



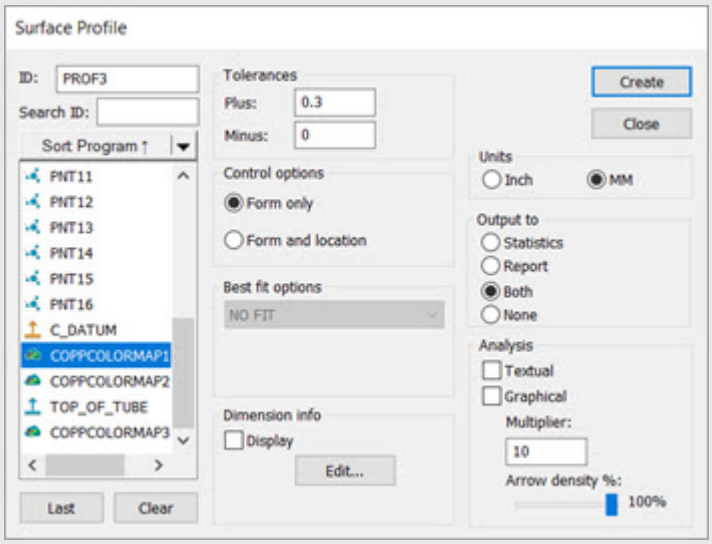
This area only appears in the dialog box if you select the **Form Only** option in the **Control options** area.

The **Best Fit options** area in the **Surface Profile** dialog box (**Insert | Dimension | Profile | Surface**) lets you create an internal Best Fit Alignment on the dimensioned feature.

NO FIT - This does not create an alignment.

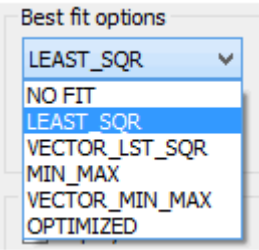
For descriptions of **LEAST_SQR**, **VECTOR_LST_SQR**, **MIN_MAX**, and **VECTOR_MIN_MAX**, see "The Best Fit Alignment Methods" in the "Creating and Using Alignments" chapter.

For legacy surface profiles, if you select a colormap from the Feature List Box, PC-DMIS automatically selects the **NO FIT** option for the surface profile and disables the **Best fit options** list.



Surface Profile dialog box with colormap feature selected

Best Fit Options for Line Profile Dimensions



This area only appears in the dialog box if you select the **Form Only** option in the **Control options** area.

The **Best Fit Options** area in the **Line Profile** dialog box (**Insert | Dimension | Profile | Line**) lets you create an internal Best Fit alignment on the dimensioned feature using one of these available fitting methods:

NO FIT - This does not create an alignment.

For descriptions of **LEAST_SQR**, **VECTOR_LST_SQR**, **MIN_MAX**, and **VECTOR_MIN_MAX**, see "The Best Fit Alignment Methods" in the "Creating and Using Alignments" chapter.

OPTIMIZED - This fit uses a genetic algorithm to determine if the data passes or fails the Line Profile dimension. You can also specify the lower tolerance value. (Typically, with the other fitting methods, you can't change the tolerance from 0.0.)

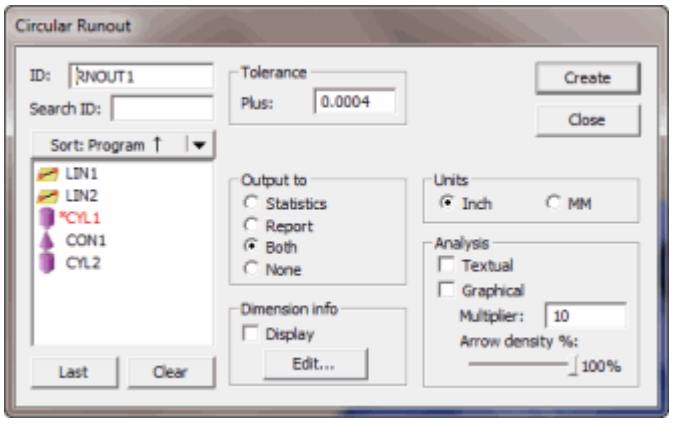
Workplane

When you use the line profile dimension, PC-DMIS creates an internal two-dimensional alignment that rotates and translates in all directions within the selected workplane to minimize the deviations of the individual hits. If you select a workplane that differs from the two-dimensional projection of the curve, an incorrect calculation results.

Dimensioning Runout - Circular or Total

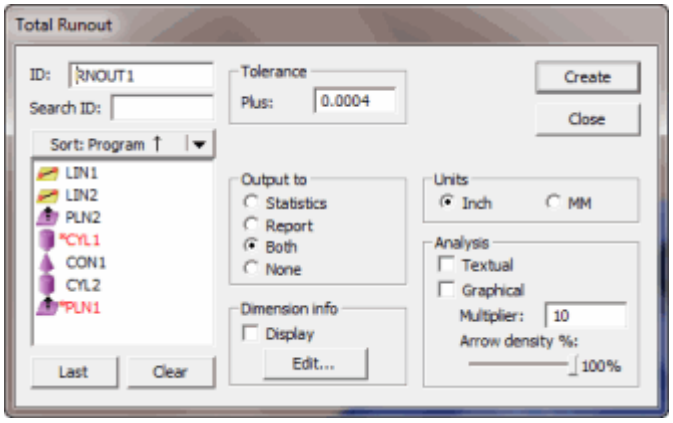
The **Insert | Dimension | Runout | Circular** and **Total** menu options determine the runout of the first feature with respect to the second feature (i.e., the second feature becomes the datum feature). If only one feature is selected, the origin and the workplane become the datum feature. In this case, PC-DMIS uses the position from the origin and the direction from the workplane for the datum. The text in the Edit window for the datum feature will read "THE ORIGIN".

- Circular Runout works for circles, cones, cylinders, and spheres.



Circular Runout Dialog Box

- Total Runout works for cylinders, cones, and planes.

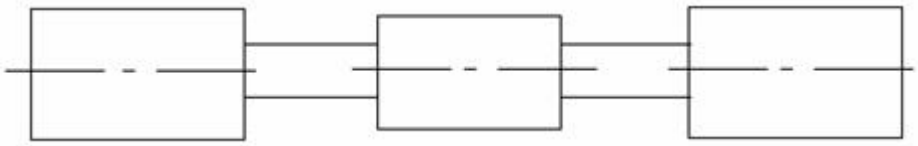


Total Runout Dialog Box

This dimension type is considered one sided, meaning a single positive value tolerance is applied.

Understanding Runout

Runout dimensioning is generally used in camshaft operations. A camshaft is designed to rotate around a center line. Since the separate cylinders comprising the camshaft are all on the same center line, you need to ensure that the centerline is not only parallel, but that the cylinders are also coaxial (or concentric).



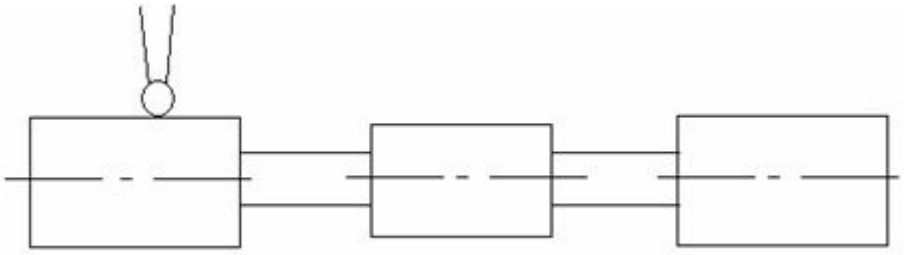
A sample Camshaft.

Additionally, you need to make sure the surface of the cylinders is round and straight (straight when compared to a separate datum axis, not just its own axis).

The main difference between runout and parallelism is that runout is checking points on a *surface* of a cylinder, and not just the *axis* of the cylinder. Runout also differs from a cylinder's straightness because it compares the surface of the cylinder to a datum axis, not just to itself. A runout dimension checks for these conditions.

How Runout is Measured

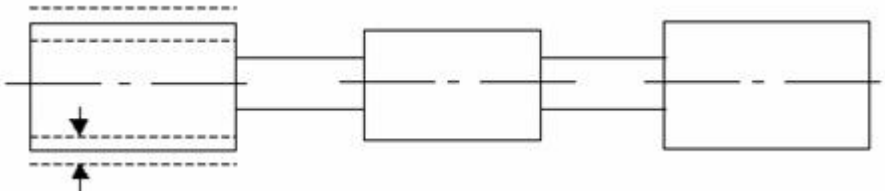
The typical, non-CMM way to measure runout is to put a small dial indicator on the surface of the cylinder, zero-out the indicator, and then spin the cylinder. This indicator measures any difference along that circle as the cylinder rotates.



Example of a runout being measured with a dial indicator.

A CMM essentially does the same thing. Instead of spinning the cylinder, however, the CMM's probe rotates around the cylinder and takes a finite number of hits.

The tolerance band for runout would look something like this:



Example showing a runout tolerance band (dotted lines).

The tolerance band has these properties:

- It has a width the size of the plus tolerance.
- It is parallel to the datum vector (the axis of some other line or cylinder).
- It is fixed at a certain radius from the cylinder’s axis.

Two Categories of Runout: Circular or Total

There are two categories for runout:

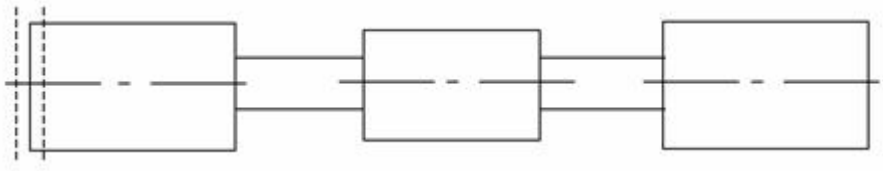
- Circular Runout measures just one circle—one row of hits—around the cylinder.
- Total Runout measures multiple circles up and down the entire surface of the cylinder with multiple rows of hits.

Obviously, you are somewhat limited using a CMM for total runout because you probably will not take 100 rows of hits around your cylinder, and something as little as 3 rows of hits clearly isn’t enough for determining total runout.

Nevertheless, PC-DMIS provides you with the ability to dimension both circular and total runout and lets you determine whether or not you've measured enough rows of the cylinder.

Using Runout to Check a Cylinder End

PC-DMIS also allows you to test for another case of runout specified in the standard: Checking the plane of one of the cylinder's ends. The tolerance for this type of runout is at a fixed orientation perpendicular to the datum axis.



Example showing runout on a cylinder end.

To Dimension a Feature Using the RUNOUT Option:

1. Select **Insert | Dimension | Runout | Circular** or **Insert | Dimension | Runout | Total** from the submenu. The **Total Runout** or **Circular Runout** dialog box appears.
2. Select the feature(s) to dimension from the **Feature List** box.
3. Type the plus tolerance value in the **Plus** box.
4. Select either **Inch** or **MM** in the **Units** area.
5. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both**, or **None** option.
6. Select the optional **Display** check box if you want to view dimension information in the Graphic Display window.
7. Select the desired analysis options by marking the **Textual** check box or the **Graphical** check box. If the **Graphical** check box was marked, enter the Multiplier value in the **Multiplier** box.
8. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format you would like displayed in the Graphic Display window.
9. Click the **Create** button.

The dimension will appear in the Edit window with this information:

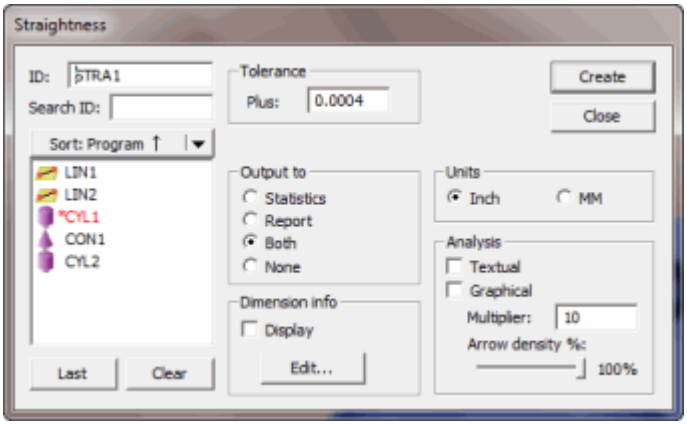
```
dimension_name = RUNOUT,OF feat_1,TO feat_2
```

AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
M	0.0000	0.0100	0.0100	5.0000	0.0000	0.0000	0.0000	0.0000

Plus Tolerance for Runout Dimensions

The **Plus** box in the **Total Runout** or **Circular Runout** dialog box (**Insert | Dimension | Runout | Total** or **Insert | Dimension | Runout | Circular**) enables you to enter a tolerance value along the plus direction. This means that any runout that differs from your nominal or theoretical runout can still be a valid measurement as long as it falls within the tolerance range specified.

Dimensioning Straightness



Dimension Straightness Dialog Box

A minimum of three hits are necessary to determine the straightness of a line.

The **Insert | Dimension | Straightness** option calculates the straightness of a line. This dimension type is considered one sided, meaning a single positive value tolerance is applied.

To Dimension a Feature Using the STRAIGHTNESS Option:

1. Select **Insert | Dimension | Straightness** from the submenu. The **Straightness** dialog box appears.
2. Select the feature(s) to dimension from the **Feature List** box.
3. Type the plus tolerance value in the **Plus** box.
4. Select either **Inch** or **MM** in the **Units** section.
5. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both**, or **None** option.
6. Select the optional **Display** check box if you want to view dimension information in the Graphic Display window.
7. Select the desired Analysis options by marking the **Textual** check box or the **Graphical** check box. If the Graphical check box was marked, enter the Multiplier value in the **Multiplier** box.
8. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format you would like displayed in the Graphic Display window.
9. Click the **Create** button.

The dimension will appear in the Edit window with this information:

```
dimension_name = STRAIGHTNESS,OF feat_1
```

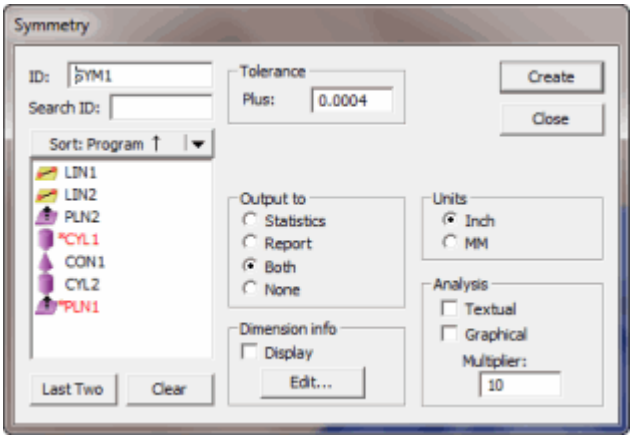
AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
M	0.0000	0.0100	0.0100	5.0000	0.0000	0.0000	0.0000	0.0000

Plus Tolerance for Straightness Dimensions

This **Plus** box in the **Straightness** dialog box (**Insert | Dimension | Straightness**) enables you to enter a tolerance value along the plus direction. This means that any straightness that differs from your nominal or theoretical straightness can still be a valid measurement as long as it falls within the tolerance range specified.

For information on how PC-DMIS reports tolerance zones for form dimensions, see "Reported Tolerance Zones for Form Dimensions" in the "Reporting Measurement Results" chapter.

Dimensioning Symmetry



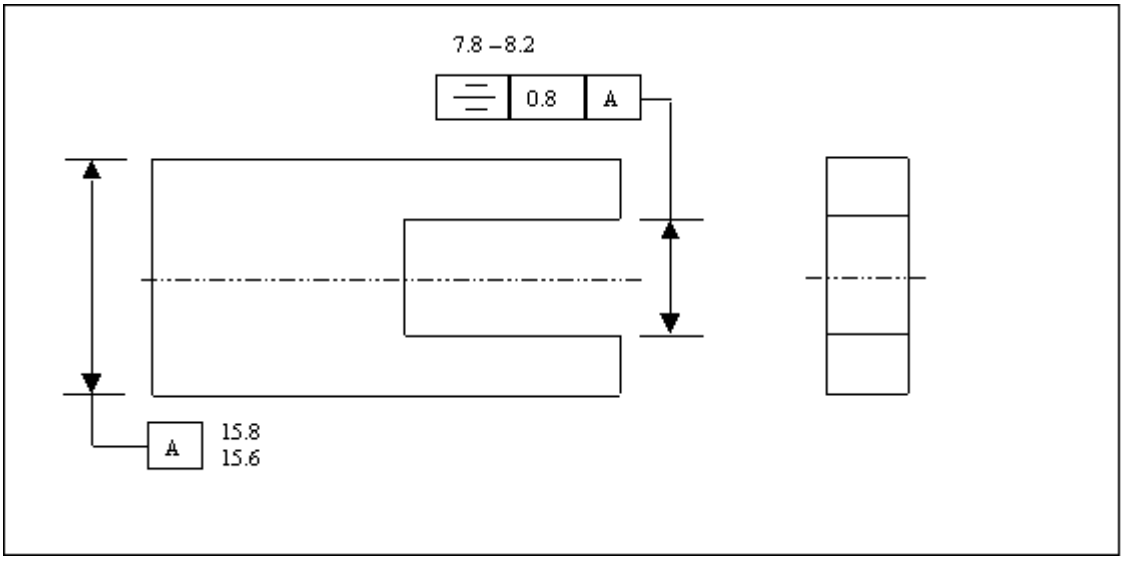
Symmetry Dialog Box

The **Insert | Dimension | Symmetry** menu option calculates the symmetry of a set of points with a datum feature, or two opposing lines with a datum feature.

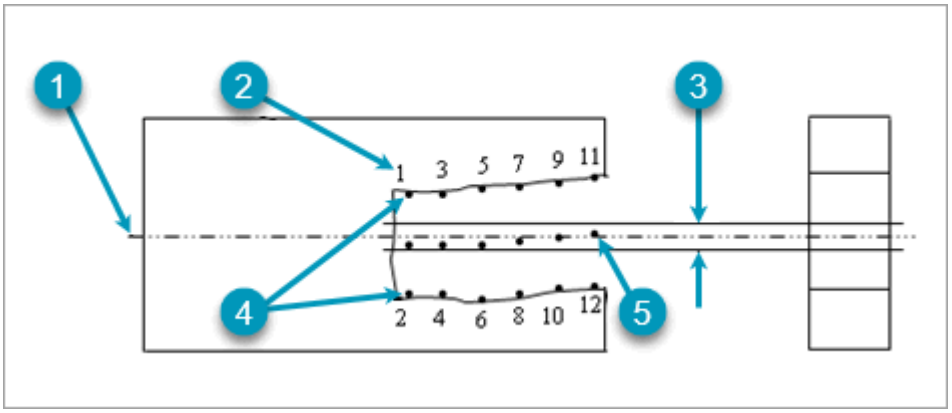
- If the first feature is a *set*, the second feature that is entered is the datum feature and must be either a plane or a line.

- If the first feature is a *line*, the second feature must also be a line and the third feature that is entered is the datum feature. In this case the third feature must be a plane or a line. This dimension type is considered one sided, meaning a single positive value tolerance is applied.
- If the third feature is a *plane*, the symmetry algorithm attempts to find a line on that plane that represents the datum. To find the correct line, it intersects (or crosses) the chosen plane with the workplane. For this reason, you should ensure that you are using the correct workplane.

According to the geometric dimensioning and tolerancing standard, the following graphic indicates how a symmetry dimension is displayed and interpreted.



Example of a symmetry dimension.



Example showing the interpretation of the symmetry dimension.

1 - The center plane of datum feature A.

2 - Order of point measurements.

3 - 0.8 wide tolerance zone.

4 - Opposed elements, with alternating points.

5 - Derived median points.

Explanation of Previous Graphic

Within the limits of size and RFS, all median points of opposed elements of the slot must lie between two parallel planes 0.8 apart, the two planes being equally disposed about datum plane A. The specified tolerance and the datum reference can only apply on an RFS basis.

Because of the way the symmetry is defined, PC-DMIS limits the features that can be used for the symmetry dimension. Since the points must be equally arranged about the datum in order to find midpoints between them, you must either select a feature set with alternating points or two opposing lines with the same number of points.

To Dimension a Feature Using the SYMMETRY Option:

1. Select **Insert | Dimension | Symmetry** from the submenu. The **Symmetry** dialog box appears.
2. Select the feature(s) to dimension from the **Feature List** box.
3. Type the plus tolerance value in the **Plus** box.
4. Select either **Inch** or **MM** in the **Units** area.
5. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both**, or **None** options.
6. Select the optional **Display** check box if you want to view dimension information in the Graphic Display window.
7. Select the desired **Analysis** options by selecting one or both of the check boxes. If the **Graphical** check box was selected, enter the multiplier value in the **Multiplier** box.
8. If desired, select the **Display** check box in the **Dimension Info** area and click **Edit** to select the Dimension Info Format you would like displayed in the Graphic Display window.
9. Click the **Create** button.

The dimension will appear in the Edit window with this information:

```
dimension_name = SYMMETRY,FROM feat_1 TO feat_2
```

or

```
dimension_name = SYMMETRY,FROM feat_1 AND feat 2 TO feat 3
```

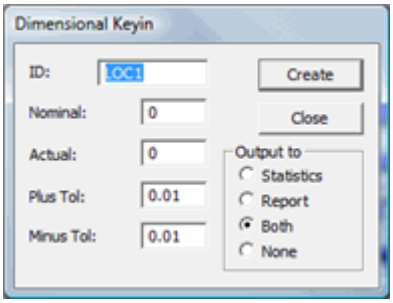
AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
M	0.0000	0.0100	0.0100	2.0000	0.0000	0.0000	0.0000	0.0000

After the dimension is created, the dialog box remains open. If desired, use your **Edit** button at this time to edit aspects of your dimension's information. See "Edit Default Dimension Info".

Plus Tolerance for Symmetry

This **Plus** box in the **Symmetry** dialog box (**Insert | Dimension | Symmetry**) enables you to enter a tolerance value along the plus direction. This means that any symmetry that differs from your nominal or theoretical symmetry can still be a valid measurement as long as it falls within the tolerance range specified.

Dimensioning through Keyboard Input



Dimensional Keyin Dialog Box

The **Insert | Dimension | Keyin** menu option allows you to capture and "key in" through the keyboard data not measured with the CMM (for instance, adding a dimension that is measured with calipers). This option allows you to print out all inspection results on the inspection report (not just features measured with the CMM). It is also useful when collecting data for statistical analysis.

To Add Dimensions Using the KEY IN Option:

1. Select **Insert | Dimension | Keyin** from the submenu. The **Dimensional Keyin** dialog box appears.
2. Type the ID number for the dimension in the **ID =** box.
3. Type the nominal value in the **Nominal** box.

4. Type the actual value in the **Actual** box.
5. Select where to output the dimension information. Select the **Statistics**, **Report**, **Both**, or **None** option.
6. Click the **Create** button.

The dimension then appears in the Edit window with this information:

```
dimension_name = KEYIN,feat_1
```

AX	NOM	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUT-TOL
M	5.0000	0.0100	0.0100	5.0000	0.0000	0.0000	0.0000	0.0000

Nominal

The **Nominal** box in the **Dimensional Keyin** dialog box (**Insert | Dimension | Keyin**) enables you to enter in the nominal (or theoretically perfect) measurement for a feature.

Actual

The **Actual** box in the **Dimensional Keyin** dialog box (**Insert | Dimension | Keyin**) enables you to enter in the actual measurement for a feature.

Tolerances for Keyboard Created Dimensions

You can type tolerances along the plus and minus directions of the newly generated dimension.

Plus Tolerance

The **Plus Tol** box enables you to enter a tolerance value along the plus direction. This means that any measurement that measures more than your nominal or theoretical

measurement can still be a valid measurement as long as it falls within the tolerance range specified.

Minus Tolerance

The **Minus Tol** box enables you to enter a tolerance value along the minus direction. This means that any measurement that measures less than your nominal or theoretical measurement can still be a valid measurement as long as it falls within the tolerance range specified.

Dimensioning Variables

There may be instances when working with expressions and variables that you want to create dimensions from variables that contain stored values. One popular way to do this is to first create a generic feature, populate the fields of the Generic Feature with the variable expressions you want to use, and then create a dimension of the Generic Feature.

For information on Generic Features, see the "Creating Generic Features" chapter. For information on variables, see the "Using Expressions and Variables" chapter.

Dimensioning a Variable Example

Suppose that you have these variables and you want to create a Location dimension using them:

```
ASSIGN/V_THEOX=10
ASSIGN/V_THEOY=5
ASSIGN/V_THEOZ=1
ASSIGN/V_MEASX=10.008
ASSIGN/V_MEASY=5.035
ASSIGN/V_MEASZ=0.997
```

For ease of use, this example gives the variables constant values. In real life application, your variables will most likely have dynamic values that change based on user input or from other external sources.

To dimension these variables:

1. Select the **Insert | Feature | Generic** menu option to open **Construct Generic Feature** dialog box.

2. Select the **Point** option.
3. Select the **Measured Values** option and type zero values into the X, Y, and Z boxes, then select **Nominal Values** and do the same thing.
4. Click **OK**. PC-DMIS inserts an empty Generic Feature (usually labeled F1 if it's your first Generic Feature) into the Edit window.
5. Place the Edit window in Command Mode to see the generic feature:

```
F1   =GENERIC/POINT,DEPENDENT,RECT,$
      NOM/XYZ,0,0,0,$
      MEAS/XYZ,0,0,0,$
      NOM/IJK,0,0,1,$
      MEAS/IJK,0,0,1
```

6. Now, navigate to the line `NOM/XYZ` , and in the first three zero fields, type **V_THEOX**, **V_THEOY**, and **V_THEOZ** respectively. These are your nominal variables.
7. Do the same thing on the `MEAS/XYZ` line, except type **V_MEASX**, **V_MEASY**, and **V_MEASZ** into the three zero fields of that line. Your command should now look like this:

```
F1    =GENERIC/POINT,DEPENDENT,RECT,$
       NOM/XYZ,V_THEOX,V_THEOY,V_THEOZ,$
       MEAS/XYZ,V_MEASX,V_MEASY,V_MEASZ,$
       NOM/IJK,0,0,1,$
       MEAS/IJK,0,0,1
```

8. Press F3 to mark the Generic Feature.
9. Create a Location dimension using this feature. Give it a plus and minus tolerance of .02.
10. Execute the measurement routine.

You should get a dimension that looks something like this in your report:

MM | DIM LOC1= LOCATION OF POINT F1

AX	NOMINAL	+TOL	-TOL	MEAS	MAX	MIN	DEV	OUTTOL
X	10.000	0.020	0.010	10.008	10.008	10.008	0.008	0.000
Y	5.000	0.020	0.020	5.035	5.035	5.035	0.035	0.015
Z	1.000	0.020	0.010	0.997	0.997	0.997	-0.003	0.000

Using Geometric Tolerances

Introduction to Geometric Tolerances and Feature Control Frames

- Comparisons to Past Practice

Introduction

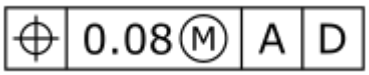
A manufactured part has functional requirements. These requirements often involve the shapes, sizes, orientations, and locations of the features—they are geometric requirements. The features must meet the geometric requirements either alone or with other features.

Geometric tolerances communicate the geometric requirements precisely. A drawing or CAD model specifies geometric tolerances in these ways:

- Feature Control Frames (ASME Y14.5)
- Tolerance Indicators (ISO 1101)

Terminology Note: ASME feature control frames and ISO tolerance indicators appear and function similarly to each other. Because of this, we use the term "Feature Control Frame" to refer to either one. We also use the term "Geometric Dimensioning and Tolerancing Standard" (or "GD&T Standard" for short). This term refers to both the standards involved (ASME Y14.5 or ISO 1101) even though the ISO term is “geometrical product specifications.”

A Feature Control Frame (FCF) uses numbers and symbols in rectangular boxes, like this:



While PC-DMIS can verify geometric tolerances according to any standard, it can most easily do this when tolerances are written according to these specific standards:

- ASME Y14.5 1994 / 2009 / 2018
- ASME Y14.5.1 1994 / 2019
- ISO 1101 : 2012/2017
- ISO 5459 : 2011
- ISO 5458 : 1998
- ISO 14405-1 : 2010
- ISO 17450-3 : 2016
- ISO 2692 : 2014
- ISO 1660 : 2017

Terminology Note: For brevity, we refer to the ASME group of standards as "ASME Y14.5" and the ISO group of standards as "ISO 1101".

Conceptual Process for Evaluating Geometric Tolerances

A geometric tolerance always includes these items:

- One or more toleranced features
- A tolerance zone for each toleranced feature
- Zero or more datum features. These constrain how toleranced features may be optimized into the tolerance zone or zones.

When you evaluate a geometric tolerance, you need to know all the basic dimensions (ASME Y14.5) or the theoretically exact dimensions (ISO 1101). These are the nominal relationships between all the features in question. This means all the features must have correct nominals (THEOs). If these are incorrect, PC-DMIS can evaluate the geometric tolerances incorrectly.

The easiest way to ensure the nominals are correct is to construct the measurement routine from the CAD model.

Specification Versus Verification

The ASME and ISO standards families for GD&T are *specification* standards. Geometric tolerances are one type of specification. The standards define the specifications—what the

tolerances mean—but they do not tell you how to verify that your part meets its specification.

The specification world deals with *perfect* information. The specification is defined in terms of the entire actual surface. There are infinite points with zero measurement uncertainty.

The verification world deals with *imperfect* information. The verification is defined in terms of the measured points. These are finite points with measurement uncertainty. When you choose math options, your goal is to make the verification math yield a result as close as possible to the specification. In other words, the specification is what you're trying to measure (the "measurand"), while the measurement is your best approximation to the specification. Sometimes the best verification math is very different than the specification math.

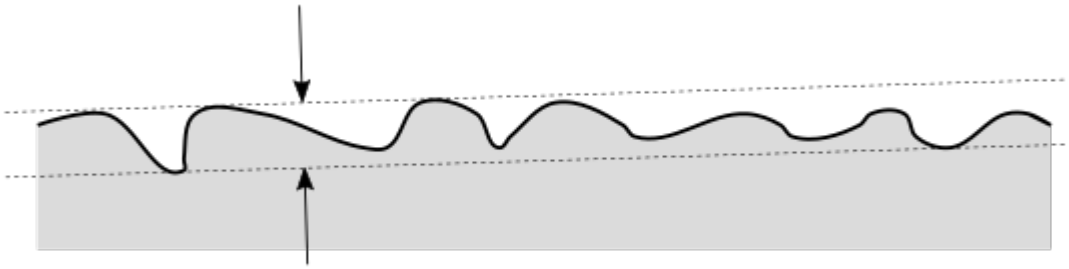
Because of this difference between specification and verification, datums and tolerance values usually come in pairs. For example, there are both actual datums and measured datums, as well as actual tolerances and measured tolerances:

- Actual datums and actual tolerance values are defined by the specification using perfect information about the actual surface.
- Measured datums and measured tolerance values are approximations to actual datums and tolerance values based on measured data.

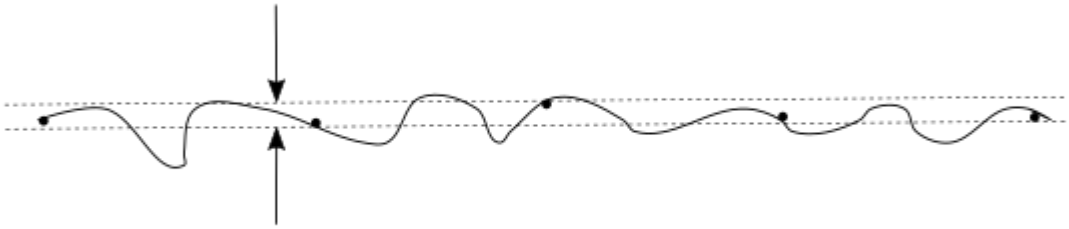
Unfortunately, there are no verification standards for GD&T, so it is very difficult to meaningfully compare different software packages that are intended to evaluate the same specification. Different software packages use different algorithms to approximate the actual datums and tolerance values, so they get different measured datums and different measured values.

For example, the actual straightness of a line is based on perfect information about the surface. The measured straightness is based on the measured points. The measured straightness can be smaller than the actual straightness if the actual high and low points are not measured. Alternatively, the measured straightness can be larger than the actual straightness if the measured points' uncertainty is large.

Below is an illustration of a surface's actual straightness. The entire actual surface cross section must lie between two parallel lines, where the distance between the lines is minimal. The distance between the lines is the actual value.



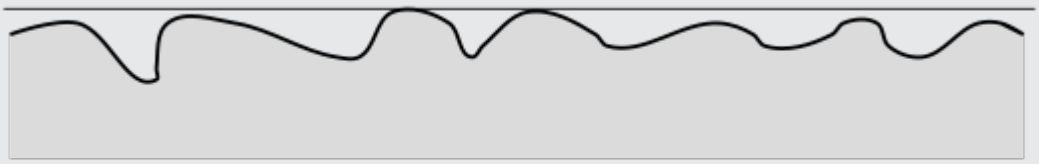
Below is an illustration of a surface's measured straightness. The measured points on the surface cross section must lie between two parallel lines. The distance between the lines is the measured value. The thin solid line represents the actual surface (perfect information), while the small dots represent the measured surface points (imperfect information). In this case, too few points were measured, so the measured value is smaller than the actual value.



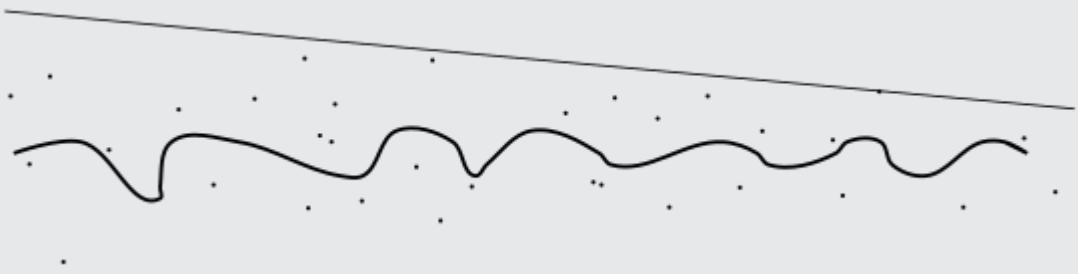
In the specification world, ISO 5459 : 2011 tells us that a primary datum plane is defined as a constrained min-max plane. This plane is external to the material. It contacts at least one high point, and it minimizes the deviations to the low points (after filtering the surface).

In the verification world, if we've measured our points densely (lots of points) and we have much lower measurement uncertainty than the form error, then the best algorithm in this verification situation is a constrained min-max algorithm. That algorithm ensures our measured datum plane matches the specified datum plane as closely as possible. On the other hand, in the verification world, if our measured points have larger measurement uncertainty than the form error (this is common), then we should probably use a plain (unconstrained) least-squares algorithm. This is because almost all of the measured form error is really measurement error, and so contacting the high points is going to put the datum plane way off the actual surface. In this case, plain least squares is the better choice.

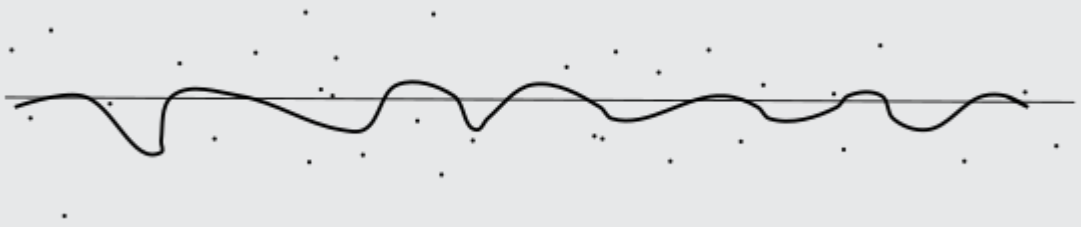
Below is an example of a primary datum plane, containing form error. The actual datum specified by ISO 5459 : 2011 is shown by the thin straight line.



Below is an example of that primary datum plane, which has been measured by a sensor where each measured point has large measurement uncertainty. The solid wavy line represents the actual surface. If you use the specification math (constrained min-max after void filtration), the measured datum is very far from the actual datum, as shown by the thin straight line.



Below is an example of the same primary datum, with the same measured points, but using plain (unconstrained) least-squares math. This measured datum is a much better approximation to the actual datum.



Frequently, you may need to use different algorithms during verification than the specification uses. Because of this, geometric tolerance commands give you *math options* that allow you to control what algorithms are used for the verification. You may find it difficult to choose the best math options. The only way to really be certain you've chosen the best math options is to do a careful study.

Recommended Steps for a Careful Study

1. Take several actual parts that represent the variety of errors the manufacturing process can produce.
2. Densely measure all the parts with lots of cross sections and use equipment that offers much less measurement uncertainty than the form error.
3. Choose math types that closely approximate the specification.
4. Measure the same parts in the way you expect to actually measure your parts in production. Use the same sensors and measurement strategies you plan to use.
5. Choose a wide variety of math types and compare how well those math types approximate your dense-and-high-accuracy measurements. That lets you pick the math type combination that most closely approximates the specification.

Typically, the best math option depends on the ratio between your measurement uncertainty and your form error. If the measurement uncertainty is much larger than the form error, then you can't measure the real form error with your sensor anyway, and it's best to choose something simple like plain least squares for the datum and feature math types. On the other hand, if the measurement uncertainty is much less than the form error, then it's best to choose math types that closely approximate the specification.

The discussion of how to pick math types is completely separate from the question of whether your sensor is able to verify your specifications. That complex topic will not be discussed in this documentation. However, it's critical that verification engineers choose sensors and measurement strategies that are accurate enough, with the chosen math types, to verify the specification.

Considered and Toleranced Features

There is a difference between considered features and toleranced features.

A considered feature is a measured surface that represents the controlled surface. You measure the considered features in your measurement routine. A considered feature is, in the language of ISO 1101, a measurement of a real integral feature. When you use the geometric tolerance command, you choose the considered features for each tolerance.

The toleranced feature is what goes inside the tolerance zone. The tolerance feature is sometimes the considered feature surface. Sometimes it is something derived from the considered feature surface. For example, it might be the axis of the unrelated actual mating envelope (ASME Y14.5) or the extracted median line (ISO 1101). For more information, see "Deriving the Toleranced Feature".

Phases of Evaluation

The actual evaluation of a geometric tolerance then consists of several phases:

1. Measurement of the considered features' surfaces and datum features' surfaces
2. Computation of the datums in their hierarchical order of precedence
3. Production of the toleranced feature from the considered feature as necessary
4. Evaluation of each toleranced feature within its tolerance zone. This is subject to the datums' constraints.
5. Reporting the evaluated result

In most cases, you are responsible for phase 1 of this evaluation process. The PC-DMIS geometric tolerance command handles the other phases in a way that complies with ASME Y14.5 or ISO 1101.

Because you are responsible for phase 1 of this evaluation process, you must measure the surfaces densely enough, and with enough cross sections, so that the measured datums and measured values can closely approximate the actual datums and actual values. This means you must thoroughly understand the specifications, the strengths and weaknesses of your measurement equipment, and the types of errors your manufacturing process can produce.

Comparisons to Past Practice

PC-DMIS 2020 R2 introduced the geometric tolerance command. Before this, PC-DMIS had some FCF capabilities that supported older standards and that were more limited.

Terminology Note: This documentation refers to the old capabilities as "XactMeasure". This is because in prior versions of PC-DMIS, the feature control frame dialog box had the text “XactMeasure” in its title bar. The current geometric tolerance command has the text “Geometric Tolerance”.

Several comparisons to past practice are in this documentation. They compare the XactMeasure capabilities and behavior to the geometric tolerance command’s capabilities and behavior.

Structuring your Measurement Routine for Geometric Tolerances

In this Topic

Structuring your Measurement Routine for Geometric Tolerances
- Introduction
  - Comparison to Past Practice - Referencing the GD&T Standard
  - Comparison to Past Practice - Constructed Features
  - Comparison to Past Practice - Measured Data in Cross Sections
  - Comparison to Past Practice - Considered Features and Measured Data
  - Comparison to Past Practice - ISO Math Types

Introduction

Starting with PC-DMIS 2023.2, when you create a new measurement routine, the **New Measurement Routine** dialog box requires that you select the appropriate GD&T standard (see "Creating New Measurement Routines" in the PC-DMIS Core documentation). PC-DMIS applies the GD&T standard that you select (ASME Y14.5 1994, ASME Y14.5 2009, ASME Y14.5 2018 or ISO 1101 2012/2017) for every Geometric Tolerance and Size command that you create in your new measurement routine. For more information, see the "Comparison to Past Practices - Referencing the GD&T Standard" section below.

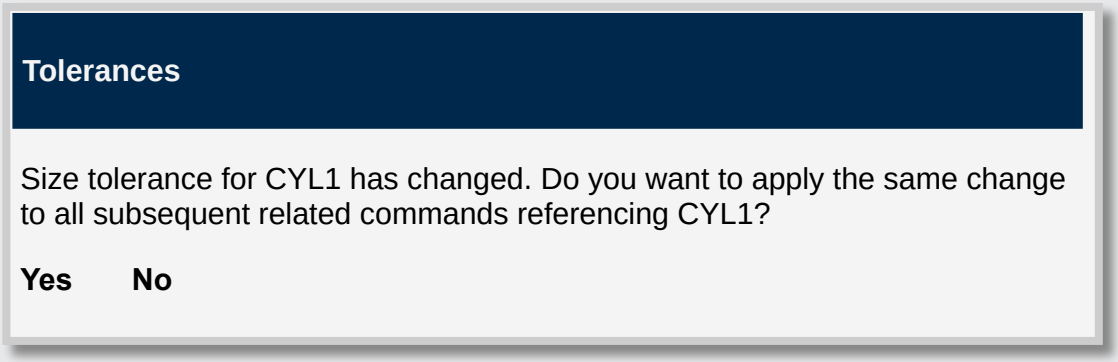
In most cases, for your measurement routine, we recommend a simple structure like this:

1. Construct an initial alignment to find the part in 3D space. For information, see the "Creating and Using Alignments" chapter in the PC-DMIS Core documentation.
2. Measure all the considered feature surfaces and datum feature surfaces.
3. Define the datums using datum definition commands.
4. Define the specified size tolerances and geometric tolerances using geometric tolerance commands.
5. Define any simultaneous tolerances using simultaneous tolerance commands.

You need to create the size tolerances and geometric tolerances on datums before any geometric tolerances that reference those datums. This is because geometric tolerances that reference a datum frequently need to know about any size tolerances and geometric tolerances on that datum. If you later edit any size tolerance on a datum, please ensure that all subsequent geometric tolerances that reference that datum have the correct size tolerance information for the datum. For more information, see "How PC-DMIS Solves and Uses Datums" in the PC-DMIS Core documentation.

If you edit a feature's upper or lower tolerances from the Edit window or from the **Geometric Tolerance** dialog box (**Feature Control Frame** or **Nominals** tab), and the same feature is used as a datum or as a considered feature, PC-DMIS displays a message asking if you want to apply the same changes to all subsequent commands referencing that feature.

For example:



If you click **Yes**, PC-DMIS updates the size tolerances for any Geometric Tolerance commands below the cursor position that references the same feature, either as a considered feature or datum.

If you click **No**, PC-DMIS updates the edited size tolerance only. PC-DMIS does not update any of the respective size tolerances for any related Geometric Tolerance commands below the cursor position that uses the same edited feature either as a considered feature or datum.

We do not recommend using copy/paste or paste-with-pattern to replicate the geometric tolerance command. There are some cases where it works, and there are other cases where paste-with-pattern is fundamentally incapable of working correctly. We also do not recommend putting the geometric tolerance command inside a loop, for similar reasons: some cases work, and some cases cannot ever work. It is okay to put the entire measurement routine inside of one loop.

Comparison to Past Practice - Referencing the GD&T Standard

In the past, XactMeasure allowed you to create feature control frame commands that reference different GD&T standards within the same measurement routine. You could also toggle the referenced GD&T standard from within the command. Earlier versions of the

Geometric Tolerance command also supported this behavior for migration purposes. However, it does not make sense to mix GD&T standards within the same measurement routine. This is because parts are designed according to only one standard.

For this reason, starting with PC-DMIS 2023.2, you can no longer reference both ASME and ISO standards within the same measurement routine.

Comparison to Past Practice - Constructed Features

In the past, because of XactMeasure limitations, you often had to use constructed feature commands. These were mid-planes, intersection lines, and so on. You used them as either considered features or datum features.

With Geometric Tolerances, however, most constructed feature commands get in the way. Constructed features can impede a Geometric Tolerance from understanding the measured surface. However, in these few cases it makes sense to use a constructed feature command:

- Constructed width commands are necessary to represent a width (ASME Y14.5) or opposed parallel plane (ISO 1101) features. This is because there is not yet an auto-width command in PC-DMIS. Constructed width commands keep all the surface data, and so they do not impede the geometric tolerance command.
- Constructed set commands are sometimes necessary. When all the inputs represent measured surfaces, constructed sets keep all the surface data, and so they do not impede the geometric tolerance command.
- In rare cases, it makes sense to measure a feature with separate point commands like vector points. You can then construct a Best Fit Recompensated (BFRE) feature from the vector points. The constructed feature retains the surface data, and so this does not impede the geometric tolerance command.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

- In rare cases, a considered feature or datum feature might need to be a derived geometry. This means it has no surface. An example of this is the minimum circumscribed circle that contains three pins in ASME Y14.5 2018 Figure 7-42 (b). In such cases, the only way to convey the specified intent to the geometric tolerance command is to construct a feature that lacks surface data. If you do this, you are responsible to comply with applicable standards.

The geometric tolerance command uses constructed features without surface information in these ways:

- As the toleranced feature
- As the pre-resolved datum feature (situation feature in ISO 5459 language)

In such cases, you are taking over phases 2 and 3 of the conceptual evaluation process. It is your responsibility to construct the feature according to appropriate standards. For information about the conceptual evaluation process, see "Introduction to Geometric Tolerances and Feature Control Frames" in the PC-DMIS Core documentation. For information about which feature types have and do not have surface data, see "Feature Types With and Without Surface Data" in the PC-DMIS Core documentation.

Comparison to Past Practice - Measured Data in Cross Sections

Certain types of geometric tolerances require evaluation of measured data in cross sections. For example, consider the specification of axis straightness on a cylinder. You need to measure the cylinder in several cross sections for these reasons:

- To compute the center of each cross section
- To evaluate the axis straightness of the circles' centers

The XactMeasure command required you to measure several circle commands. These may also have been child features of a scanning strategy. You then had to construct a 3D Best Fit (BF) line through the circle centers. Finally, you created an XactMeasure axis straightness tolerance on the BF line.

With the geometric tolerance command, you no longer need to go through so many steps. Now, you measure the cylinder (using a measurement strategy or not). You then evaluate axis straightness on the cylinder. The geometric tolerance command automatically divides the data into cross-sections (based on the distribution of the points). It then computes each circle's center and evaluates straightness on the centers.

Starting with PC-DMIS 2025.1, the geometric tolerance command vastly improved its automatic sectioning to support a wider range of different distribution of points within a feature and still calculate cross sections. This enhancement was mainly intended to support features measured with a laser sensor but is applied to all sensor types to allow more flexibility. Laser data is rarely organized into clean cross sections, and our previous cross section capabilities limited the types of tolerances that could be

evaluated. For example, you were previously unable to evaluate circularity, circular runout, or straightness (surface or axis) of a laser cylinder because there were typically no clean cross sections. In most cases, the enhanced cross sectioning functionality is now able to automatically extract linear or circular cross sections from any point pattern when features are measured with adequate point density. However, this may result in unwanted behavior in some cases. For example, a minimum of three hits spanning a minimum 90 degrees of arc are required for each circular cross section. This means that these extreme cases may fail:

- Features with very sparse hit data.
- Features with spiral hit patterns consisting of a single or very few revolutions and a steep pitch (Adaptive Spiral scan cylinders, auto cylinders, or auto cones with a pitch applied, constructed BF/BFRE cylinders or cones, manually measured cones or cylinders).
- Features with partial coverage.

In general, if you want to ensure that the geometric tolerance command sections the data exactly as you desire, you should measure the data in cross sections (as was required for previous PC-DMIS versions). For manual devices (such as portable arms), it is recommended to utilize Auto-Triggers to provide control to ensure the data is collected in a cross section. This also helps to maintain consistency when there are multiple users of the device.

Comparison to Past Practice - Considered Features and Measured Data

With the geometric tolerance command, every considered feature has a measured value. In some cases, this is different than XactMeasure's behavior.

For example, take a surface profile tolerance of three circles. In XactMeasure it yielded only one measured value. But with a geometric tolerance command, it now yields three measured values.

This means if you only want a single measured value, you need to construct a set of the input features and make the set the considered feature.

We chose this new behavior because it gives more flexibility in how to report measured values. Single measured values are still available with a constructed set. But separate measured values are also available where they weren’t before.

Comparison to Past Practice - ISO Math Types

In versions of PC-DMIS earlier than version 2025.1, when you selected ISO 1101 as the GDT standard, any of these three geometric tolerance command math types were available:

- **FEATURE_MATH** - This math type determined which math (**DEFAULT** or **LSQ**) that PC-DMIS would use for considered features. PC-DMIS would apply it to

both the size calculation and the way in which the considered feature was calculated for comparison to the associated geometric tolerance specification.

- **DATUM_MATH** - This math type determines which math (**DEFAULT**, **LSQ**, or **CL2**) that PC-DMIS uses for datum features. PC-DMIS applies it to both the datum size calculation and the datum fitting.

- **TOLERANCE_ZONE_MATH** - This math type determined which math (**DEFAULT** or **LSQ**) that PC-DMIS would use for form or profile calculations.

If you changed the feature math or, if your tolerance referenced the considered feature at MMC/LMC, it also affected the way size was reported (for details, see the "Evaluating Size with the Geometric Tolerance Command" topic in the PC-DMIS Core documentation). This made it easier to manually verify bonus calculations because all relevant size information was presented in the report.

Due to the rule of independency (see ISO 8015), ISO allows all characteristics of a geometric tolerance to be calculated separately. Starting with PC-DMIS 2025.1, the geometric tolerance command adopts these changes:

- **SIZE_MATH** - This is a new math type which PC-DMIS can use to determine how it calculates the feature's size. You can select **DEFAULT**, **LSQ**, or add an ISO modifier. For details on how to add an ISO modifier, see the "ISO Size Modifiers" section of the "Evaluating Size with the Geometric Tolerance Command" topic in the PC-DMIS Core documentation.

- **FEATURE_MATH** - This math type only determines the way in which the considered feature is calculated for comparison to the geometric tolerance specification. You can select **DEFAULT**, **LSQ**, or add an ISO Associated Toleranced Feature modifier to the tolerance section of the Feature Control Frame.

- **DATUM_MATH** - This math type determines which math (**DEFAULT**, **LSQ**, or **CL2**) that PC-DMIS uses for datum features. PC-DMIS applies it to both the datum size calculation and the datum fitting.

- **TOLERANCE_ZONE_MATH** - This math type separates form and profile tolerances as described below:

    - Form tolerances - You can select between **DEFAULT**, **LSQ**, or you can add an ISO Reference Feature Association modifier to the tolerance section of the Feature Control Frame.

    - Profile tolerances (without a datum reference) - You can select between **DEFAULT** and **LSQ**.

Depending on the combination of math types or modifiers that you select, be aware that it may no longer be possible in every situation to manually verify bonus calculations. PC-DMIS always uses the applicable mating envelope (E) to determine ISO bonus values, but that size may not be present in the report if you select an alternative size modifier.

For more information, please refer to ISO 1101:2017, section 8.2.2.2.2 (Associated Tolerance Feature specification element), and 8.2.3.1 (Reference Feature Associated specification element). Also see the "Deriving the Toleranced Feature" and "Evaluating Size with the Geometric Tolerance Command" sections of the PC-DMIS Core documentation.

Defining and Using Datums

Most geometric tolerances reference one or more datums. A datum reference consists of a datum identifier that refers to one or more datum features. A datum identifier is usually a single datum letter such as A or D, but it can be a sequence of up to five letters. In PC-DMIS, a datum identifier can refer to any of these:

- A single feature, such as a plane, line, point, cylinder, circle, cone, sphere, or width—this is often called a *single datum.*
- A pattern of like features of size that all have the same nominal size and size tolerance; this case is restricted to cylinders, circles, spheres, and widths—this is often called a *datum pattern.*

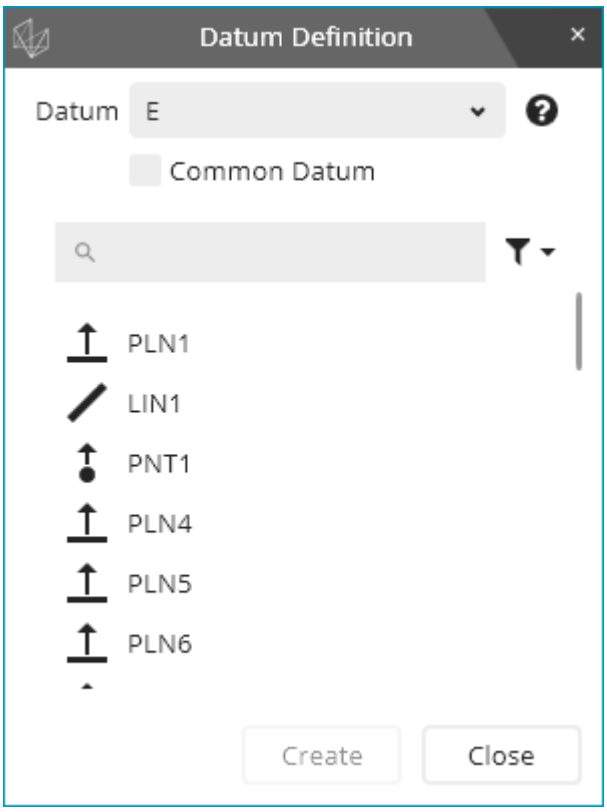
PC-DMIS only allows you to use a single 1D width as a datum. You cannot use patterns of 1D widths as a datum.

A geometric tolerance may reference two or more datum identifiers at once by joining them with a hyphen, such as C-D; this is often called a common datum. PC-DMIS supports many combinations of features as common datums. For more information see “Common Datums”.

Datum Definition Dialog Box Usage and Command Syntax

Before you can use a datum reference, you must define it in your measurement routine. You can do this with the Datum Definition command (`DATDEF`). To define a datum reference and create this command, from the menu, select **Insert | Dimension | Datum Definition**.

The **Datum Definition** dialog box appears:



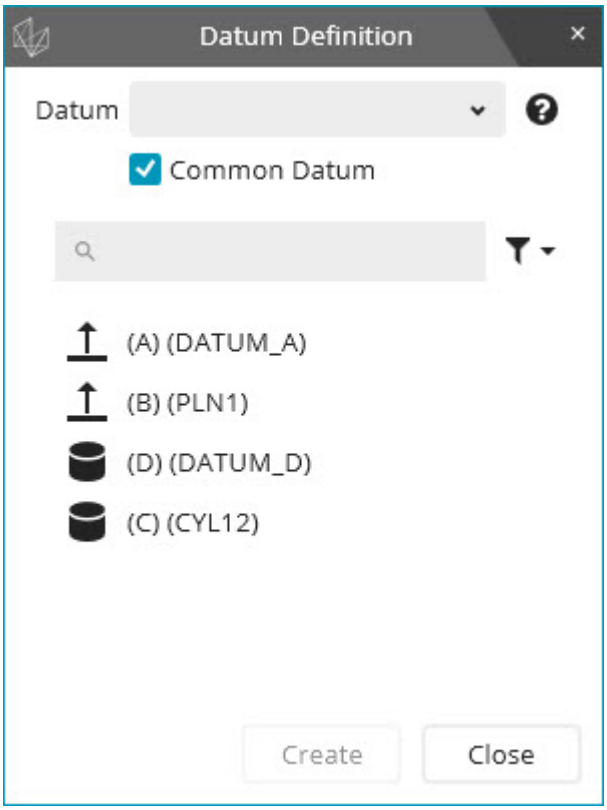
1. In the **Datum** box, type or select the datum name.
2. From the list of datum features, select one or more datum features.
3. If you select one feature, the datum reference represents a single datum. After you select that feature, PC-DMIS filters the feature list so that it only shows other features with the same characteristics. For example, if you select a circle with a diameter of 25 mm, it filters the list by other circles of that same diameter. This makes it easier for you to select additional, similar features so that your datum reference represents a datum pattern.
4. Click **Create**.
5. As needed, continue to use the dialog box to create additional datums and common datums.

The Datum Definition command's Edit window syntax in Command Mode might look like this:

```
DATDEF/A,FEATURES=PLN2,,
```

Datum - This box defines the name of the datum reference. It is typically a single letter such as E or a sequence of a few letters such as BG.

Common Datum - This check box lets you define a common datum. If you mark this check box, the feature list doesn't show features anymore; instead, it shows datums you have already defined, and the features associated with the datums.



Datum Definitions Dialog Box - Common Datum Check Box

For example, to define the common datum A-B, first, define datum A, then, define datum B then select the **Common Datum** check box. From the list of available datums, select datum A and then datum B to define the common datum A-B.

If you use a common datum, the Datum Definition command's Edit window syntax in Command Mode might look like this:

```
DATDEF/A-B,FEATURES=DATUM_A,PLN1,
```

Single Datums

A *single datum* refers to a datum identifier like A or AC that refers to only one datum feature. A single datum may refer to one of the following types of features:

- Plane
- Line
- Point
- Cylinder

- Circle
- Sphere
- Cone
- Width

Most datums in the geometric tolerance command are like the datum features on an inspection gage:

- They have a fixed distance and orientation with respect to each other.
- They engage the part in a fixed order of precedence.

Comparison to past practice:

Under XactMeasure, PC-DMIS treated datum features like alignment features in most cases. They defined the level, rotation, and origin.

The geometric tolerance command is more accurate, because it simulates how the datum reference frame contacts the mating part.

Feature Types that Represent a Planar Surface

A datum feature can represent a planar surface with a plane feature, a line feature measured on a surface, or a point feature measured on a surface.

While you can measure a surface line or surface point feature on a non-planar feature, PC-DMIS always treats them as coming from planar surfaces when referenced as datums in the geometric tolerance command. For more details, see "How PC-DMIS Solves Datums".

Feature Types that Represent a Cylindrical Surface

A datum feature can represent a cylindrical surface with a cylinder feature or a circle feature. While you can measure a circle on a non-cylindrical feature, PC-DMIS always treats circles as coming from cylindrical surfaces when referenced as datums in the geometric tolerance command. For more details, see "How PC-DMIS Solves Datums".

Common Datums

A *common datum* refers to a datum identifier like A-B or A-BC-D. It has one or more hyphens that separate defined datum identifiers. PC-DMIS supports many combinations of common datums described in this section of the documentation.

Common Datums: Best Practices

When you reference features as common datums, we recommend you use 3D features for these reasons:

- 3D features represent feature surface(s) and capture more data to properly evaluate your datums.
- 3D features properly control the applicable Degrees of Freedom (DOF) which you can then use as primary, secondary, and tertiary datums.
- You can only reference 2D and 1D width features as secondary or tertiary datums.

PC-DMIS does not support a pattern of 2D features as part of a common datum. PC-DMIS only allows datum patterns made up of cylinders, spheres, or 3D widths as part of a common datum.

Common Datums: General Guidelines

In this Topic

Common Datums: General Guidelines
Example 1: Plane A and Parallel Plane B as Common Datum A-B
Example 2: External Cylinder B with a Pattern of External Cylinders C as Common Datum B-C
Example 3: External Width A with an External Width B as Primary Common Datum A-B
Example 4: Internal Cylinder C with an Internal Cylinder D as Secondary Common Datum C-D
Example 5: Pattern of Internal Cylinders B and Pattern of External Cylinders C as Common Datum B-C
Example 6: Plane A and External Cylinder B as Common Datum A-B
Example 7: External Cylinder A and Coaxial Internal Cone B as Common Datum A-B
Example 8: External Cylinder A and Coaxial External Cylinder B as Common Datum A-B

For common datums, PC-DMIS allows you to mix the same feature types. You can combine individual features with a pattern or multiple patterns. PC-DMIS ***only*** allows you to mix different feature types in these cases:

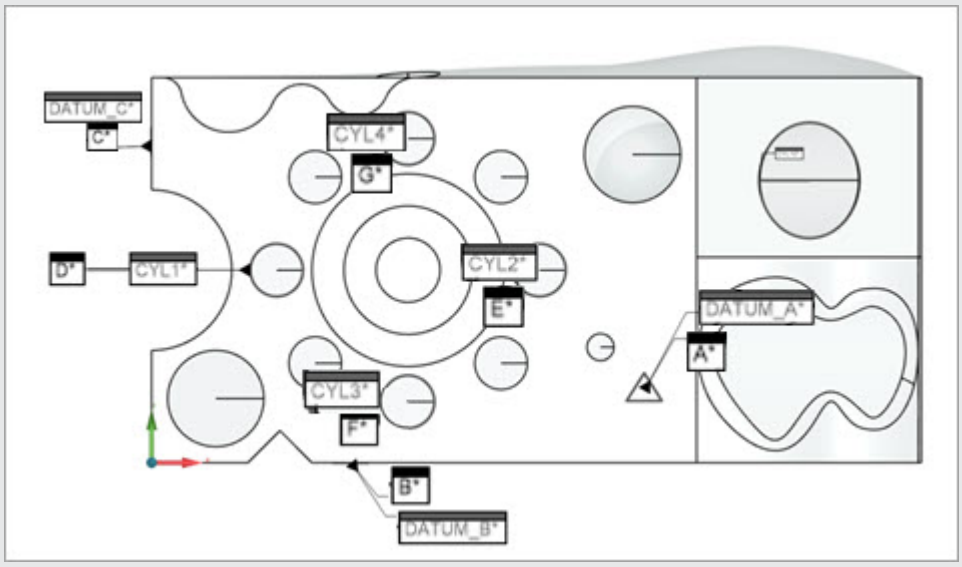
# of Input Features	Common Datum Feature #1	Common Datum Feature #2	Common Datum Features #3-5 (When Selected)	Comments
Minimum of two features	Plane	Plane	Plane	Only multiple parallel planes. See Example 1.
2		Cylinder	-	Only a single Plane & single Cylinder that is perpendicular to the plane. See Example #6.
2	Cylinder	Cone	-	Only a single Co-axial Cone and Cylinder. See Example #7.
2		Plane	-	Only a single Plane and single Cylinder that is perpendicular to the plane. See Example #6.

Minimum of two features		Circle	Circle or Cylinder	Only Co-axial Circles and Cylinders may be used for a primary common datum. See Example #8. This co-axiality restriction does not apply to secondary or tertiary common datums.
Minimum of two features		Cylinder or Pattern of Cylinders	Cylinder or Pattern of Cylinders	Each feature or pattern can be internal or external features of size and have different nominal sizes. See Examples #2, 4, and 5.
Minimum of two features	Pattern of Cylinders	Cylinder or Pattern of Cylinders	Cylinder or Pattern of Cylinders	
Minimum of two features	Circle	Circle or Cylinder	Circle or Cylinder	Only Co-axial Circles and Cylinders may be used for a primary common datum. See Example #8. This co-axiality restriction does not apply to secondary or tertiary common datums.

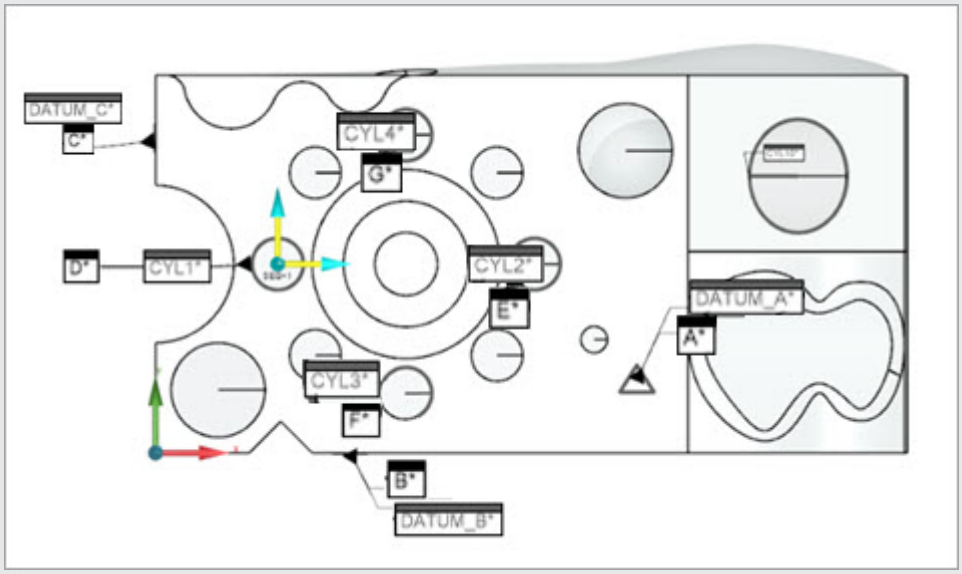
2	Cone	Cylinder	-	Only a single Co-axial Cone and Cylinder. See Example #7.
Minimum of two features	Sphere	Sphere or Pattern of Spheres	Sphere or Pattern of Spheres	Each feature or pattern must be internal or external spheres and have the same nominal size.
	Pattern of Spheres	Sphere or Pattern of Spheres	Sphere or Pattern of Spheres	

Minimum of two features	3D Width	3D Width or Pattern of 3D Widths	3D Width or Pattern of 3D Widths	Each feature or pattern can be internal or external features of size and have different nominal sizes. See Example #3. When you select multiple widths (or a pattern of widths), they need a common workplane direction to be an acceptable datum. The workplane direction is necessary to simulate the Datum Reference Frame (DRF), similar to a functional gage sliding into various widths.
	Pattern of 3D Widths	3D Width or Pattern of 3D Widths	3D Width or Pattern of 3D Widths	

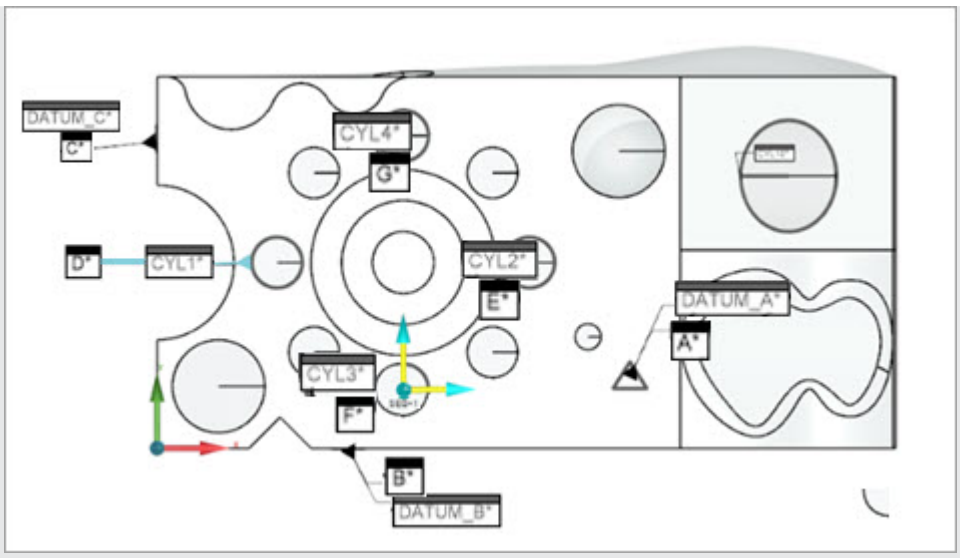
In some cases, the location of the coordinate system trihedron may be different than the axes shown on the drawing for the part. For example, the part below shows four cylindrical datums (D, E, F, and G):



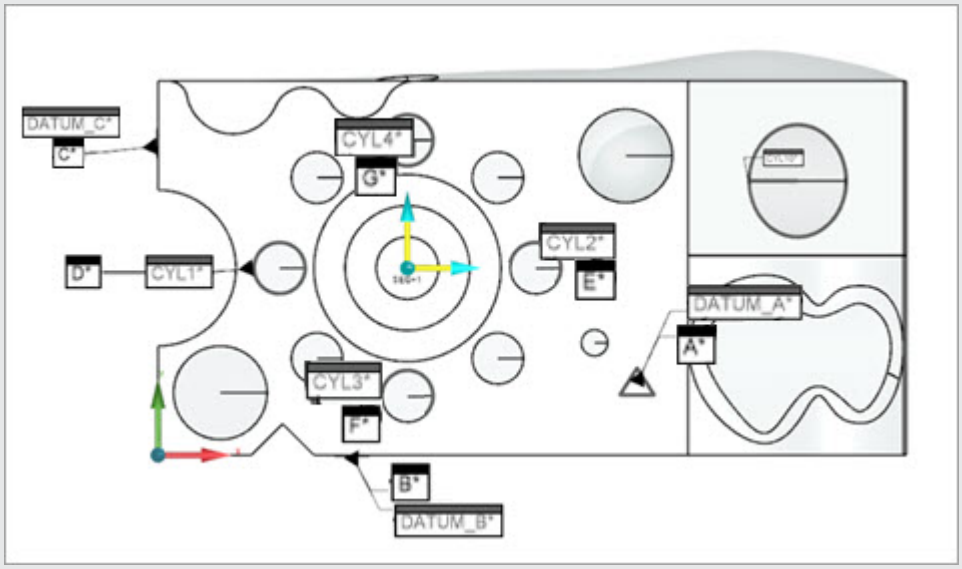
For 
, PC-DMIS would center the trihedron on datum D as shown below:



For 
, PC-DMIS would center the trihedron on datum F as shown below:



For 
, PC-DMIS would position the trihedron mid-way between all four datums (the center of the pattern), as shown below:



PC-DMIS allows you to easily change the trihedron's location and orientation. To do this, first create or select an appropriate alignment command and then change the display coordinates of the Geometric Tolerance command from **Datum Reference Frame** to **Current Alignment**. For details, see the "Display Coordinates" section of the "Nominals Tab" topic in the "Using Geometric Tolerances" chapter of the PC-DMIS Core documentation.

Any unsupported combination of features results in an error message when you attempt to create the Feature Control Frame (FCF), such as:

PC-DMIS

Multi-feature datum error. This may be caused by incorrect nominals (x, y, z or i, j, k vector) or an unsupported combination of features.

When you select datum features as a common datum, ensure that they either all have surface data, or that they all do not have surface data.

If you must combine datum features with and without surface data, it is only supported with Material Condition Modifiers (M or L). The datum math is available, but it only applies to datum features with surface data. PC-DMIS does not recalculate datum features with no surface data because they use the math from the feature command that represents the datum.

When you create common datums in the **Datum Definitions (DATDEF)** dialog box, PC-DMIS only performs a limited error check. All validity checks are performed by the Geometric Tolerance command when the FCF is built.

- Once the FCF is completely built, PC-DMIS performs the final verification that the common datum is supported. If the FCF verification fails, PC-DMIS indicates this failure with an error message.
- If the common datum has an error, please refer to the above table and general guidelines regarding Common Datums in order to address and resolve any problems with the Common Datum.
- PC-DMIS currently supports a maximum of five single datums or datum patterns combined to define a common datum (for example: A – B – C – D – E).
- PC-DMIS does not support the mixing of datum features that have surface data with datum features that do not have surface data. For more information, see "Feature Types With and Without Surface Data".

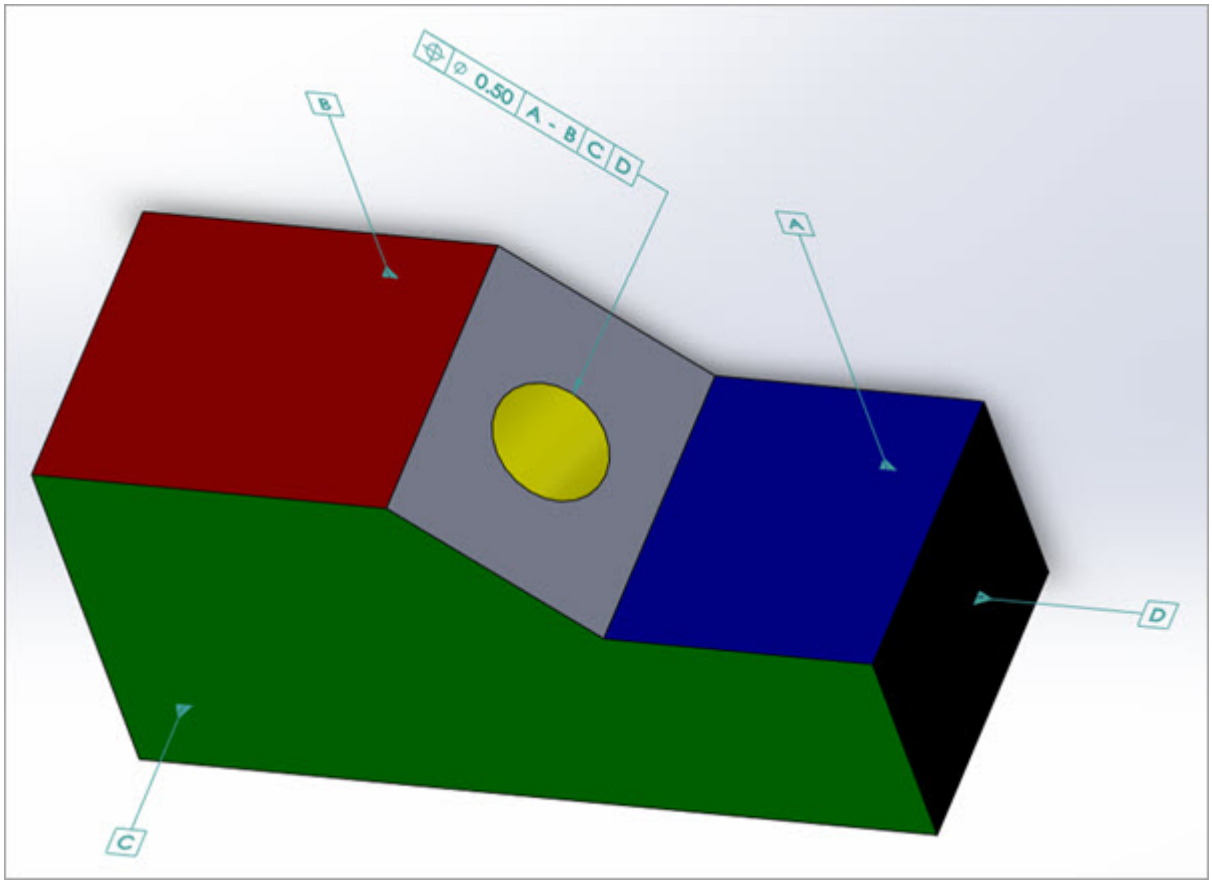
As required by ASME Y14.5 and ISO 5459, the common datum simulators for the pattern are nominally oriented and located with respect to each other. PC-DMIS supports the use of a modifier (MMB or LMB) on the common datum, when ALL the features (within the common datum) are “features of size”. When any of the features are NOT a feature of size, modifiers are not allowed.

In order for PC-DMIS to correctly grow or shrink the simulator sizes simultaneously and correctly calculate the material boundaries (when using MMB or LMB), you must have first toleranced each datum to its higher precedence datums. Also, you must make sure to include their size tolerances before you allow any other geometric tolerances to reference those datums.

That is, the tolerances on the datum must be EARLIER in the measurement routine than the geometric tolerances that reference those datums.

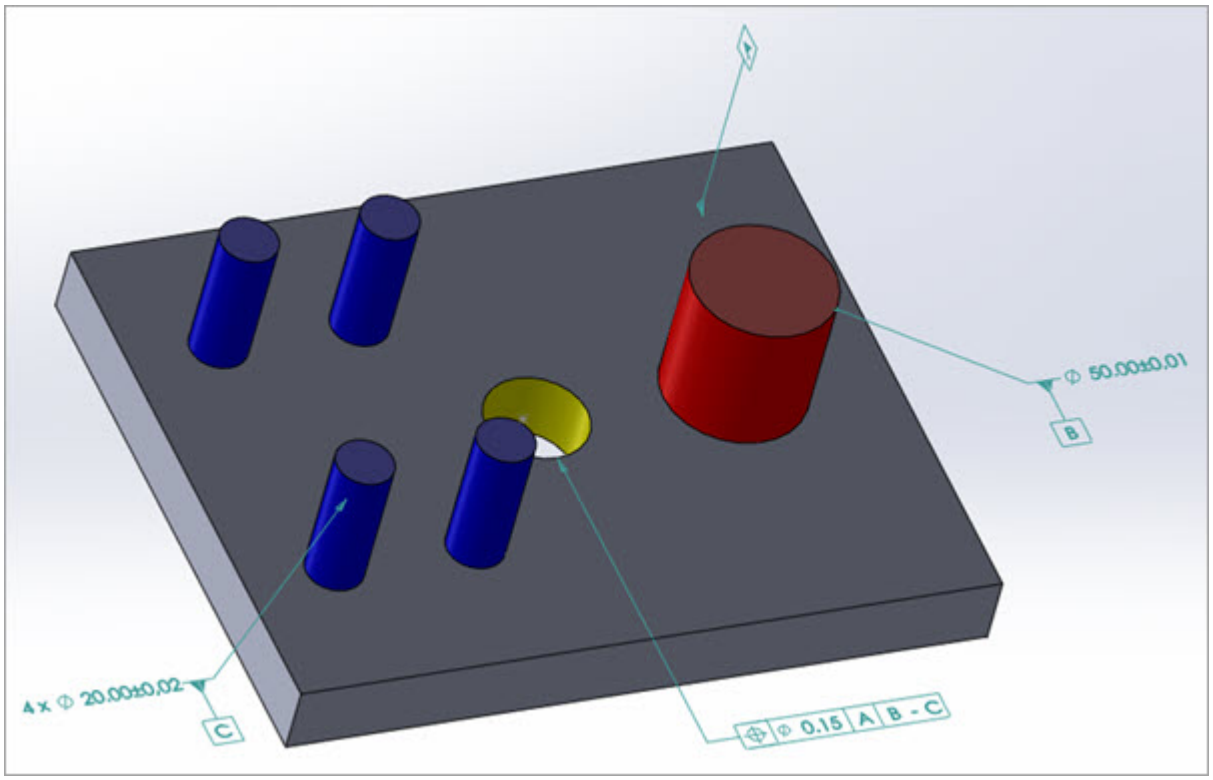
Examples of supported common datum combinations are described in the examples below.

Example 1: Plane A and Parallel Plane B as Common Datum A-B



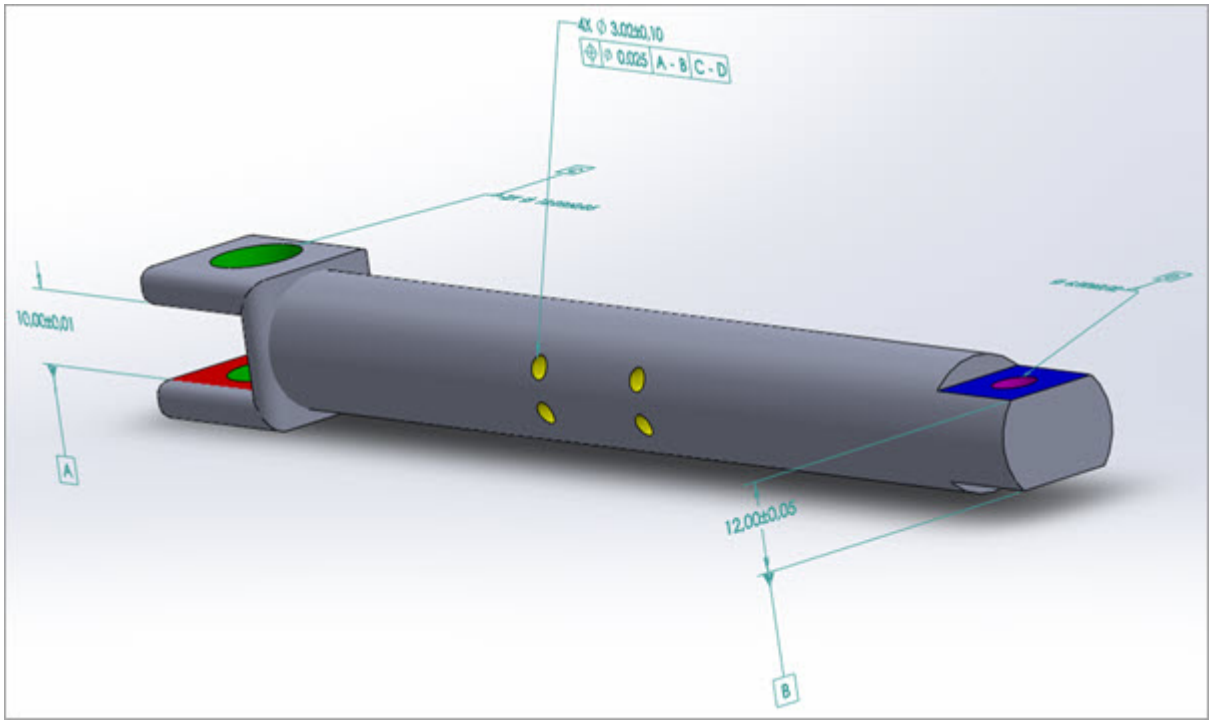
Example 1: Plane A (blue) and Parallel Plane B (red) as Common Datum A-B

Example 2: External Cylinder B with a Pattern of External Cylinders C as Common Datum B-C



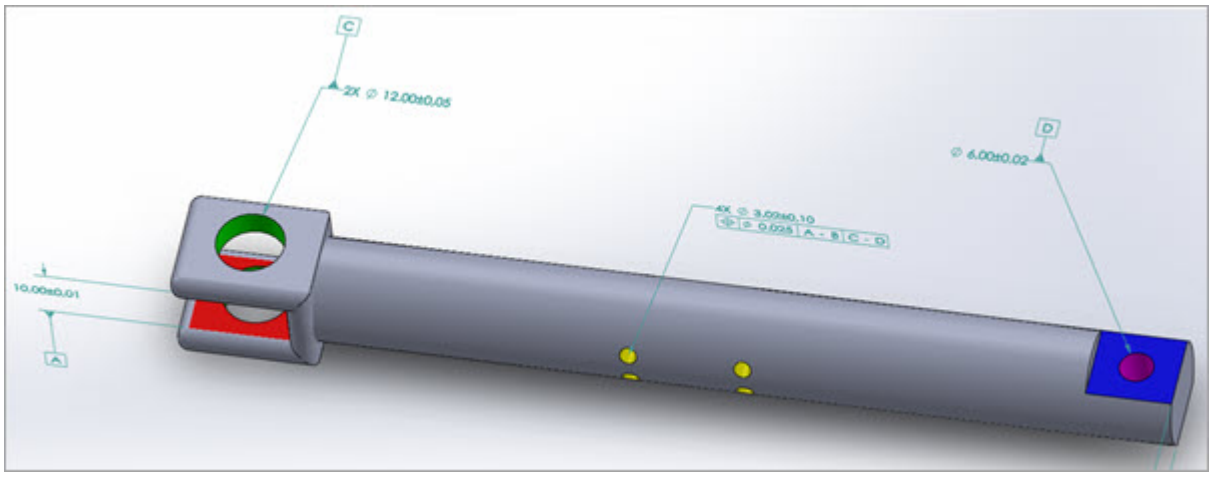
Example 2: External Cylinder B (red) with a Pattern of External Cylinders C (blue) as Common Datum B-C

Example 3: External Width A with an External Width B as Primary Common Datum A-B



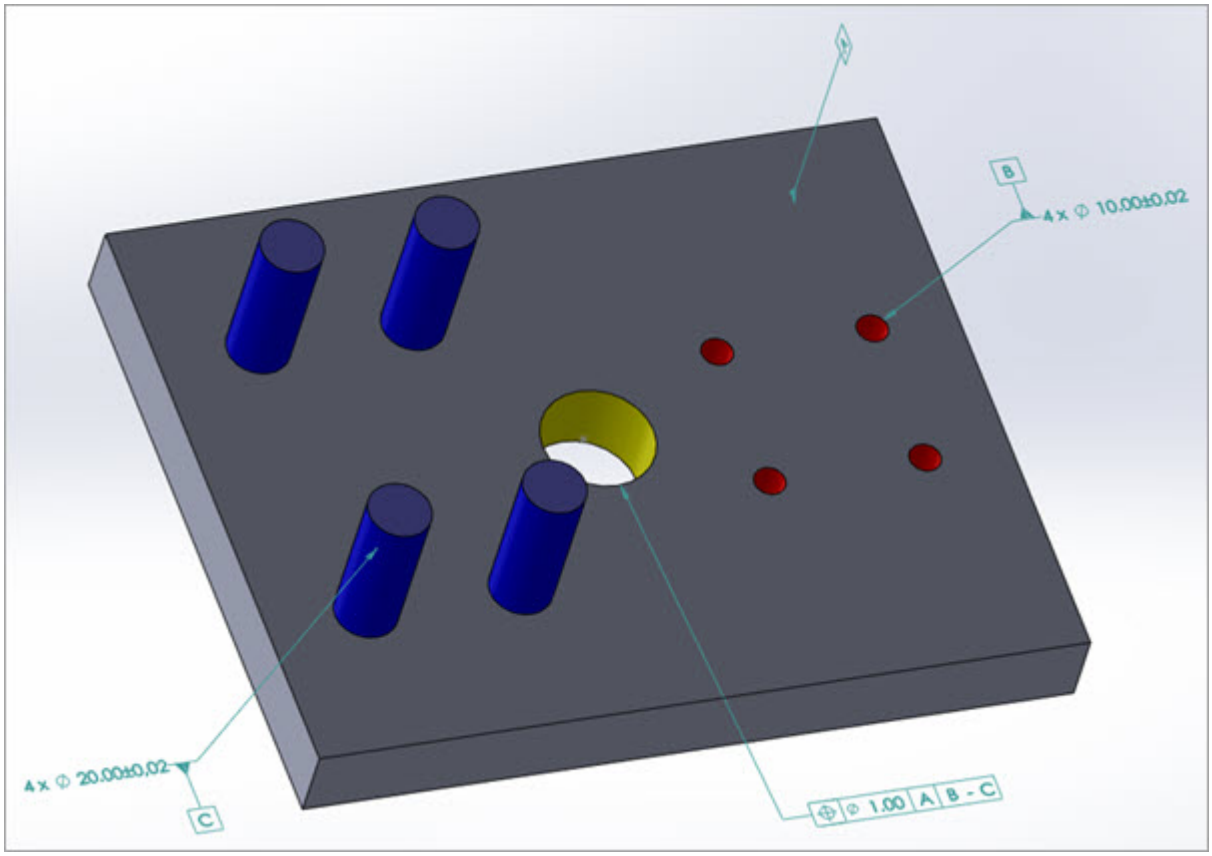
Example 3: External Width A (blue) with an External Width B (red) as Primary Common Datum A-B

Example 4: Internal Cylinder C with an Internal Cylinder D as Secondary Common Datum C-D



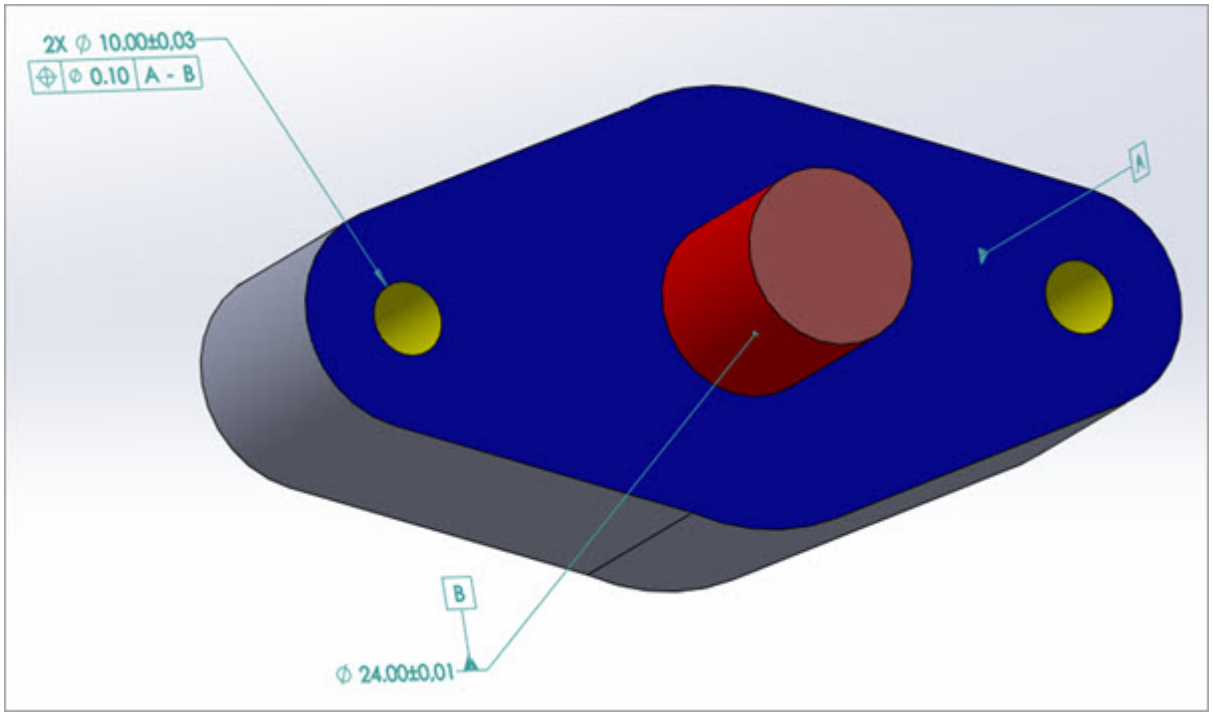
Example 4: Internal Cylinder C (green) with an Internal Cylinder D (magenta) as Secondary Common Datum C-D

Example 5: Pattern of Internal Cylinders B and Pattern of External Cylinders C as Common Datum B-C



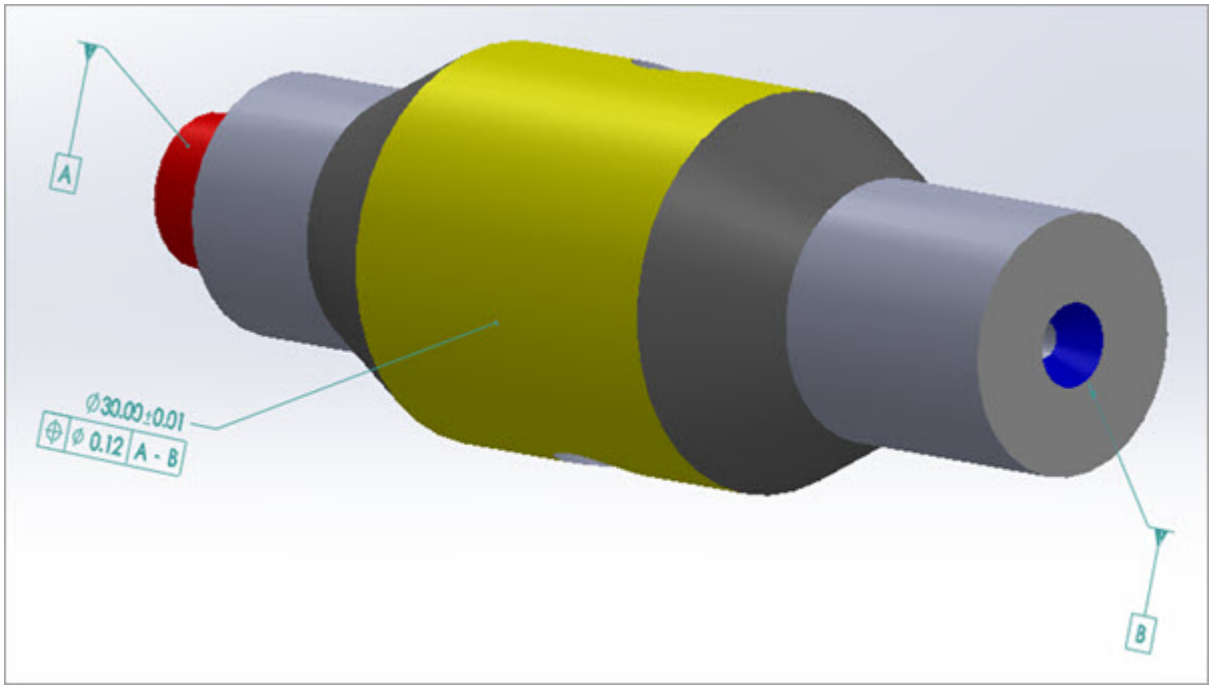
Example 5: Pattern of Internal Cylinders B (red) and Pattern of External Cylinders C (blue) as Common Datum B-C

Example 6: Plane A and External Cylinder B as Common Datum A-B



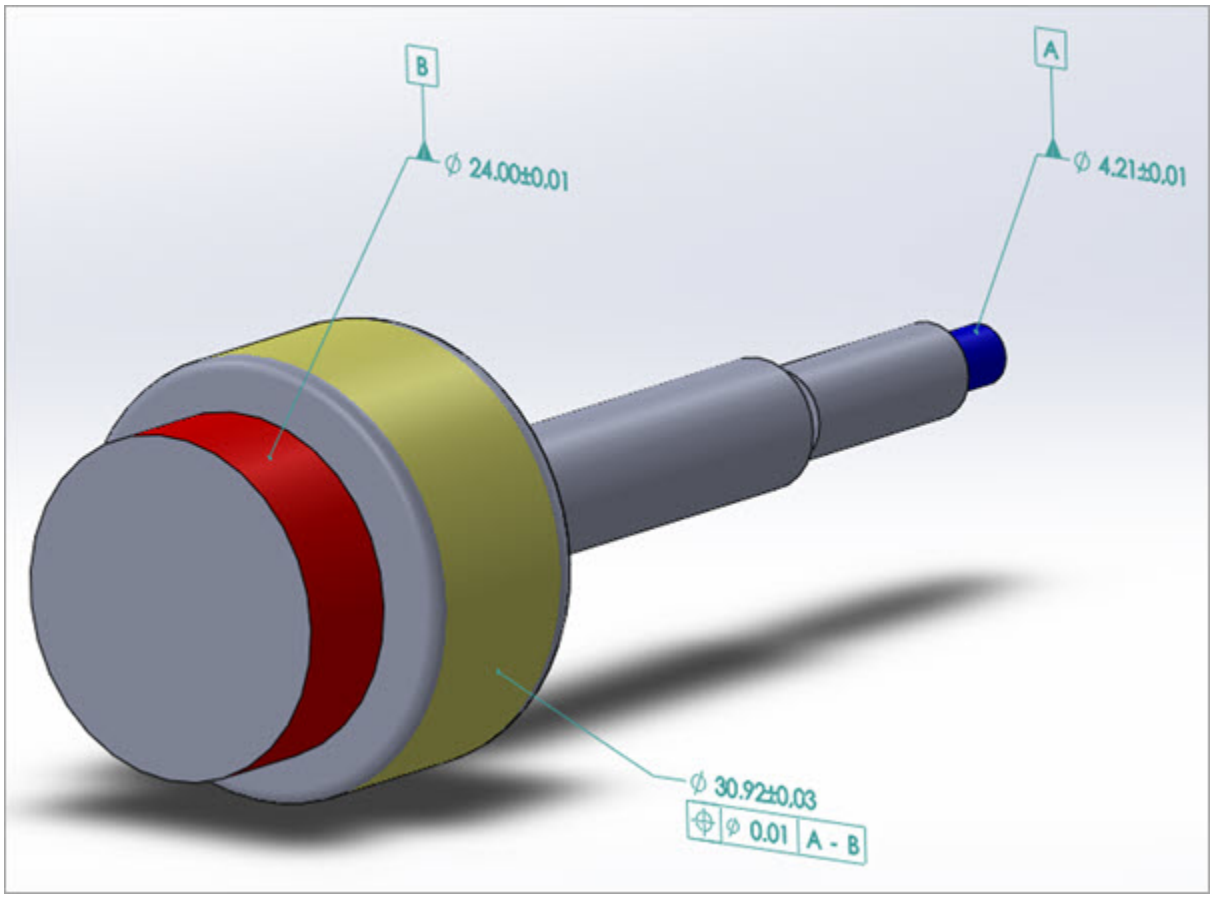
Example 6: Plane A (blue) and External Cylinder B (red) as Common Datum A-B

Example 7: External Cylinder A and Coaxial Internal Cone B as Common Datum A-B



Example 7: External Cylinder A (red) and Coaxial Internal Cone B (blue) as Common Datum A-B

Example 8: External Cylinder A and Coaxial External Cylinder B as Common Datum A-B



Example 8: External Cylinder A (blue) and Coaxial External Cylinder B (red) as Common Datum A-B

Datum Patterns

A *datum pattern* refers to a datum identifier like A or AC that refers to multiple similar features of size that all have the same size tolerance. For example, a pattern of holes might be referenced as a datum pattern B. Technically (per the ASME Y14.5 and ISO 5459 standards), a datum pattern is a type of common datum, but this documentation does not use that terminology.

For more information, see "Datum Patterns" in "How PC-DMIS Solves and Uses Datums".

Defining Geometric Tolerances and Controlling Reporting

In PC-DMIS, you can define geometric tolerances with the Geometric Tolerance command. This topic and its related topics describe how to use the **Geometric Tolerance** dialog box to define and control geometric tolerance commands. It also describes the reporting options to control the report. Finally, each geometric tolerance type is discussed in detail.

Command Mode Syntax

The Geometric Tolerance dialog box is the main way to create or modify a geometric tolerance command. For more information, see the "Geometric Tolerance Dialog Box" topic in the PC-DMIS Core documentation. However, you can also create or modify a geometric tolerance command from the Edit window's Command Mode. Below are a couple of examples to help you understand how to use the Edit window command.

Simple Example

In the Edit window's Command Mode, a relatively simple geometric tolerance might look like this:

```
  FCFCYLY1    =GEOMETRIC_TOLERANCE/STANDARD=ISO
1101,SHOWEXPANDED=NO,

            SEGMENT_1,CYLINDRICITY,0.05,,REFERENCE_FEATU
RE_MATH=DEFAULT,
              FEATURES/CYL4,,
```

There are several parts to this Edit window syntax:

- `FCFCYLY1` is the dimension ID.
- `GEOMETRIC_TOLERANCE` identifies the command as a geometric tolerance.
- `STANDARD=ISO 1101` shows that the geometric tolerance is evaluated with respect to the ISO 1101 family of standards.
- `SHOWEXPANDED=NO` indicates that the display in the Edit window is condensed and simplified (doesn't show much detail). If you set this to YES, you'll see that it shows much more information as described in the "Complex Example" topic below.
- `SEGMENT_1` begins the information about the first segment.
- `CYLINDRICITY` indicates the segment is a cylindricity tolerance.
- `0.05` is the tolerance.
- `REFERENCE_FEATURE_MATH=DEFAULT` indicates the tolerance zone math type. For details, see the "Cylindricity" topic in the PC-DMIS Core documentation.
- `FEATURES/CYL4,,` indicates the tolerance applies to the CYL4 feature.

Please notice that `SHOWEXPANDED=NO` . This hides much of the detail.

Complex Example

Here is an example of the Command Mode syntax for a more complex geometric tolerance, with `SHOWEXPANDED=YES` :

```
  FCFLOC1    =GEOMETRIC_TOLERANCE/STANDARD=ISO
1101,SHOWEXPANDED=YES,
              DESCRIPTION=ON,Multi-segment position of
4x Ø8.2mm hole pattern,

            FEATURE_MATH=MODIFIER_SELECTED,SIZE_MATH=MOD
IFIER_SELECTED,DATUM_MATH=DEFAULT,DISPLAY_COORDS=DRF,
              UNITS=MM,OUTPUT=BOTH,ARROWDENSITY=100,
              SIZE/NOMINAL=8.2,TOLERANCE SPECIFICATION
MODE=NOMINAL_WITH_DEVIATIONS,
              UPPER TOLERANCE=0.1,LOWER TOLERANCE=-0.1,
              UPPER_SPECIFICATION_MODIFIER=__,
              LOWER_SPECIFICATION_MODIFIER=(LP),
                CYL4:
                  MAX LOCAL SIZE:8.202,
                  MIN LOCAL SIZE:8.175,
                CYL6:
                  MAX LOCAL SIZE:8.200,
                  MIN LOCAL SIZE:8.160,
                CYL8:
                  MAX LOCAL SIZE:8.203,
                  MIN LOCAL SIZE:8.168,
                CYL10:
                  MAX LOCAL SIZE:8.209,
                  MIN LOCAL SIZE:8.166,
              SEGMENT_1,POSITION,DIAMETER,0.4,
(G),__,<len>,A,D,MMB,__,B,__,

            SHOW_OPT_SHIFT=OFF,TEXT=OFF,CADGRAPH=OFF,REP
ORTGRAPH=OFF,MULT=10,
                MEASURED:
                  CYL4:0.110,
                  CYL6:0.094,
                  CYL8:0.110,
                  CYL10:0.110,
              SEGMENT_2,POSITION,COMPOSITE,DIAMETER,0.2,
(G),__,<len>,A,<dat>,<dat>,

            SHOW_OPT_SHIFT=OFF,TEXT=OFF,CADGRAPH=OFF,REP
ORTGRAPH=OFF,MULT=10,
                MEASURED:
                  CYL4:0.108,
                  CYL6:0.100,
                  CYL8:0.108,
                  CYL10:0.108,
              ADD
              DATUMS/REPORTDATUMSIZE=OFF,
                D(DATUM_D):NOM=30,+Tol=0.2,-Tol=-0.2,
              FEATURES/CYL4,CYL6,CYL8,CYL10,,
```

This expanded view has the following items:

- `FCFLOC1` is the dimension ID.
- `GEOMETRIC_TOLERANCE` identifies the command as a geometric tolerance.
- `STANDARD=ISO 1101` shows that the geometric tolerance is evaluated with respect to the ISO 1101 family of standards.
- `SHOWEXPANDED=YES` indicates that the display in the Edit window is expanded (shows more detail). If you set this to NO, you'll see that it shows much less information as described in the "Simple Example" topic above.
- `DESCRIPTION=ON` indicates that the description text "Multi-segment position of 4x Ø8.2mm hole pattern" appears in the report as explained in the "Description Tab" topic in the PC-DMIS Core documentation.
- `FEATURE_MATH=MODIFIER_SELECTED` indicates that the feature math uses an ISO Associated Tolerance Feature modifier as explained in the "Deriving the Toleranced Feature" topic in the PC-DMIS Core documentation.
- `SIZE_MATH=MODIFIER_SELECTED` indicates that PC-DMIS calculates the size of the feature using an ISO 14405-1 size modifier as explained in the "Evaluating Size with the Geometric Tolerance Command" topic in the PC-DMIS Core documentation.
- `DATUM_MATH=DEFAULT` indicates that the datum math uses the default method — a void filtration and a constrained least squares best fit — as explained in the "How PC-DMIS Solves and Uses Datums" topic.
- `DISPLAY_COORDS=DRF` indicates that the results are reported in datum reference frame coordinates (as opposed to current alignment coordinates).
- `UNITS=MM` indicates the dimension units are millimeters.
- `OUTPUT=BOTH` indicates that the results are sent to both the statistics and the report.
- `ARROWDENSITY=100` is the arrow density used with graphical analysis.

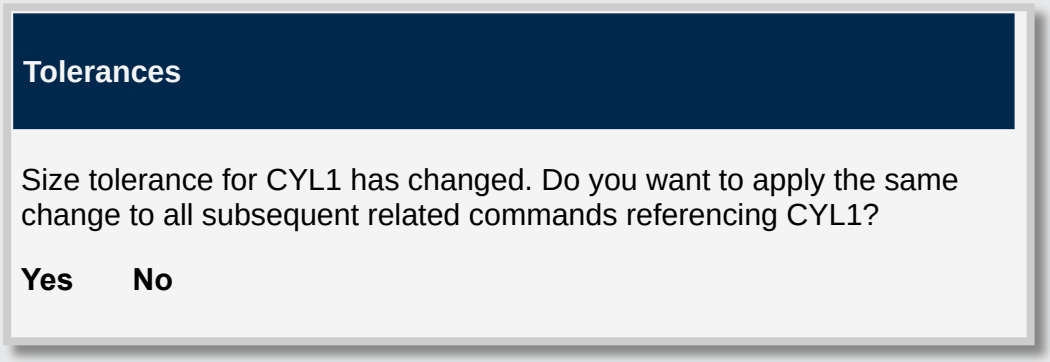
Alternate Command Block 1

```
SIZE/NOMINAL=8.2,TOLERANCE SPECIFICATION
MODE=NOMINAL_WITH_DEVIATIONS,
     UPPER TOLERANCE=0.1,LOWER TOLERANCE=-0.1,
     UPPER_SPECIFICATION_MODIFIER=__,
     LOWER_SPECIFICATION_MODIFIER=(LP),
     CYL4:
       MAX LOCAL SIZE:8.202,
       MIN LOCAL SIZE:8.175,
    CYL6:
       MAX LOCAL SIZE:8.200,
       MIN LOCAL SIZE:8.160,
    CYL8:
       MAX LOCAL SIZE:8.203,
       MIN LOCAL SIZE:8.168,
    CYL10:
       MAX LOCAL SIZE:8.209,
       MIN LOCAL SIZE:8.166,
```

This command block represents the size tolerance, including the nominal size, upper tolerance, lower tolerance, and the upper and lower specification modifiers (if selected). In this case, the (LP) modifier specifies the max and min two-point local size. The respective measured values are then listed below for each of the four features.

If you edit a feature's upper or lower tolerances from the Edit window or from the **Geometric Tolerance** dialog box (**Feature Control Frame** or **Nominals** tab), and the same feature is used as a datum or as a considered feature, PC-DMIS displays a message asking if you want to apply the same changes to all subsequent commands referencing that feature.

For example:



If you click **Yes**, PC-DMIS updates the size tolerances for any Geometric Tolerance commands below the cursor position that references the same feature, either as a considered feature or datum.

If you click **No**, PC-DMIS updates the edited size tolerance only. PC-DMIS does not update any of the respective size tolerances for any related Geometric Tolerance commands below the cursor position that uses the same edited feature either as a considered feature or datum.

Alternate Command Block 2

```
SEGMENT_1,POSITION,DIAMETER,0.4,
(G),__,<len>,A,D,MMB,__,B,__,
SHOW_OPT_SHIFT=OFF,TEXT=OFF,CADGRAPH=OFF,REPORTGRAPH=OFF
,MULT=10,
    MEASURED:
      CYL4:0.110,
      CYL6:0.094,
      CYL8:0.110,
      CYL10:0.110,
```

This command block represents the first segment, which is a position tolerance with a diametric tolerance zone, 0.4 tolerance, a (G) modifier, and a datum reference frame that consists of A | D MMB | B. Show optimized shift is off, the textual analysis is off, the CAD graphical analysis is off, the report graphical analysis is off, and the arrow multiplier is 10. It also includes the measured position values of each of the four features.

Alternate Command Block 3

```
SEGMENT_2,POSITION,COMPOSITE,DIAMETER,0.2,
(G),__,<len>,A,<dat>,<dat>,

   SHOW_OPT_SHIFT=OFF,TEXT=OFF,CADGRAPH=OFF,REPORTGRAPH=
OFF,MULT=10,
     MEASURED:
        CYL4:0.108,
        CYL6:0.100,
        CYL8:0.108,
        CYL10:0.108,
```

This command block represents the second segment, which is a lower segment of a composite position tolerance having a diametric tolerance zone, 0.2 tolerance, a (G) modifier, and a datum reference frame that consists of A. Show optimized shift is off, the textual analysis is off, the CAD graphical analysis is off, the report graphical analysis is off, and the arrow multiplier is 10. The command block also includes the measured position values of each of the four features.

Alternate Command Block 4

```
ADD
     DATUMS/REPORTDATUMSIZE=OFF,
        D(CYL2):NOM=30,+TOL=0.2,-TOL=-0.2,
     FEATURES/CYL4,CYL6,CYL8,CYL10,,
```

- `ADD` is a control that you can use to add another segment to the composite position tolerance. To use it, hover over the `ADD` command for couple of seconds, then click once on it, and then click the **ADD** button that appears.
- `DATUMS/REPORTDATUMSIZE=OFF,`

  `D(CYL2):NOM=30,+Tol=0.2,-Tol=-0.2,`

  This part of the command indicates that the measured datum sizes are not included in the report. It also shows the size tolerance on datum D (which is CYL2). The size tolerance on datum features can be important in several situations, such as datums referenced with a material modifier Ⓜ or Ⓛ, and datum patterns with or without a modifier. We recommend that you always make sure that the size tolerances on the datum features are correct. For details, see the "Determining the Size of the Material Boundary" section in the "How PC-DMIS Solves and Uses Datums" topic in the PC-DMIS Core documentation.
- `FEATURES/CYL4,CYL6,CYL8,CYL10,,`

This part of the command indicates the composite position tolerance applies to the CYL4, CYL6, CYL8, and CYL10 features.

Geometric Tolerance Dialog Box

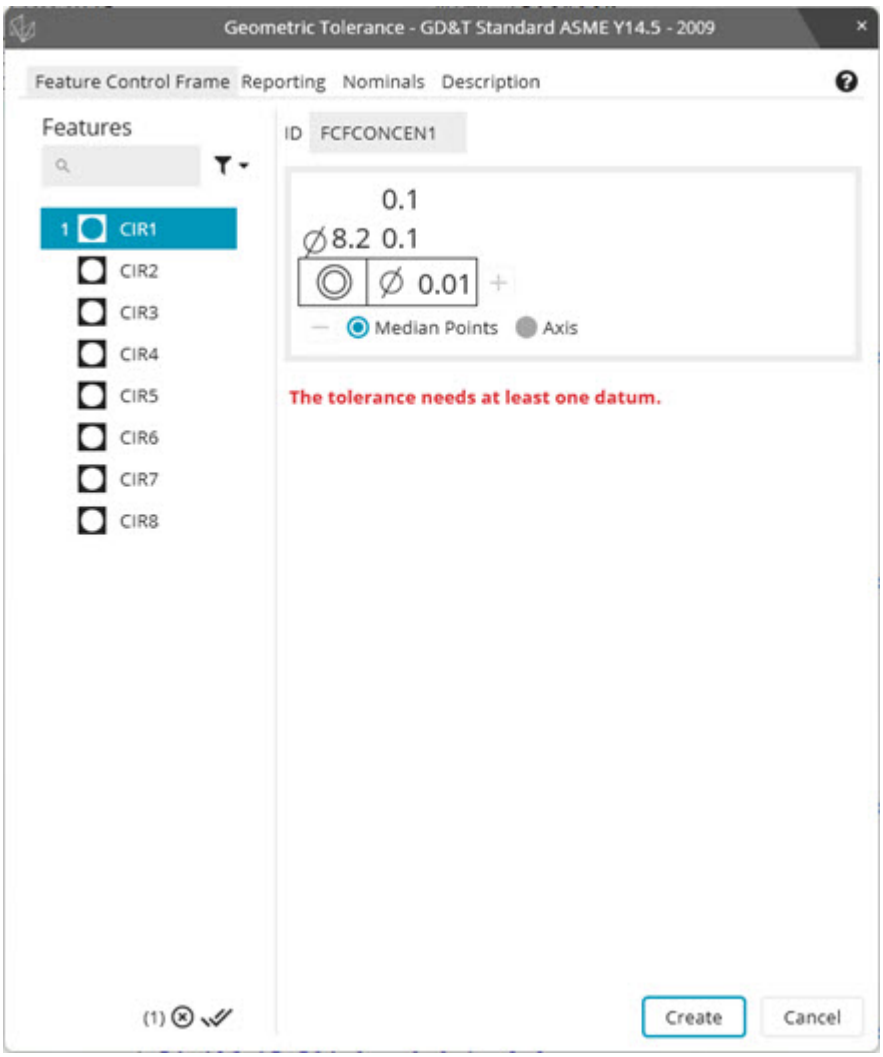
The **Geometric Tolerance** dialog box is the main way to create or modify the geometric tolerance command. To use this dialog box to create a geometric tolerance, select **Insert | Dimension | <geometric tolerance type>** from the menu, or you can select a geometric tolerance type from the **Dimension** toolbar.

The geometric tolerance types are:

- Angularity
- Circular Runout
- Circularity
- Concentricity
- Cylindricity
- Flatness
- Parallelism
- Perpendicularity
- Position
- Profile of a Line
- Profile of a Surface
- Straightness
- Symmetry
- Total Runout

The other tolerance types (Location, Angle, and so on) are not geometric tolerances and so are not handled via the geometric tolerance command.

After you select **Insert | Dimension | <tolerance type>** from the menu (or from the **Dimension** toolbar), PC-DMIS shows the **Geometric Tolerance** dialog box:



This dialog box starts out nearly empty. In the example image above, the dialog box has these properties:

- The default dimension ID is FCFCONCEN2
- The symbol from the selected tolerance type is Concentricity
- The recently-used tolerance value is 0.01
- The red error message indicates that you haven't selected any datum references yet

We recommend this workflow when you use the **Geometric Tolerance** dialog box:

1. Choose your tolerance type from the **Insert | Dimension | <tolerance type>** menu (or from the **Dimension** toolbar) to open the **Geometric Tolerance** dialog box.
2. From the list of features, choose your considered features for the tolerance. The list only shows those features above your pointer's current position in the Edit window.
3. Edit the feature control frame. To do this, add symbols, modifiers, segments, zone orientation specifications, and so forth.
4. Click the **Reporting** tab and make sure all options are set as desired.

5. Click the **Nominals** tab (when present) and make sure all settings are set as desired.
6. Click the **Description** tab and click the **Add** button to add descriptive information as needed. Click the **Show on report** check box if you want to add the text in your reports.
7. Click **Create** to create the geometric tolerance command in your measurement routine.

In the Edit window, you can press F9 at any time on that command to edit that command in the **Geometric Tolerance** dialog box. If you edit an existing geometric tolerance, the **Geometric Tolerance** dialog has an **OK** button instead of a **Create** button.

Feature Control Frame Tab

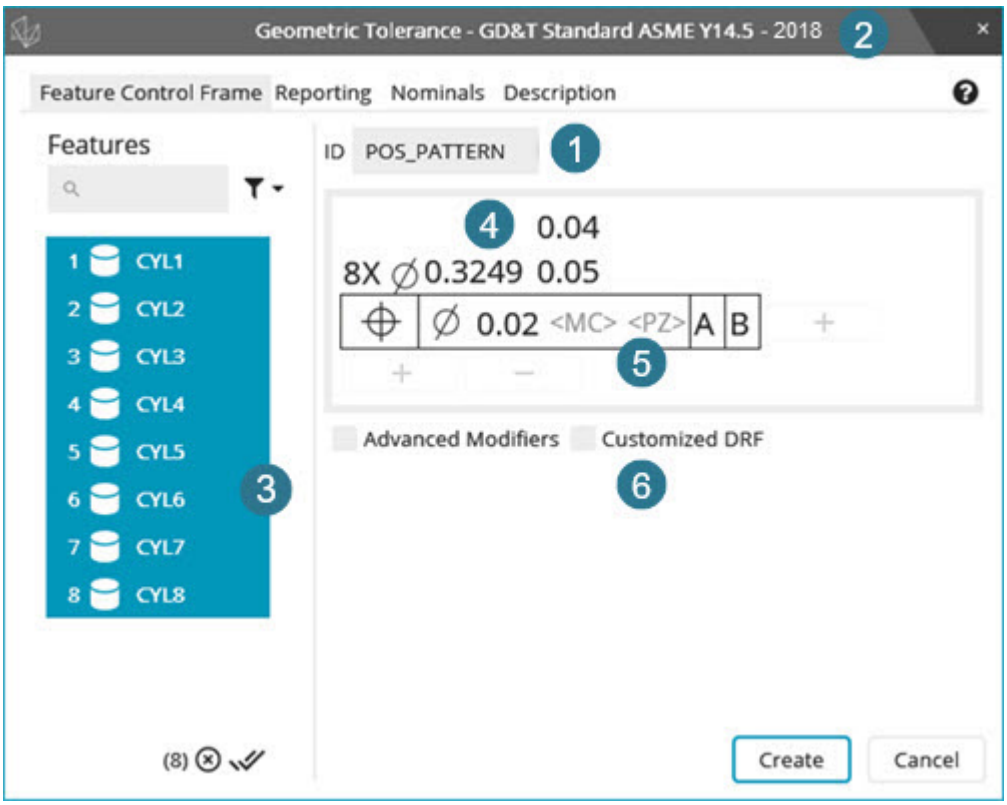
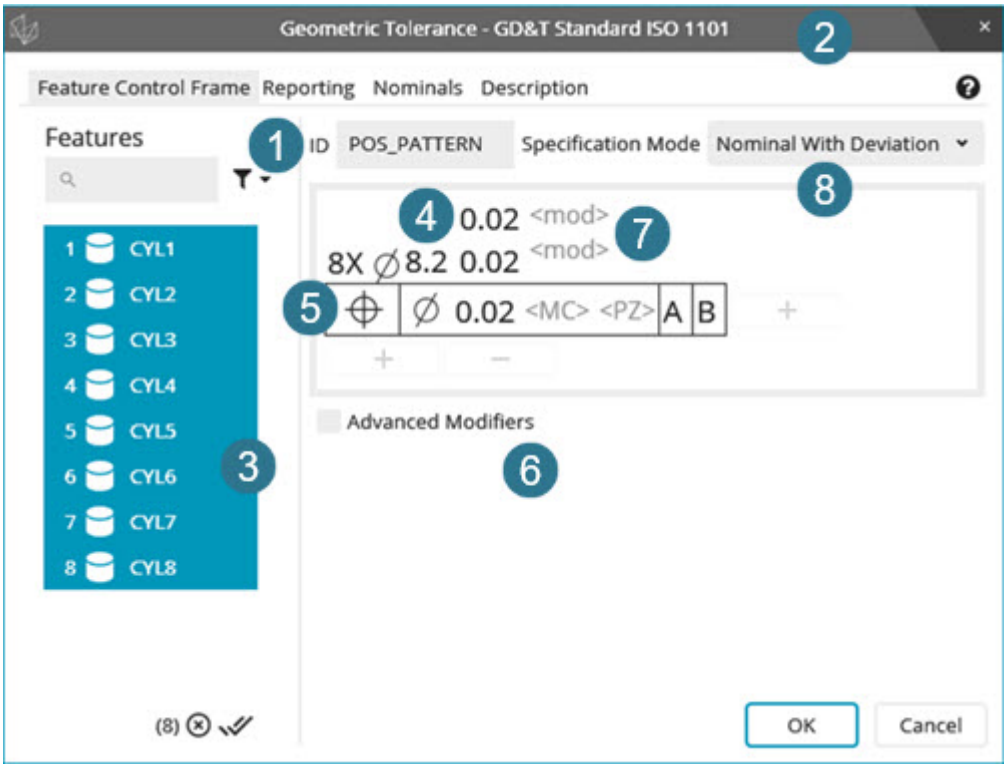
Introduction

The **Feature Control Frame** tab of the **Geometric Tolerance** dialog box is where most of your editing takes place. A typical position tolerance might look like this in the dialog box:



The ASME version of the Geometric Tolerance dialog box showing the Feature Control Frame tab



The ISO version of the Geometric Tolerance dialog box showing the Feature Control Frame tab

1. **ID** - This box defines the dimension's ID. In the picture above, it was edited to say POS_PATTERN. For the position tolerance, the **ID** defaults to something like

FCFLOC1, 2, 3... etc. if you do not edit it. For the rules that apply when you type an ID, see "Setup Options: ID Setup tab" in the "Setting Your Preferences" chapter.

2. **GD&T Standard** - This shows the standard to use in the tolerance. It should match the standard used by your print. We support prints based on ASME Y14.5 and ISO 1101; the specific versions of the standards we support (including supporting standards like ISO 5459) are detailed in the "Introduction to Geometric Tolerances and Feature Control Frames" topic.

3. **Feature List** - This list shows the available features for the type of geometric tolerance. For more information, see "The Feature List" below.

4. **Size Tolerance Editor** - The first row in the tolerance editing pane shows the size and plus and minus tolerance information. For more information, see "The Size Tolerance Editor" below.

5. **Feature Control Frame Editor** - The second row in the tolerance editing pane is the main editing area. For more information, see "The Feature Control Frame Editor" below.

6. **Additional Options** - This area of the dialog box contains advanced and other options for your tolerance. For more information, see "Additional Options" below.

7. **Upper and Lower Modifiers** (ISO only) - This area of the dialog box allows you to select the appropriate ISO Size modifiers. For details, see the "ISO Size Modifiers" section below.

8. **Specification Mode** (ISO only) - This list allows you to select the ISO specification mode. The options are **Nominal with Deviation** or **ISO Code**. For more details, see the "Specification Mode" section below.

The Feature List

The first thing to do when you start to create a geometric tolerance is to select the considered feature or features. When the dialog box opens, no features are selected. Every feature in the measurement routine that is allowed for the tolerance type is shown. If you don't see an expected feature, make sure your pointer in the Edit window is below that feature before you access the **Geometric Tolerance** dialog box.

In large routines with many features, you may find it helpful to search for a feature with the search bar.

After you select one feature, PC-DMIS filters the feature list so that only similar features or features with the same characteristics are shown (such as cylinders with the same diameter). You may then select additional features at that point.

The Size Tolerance Editor

The first row of the tolerance editing pane is the Size Tolerance Editor. It is available when your considered features are features of size (cylinders, circles measured on a surface, spheres, or widths) and your geometric tolerance type allows size tolerances.

The Size Tolerance Editor looks like this:

This line contains several types of information and two controls:

- 8X means there are eight considered features; it is not visible when there is only one considered feature. You cannot edit the symbol.
- ∅ means the features are cylinders or circles measured on a surface. The symbol is different for different kinds of features of size. Spherical features have a S∅ symbol. Width features do not have a symbol. You cannot edit the symbol.
- The first number after the above symbol is the nominal size. You cannot edit this value because the geometric tolerance command requires all features to have correct nominals. The nominal size comes from the feature's THEO (theoretical) size.
- The second number, the one on the far right on top (0.04 in the above example), is the plus tolerance for the feature's size. You can edit it. The upper limit of size is equal to the nominal size plus the plus tolerance.
- The third (and final) number, the one on the far right on bottom (0.05 in the above example), is the minus tolerance for the feature's size. You can edit it. The lower limit of size is equal to the nominal size minus the minus tolerance, when the **Minus tols show negative** check box in the **Dimension** tab of the **Setup Options** dialog box is cleared. If you mark **Minus tols show negative**, then the lower limit of size is equal to the nominal size plus the minus tolerance. You may prefer to mark this check box to make the size tolerance look like your print. For information on this check box, see the "Minus Tols Show Negative" topic in the "Setting Your Preferences" chapter. This check box exists so you don't have to type the minus sign for minus tolerances.

The Feature Control Frame Editor

The most complex part of the tolerance editing pane is the Feature Control Frame Editor. It looks like this:

There are several parts to this editor, which are detailed below.

The Tolerance Symbol

The tolerance symbol shows up in the left-most box of the Feature Control Frame Editor. It shows the symbol for the tolerance type you chose. You can change the symbol to change the tolerance type. You click the tolerance symbol to choose another valid geometric type for the features that you selected; the other symbols appear in a drop-down window.

The Zone, Feature, and Characteristic Section

The zone, feature, and characteristic section of the feature control frame includes the tolerance zone shape, the tolerance value, and any tolerance modifiers. Therefore, this section contains several controls. Their availability varies depending on what tolerance type and what considered features are chosen.

- The tolerance zone shape symbol is first. It is Ø for diametric zones, SØ for spherical zones, and blank for planar zones (and for radial arc and right angle to radial zones). If you click the symbol, you can edit which symbol appears, but the only available symbols are those that make sense for the considered features and the tolerance type you chose.

- The tolerance value is second. It is a number (0.02 in the above picture). You may edit it to any positive value.

- When it makes sense for your considered features and tolerance type, the material condition control is next. It appears as <MC> when there is no material condition modifier. That means the feature is referenced at regardless of feature size (RFS). When there is a maximum material condition (MMC) modifier, it appears as Ⓜ. When there is a least material condition (LMC) modifier, it appears as Ⓛ. Click the <MC>, Ⓜ, or Ⓛ to switch between no material condition modifier, the MMC modifier, or the LMC modifier. ISO orientation tolerances (angularity, parallelism, and perpendicularity) and location tolerances (position, concentricity, and symmetry) allow the selection of an Associated Toleranced Feature Modifier within this control. ISO form tolerances (circularity, cylindricity, flatness and straightness of a surface) allow the selection of a Reference Feature Association modifier within this control.

  > **!** You cannot combine an Associated Toleranced Feature Modifier (ATFM) or a Reference Feature Association Modifier (RFAM) with a material condition modifier (MMC/LMC).

  For details, see the "Deriving the Toleranced Feature" topic in the PC-DMIS Core documentation.

- When it makes sense for your considered features and tolerance type, the projected zone control is next. It appears as <PZ> when there is no projected zone modifier. When there is a projected zone modifier, it appears as Ⓟ with a

projected length number that immediately follows it, like this: Ⓟ 0.8. Click the projected length number to edit it. Click the <PZ> or Ⓟ to switch between no projected zone modifier or the projected zone modifier.

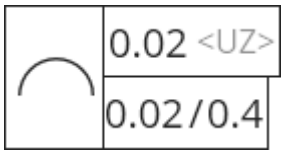
- When it makes sense for your considered features and tolerance type, the tangent plane control is next. It appears as <T> when there is no tangent plane modifier. When there is a tangent plane modifier it appears as Ⓣ. Click the <T> or Ⓣ to switch between no tangent plane modifier or the tangent plane modifier.

> The tangent plane modifier is not available for ASME Y14.5 1994.

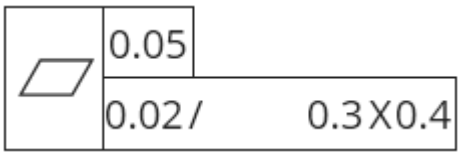
- For profile tolerances, the profile modifier control appears after the tolerance. It appears as <UZ> when there is no profile modifier. When there is an ASME unequal disposition modifier, it appears as Ⓤ with an unequal disposition distance that immediately follows it, like this: Ⓤ 0.02. When there is an ISO unequal disposition modifier, it appears as UZ with an unequal disposition distance that immediately follows it, like this: UZ 0.02. When there is an ASME dynamic profile modifier, it appears as △. When there is an ISO offset zone modifier, it appears as OZ.

> The tangent plane modifier Ⓣ and unequal disposition modifier Ⓤ are not available for ASME Y14.5 1994.
>
> The dynamic profile modifier △ is not available for ASME Y14.5 1994 or ASME Y14.5 2009.

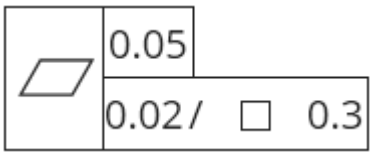
- For per-unit straightness and per-unit profile of a line, you can edit the per-unit length right after the / symbol, as shown in the lower segment below:



- For per-unit flatness, to the right of the / symbol, there is the unit shape control. It appears blank when the unit is rectangular, and it appears as a square □ when the unit shape is square. Rectangular unit shapes give you a length and a width to edit, while square unit shapes give you only a length. Click the blank or the square to switch between the two.



Rectangular Unit Shape



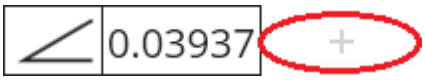
Square Unit Shape

Datum Section

The datum section of a feature control frame (or of a tolerance indicator) is just to the right of the zone, feature, and characteristic section. This consists of zero to three boxes. Each box contains a datum reference (potentially a common datum reference) and zero or more datum modifiers.

The Add-Datum Button

The **+** button to the right of the Feature Control Frame Editor lets you add datums:

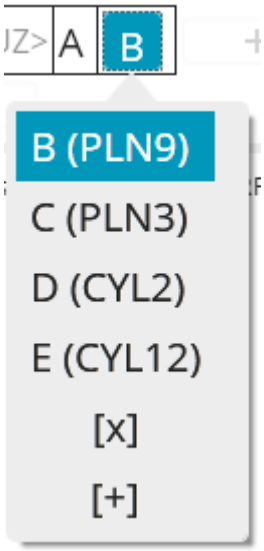


When you click this button, PC-DMIS adds a pre-defined datum to your feature control frame. Each time you click it, it adds a pre-defined datum that has not already been added to this feature control frame.

If no pre-defined datum exists that has not already been added to the feature control frame (or if no pre-defined datums exist at all), then this button shows the **Datum Definition** dialog box. You can use that dialog box to define a datum. (For information on the dialog box, see "Dialog Box Usage and Command Syntax".) This inserts a datum definition command just above your geometric tolerance command. However, the new datum is not automatically selected for you. This means you need to click the add-datum button (**+**) again to select the new datum reference.

Modifying a Datum Reference

To change a datum reference inside a datum box, click the datum reference. A drop-down menu appears from which you can choose a new reference:



From the drop-down menu, you can select a pre-defined datum reference, where the feature name is shown in parentheses next to the datum reference (datum patterns only show one feature name, and common datums don't show any feature names).

If you choose the [x] option, the datum box is deleted.

If you choose the [+] option, the **Datum Definition** dialog box opens up, so that you can define a new datum. (For information on the dialog box, see "Dialog Box Usage and Command Syntax".) However, the new datum is not automatically selected for you. This means you need to click the old datum reference from the datum box and then choose the new datum reference.

Datum Modifiers

To the right of each datum reference, there are the controls for any datum modifiers.

- When it makes sense for your datum and tolerance type, the material boundary control is first. It appears as <MC> when you reference the datum without a material modifier. That means the datum is referenced at regardless of material boundary (RMB). When there is a maximum material boundary (MMB) modifier, it appears as Ⓜ. When there is a least material boundary (LMB) modifier, it appears as Ⓛ. Click the <MC>, Ⓜ, or Ⓛ to switch between no material modifier, the MMB modifier, or the LMB modifier.

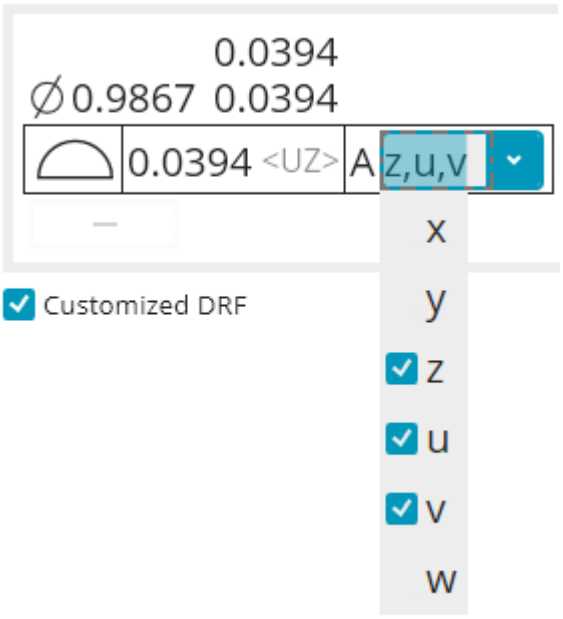
- When a datum is referenced at MMB or LMB, and you marked the **Advanced Modifiers** check box, you can specify a material boundary size. This is not the nominal size of the datum feature, nor is it the maximum or minimum material condition size of the datum feature. For more information about material boundary sizes, see the "Determining the Size of the Material Boundary" sub-topic of the "How PC-DMIS Solves and Uses Datums" topic. For datum cylinders, this modifier looks like this

if you haven't specified a material boundary size: [Ø<size>]. After you specify a material boundary size, the modifier looks like this: [Ø9.2], with whatever size you specified. To remove a specified material boundary size, delete the size value and then press tab to move off the modifier. For more information, see the "Additional Options" section below.

- When the datum is a secondary or tertiary datum, and you marked the **Advanced Modifiers** check box, the translation control appears next. It appears as <TR> when the datum is referenced without a translation modifier. When there is a translation modifier, it appears as ▷. Click the <TR> or ▷ to switch between no translation modifier and the translation modifier. For more information, see the "Additional Options" section below.

> The translation modifier is not available for ASME Y14.5 1994.

- Position and profile ASME tolerances have a **Customized DRF** check box. For more information, see the "Additional Options" section below.



If you mark this check box, PC-DMIS enables access to customized datum reference frames and removes access to advanced datum modifiers. Wherever possible, PC-DMIS will determine the degrees of freedom that each datum would naturally constrain. Where it is not possible for the software to determine which degrees of freedom to constrain, the customization will show <DOF> and you must make a manual selection. The software clears this check box by default because, more often than not, you do not need customized datum reference frames.

Customized DRF's are not available for ASME Y14.5 1994.

For more information on customized datum reference frames and their associated rules, please refer to ASME Y14.5 2018 section 7.22 and figures 7-55, 7-56 & 7-57.

Additional Options

Advanced Modifiers check box

This check box is not available if you select ASME Y14.5 1994 as your GD&T standard. For all other GD&T standard selections, you can find it under the tolerance editing pane as shown here:

Position and profile tolerances have an **Advanced Modifiers** check box. If you mark this check box, PC-DMIS enables access to translation modifiers (ASME), specified material boundary modifiers (ASME), and the [DF] modifier (ISO). It also removes access to customized datum reference frames. This check box is cleared by default because most users do not need these advanced modifiers.

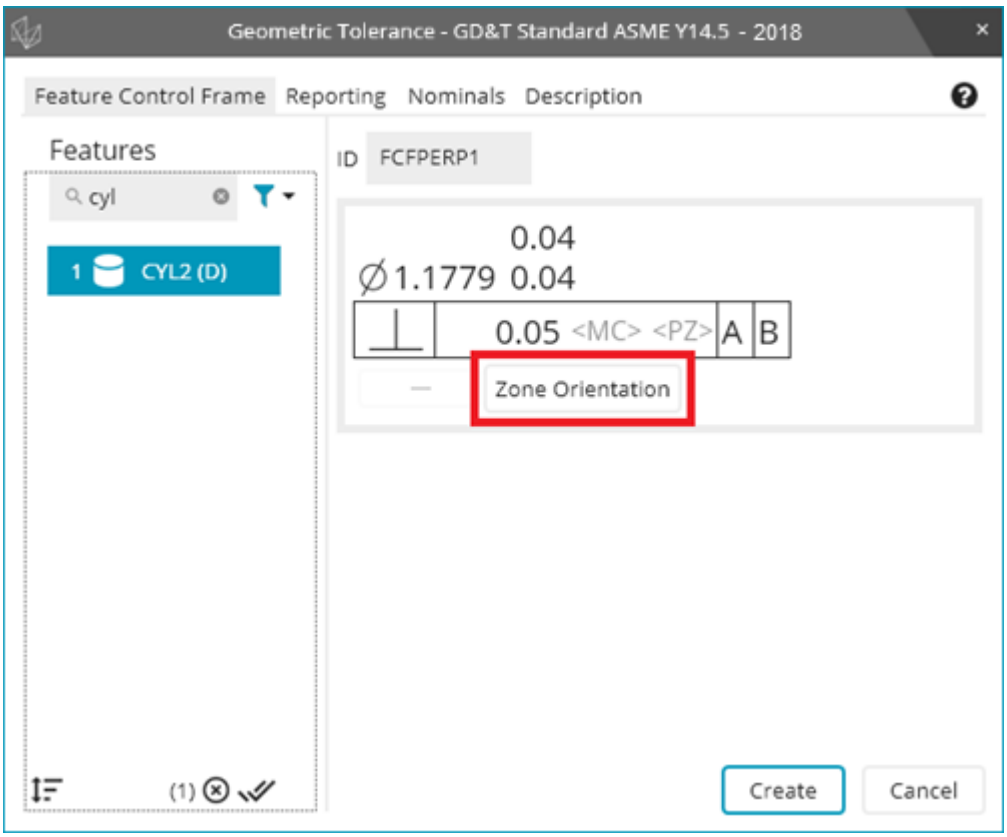
Customized DRF check box

This check box is not available if you select ASME Y14.5 1994 or ISO 1101 2012/2017 as your GD&T standard. For all other GD&T standard selections, you can find it under the tolerance editing pane as shown here:

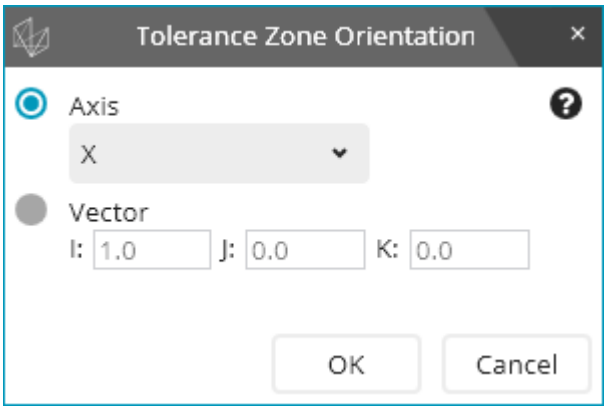
Position and profile ASME tolerances have a **Customized DRF** check box. If you mark this check box, PC-DMIS enables access to customized datum reference frames and removes access to advanced datum modifiers. This check box is cleared by default because most users do not need customized datum reference frames.

Zone Orientation

When it makes sense for the chosen tolerance zone shape symbol, tolerance type, and considered features, the **Zone Orientation** button becomes visible:



If you click the **Zone Orientation** button, the **Tolerance Zone Orientation** dialog box appears. This dialog box allows you to control the orientation of the tolerance zone:



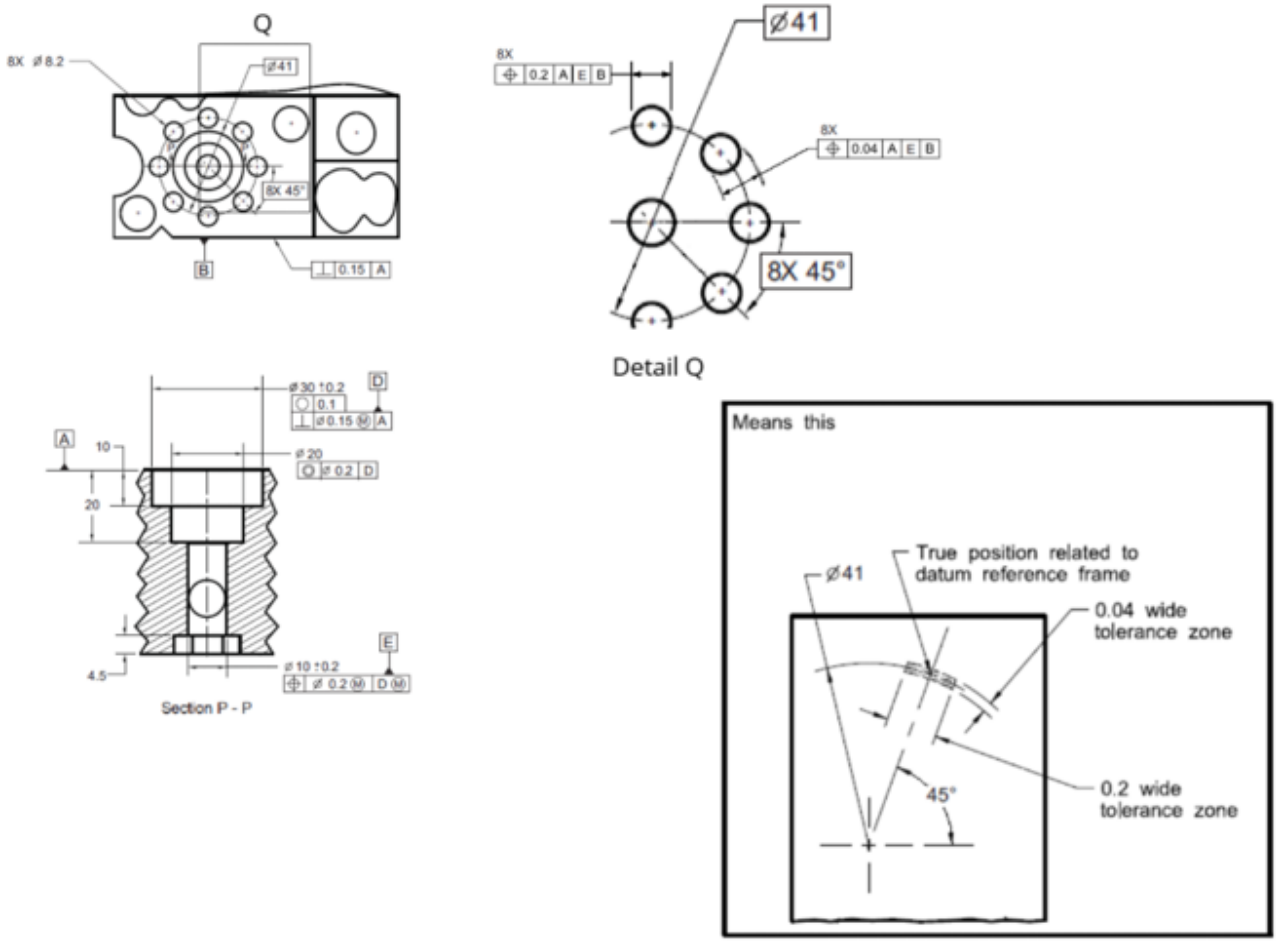
The **Tolerance Zone Orientation** dialog allows you to define the surface normal vector of the planar tolerance zone, or the axis vector of the diametric tolerance zone. The **Axis** drop-down list is for when the vector is along the X, Y, or Z axes (respectively). Alternatively, you can select an arbitrary vector with the **Vector** option and boxes under it.

As an example, if a position tolerance controls the X component of the position (planar tolerance zone), the tolerance zone surface normal vector should be X.

The zone orientation vector is always in part coordinates, never datum reference frame coordinates. It is also always normalized (has length equal to 1) and always compatible with the orientation of the considered feature.

To select a polar tolerance zone (radial arc or right angle to radial), click the **Zone Orientation** button, and from the **Axis** drop-down list, select **Radial Arc** or **Right Angle to Radial**.

Consider the following requirement on a drawing:



To satisfy this requirement, you would create two position commands, each with a planar tolerance zone. For the 0.04 position, you would click the **Zone Orientation** button and select **Radial Arc** from the **Axis** drop-down list. For the 0.2 position, you would click the **Zone Orientation** button and select **Right Angle to Radial** from the **Axis** drop-down list.

Setting `CADGRAPH=ON` may help you to visualize the tolerance zone shape and orientation more easily in the PC-DMIS graphic window.

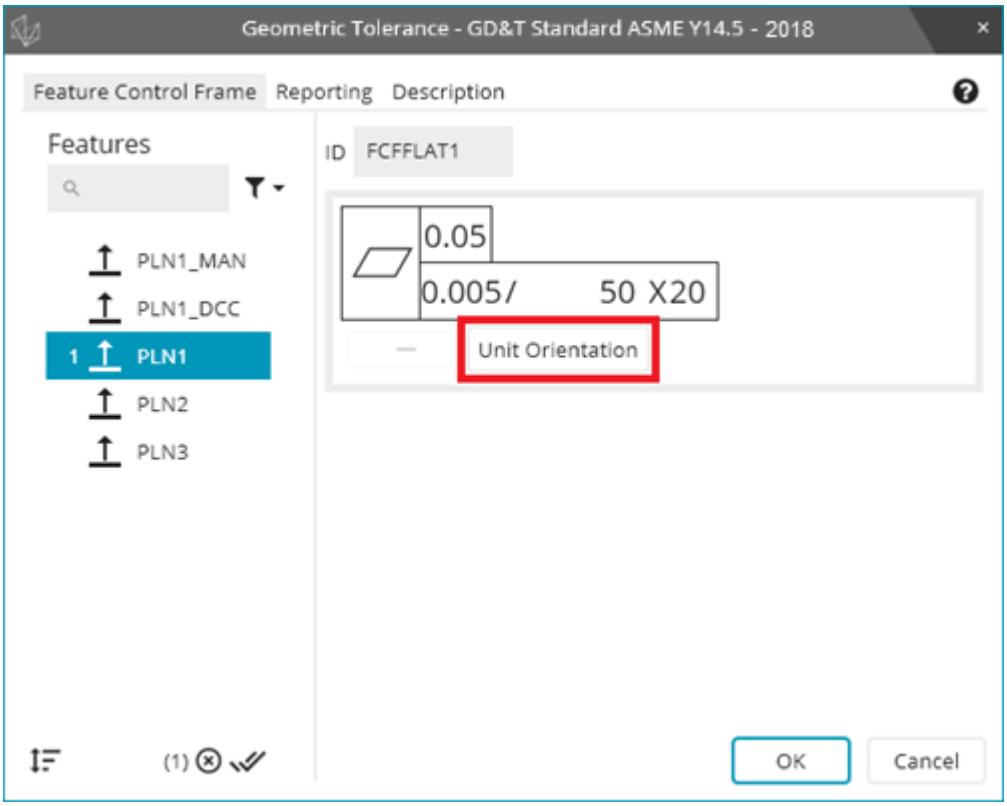
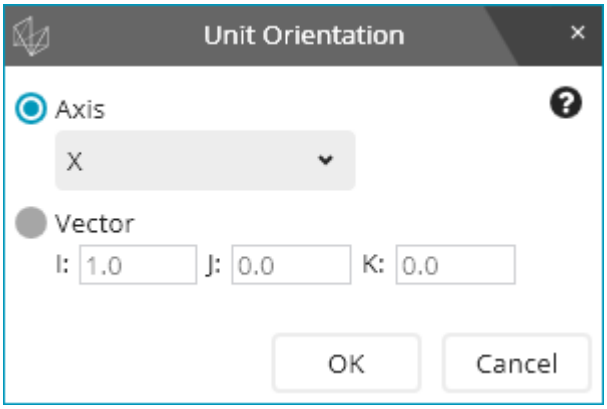
Unit Orientation

Per-unit flatness tolerances have square or rectangular units, as described in the "Flatness" topic. The geometric tolerance command needs to know how to orient the unit on the planar surface. You can enable per-unit flatness with the plus sign that adds the lower segment:

The **Unit Orientation** button becomes visible:



If you click the **Unit Orientation** button, the **Unit Orientation** dialog box appears. This dialog box allows you to control the unit orientation:



The **Unit Orientation** dialog box allows you to define the unit's orientation vector. For more information, see "Flatness Per Unit" in the "Flatness" topic.

Cone Half Angle

This check box is under the tolerance editing pane, and it looks like this:

For circular runout tolerances on circles, the geometric tolerance command allows you to treat the circle as a cross section of a cone instead of a cross section of a cylinder. To do this, you can select the **Half Cone Angle** check box and then type an angular value for the cone half angle. For more information, especially the meaning of the sign of the cone half angle, see "Circular Runout".

Circularity versus Conicity

The **Conicity** check box is under the tolerance editing pane, and it looks like this:

As discussed in the "Circularity" topic, PC-DMIS can evaluate circularity tolerances on cones as true circularity or as conicity. By default, it is evaluated as true circularity, but you can change it to conicity by selecting this check box.

Lengthwise versus Widthwise Slots

These left and right options appear inside the tolerance editing pane if your considered features are slots:

The left option considers the slot in a widthwise fashion. The size of the slot is its width, and the tolerance zone controls the slot's position in the width direction.

The right option considers the slot in a lengthwise fashion. The size of the slot is its length, and the tolerance zone controls the slot's position in the length direction.

Median Points versus Axis

These options appear inside the tolerance editing pane if you have concentricity or symmetry tolerance with ASME:

For concentricity and symmetry ASME Y14.5 1994 or ASME Y14.5 2009 tolerances, when the considered features have surface data, PC-DMIS can interpret them in terms of the **Median Points** or in terms of the **Axis**. You can choose the desired option to control the interpretation. **Median Points** is the default.

Adding and Removing Segments

Underneath the Feature Control Frame Editor, there are **+** and **-** buttons to add and remove segments, respectively. When it does not make sense to add any more segments, the **+** button is not available.

The buttons look like this:

You can use these buttons to construct composite position tolerances, composite profile tolerances, and per-unit tolerances.

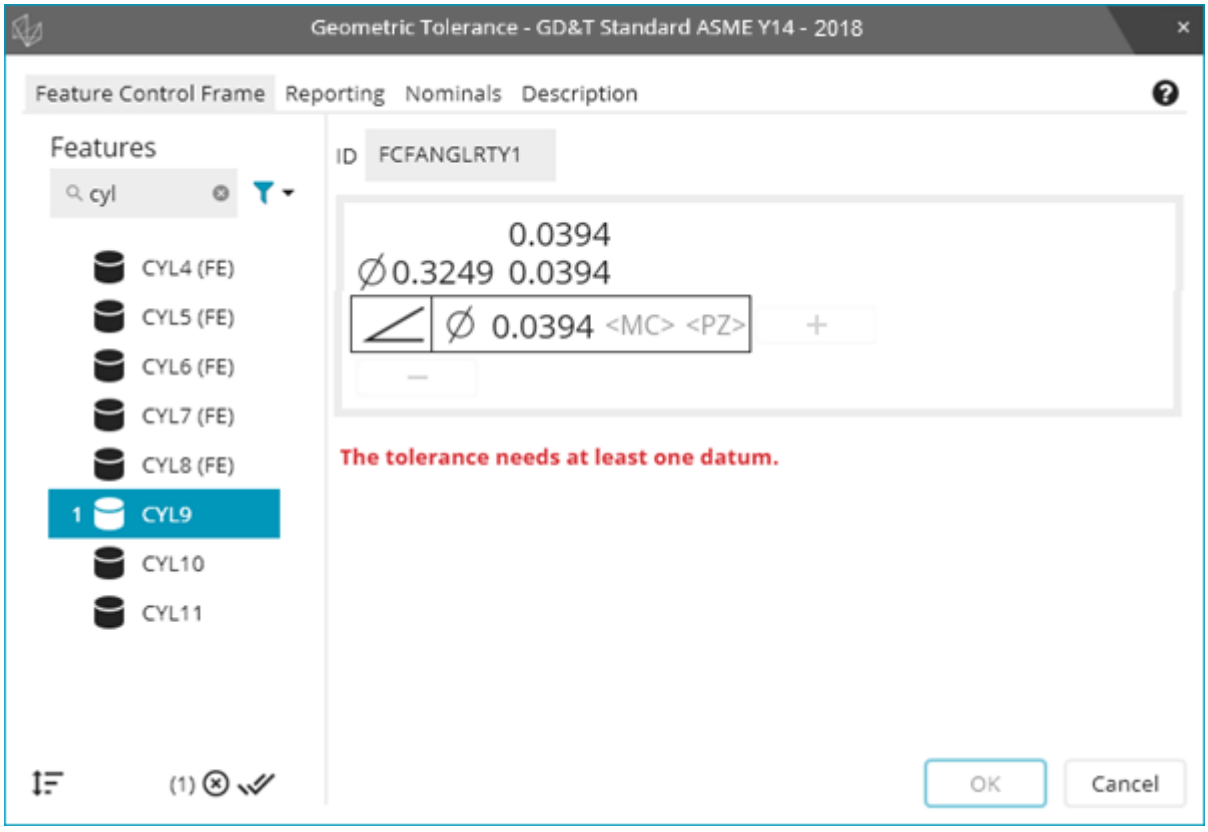
The Information Section

Underneath all of these feature control frame options, PC-DMIS shows error messages, warnings, and other informational messages. For information on how to resolve error or warning messages, see "Troubleshooting Error Messages and Warnings".

Error messages - Error messages show up in **red**.

When there is an error message, you cannot click **Create** or **OK** in the dialog box.

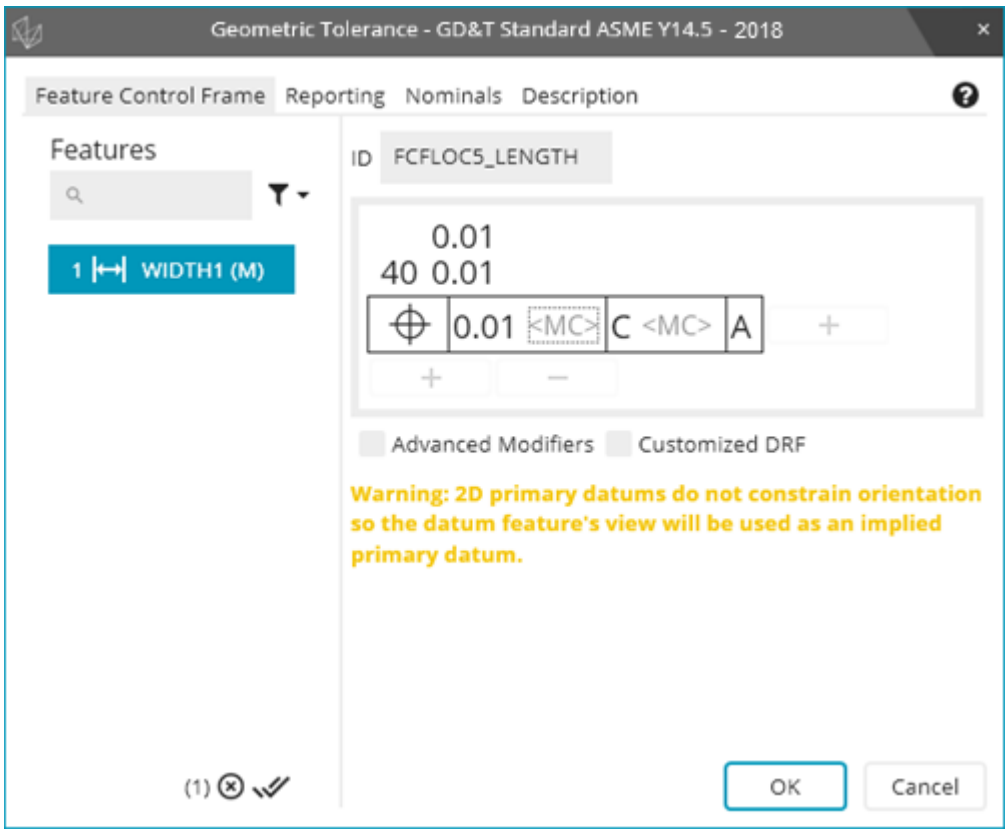
Error messages look like this:



Warning messages - Warning messages show up in **yellow**.

When there is a warning message, you can press **Create** or **OK** in the dialog box.

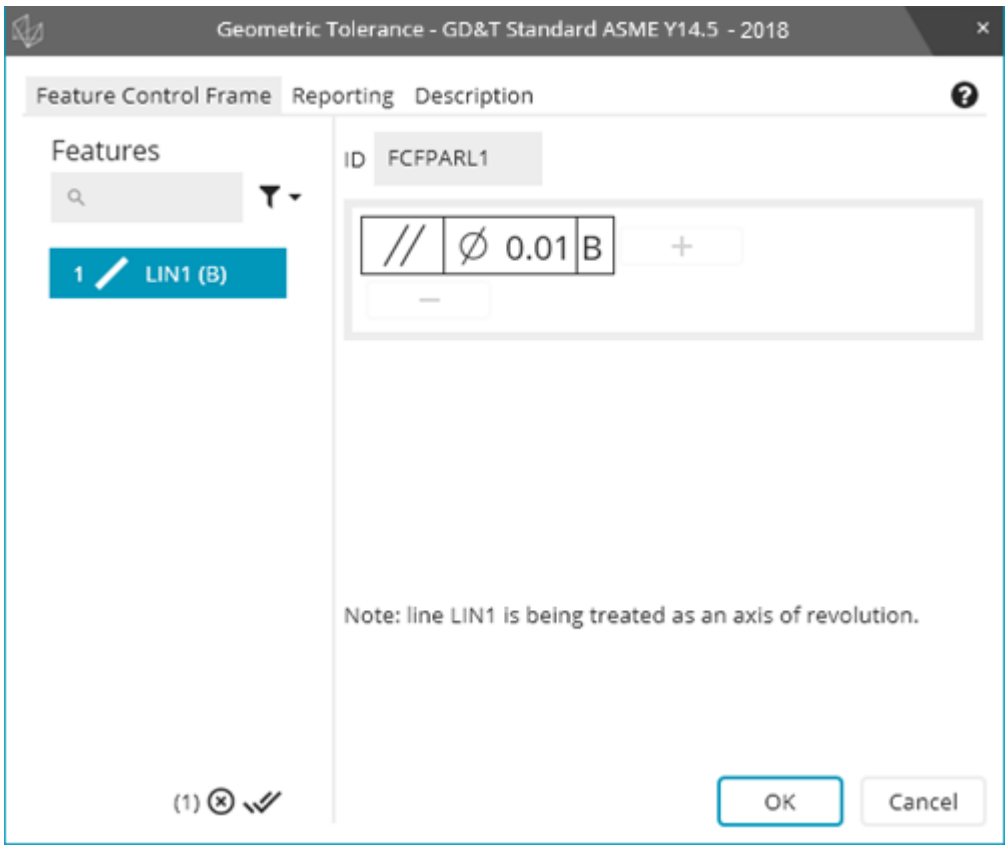
Warning messages look like this:



Interpretation messages - Interpretation messages show up in black.

Interpretation messages appear when you use a constructed line feature as a datum feature or as a considered feature. The message lets you know whether PC-DMIS interprets the feature as a line on a surface (such as a cross section of a planar surface) or as an axis of revolution (such as a surfaceless axis). For more information about what line types are considered a line on a surface, versus what line types are considered an axis of revolution, see "Feature Types With and Without Surface Data".

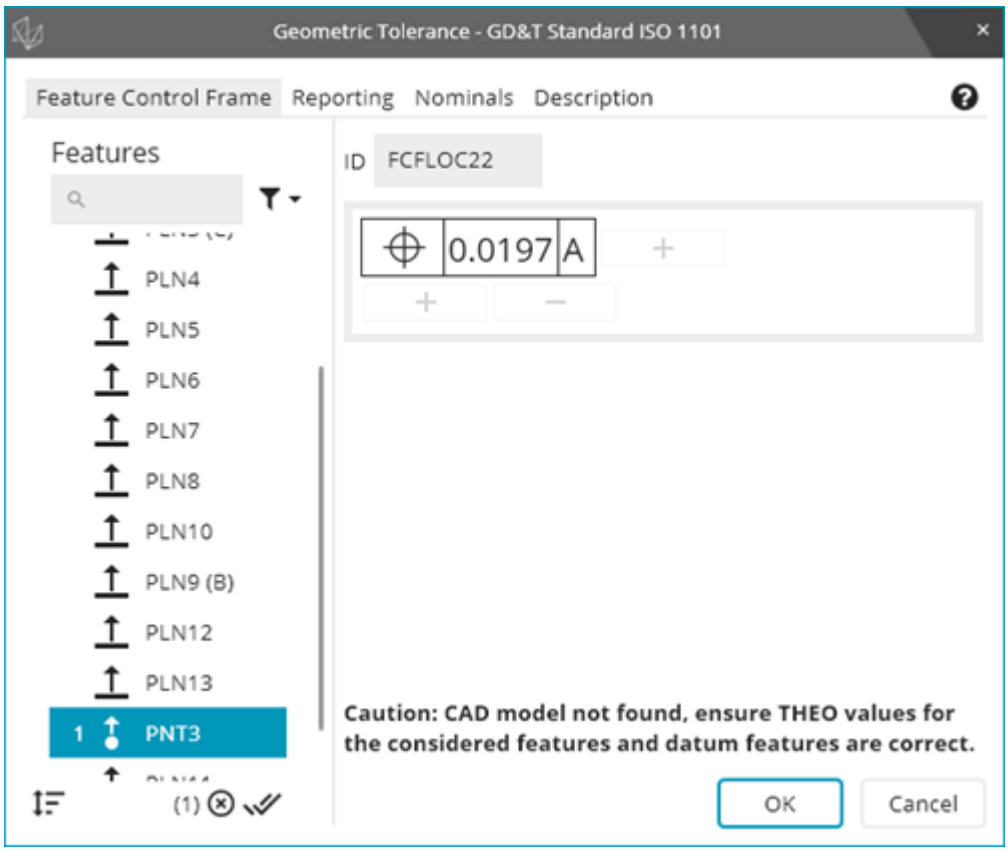
Interpretation messages look like this:



CAD Warning messages - There is an additional type of warning message that appears in black just above the main command buttons on the dialog box.

If you do not have a CAD model, PC-DMIS cannot ensure that your program THEO values are all correct. The **Geometric Tolerance** dialog box shows a warning message that cautions you to ensure your THEO values are all correct. You can still click **Create** or **OK** in the dialog box.

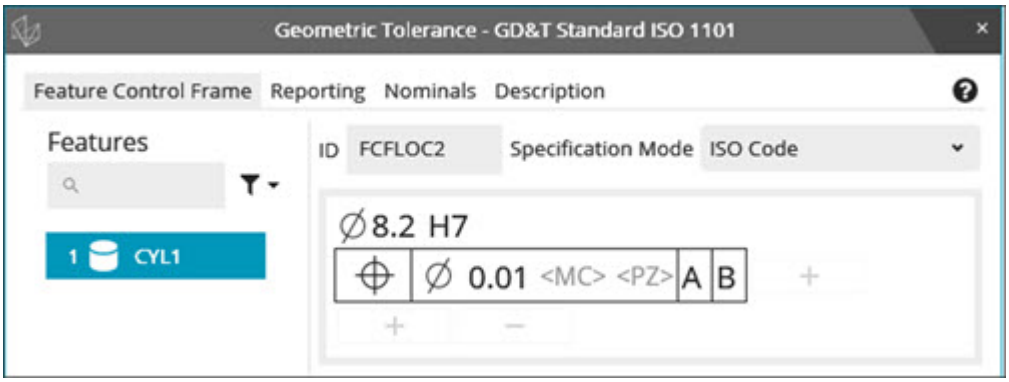
This CAD warning looks like this:



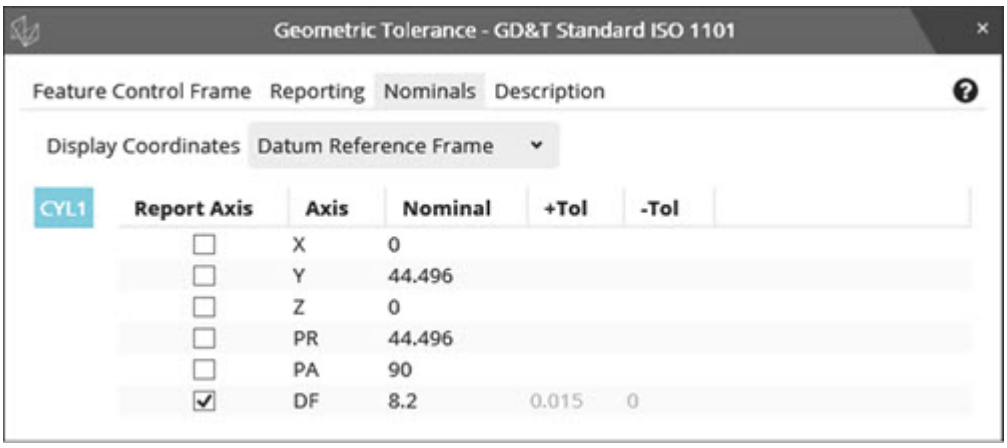
Specification Mode

The **Specification Mode** list controls the **Size Tolerance** editor. For a feature of size, when you select the **Nominals With Deviation** option, tolerances are entered as described in the "The Size Tolerance Editor" section.

When you select the **ISO Code** option, the size tolerance editor displays a default ISO H7 code. Type in the appropriate limit as defined with ISO 286-1. The ISO 286-1 standard defines hundreds of tolerance codes that look somewhat like "E9" and "H7". The ISO 286-1 standard is case-sensitive, for example, holes are uppercase and shafts are lowercase. You can type the standard in either uppercase or lowercase. PC-DMIS determines whether the considered feature is an internal or external feature type and then auto-corrects your entry to the appropriate case if necessary.



In the **Nominals** tab, PC-DMIS shows the appropriate tolerance based on the nominal size.



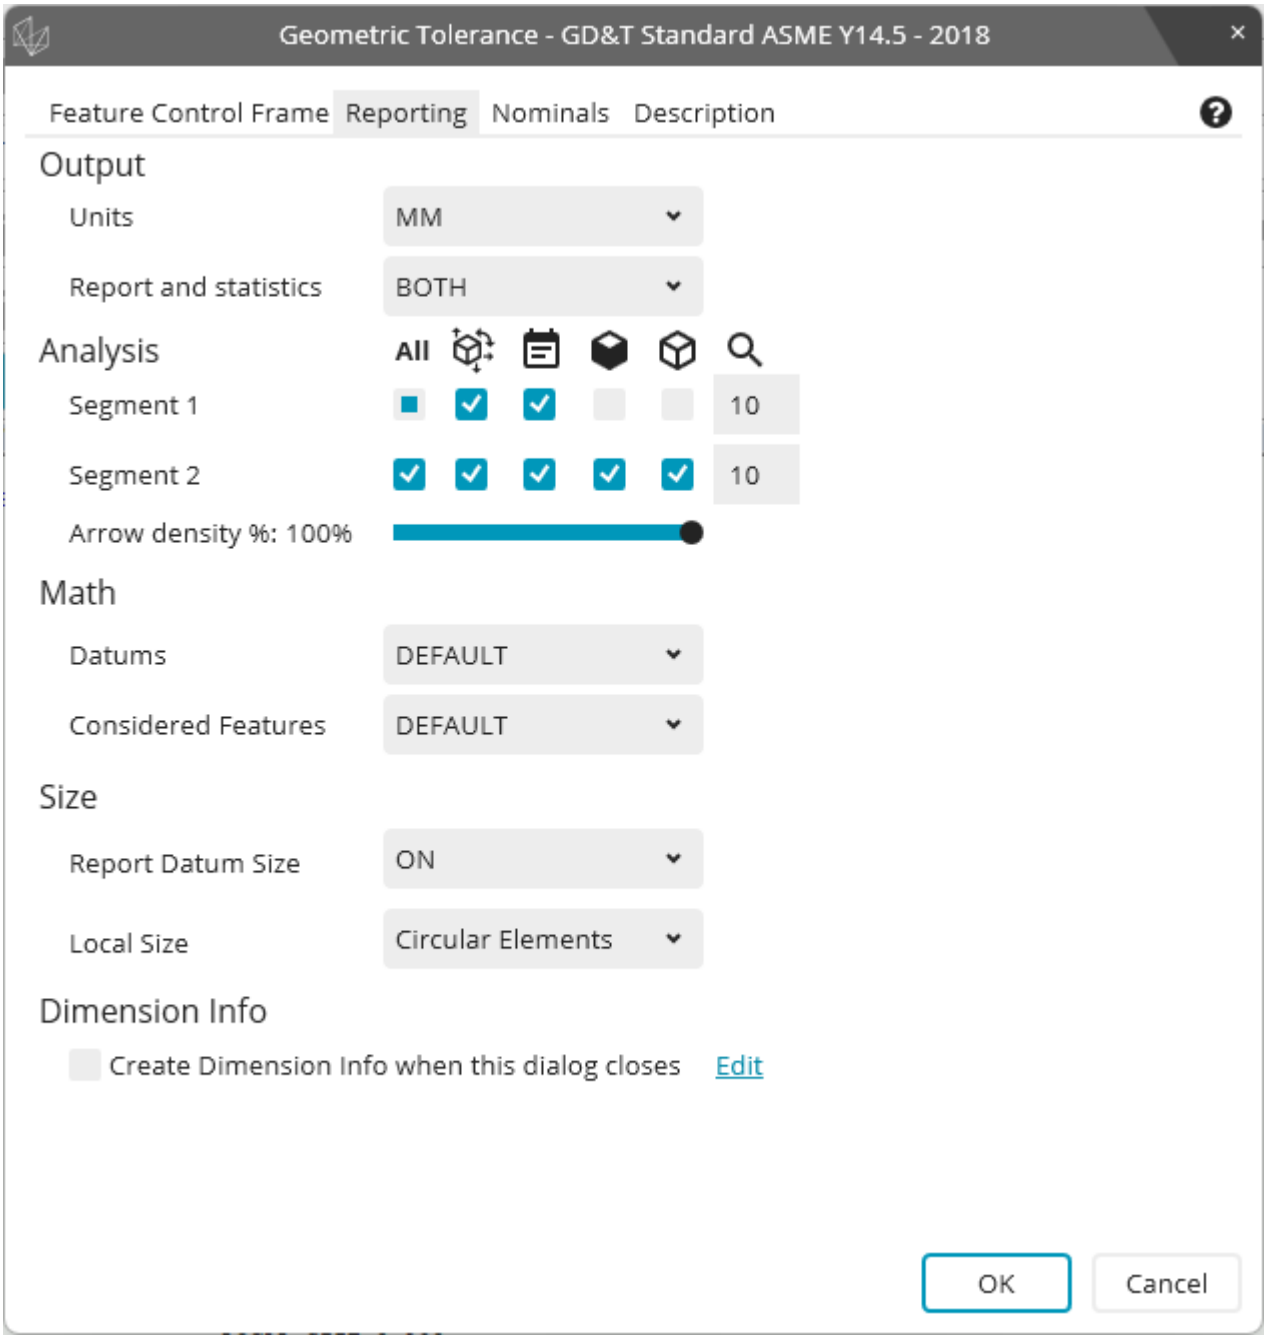
Reporting Tab

In this Topic

Reporting Tab
Introduction
Output
Analysis
Math
Size or Workplane areas
Dimension Info

Introduction

The **Reporting** tab of the **Geometric Tolerance** dialog box has several options to control how PC-DMIS evaluates and reports the calculations. The **Reporting** tab looks like this:



Output

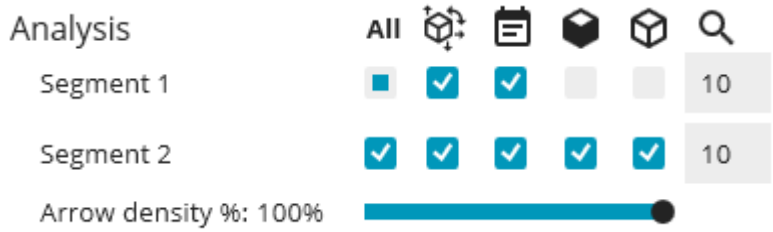
The **Output** area of the **Reporting** tab has these two drop-down lists:

Units - This allows you to report results in either inches or mm, regardless of the dimensions of your measurement routine.

Report and statistics - This allows you to send the results to the **REPORT**, to the **STATS**, to **BOTH**, or to **NONE**.

Analysis

The **Analysis** area of the **Reporting** tab allows you to control the textual and graphical analysis options. There is a row of check boxes for each segment of the geometric tolerance command. For example, with two segments the **Analysis** area looks like this:



The icon above each column of check boxes is a label for which kind of analysis that column of check boxes controls:

All - Selecting or clearing it selects or deselects the entire row of check boxes.

- This shows or hides optimized shift information in the report for position or profile tolerances. You can hover your pointer over the icon to see a tooltip that it is to show optimized shift. For more information, see the "Optimized Shift" section in the "How PC-DMIS Solves and Uses Datums" topic.

- This turns textual analysis on or off. You can hover your pointer over the icon to see a tooltip that it is for report textual analysis.

- This turns CAD graphical analysis on or off. You can hover your pointer over the icon to see a tooltip that it is for CAD graphical analysis.

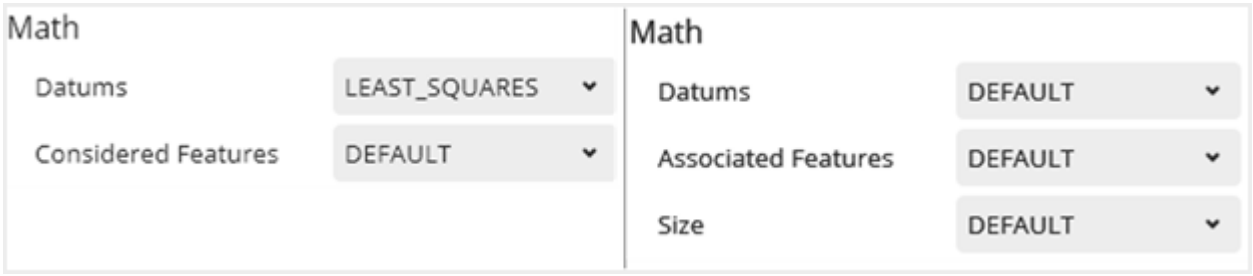
- This turns the report graphical analysis on and off. You can hover your pointer over the icon to see a tooltip that it is for report graphical analysis.

- These boxes show the numeric values of the arrow multipliers for each segment.

Arrow density % slider bar - You can use this slider bar to adjust the arrow density percentage value.

Math

The **Math** area of the **Reporting** tab allows you to control the math options for evaluating the geometric tolerance. The available math type options depend on if you select the ASME or ISO standard.



Math Area showing ASME (left) and ISO (right).

ASME Math Types

The **Considered Features** list controls the math to solve size tolerances and/or create the toleranced feature from the considered feature. It is available when the considered features have surface data and either (a) there is a size tolerance or (b) the toleranced feature is different than the considered feature. For details of what the options mean, see "Deriving the Toleranced Feature" and "Evaluating Size with the Geometric Tolerance Command".

The **Tolerance Zone** list (not pictured) controls the math for optimizing the toleranced feature into the tolerance zone. It appears for form tolerances and for profile tolerances without a datum. For details of the options' meaning, see these topics:

- Circularity
- Cylindricity
- Flatness
- Profile of a Line
- Profile of a Surface
- Straightness

ISO Math Types

The **Associated Features** list controls the math to create the toleranced feature from the considered feature. It is available when the considered features have surface data and either (a) there is a size tolerance or (b) the toleranced feature is different than the considered feature. For details of what the options mean, see the "Deriving the Toleranced Feature" and "Evaluating Size with the Geometric Tolerance Command" topics in the PC-DMIS Core documentation.

The **Size** list controls the math to solve size tolerances. It is available when the considered features have surface data and either (a) there is a size tolerance or (b) the toleranced feature is different than the considered feature. For details of what the options mean, see the "Deriving the Toleranced Feature" and "Evaluating Size with the Geometric Tolerance Command" topics in the PC-DMIS Core documentation.

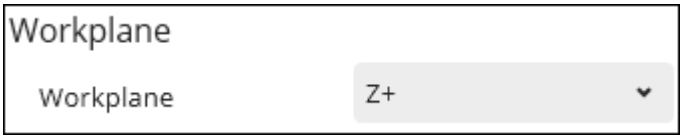
The **Tolerance Zone** list (not pictured) controls the math for optimizing the toleranced feature into the tolerance zone. It appears for all form tolerances and for profile tolerances without datum references.

Size or Workplane areas

The **Size** area of the **Reporting** tab is available for most features. It lets you control whether to report local sizes. It can look like this:

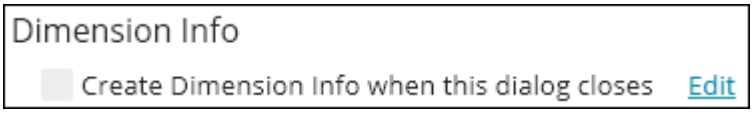
The **Local Size** option is either **ON** or **OFF**. It is available for considered features that have surface data, when there is a size tolerance. For more information, see "Evaluating Size with the Geometric Tolerance Command".

For other features, such as a Line Profile, the **Size** area changes to the **Workplane** area which allows you to select the workplane from the list. It can look like this:



Dimension Info

The **Dimension Info** area of the **Reporting** tab looks like this:



If you mark the check box, PC-DMIS inserts a dimension info command into your measurement routine after the geometric tolerance command. You can click **Edit** to the right of the check box to modify the dimension info command options.

Nominals Tab

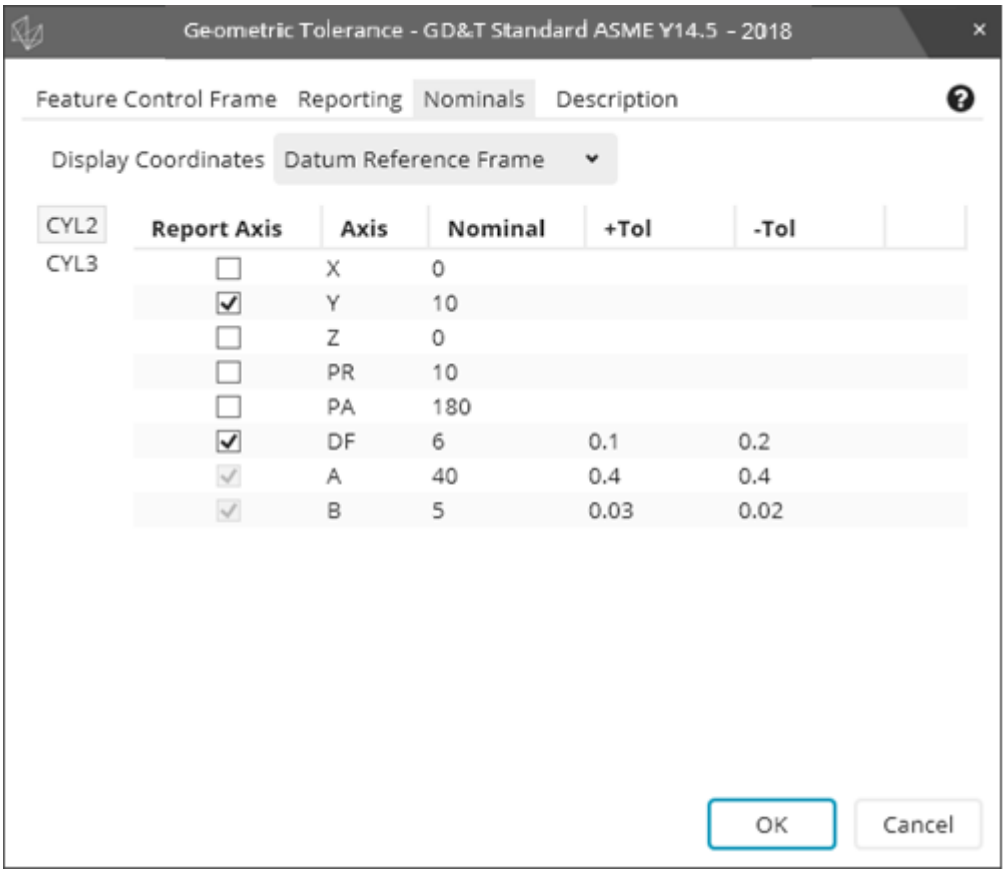
In this Topic

Nominals Tab
Introduction
Display Coordinates
Nominals Table
Select the Considered Feature
Report Axis Column
Axis Column
Nominal Column
+Tol Column
-Tol Column

Introduction

The **Nominals** tab of the **Geometric Tolerance** dialog box is available for position tolerances and for geometric tolerances that have a size tolerance.

It looks like this:

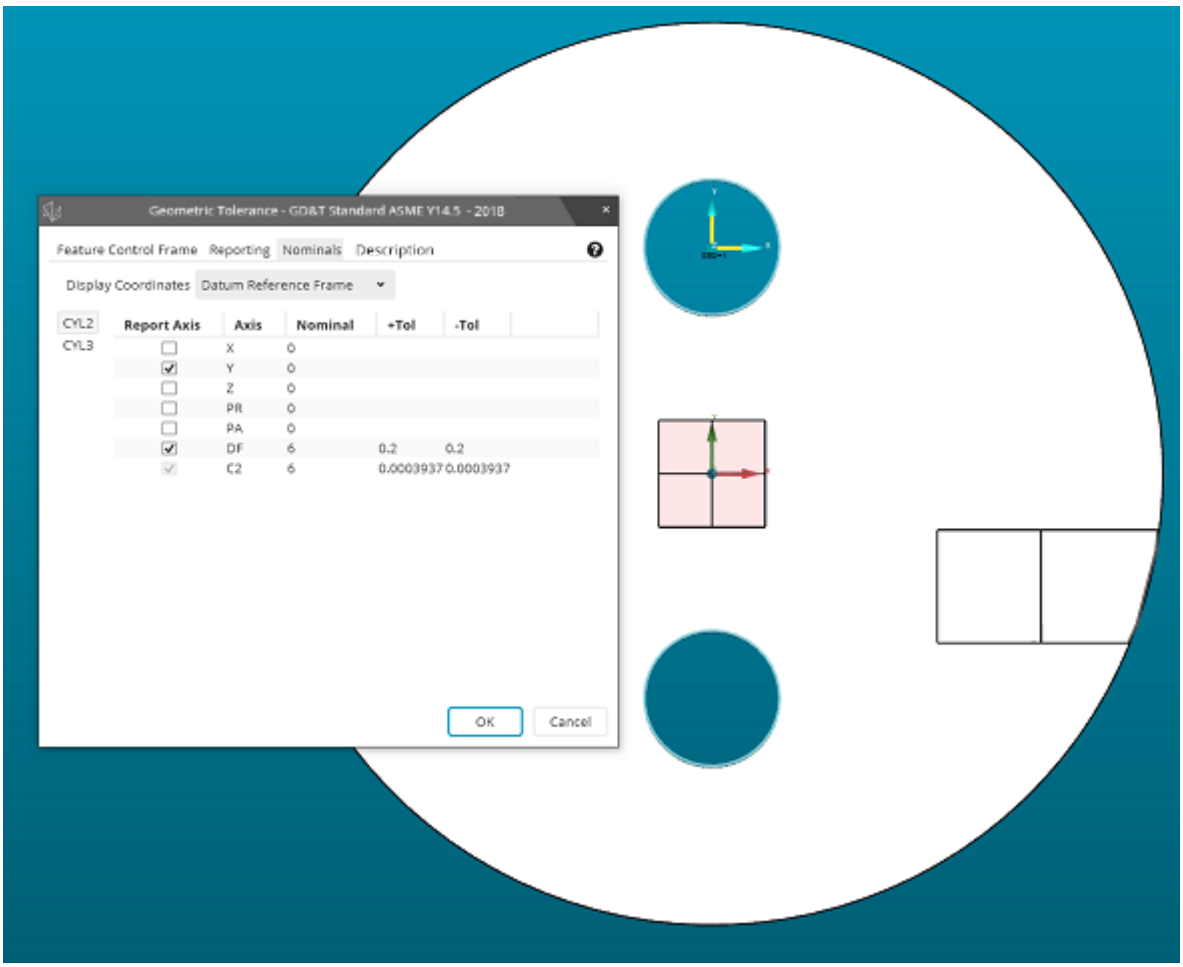


Display Coordinates

This list controls the coordinate system that the nominals are reported in. You can switch between **Datum Reference Frame** and **Current Alignment** to change the nominals that you see.

After you click **OK** or **Create**, PC-DMIS changes the coordinate system that the results are reported in.

You can visualize the two coordinate systems in the Graphic Display window, like this:



In the example picture above, the trihedron for the current alignment is at the center of the part. The trihedron for the datum reference frame coordinate system is shown in the upper bore.

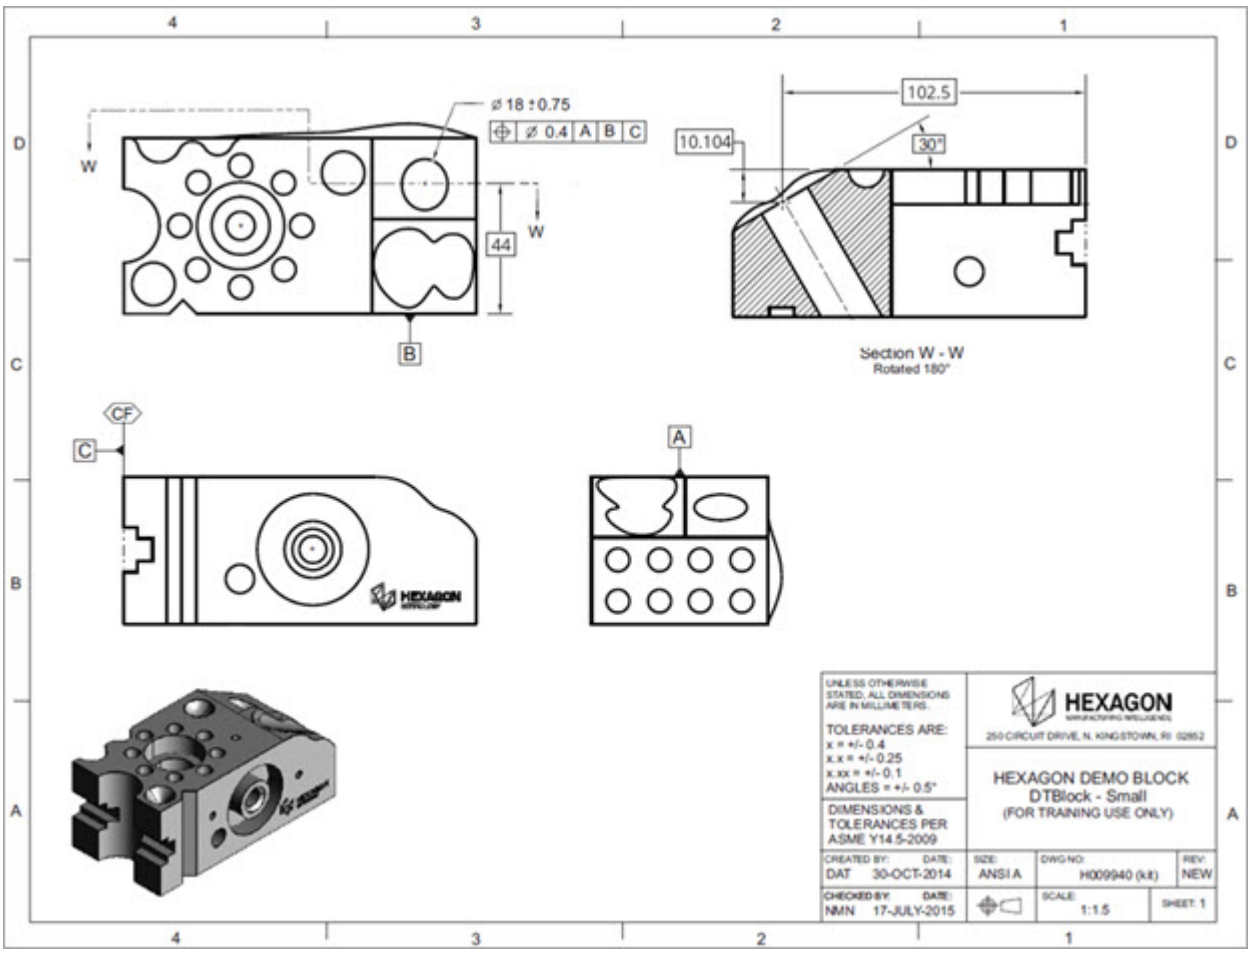
The **Current Alignment** option can be useful for cases where the location or orientation of the Datum Reference Frame trihedron does not match the axes depicted on the drawing. It can also serve to provide adjustment information to production. Note the location and orientation of the Datum Reference Frame trihedron for the following position tolerance.

	PART NAME : POSITION_EXAMPLE					April 16, 2024	12:50
	REV NUMBER :		SER NUMBER :			STATS COUNT : 1	
FCFLOC1 Size	MM	Ø 18 +0.75/-0.75			DEFAULT	ASME Y14.5 2018	

Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
CYL 10	18.000	0.750	0.750	18.000	0.000	0.000

FCFLOC1	MM	Ø0.4 A B C	DEFAULT	ASME Y14.5 2018

Feature	AX	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL	BONUS
	X	102.500			102.564	0.064		
	Y	44.000			43.980	-0.020		
CYL 10	Z	-10.104			-10.141	-0.037		
(START PT)	TP	0.000	0.400	0.000	0.154	0.154	0.000	0.000



Although the X, Y, and Z coordinates displayed in the summary table match the basic dimensions on the drawing, it is often more useful to create an alignment that is centered on and orientated to the hole. Once this is done, you should switch the display coordinates from **Datum Reference Frame** to **Current Alignment** as shown below.

```
A1          =ALIGNMENT/START,RECALL:STARTUP,LIST=YES
              ALIGNMENT/TRANS_OFFSET,XAXIS,102.5
              ALIGNMENT/TRANS_OFFSET,YAXIS,44
              ALIGNMENT/TRANS_OFFSET,ZAXIS,-10.104
              ALIGNMENT/ROTATE_OFFSET,30,ABOUT,YPLUS
            ALIGNMENT/END
FCFLOC1     =GEOMETRIC_TOLERANCE/STANDARD=ASME Y14.5-2018,SHOWEXPANDED=YES,
            DESCRIPTION=OFF,,
            FEATURE_MATH=DEFAULT,DATUM_MATH=DEFAULT,DISPLAY_COORDS=CURRENT_ALIGNMENT,
            UNITS=MM,OUTPUT=BOTH,ARROWDENSITY=100,
            SIZE/NOMINAL=18,UPPER TOLERANCE=0.75,LOWER TOLERANCE=0.75,
            REPORT_LOCAL_SIZE=OFF,
              CYL1:
                UAME SIZE:18.000,
            SEGMENT_1,POSITION,DIAMETER,0.4,__,__,<len>,__,A,B,__,C,__,
            TEXT=OFF,CADGRAPH=OFF,REPORTGRAPH=OFF,MULT=10,
              MEASURED:
                CYL1:0.154,
            ADD
            FEATURES/CYL1,,
```

	PART NAME : POSITION_EXAMPLE					April 16, 2024	11:38	
	REV NUMBER :		SER NUMBER :			STATS COUNT : 1		
FCFLOC1 Size	MM	Ø 18 +0.75/-0.75			DEFAULT	ASME Y14.5 2018		
Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL		
CYL 1	18.000	0.750	0.750	18.000	0.000	0.000		
FCFLOC1	MM	⌖ Ø0.4 A B C			DEFAULT	ASME Y14.5 2018		
Feature	AX	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL	BONUS
	X	-0.000			0.074	0.074		
	Y	0.000			-0.020	-0.020		
CYL 1	Z	0.000			0.000	0.000		
(END PT)	TP	0.000	0.400	0.000	0.154	0.154	0.000	0.000

The X, Y, and Z deviation values are now much more useful to a machinist who can now see how much adjustment is required in each direction to bring the hole position closer to nominal.

Note that in both examples, the MEAS TP value remains the same (0.154 mm). The display coordinates do not affect the datum fitting or geometric tolerance calculation, they only affect the way the data is presented in the report.

The trihedron does not update dynamically while you use the **Geometric Tolerance** dialog box. You need to click **Create** or **OK** to see the updated trihedron.

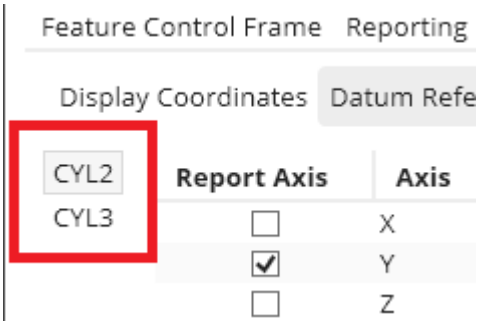
Nominals Table

The table of items allows you to do the following:

- View the nominal locations of the considered features in the chosen display coordinates.
- Control the size tolerances of the considered features and datum features.
- Control which axes to include in the report.

Select the Considered Feature

You can control which considered feature to view with the tabs on the left. Each feature has a small tab that you can click on, like this:



Each feature's tab lets you view the nominal location of that considered feature.

Report Axis Column

The **Report Axis** column of the nominals table determines whether to include that axis in the report. You can mark the check boxes to show the desired information.

Axis Column

The **Axis** column of the nominals table contains the names of the axes you may want to report. These names stand for the following items:

- **X** - This means the X coordinate.
- **Y** - This means the Y coordinate.
- **Z** - This means the Z coordinate.
- **PR** - This means the polar radius.

- **PA** - This means the polar angle.
- **DF** - This means diameter of the feature (or size).

As you can see in the image below, the datum names are also in the axis column:

Report Axis	Axis	Nominal	+Tol	-Tol	
☐	X	0			
☑	Y	10			
☐	Z	0			
☐	PR	10			
☐	PA	180			
☑	DF	6	0.1	0.2	
☑	A	40	0.4	0.4	
☑	B	5	0.03	0.02	

Only datum features of size appear. The **Report Axis** check box is not available for these rows.

Nominal Column

The **Nominal** column of the nominals table contains the nominal values of the reportable axes, and the nominal sizes of the datum features of size.

+Tol Column

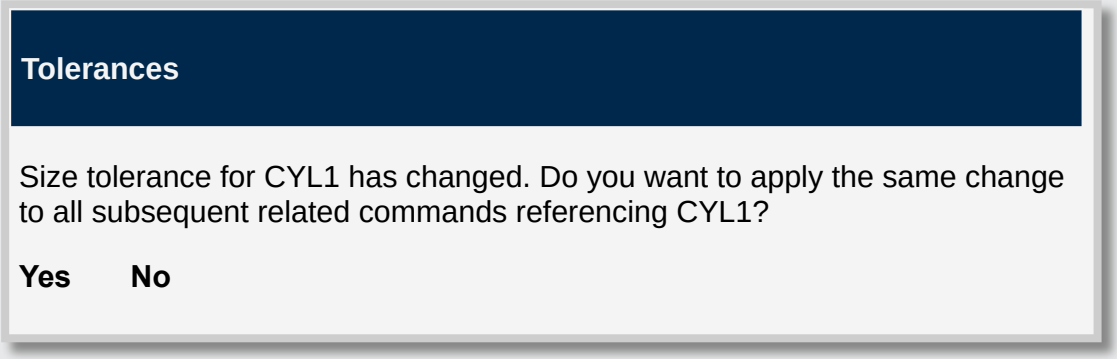
The **+Tol** column of the nominals table contains the plus size tolerances of the considered features and datum features of size. See note below if you make changes to this value.

-Tol Column

The **-Tol** column of the nominals table contains the minus size tolerances of the considered features and datum features of size. See note below if you make changes to this value.

If you edit a feature's upper or lower tolerances from the Edit window or from the **Geometric Tolerance** dialog box (**Feature Control Frame** or **Nominals** tab), and the same feature is used as a datum or as a considered feature, PC-DMIS displays a message asking if you want to apply the same changes to all subsequent commands referencing that feature.

For example:



If you click **Yes**, PC-DMIS updates the size tolerances for any Geometric Tolerance commands below the cursor position that references the same feature, either as a considered feature or datum.

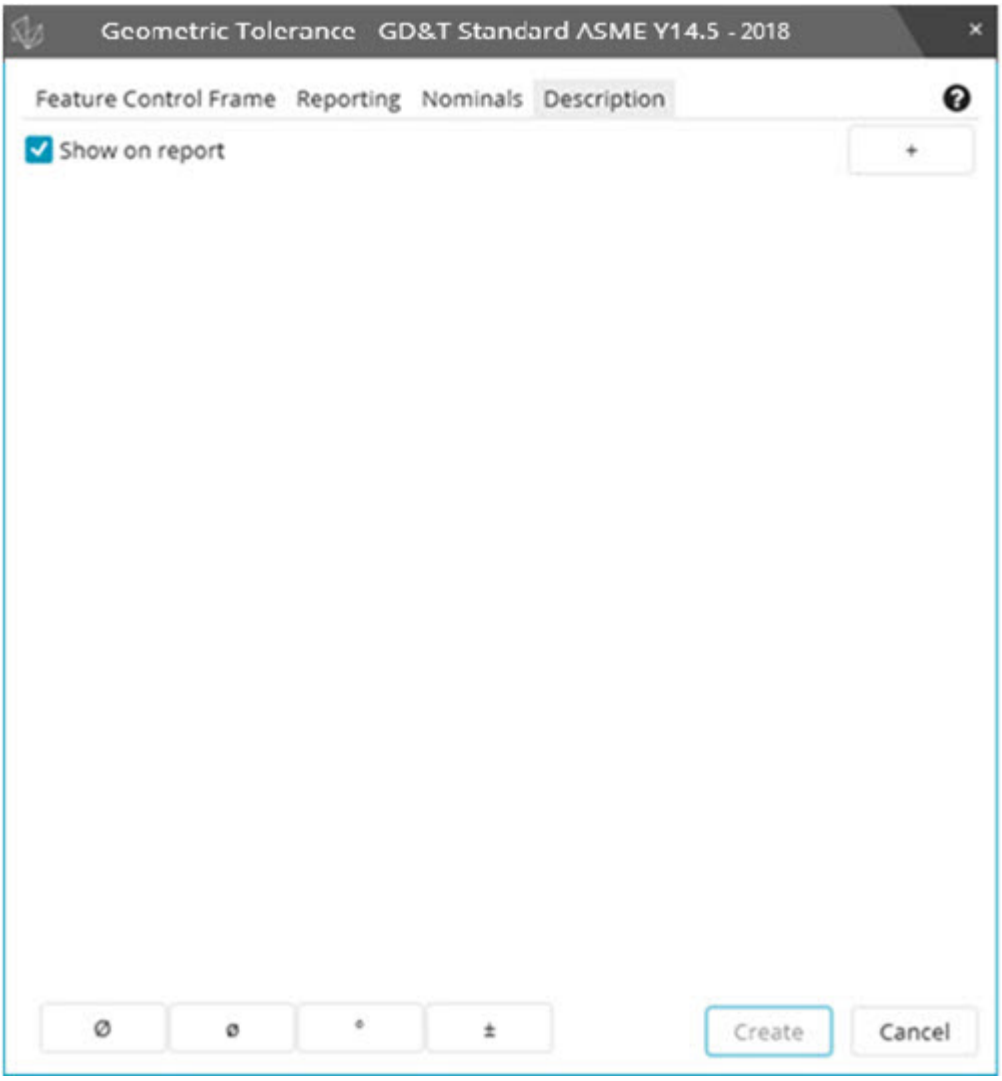
If you click **No**, PC-DMIS updates the edited size tolerance only. PC-DMIS does not update any of the respective size tolerances for any related Geometric Tolerance commands below the cursor position that uses the same edited feature either as a considered feature or datum.

The **Minus Tols Show Negative** check box on the **Dimension** tab of the **Setup Options** dialog box applies the same here as it does in the **Feature Control Frame** tab. For information, see the "Feature Control Frame Tab" topic.

- When it is cleared, the minus tolerances are typically positive.
- When it is selected, the minus tolerances are typically negative.

Description Tab

If you have experience creating comments in XactMeasure, the functionality of the **Description** tab on the **Geometric Tolerance** dialog box may look familiar, but it is more useful than its predecessor. You no longer need to describe features or dimensions in their ID names. This can make them extremely long and cumbersome. The **Description** tab provides a way for you to link dimensions to callouts on prints without the need for lengthy, descriptive features or dimension names.



This tab enables you to create pure text fields that you can use to link dimensions with prints. You can use any symbol or characters since these fields are strictly for text. The symbol buttons at the bottom of the dialog box allow you to insert commonly used symbols.

You must resolve any errors on the **Feature Control Frame** tab before PC-DMIS enables the **Create** button on this dialog box.

To create a **Description** text:

1. Click the Add (**+**) button in the upper-right corner of the dialog box to create and open a new description text field.
2. Enter your text into the field. Use the symbol buttons as needed to insert specific symbols.
3. Press Enter or click the Add (**+**) button again to create another description text field. To delete a field, select it and click the Remove (**-**) button.

4. Select the **Show in report** check box to include the description text in the report.
5. Click the **Create** button to create the description field.

Geometric Tolerance Types

There are fourteen types of geometric tolerances, often grouped into these five categories: Form, Orientation, Location, Profile, and Runout.

The tolerance topics below go through each tolerance type. Those topics provide details about what each type means, its allowed modifiers, and allowed command options.

Form

Form tolerances are the simplest because they do not reference datums:

- Circularity
- Cylindricity
- Flatness
- Straightness

Orientation

- Angularity
- Parallelism
- Perpendicularity

Location

- Concentricity
- Position
- Symmetry

Profile

- Profile of a Line
- Profile of a Surface

Runout

- Circular Runout
- Total Runout

You can find further details in these topics:

- Feature Types With and Without Surface Data

- How PC-DMIS Solves and Uses Datums
- Deriving the Toleranced Feature

Actual and Measured Values

For each geometric tolerance type, we distinguish between “actual values” and “measured values.”

> An *actual value* deals with the specification, and it is defined by a specification standard like ASME Y14.5.1 or ISO 1101. An actual value uses all the points of the surface, with no measurement uncertainty. This value tells us whether the surface conforms to its specification or not. It gives us some idea how close a conforming surface is to non-conformance.
>
> A *measured value* is a measured approximation to an actual value. The measured value uses some subset of the points of the surface. Each measured point of the surface includes measurement uncertainty. The algorithms we use to derive a measured value may or may not be similar to the mathematical definition of the actual value. This is because sometimes the best measured approximation to the actual value uses very different mathematics than the actual value uses.

For more information, refer to "Specification Versus Verification".

Circularity

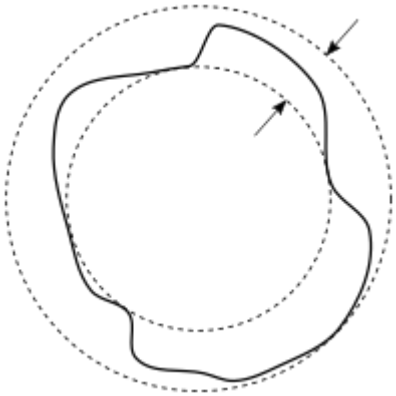
In this Topic

Circularity
- Introduction
- Allowed Feature Types
- Circular Features
- Cylindrical Features
- Conical Features
- Spherical Features
- Allowed Modifiers
- Exposed Options
- Report

Introduction

A circularity specification controls how much the feature's cross sections can deviate from a perfect circle. In other words, circularity evaluates how circular the feature is. Circularity is defined from a feature's cross sections.

> Actual Value:
> This is the minimum distance between two concentric circles that contain the entire cross section between them:



The actual value for circularity of a whole feature is the worst actual value of all possible cross sections.

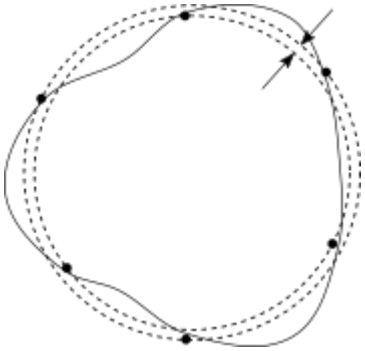
Allowed Feature Types

You can use circular, cylindrical, conical, or spherical features that have surface data. For details on the circles, cylinders, cones, and spheres that have surface data, refer to "Feature Types With and Without Surface Data".

Circular Features

Circular features are interpreted as a single cross section.

Measured Value:
This is the distance between two concentric circles that contain all the measured points between them. A best-fitting routine defines the center-point of the circles. Depending on the measurement uncertainty, how many points you measured, and where you took the points, this can be larger or smaller than the actual value. Here's an illustrated case where too few points were measured, so the measured value is smaller than the actual value:



Cylindrical Features

Circularity tolerances on cylindrical features divide up the data into cross sections. The tolerances evaluate circularity on each cross section. The measured value of the entire feature is the measured value of the worst cross section. To maximize your chances of finding the worst actual cross section, we recommend that you measure

the cylinder with many cross sections. If PC-DMIS is unable to extract cross sections from the measured data, PC-DMIS gives you an error.

Conical Features

Circularity tolerances on conical features divide up the data into cross sections. The tolerances evaluate circularity on each cross section. The measured value of the entire feature is the measured value of the worst cross section. To maximize your chances of finding the worst actual cross section, we recommend that you measure the cone with many cross sections. If PC-DMIS is unable to extract cross sections from the measured data, PC-DMIS gives you an error.

An alternate way to evaluate the form of a conical feature is using conicity. Conicity does not divide the data into cross sections. Instead, the measured value is the distance between two coaxial same-angle cones. These cones contain the measured points between them. A best-fitting routine defines the axis and the cone angle. Conicity includes both circularity and straightness errors. It does not require the measured data to be measured in cross sections.

Spherical Features

Circularity of a sphere is equivalent to sphericity (see ASME Y14.5.1 and ISO 1101). This sphericity tolerance operates on all the data at once. The measured value is the distance between two concentric spheres that contain the measured points between them. A best-fitting routine defines the center-point of the spheres. It does not require the measured data to be measured in cross sections.

Allowed Modifiers

For the ASME standard, this geometric tolerance does not allow modifiers.

For the ISO standard, C or G modifiers are allowed. For details, see the "ISO Reference Feature Association Modifiers (RFAM)" section in the "Deriving the Toleranced Feature" topic in the PC-DMIS Core documentation.

Exposed Options

For the ASME standard, the tolerance zone math type controls the best fitting routine.

For the ISO standard, the selected reference feature association modifier or tolerance zone math type controls the best fitting.

DEFAULT - This does a minimum-zone best fit (also called min-max). This best fit finds the smallest measured value given the data and the measured-value definition. It is mathematically very similar to the specification, because if you measure the points and cross sections densely and with high accuracy, the measured value closely approximates the actual value. For the ISO standard, if you select the C modifier, it is equivalent to the **DEFAULT** math type.

LSQ - This does a least-squares best fit. It minimizes the sum of the squares of the deviations to a least-squares shape. This option produces a larger measured value (it is more conservative than the **DEFAULT** option). But in general, this option computes more quickly. For the ISO standard, if you select the G modifier, it is equivalent to the **LSQ** math type.

The **CIRCULARITY** and **CONICITY** toggle controls the behavior of circularity of a cone.

CIRCULARITY - Evaluates the circularity of each cross section. In the dialog box, you can clear the **Conicity** check box to use this.

CONICITY - Evaluates the conicity of the entire feature. The conicity interpretation is more conservative than the **CIRCULARITY** option. In the dialog box, you can mark the **Conicity** check box to use this.

Report

Here is an example report for a circularity tolerance:

FCFCIRTY1	MM	○ 0.01	DEFAULT	ASME Y14.5 2018

Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL

Cylindricity

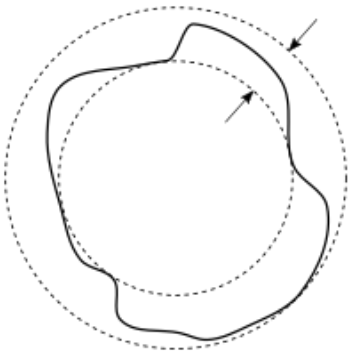
In this Topic

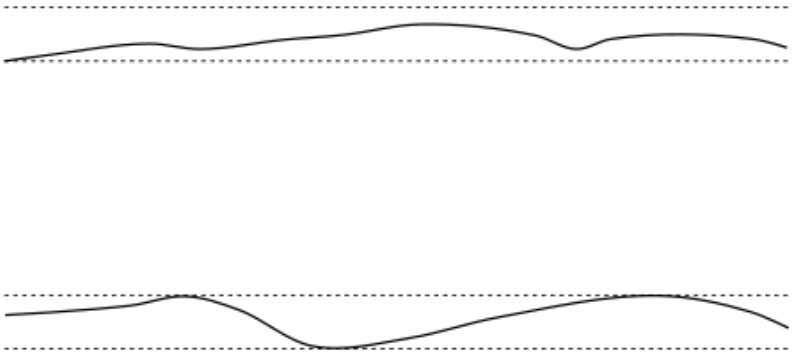
- Cylindricity
  - Introduction
  - Allowed Feature Types
  - Allowed Modifiers
  - Exposed Options
  - Report

Introduction

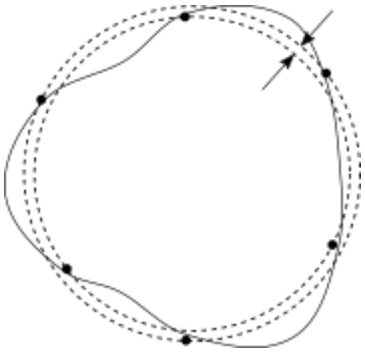
A cylindricity specification controls how much a feature can deviate from a perfect cylinder. In other words, cylindricity evaluates how cylindrical the feature is.

Actual Value:
This is the minimum distance between two concentric cylinders that contain the entire surface between them:





Measured Value:
This is the distance between two concentric cylinders that contain all the measured points between them. A best-fitting routine defines the axis of the two cylinders. Depending on the measurement uncertainty, how many points you measured, and where you took the points, this can be larger or smaller than the actual value. Here's an illustrated case where too few points were measured, so the measured value is smaller than the actual value:



Allowed Feature Types

You can use cylindrical features with surface data. For details on cylinders that have surface data, refer to "Feature Types With and Without Surface Data".

Allowed Modifiers

For the ASME standard, this geometric tolerance does not allow modifiers.

For the ISO standard, C or G modifiers are allowed. For details, see the "ISO Reference Feature Association Modifiers (RFAM)" section in the "Deriving the Toleranced Feature" topic in the PC-DMIS Core documentation.

Exposed Options

The tolerance zone math type controls how to compute the axis of the two concentric cylinders:

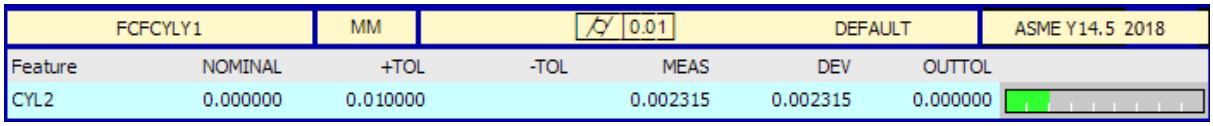
DEFAULT - This does a minimum-zone best fit (also called min-max). This best-fit finds the axis of the two concentric cylinders that contain the points between them that has minimum distance between them. Thus, this option produces the smallest measured value to evaluate cylindricity. It is also mathematically very similar to the

specification, because if you measure points densely and with high accuracy, the measured value closely approximates the actual value. For the ISO standard, if you select the C modifier, it is equivalent to the **DEFAULT** math option.

LSQ - This does a least-squares best fit. It minimizes the sum of the squares of the deviations to a least-squares cylinder. This option produces a larger measured value (it is more conservative than the **DEFAULT** option). But in general, this option computes more quickly. For the ISO standard, if you select the G modifier, it is equivalent to the **LSQ** math option.

Report

Here is an example report for a cylindricity tolerance:



FCFCYLY1	MM	⌭ 0.01		DEFAULT		ASME Y14.5 2018
Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL

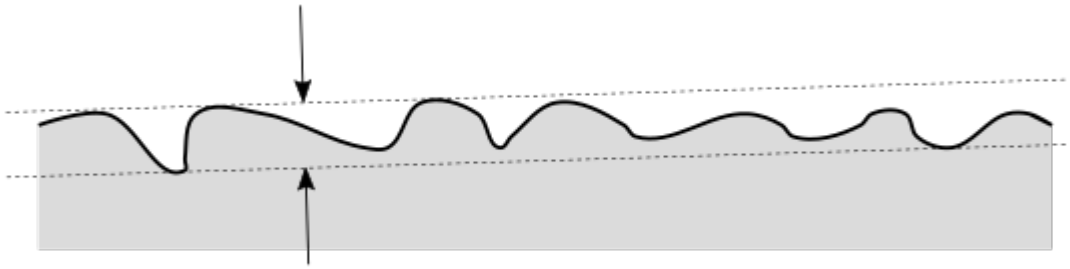
Introduction

A flatness specification controls how much the feature can deviate from being perfectly flat. In other words, flatness evaluates how flat the feature is. PC-DMIS only supports flatness specifications on planes.

Actual Value:
This is the minimum distance between two parallel planes that contain the entire surface between them.



Measured Value:
This is the distance between two parallel planes that contain all the measured points between them. A best-fitting routine determines the surface normal of the two planes. Depending on the measurement uncertainty, how many points you measured, and where you took the points, this can be larger or smaller than the actual value. Here's an illustrated case where too few points were measured, so the measured value is smaller than the actual value:

Allowed Feature Types

You can use planar features that have surface data. For details on planes that have surface data, refer to "Feature Types With and Without Surface Data".

Allowed Modifiers

For the ASME standard, this geometric tolerance does not allow modifiers.

For the ISO standard, C or G modifiers are allowed. For details, see the "ISO Reference Feature Association Modifiers (RFAM)" section in the "Deriving the Toleranced Feature" topic in the PC-DMIS Core documentation.

Exposed Options

For the ASME standard, the tolerance zone math type controls the best fitting routine.

For the ISO standard, the selected reference feature association modifier or tolerance zone math type controls the best fitting.

DEFAULT - This computes a minimum-zone best fit plane (also called min-max). It finds the smallest measured value given the surface data. It is mathematically very similar to the specification, because if the points were measured densely and with high accuracy, the measured value will closely approximate the actual value. For the ISO standard, if you select the C modifier, it is equivalent to the **DEFAULT** math type.

LSQ - This computes a least-squares best fit plane, minimizing the sum of the squares of the deviations to the best fit plane. This option produces a larger measured value (it is more conservative than the **DEFAULT** option). But in general,

this option computes more quickly. For the ISO standard, if you select the G modifier, it is equivalent to the **LSQ** math type.

Report

Here is an example report for a flatness tolerance:

FCFFLAT1	MM	⏥ 0.01		DEFAULT		ASME Y14.5 2018
Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
PLN1	0.000000	0.010000		0.000221	0.000221	0.000000

Flatness Per Unit-Tolerances

If you select the **per unit** check box, flatness has two segments. The first (upper) segment is the overall flatness as described above. The lower segment is the per-unit flatness, which defines a unit's size, shape, and orientation. The per-unit tolerances control how flat every possible unit of the toleranced feature is.

You are responsible to do the following:

- Select a square or rectangular unit.
- Choose the size or sizes of each unit.
- Control the orientation of the unit.

Controlling the Unit Orientation

The unit orientation vector controls how the unit is oriented within the planar surface. It is always normalized and always perpendicular to the nominal surface normal of the plane. You can edit the vector with the **Unit Orientation** button in the **Feature Control Frame** tab of the **Geometric Tolerance** dialog box. For more information, see "Unit Orientation" under "Feature Control Frame Tab". With a rectangular unit, the orientation vector represents the direction of the first dimension of the unit area. For example, if the unit area is 5x3, then the unit orientation vector corresponds to the 5. With a square unit, the vector represents the direction of one of the sides of the square.

Actual Value:
Conceptually, the entire toleranced feature is divided into an infinite number of overlapping units. Each unit has the defined unit size, shape, and orientation. Each unit has its own flatness actual value. The flatness actual value for the entire feature is the actual value of the worst unit.

Measured Value:
There are a very large number of overlapping units containing subsets of the measured points. For any given unit, the measured value is the minimum distance between two parallel planes. These planes contain the unit's subset of measured

points between them. This the same as the **DEFAULT** tolerance zone math type. The least squares tolerance zone math type is not available for per-unit tolerances.

The measured value for the entire feature is the measured value of the worst unit.

The algorithm that the geometric tolerance command uses does not check every possible unit. Instead, it does an intelligent search for the worst unit. It always finds the worst unit. It can do this with much less computation time than if it checked every possible unit.

Comparison to Past Practice 1

In PC-DMIS 2020 R2 and later, you can control the unit orientation. The unit orientation vectors are in part coordinates. In earlier versions, with XactMeasure per-unit flatness, you could not control the unit orientation. Also, the units were aligned with the machine coordinate system rather than the part coordinate system.

Comparison to Past Practice 2

In PC-DMIS 2020 R2 and later, the per-unit flatness algorithm is conservative. This means the algorithm always finds the worst unit. In earlier versions, XactMeasure per-unit flatness evaluated a large number of units, but it did not always find the worst unit.

Report

Here is an example report for a flatness per-unit tolerance. The upper label is for the overall flatness, and the lower label is for the per-unit flatness.

Report

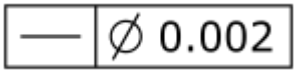
Introduction

A straightness specification controls how much the feature can deviate from being perfectly straight. In other words, straightness evaluates how straight the feature is.

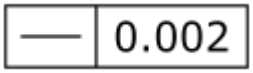
Straightness falls into two broad types:

- Straightness of an axis
- Straightness of a surface

An axis tolerance has a diametric zone symbol before the tolerance value:



A surface tolerance does not have the diametric zone symbol:



Straightness of an Axis

Straightness of an axis operates on a derived median line (or extracted median line in ISO 1101 language). This line represents the straightness form error of a cylinder's or cone's axis.

Actual Value:
This is the diameter of the smallest cylinder that contains the derived median line.

Allowed Feature Types

You can use these features:

- Cylindrical or conical features that have surface data. For details on the cylinders and cones that have surface data, refer to "Feature Types With and Without Surface Data".
- 3D constructed BF lines where the input points are the centers of circles

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

Cylindrical Features

On cylindrical features, straightness tolerances of an axis divide up the surface data into cross sections. It then computes the center of each cross section. To maximize your chances of finding the worst cross section, we recommend that you measure the cylinder with many cross sections.

Measured Value:
This is the diameter of a cylinder that contains all the cross-sectional centers. A best-fitting routine determines the axis of the cylinder. If PC-DMIS is unable to extract cross sections from the measured data, PC-DMIS gives you an error.

Conical Features

On conical features, straightness tolerances of an axis divide up the surface data into cross sections. It then computes the center of each cross section. To maximize your chances of finding the worst cross section, we recommend that you measure the cone with many cross sections.

Measured Value:
This is the diameter of a cylinder that contains all the cross-sectional centers. A best-fitting routine determines the axis of the cylinder. If PC-DMIS is unable to extract cross sections from the measured data, PC-DMIS gives you an error.

Line Features

You can use only 3D constructed Best Fit (BF) lines. You cannot use Best Fit Recompensate (BFRE) lines.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

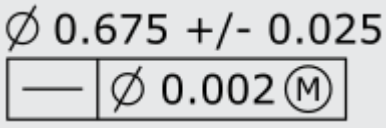
On 3D BF line features, straightness tolerances of an axis assume that the input points represent the centers of circular cross sections. To maximize your chances of finding the worst cross section, we recommend that you measure many cross sections.

Measured Value:
This is the diameter of a cylinder that contains all the input points. A best-fitting routine determines the axis of the cylinder.

Allowed Modifiers

When the feature is a cylinder, straightness tolerances of an axis allow a maximum material modifier Ⓜ to indicate the specification is at the maximum material condition (MMC). Alternatively, they allow a least material modifier Ⓛ to indicate that the specification is at the least material condition (LMC). This means that as the unrelated mating envelope size (or unrelated minimum material envelope size for LMC) deviates from the MMC (or LMC), additional tolerance or "bonus" tolerance is added to the tolerance in the feature control frame, yielding a total tolerance. For more information on this bonus tolerance, see "Evaluating Size with the Geometric Tolerance Command".

This example uses inches. Suppose a cylindrical hole has an axis straightness tolerance 0.002 at MMC:



The size tolerance is 0.675 plus or minus 0.025. This means the range of acceptable sizes is 0.650 to 0.700. The maximum material condition is then 0.650. If the unrelated measured mating envelope size is 0.661, then the bonus tolerance is 0.011, and the total tolerance is 0.013.

Exposed Options

The tolerance zone math type controls the best fitting routine:

DEFAULT - This computes a minimum-zone best fit axis (also called min-max) which finds the smallest measured value given the cross-sectional centers. It is mathematically very similar to the specification, because if the points were measured densely and with high accuracy, the measured value will closely approximate the actual value.

LSQ - This does a least-squares best fit axis. It minimizes the sum of the squares of the deviations to the best fit axis. This option produces a larger measured value (it is more conservative than the **DEFAULT** option). But in general, this option computes more quickly.

Report

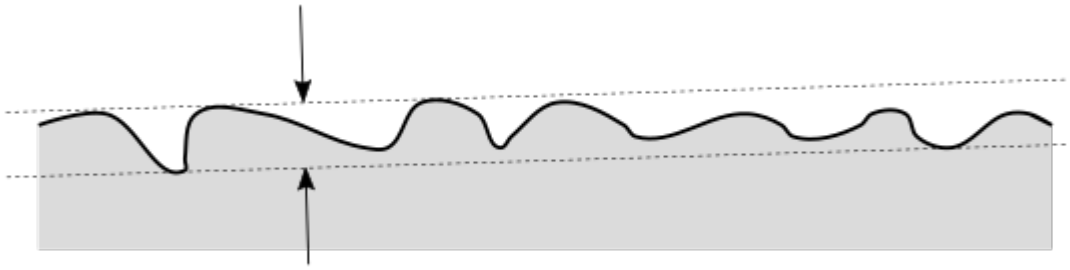
Here is an example report for a straightness of an axis tolerance:

FCFSTRA2	MM	⏤ Ø0.01		DEFAULT		ASME Y14.5
Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
CON1	0.000000	0.010000		0.000585	0.000585	0.000000

Straightness of a Surface

Straightness of a surface operates on line elements on a surface.

Actual Value:
This is the minimum distance between two parallel lines, containing the entire actual line element between them. The two parallel lines lie in an implicit workplane defined by the view of the drawing. The actual value for an entire surface is the worst actual value of all possible line elements on the surface.



Allowed Feature Types

You must use cone, cylinder, or line features that have surface data. For details on features that have surface data, refer to "Feature Types With and Without Surface Data". To maximize your chances of finding the worst actual cross-section, we recommend that you measure the surface with many lines.

Measured Value:
This is the minimum distance between two parallel lines. The lines contain the surface data between them. A best-fitting routine finds the orientation of the lines. The two parallel lines lie in a temporary (internal) workplane. The temporary workplane's surface normal is perpendicular to the line feature's line vector and to the line feature's surface normal.

Depending on the measurement uncertainty, how many points you measured, how many cross sections you measured, and where you took the points, the measured value can be larger or smaller than the actual value. Here's an illustrated case where too few points were measured, so the measured value is smaller than the actual value:

Allowed Modifiers

For the ASME standard, this geometric tolerance does not allow modifiers.

For the ISO standard, C or G modifiers are allowed. For details, see the "ISO Reference Feature Association Modifiers (RFAM)" section in the "Deriving the Toleranced Feature" topic in the PC-DMIS Core documentation.

Exposed Options

For the ASME standard, the tolerance zone math type controls the best fitting routine.

For the ISO standard, the selected reference feature association modifier or tolerance zone math type controls the best fitting.

DEFAULT - This computes a minimum-zone best fit line (also called min-max). It finds the smallest measured value given the surface data. It is mathematically very similar to the specification, because if the points and cross sections were measured densely and with high accuracy, the measured value will closely approximate the actual value.

LSQ - This computes a least-squares best fit line. It minimizes the sum of the squares of the deviations to the best fit line. This option produces a larger measured value (it is more conservative than the **DEFAULT** option). But in general, this option computes more quickly.

Report

Here is an example report for a straightness of a surface tolerance:

FCFSTRA6	MM	— 0.01		DEFAULT		ASME Y14.5 2018
Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
LIN4	0.000000	0.010000		0.006471	0.006471	0.000000

Straightness Per-Unit Tolerances

If you select the **per unit** check box, straightness has two segments: The first (upper) segment is the overall straightness as described above. The lower segment is the per-unit straightness, which defines a unit length. The per-unit tolerances control how straight every possible unit of the toleranced feature is.

Conceptually, the entire toleranced feature is divided into an infinite number of overlapping unit lengths:

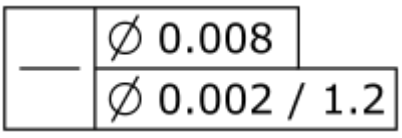
For an axis, the cylinder cross-sectional centers are divided into overlapping unit lengths.

For a surface, the surface cross section is divided up into overlapping unit lengths.

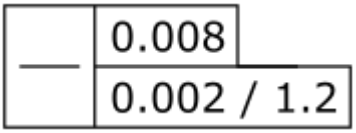
Actual Value:
Each of the infinite units has its own actual value, as defined above. The entire feature's actual value is the actual value of the worst unit.

Measured Value:
There are many overlapping units that contain subsets of the measured points. For any given unit, the measured value is defined the same way as overall straightness, except limited to the subset of the measured points. The measured value for the entire feature is the measured value of the worst unit.

Here is an example of an axis straightness per-unit tolerance. The upper segment is the overall straightness, and the lower segment is the per-unit straightness.



Here is an example of a surface straightness per-unit tolerance. The upper segment is the overall straightness, and the lower segment is the per-unit straightness.



Exposed Options

There are no exposed tolerance zone math options for the **per-unit** segment, it always uses the **DEFAULT** calculations.

Report

Here is an example report for a straightness per-unit tolerance. The upper label is for the overall straightness, and the lower label is for the per-unit straightness.

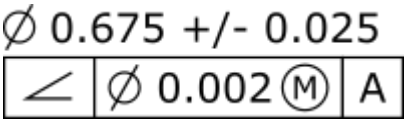
Angularity

In this Topic

- Angularity
  - Introduction
  - Allowed Feature Types
  - Allowed Modifiers
  - Tolerance Zone Shapes
  - Actual Value and Measured Value
  - Validity Rules
  - Comparison to Past Practice 1
  - Comparison to Past Practice 2
  - Exposed Options
  - Report

Introduction

An angularity specification controls how much the feature can deviate from a specified angle to a datum. Sometimes you can use a secondary datum to control the tolerance zone's orientation.



For this geometric tolerance, these three aspects work together:

- Each considered feature and each resulting toleranced feature
- Each tolerance zone
- The datum features

To evaluate this tolerance, PC-DMIS converts each considered feature to a toleranced feature. You can find this described in "Deriving the Toleranced Feature".

PC-DMIS then optimizes each toleranced feature into its respective tolerance zone. The optimization process respects whatever constraints each datum imposes.

Each toleranced feature is optimized independently.

Allowed Feature Types

You can use these feature types:

Cylinders, cones, planes, lines, 3D widths, and 2D widths

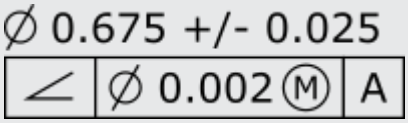
Some feature types have a different toleranced feature than the considered feature's surface data. These include 3D constructed BF lines, cylinders, cones, 3D widths, 2D widths, and planes with a tangent plane modifier. For more information, see "Deriving the Toleranced Feature".

Allowed Modifiers

When the considered feature is a cylinder or a width, this geometric tolerance type allows a maximum material modifier Ⓜ to indicate the specification is at the maximum material condition (MMC). Alternatively, it allows a least material modifier Ⓛ to indicate the specification is at the least material condition (LMC). This means that as the unrelated mating envelope size (or the unrelated minimum material envelope size for LMC) deviates from the MMC (or LMC), additional tolerance or "bonus" tolerance is added to the tolerance in the feature control frame, yielding a total tolerance. For more information on this bonus tolerance, see "Evaluating Size with the Geometric Tolerance Command".

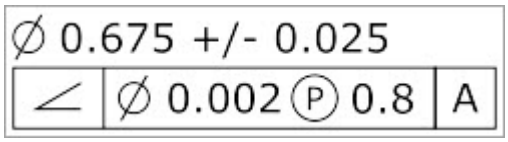
Tolerances referencing ISO 1101 allow additional Associated toleranced feature specification modifiers Ⓒ and Ⓖ for non-features of size. For features of size, Ⓒ, Ⓖ, Ⓝ, and Ⓧ are available. For details, see the "Deriving the Toleranced Feature" topic in the PC-DMIS Core documentation.

Suppose a cylindrical hole has an angularity tolerance 0.002 at MMC, as shown here:



The size tolerance is 0.675 plus or minus 0.025, meaning the range of acceptable sizes is 0.650 to 0.700. The maximum material condition is then 0.650. If the unrelated measured mating envelope size is 0.661, then the bonus tolerance is 0.011, and the total tolerance is 0.013.

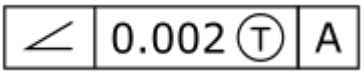
You can use a projected-zone modifier Ⓟ as shown here:



This projects (extrapolates) the measured feature axis as described in "Deriving the Toleranced Feature".

> **!** PC-DMIS only allows you to use projected tolerance zones on Auto Cylinder features. If you try to add a projected-zone modifier for any other feature type, the geometric tolerance command gives an error message stating that the feature type is invalid. This is because the projected tolerance zone needs to start at the nominal end-face of the cylinder. Measured cylinders and constructed cylinders typically do not place the nominal start point at the nominal end-face.

When the considered feature is a plane with surface data, you can use a tangent-plane modifier Ⓣ, as shown here:



This makes the toleranced feature be a perfect-form plane tangent to the actual surface, as described in "Deriving the Toleranced Feature".

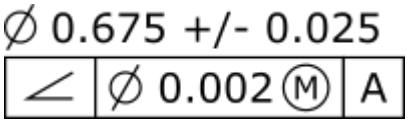
Tolerance Zone Shapes

When the considered feature has an axis, the tolerance zone shape can be diametric (with the tolerance zone shape symbol ∅) or planar (no tolerance zone shape symbol). These are the axial considered features:

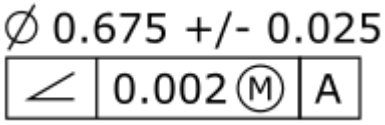
- Cylinder
- Cone
- Surfaceless axis

For information on the feature command types that correspond to these feature types, see "Feature Types With and Without Surface Data".

Here is an example of an angularity on a cylinder with a diametric tolerance zone:



Here is an example of an angularity on a cylinder with a planar tolerance zone:



Planar tolerance zones on axial considered features need a specified tolerance zone orientation. This is because the feature does not have enough information to orient the zone correctly. In these cases, the **Zone Orientation** button in the **Geometric Tolerance** dialog box becomes visible. For information on how to use this button to change the zone orientation, see "Zone Orientation" in the "Feature Control Frame Tab" topic.

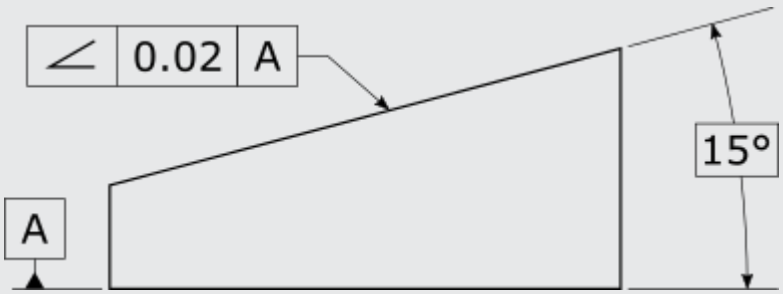
If a tolerance controls the X component of the orientation, the tolerance zone surface normal vector should be X.

Actual Value and Measured Value

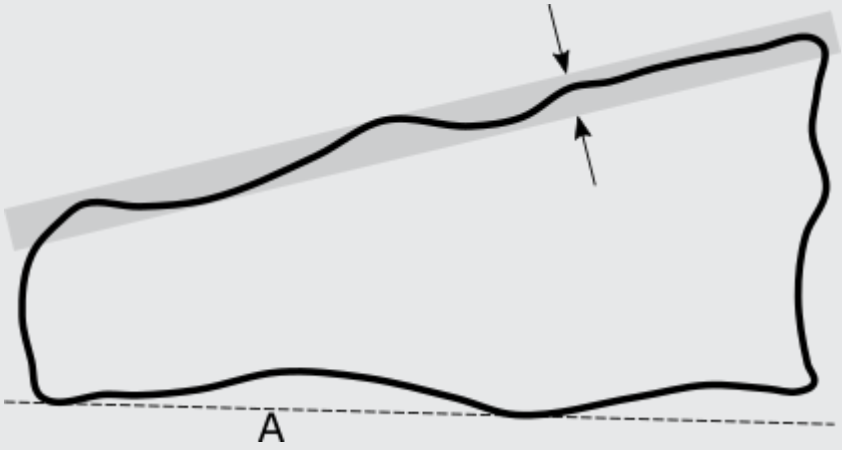
Actual Value:
This is the size of the smallest tolerance zone that contains the actual toleranced feature. The zone is nominally oriented to the actual datum or datums.

Measured Value:
This is the size of the smallest tolerance zone that contains the measured toleranced feature. The zone is nominally oriented to the measured datum or datums.

Suppose you had this angularity specification:

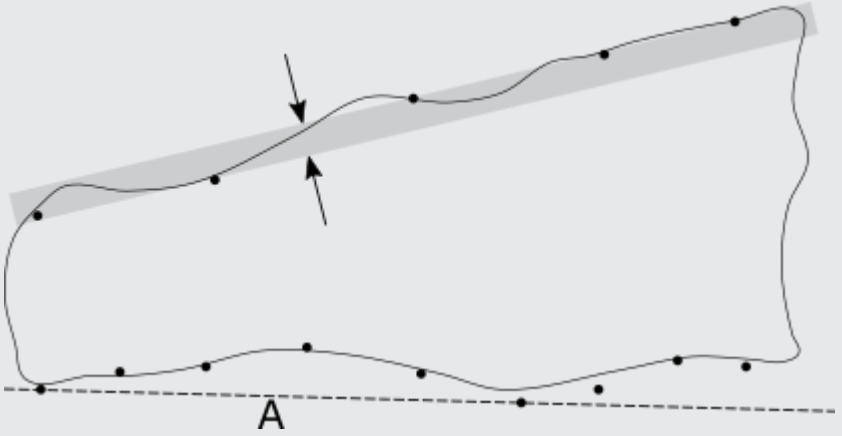


In the above specification, the actual value looks like this:



In the above image, the actual part surface uses the solid line, the actual datum uses the dashed line, and the smallest tolerance zone containing the actual toleranced feature is shown in the shaded area. The tolerance zone is exactly 15° to the actual datum.

Finally, the measured value (with **DEFAULT** datum math) looks like this:



In the above image, the measured tolerance zone is exactly 15° to the measured datum. In this case, the measured points were not measured densely enough, and so the measured value is smaller than the actual value.

Validity Rules

The considered feature or features are specified at some nominal angle to the datum feature or features.

Because of this, all input features (considered and datum) must have the correct specified nominal values. This also ensures that the tolerance command correctly identifies the optimizable degrees of freedom.

For a planar zone on axial features, the datum reference frame must fully constrain the tolerance zone orientation. The planar tolerance zone's surface normal must be perpendicular to each considered feature's axis vector.

Comparison to Past Practice 1

In PC-DMIS version 2020 R2 and later, you can no longer type in the nominal angle from the considered feature to the primary datum. Instead, you need to ensure that the features (considered and datum) have the correct nominal values.

Comparison to Past Practice 2

In PC-DMIS version 2020 R2 and later, material modifiers on datums are no longer allowed.

Exposed Options

When the considered feature has surface data, and the toleranced feature differs from the considered feature's surface data (cones, cylinders, and widths), the feature math type controls how to compute the toleranced feature from the considered feature's surface data. For information, see "Deriving the Toleranced Feature".

When at least one datum feature has surface data, the datum math type controls how to compute the measured datums from the datum features' surface data. For more information, see "How PC-DMIS Solves and Uses Datums".

Report

Here is an example report for an angularity tolerance. The cylinder's size tolerance is in the upper label, and the diametric-zone angularity is in the lower label.

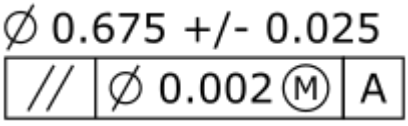
Report

Introduction

A parallelism specification controls how much the feature can deviate from being perfectly parallel to a datum. Sometimes you can use a secondary datum to control the tolerance zone's orientation.



For this geometric tolerance, these three aspects work together:

- Each considered feature and each resulting toleranced feature
- Each tolerance zone
- The datum features

To evaluate this tolerance, PC-DMIS converts each considered feature to a toleranced feature. You can find this described in "Deriving the Toleranced Feature".

PC-DMIS then optimizes each toleranced feature into its respective tolerance zone. The optimization process respects whatever constraints each datum imposes.

Each toleranced feature is optimized independently.

Allowed Feature Types

You can use these feature types:

Cylinders, cones, planes, lines, 3D widths, and 2D widths

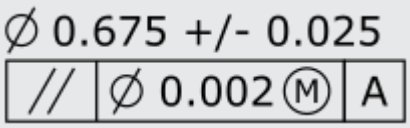
Some feature types have a different toleranced feature than the considered feature's surface data. These include 3D constructed BF lines, cylinders, cones, 3D widths, 2D widths, and planes with a tangent plane modifier. For more information, see "Deriving the Toleranced Feature".

Allowed Modifiers

When the considered feature is a cylinder or a width, this geometric tolerance type allows a maximum material modifier Ⓜ to indicate the specification is at the maximum material condition (MMC). Alternatively, it allows a least material modifier Ⓛ to indicate the specification is at the least material condition (LMC). This means that as the unrelated mating envelope size (or the unrelated minimum material envelope size for LMC) deviates from the MMC (or LMC), additional tolerance or "bonus" tolerance is added to the tolerance in the feature control frame, yielding a total tolerance. For more information on this bonus tolerance, see "Evaluating Size with the Geometric Tolerance Command".

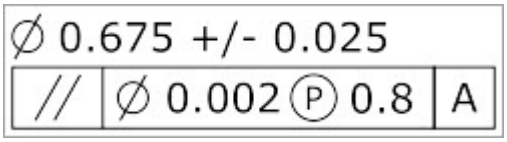
Tolerances referencing ISO 1101 allow additional Associated toleranced feature specification modifiers Ⓒ and Ⓖ for non-features of size. For features of size, Ⓒ, Ⓖ, Ⓝ, and Ⓧ are available. For details, see the "Deriving the Toleranced Feature" topic in the PC-DMIS Core documentation.

Suppose a cylindrical hole has a parallelism tolerance 0.002 at MMC, as shown here:



The size tolerance is 0.675 plus or minus 0.025, meaning the range of acceptable sizes is 0.650 to 0.700. The maximum material condition is then 0.650. If the unrelated measured mating envelope size is 0.661, then the bonus tolerance is 0.011, and the total tolerance is 0.013.

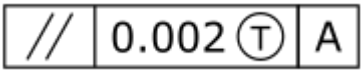
You can use a projected-zone modifier Ⓟ as shown here:



This projects (extrapolates) the measured feature axis as described in "Deriving the Toleranced Feature".

PC-DMIS only allows you to use projected tolerance zones on Auto Cylinder features. If you try to add a projected-zone modifier for any other feature type, the geometric tolerance command gives an error message stating that the feature type is invalid. This is because the projected tolerance zone needs to start at the nominal end-face of the cylinder. Measured cylinders and constructed cylinders typically do not place the nominal start point at the nominal end-face.

When the considered feature is a plane with surface data, you can use a tangent-plane modifier Ⓣ, as shown here:



This makes the toleranced feature be a perfect-form plane tangent to the actual surface, as described in "Deriving the Toleranced Feature".

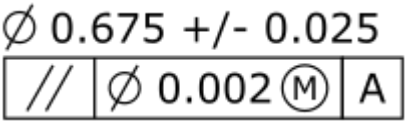
Tolerance Zone Shapes

When the considered feature has an axis, the tolerance zone shape can be diametric (with the tolerance zone shape symbol ⌀) or planar (no tolerance zone shape symbol). These are the axial considered features:

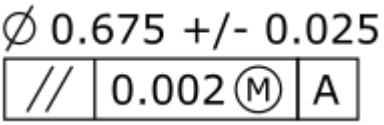
- Cylinder
- Cone
- Surfaceless axis

For information on the feature command types that correspond to these feature types, see "Feature Types With and Without Surface Data".

Here is an example of a parallelism on a cylinder with a diametric tolerance zone:



Here is an example of a parallelism on a cylinder with a planar tolerance zone:



Planar tolerance zones on axial considered features need a specified tolerance zone orientation. This is because the feature does not have enough information to orient the zone correctly. In these cases, the **Zone Orientation** button in the **Geometric Tolerance** dialog box becomes visible. For information on how to use this button to

change the zone orientation, see "Zone Orientation" in the "Feature Control Frame Tab" topic.

If a tolerance controls the X component of the orientation, the tolerance zone surface normal vector should be X.

When the considered feature is a plane, surface line, 3D width, or 2D width, the tolerance zone shape is always planar. It is oriented parallel to the nominal surface or surfaces.

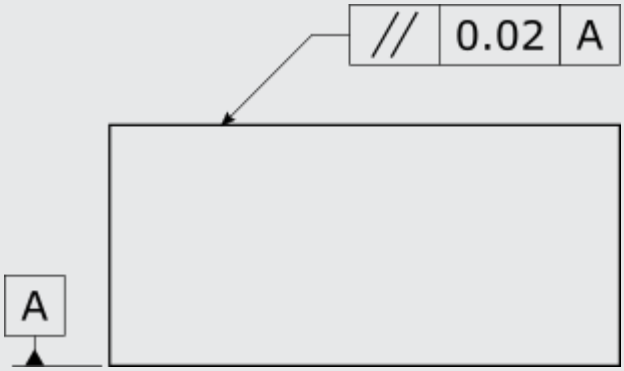
You can have more than one considered feature, but those features must all be the same type.

Actual Value and Measured Value

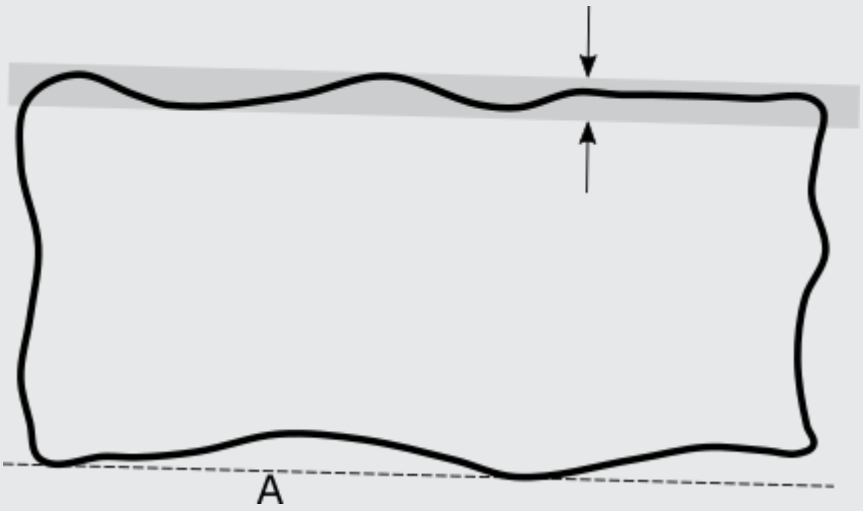
Actual Value:
This is the size of the smallest tolerance zone that contains the actual toleranced feature. The zone is nominally oriented to the actual datum or datums.

Measured Value:
This is the size of the smallest tolerance zone that contains the measured toleranced feature. The zone is nominally oriented to the measured datum or datums.

Suppose you had this parallelism specification:

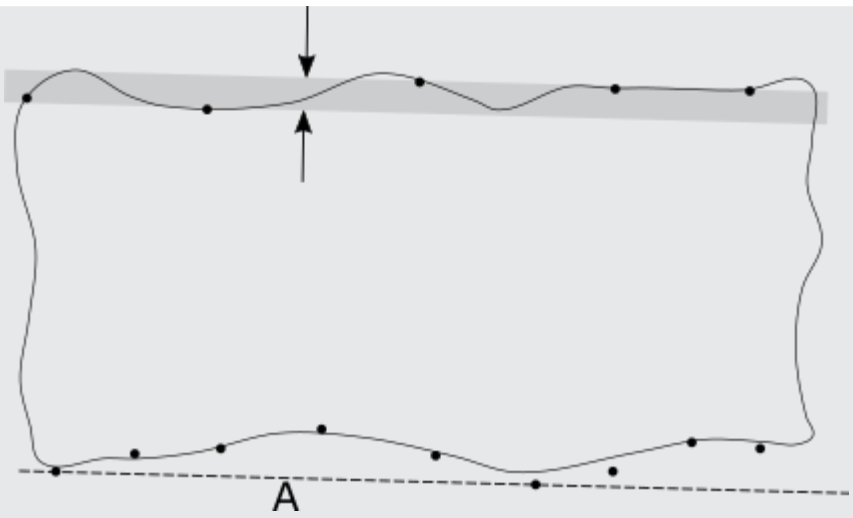


For the above specification, the actual value looks like this:



In the above image, the actual part surface uses the solid line, the actual datum uses the dashed line, and the smallest tolerance zone containing the actual toleranced feature is shown in the shaded area. The tolerance zone is exactly parallel to the actual datum.

Finally, the measured value (with **DEFAULT** datum math) looks like this:



The measured tolerance zone is exactly parallel to the measured datum. In this case, because the measured points were not measured densely enough, the measured value is smaller than the actual value.

Validity Rules

Each considered feature must be nominally parallel to the primary datum.

Because of this, all input features (considered and datum) must have the correct specified nominal values. This ensures that the tolerance zone orients correctly based on the datum features. It also ensures that the geometric tolerance command correctly identifies the optimizable degrees of freedom.

For a planar zone on axial features, the datum reference frame must fully constrain the tolerance zone orientation. The planar tolerance zone’s surface normal must be perpendicular to each considered feature's axis vector.

Comparison to Past Practice

In PC-DMIS version 2020 R2 and later, material modifiers on datums are no longer allowed.

Exposed Options

When the considered feature has surface data, and the toleranced feature differs from the considered feature’s surface data (cones, cylinders, and widths), the feature math type controls how to compute the toleranced feature from the considered feature’s surface data. For information, see "Deriving the Toleranced Feature”.

When at least one datum feature has surface data, the datum math type controls how to compute the measured datums from the datum features' surface data. For more information, see "How PC-DMIS Solves and Uses Datums".

Report

Here is an example report for a parallelism tolerance. The cylinder's size tolerance is in the upper label, and the diametric-zone parallelism is in the lower label.

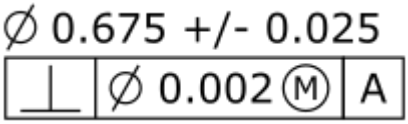
Introduction

A perpendicularity specification controls how much the feature can deviate from a perfect 90 degree angle to a datum. Sometimes you can use a secondary datum to further control the tolerance zone’s orientation.



For this geometric tolerance, these three aspects work together:

- Each considered feature and each resulting toleranced feature
- Each tolerance zone
- The datum features

To evaluate this tolerance, PC-DMIS converts each considered feature to a toleranced feature. You can find this described in "Deriving the Toleranced Feature”.

PC-DMIS then optimizes each toleranced feature into its respective tolerance zone. The optimization process respects whatever constraints each datum imposes.

Each toleranced feature is optimized independently.

Allowed Feature Types

You can use these feature types:

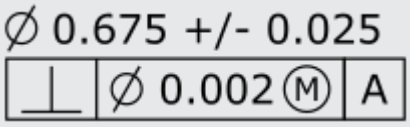
Cylinders, cones, planes, lines, 3D widths, and 2D widths

Some feature types have a different toleranced feature than the considered feature's surface data. These include 3D constructed BF lines, cylinders, cones, 3D widths, 2D widths, and planes with a tangent plane modifier. For more information, see "Deriving the Toleranced Feature".

Allowed Modifiers

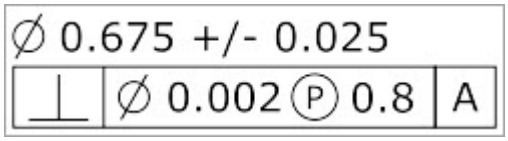
Tolerances referencing ISO 1101 allow additional Associated toleranced feature specification modifiers Ⓒ and Ⓖ for non-features of size. For features of size, Ⓒ, Ⓖ, Ⓝ, and Ⓧ are available. For details, see the "Deriving the Toleranced Feature" topic in the PC-DMIS Core documentation.

Suppose a cylindrical hole has a perpendicularity tolerance 0.002 at MMC, as shown here:



The size tolerance is 0.675 plus or minus 0.025, meaning the range of acceptable sizes is 0.650 to 0.700. The maximum material condition is then 0.650. If the unrelated measured mating envelope size is 0.661, then the bonus tolerance is 0.011, and the total tolerance is 0.013.

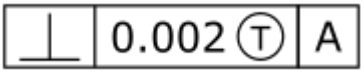
You can use a projected-zone modifier Ⓟ as shown here:



This projects (extrapolates) the measured feature axis as described in "Deriving the Toleranced Feature".

PC-DMIS only allows you to use projected tolerance zones on Auto Cylinder features. If you try to add a projected-zone modifier for any other feature type, the geometric tolerance command gives an error message stating that the feature type is invalid. This is because the projected tolerance zone needs to start at the nominal end-face of the cylinder. Measured cylinders and constructed cylinders typically do not place the nominal start point at the nominal end-face.

When the considered feature is a plane with surface data, you can use a tangent-plane modifier Ⓣ, as shown here:



This makes the toleranced feature be a perfect-form plane tangent to the actual surface, as described in "Deriving the Toleranced Feature".

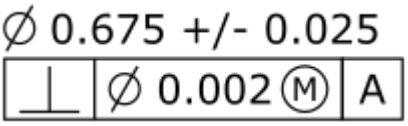
Tolerance Zone Shapes

When the considered feature has an axis, the tolerance zone shape can be diametric (with the tolerance zone shape symbol ⌀) or planar (no tolerance zone shape symbol). These are the axial considered features:

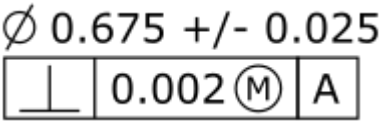
- Cylinder
- Cone
- Surfaceless axis

For information on the feature command types that correspond to these feature types, see "Feature Types With and Without Surface Data".

Here is an example of a perpendicularity on a cylinder with a diametric tolerance zone:



Here is an example of a perpendicularity on a cylinder with a planar tolerance zone:



Planar tolerance zones on axial considered features need a specified tolerance zone orientation. This is because the feature does not have enough information to orient the zone correctly. In these cases, the **Zone Orientation** button in the **Geometric**

Tolerance dialog box becomes visible. For information on how to use this button to change the zone orientation, see "Zone Orientation" in the "Feature Control Frame Tab" topic.

If a tolerance controls the X component of the orientation, the tolerance zone surface normal vector should be X.

When the considered feature is a plane, surface line, 3D width, or 2D width, the tolerance zone shape is always planar. It is oriented parallel to the nominal surface or surfaces.

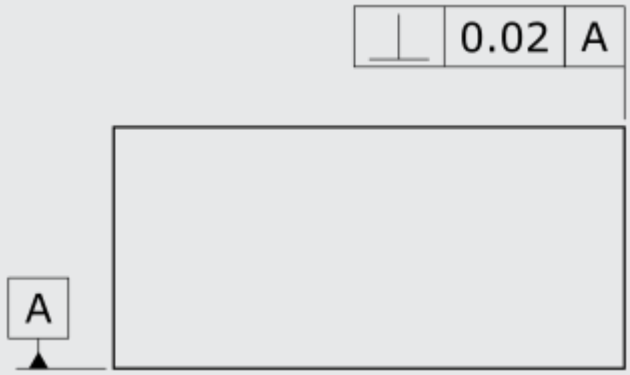
You can have more than one considered feature, but those features must all be the same type.

Actual Value and Measured Value

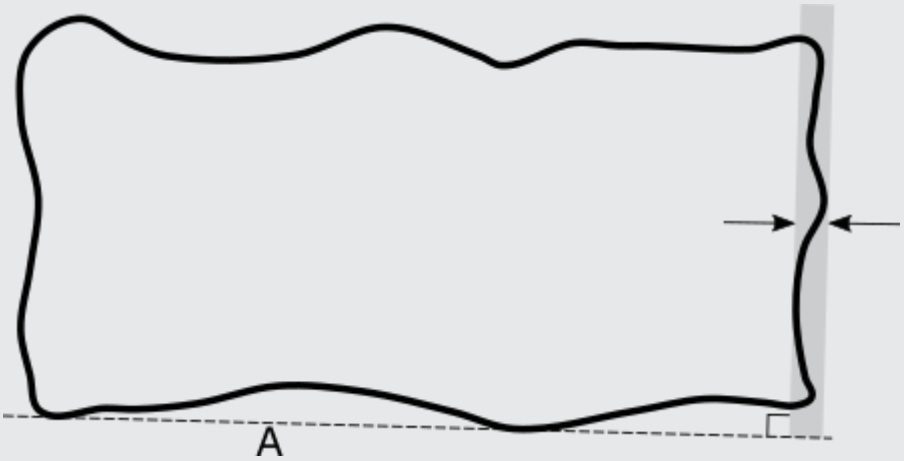
Actual Value:
This is the size of the smallest tolerance zone that contains the actual toleranced feature. The zone is nominally oriented to the actual datum or datums.

Measured Value:
This is the size of the smallest tolerance zone that contains the measured toleranced feature. The zone is nominally oriented to the measured datum or datums.

Suppose you have this perpendicularity specification:

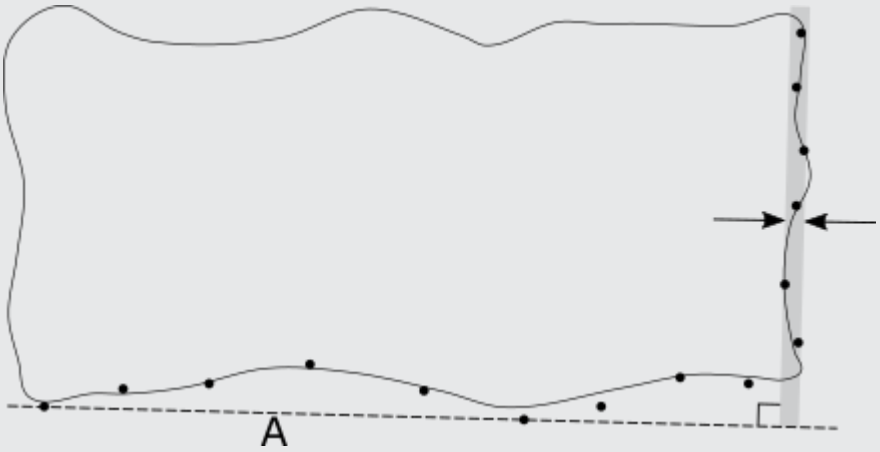


For the above specification, the actual value looks like this:



In the above image, the actual part surface uses the solid line, the actual datum uses the dashed line, and the smallest tolerance zone containing the actual toleranced feature is shown in the shaded area. The tolerance zone is exactly perpendicular to the actual datum.

Finally, the measured value (with **DEFAULT** datum math) looks like this:



In the above image, the measured tolerance zone is exactly perpendicular to the measured datum. In this case, because the measured points were not measured densely enough, the measured value is smaller than the actual value.

Validity Rules

The considered feature or features must be nominally perpendicular to the primary datum.

Because of this, all input features (considered and datum) must have the correct specified nominal values. This ensures that the tolerance zone orients correctly based on the datum features. It also ensures that the geometric tolerance command correctly identifies the optimizable degrees of freedom.

For a planar zone on axial features, the datum reference frame must fully constrain the tolerance zone orientation. The planar tolerance zone’s surface normal must be perpendicular to each considered feature's axis vector.

Comparison to Past Practice

In PC-DMIS version 2020 R2 and later, material modifiers on datums are no longer allowed.

Exposed Options

When the considered feature has surface data, and the toleranced feature differs from the considered feature’s surface data (cones, cylinders, and widths), the feature math type controls how to compute the toleranced feature from the considered feature’s surface data. For information, see "Deriving the Toleranced Feature”.

When at least one datum feature has surface data, the datum math type controls how to compute the measured datums from the datum features' surface data. For more information, see "How PC-DMIS Solves and Uses Datums".

Report

Here is an example report for a perpendicularity tolerance. The cylinder's size tolerance is in the upper label, and the diametric-zone perpendicularity is in the lower label.

Concentricity

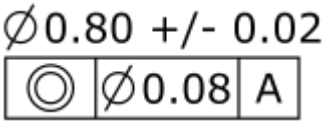
In this Topic

- Concentricity
  - Introduction
  - Allowed Feature Types
  - Allowed Modifiers
  - Tolerance Zone Shapes
  - Actual Value and Measured Value
  - Validity Rules
  - Exposed Options
  - Report

Introduction

> When you select ASME Y14.5 – 2018 as the GDT standard, two past practices, use of concentricity and use of symmetry symbols, are no longer supported. For more detail, see the main foreword and sections A-5.3, A-8.4, D-3 and D4 of ASME Y14.5 – 2018.

A concentricity specification controls how much the feature can deviate from being concentric to one or more datums.



For this geometric tolerance, these three aspects work together:

- Each considered feature and each resulting toleranced feature
- Each tolerance zone
- The datum features

To evaluate this tolerance, PC-DMIS converts each considered feature to a toleranced feature. You can find this described in "Deriving the Toleranced Feature".

PC-DMIS then optimizes each toleranced feature into its respective tolerance zone. The optimization process respects whatever constraints each datum imposes.

Allowed Feature Types

You can use these feature types:

3D constructed BF lines, cast lines, generic lines, cylinders, circles, spheres, and cones

PC-DMIS constructs the toleranced feature based on the standard you use (ASME Y14.5 or ISO 1101).

ISO 1101 (or with a feature that does not have surface data):

PC-DMIS constructs the toleranced feature in the same way as position tolerances do.

ASME Y14.5 with cylinders, circles, spheres, and cones with surface data:

PC-DMIS provides an option to switch between MEDIAN_POINTS or AXIS:

AXIS - The software constructs the toleranced feature as the axis of the unrelated mating envelope (this is the same as position tolerances).

MEDIAN_POINTS - The software constructs the toleranced feature from all the median points of the feature. It does this according to paragraph 7.6.4.2.2 of ASME Y14.5 2009.

Allowed Modifiers

When the considered feature is a cylinder, circle, or sphere, concentricity tolerances referencing ISO 1101 allow a maximum material modifier Ⓜ to indicate the specification is at the maximum material condition (MMC). Alternatively, they allow a least material modifier Ⓛ to indicate the specification is at the least material condition (LMC). This means that as the unrelated mating envelope size (or the unrelated minimum material envelope size for LMC) deviates from the MMC (or LMC), additional tolerance or "bonus" tolerance is added to the tolerance in the feature control frame, yielding a total tolerance. For more information on this bonus tolerance, see "Evaluating Size with the Geometric Tolerance Command".

Tolerances referencing ISO 1101 allow additional Associated toleranced feature specification modifiers Ⓒ and Ⓖ for non-features of size. For features of size, Ⓒ, Ⓖ, Ⓝ, and Ⓧ are available. For details, see the "Deriving the Toleranced Feature" topic in the PC-DMIS Core documentation.

Tolerance Zone Shapes

For ISO, the tolerance zone shape is always diametric. It is oriented parallel to the datum axis.

For ASME, the tolerance shapes are usually diametric, but sphere features can have a spherical or a diametric zone.

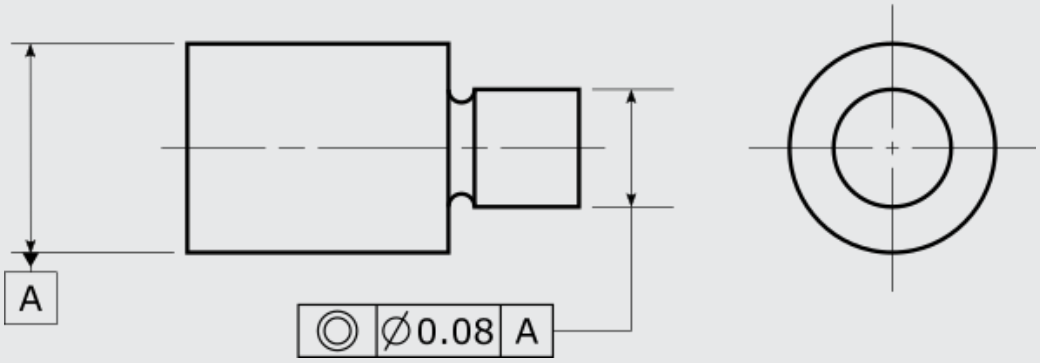
Actual Value and Measured Value

There is one special case to consider. If you have a spherical-zone concentricity of two or more spheres (thus, ASME concentricity) it is not clear from the standard whether the spheres should be considered simultaneously or independently. The PC-DMIS geometric tolerance command considers them simultaneously, since this is the more conservative choice.

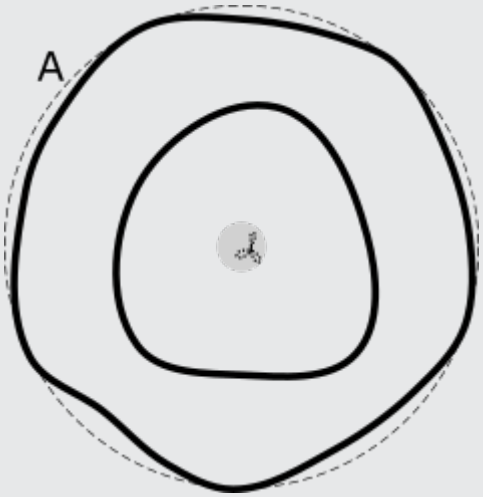
Actual Value:
This is the size of the smallest tolerance zone that contains the actual toleranced feature. The zone is nominally oriented and located to each actual datum.

Measured Value:
This is the size of the smallest tolerance zone that contains the measured toleranced feature. The zone is nominally oriented and located to each measured datum.

Suppose you have this concentricity specification:

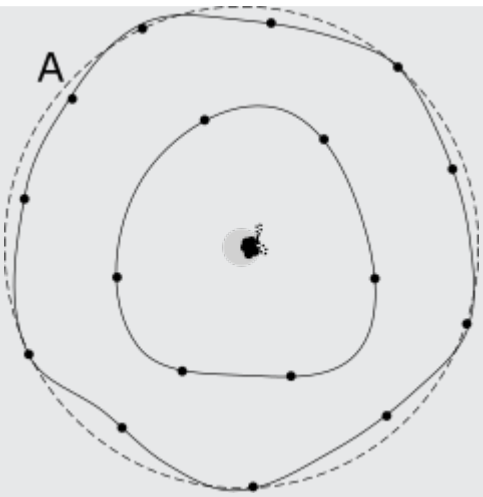


With the above specification, the actual value looks like this:



The actual part surface uses the solid line, the actual datum uses the dashed line, the toleranced feature uses the dotted line, and the smallest tolerance zone that contains the actual toleranced feature is shown in the shaded area. The tolerance zone is exactly concentric to the axis of the actual datum.

Finally, the measured value (with **DEFAULT** datum math) looks like this:



The measured tolerance zone is exactly concentric to the axis of the measured datum. In this case, the measured points were not measured densely enough, and so the measured value is smaller than the actual value.

Validity Rules

All input features (considered and datum) must have the correct specified nominal values. This ensures that the measured values are calculated correctly, and that the tolerance command correctly identifies the optimizable degrees of freedom.

The datum reference frame must be axial, and the considered feature surface or surfaces must be nominally concentric with the datum axis.

Exposed Options

Concentricity tolerances have a feature math type when the considered feature has surface data.

This math type controls how to compute the toleranced feature from the considered feature's surface data. For more information, see "Deriving the Toleranced Feature".

When at least one datum feature has surface data, the datum math type controls how to compute the measured datums from the datum features' surface data. For more information, see "How PC-DMIS Solves and Uses Datums".

Report

Here is an example report for a concentricity tolerance of a cylinder. The cylinder's size tolerance is in the upper label, and the concentricity is in the lower label.

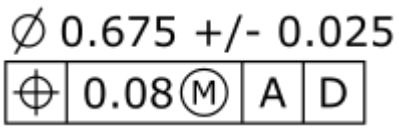
  - Introduction
  - Allowed Feature Types
  - Allowed Modifiers
  - Tolerance Zone Shapes
  - Actual Value and Measured Value
  - Validity Rules
  - Exposed Options
  - Lower Segments of Composite Position
  - Report

Introduction

A position specification controls how much the considered feature or features can deviate from a specified position relative to zero or more datums.



For this geometric tolerance, these three aspects work together:

- Each considered feature and each resulting toleranced feature
- Each tolerance zone
- The datum features (if any are referenced)

To evaluate this tolerance, PC-DMIS converts each considered feature to a toleranced feature. You can find this described in "Deriving the Toleranced Feature".

PC-DMIS then optimizes each toleranced feature into its respective tolerance zone. The optimization process respects whatever constraints each datum imposes. When there are multiple considered features, the optimization process simultaneously considers all features, so that all toleranced features are fitted into their tolerance zones at once. This process is similar to a physical gage, where all of the gage pins must fit into the workpiece's holes at the same time.

Allowed Feature Types

You can use these feature types:

Spheres, 3D surfaceless points, cylinders, circles, cones, widths, slots, notches, constructed mid planes, constructed mid lines, and constructed mid points.

ASME position tolerances also allow 3D constructed BF lines. ISO position tolerances also allow planes, lines, and surface points.

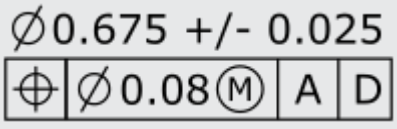
3D constructed BF lines, spheres, cylinders, circles, cones, widths, slots, and notches have a toleranced feature that is different than the considered feature's surface data. For information, see "Deriving the Toleranced Feature".

Allowed Modifiers

When the considered feature is a cylinder, sphere, or width, position tolerances allow a maximum material modifier Ⓜ to indicate the specification is at the maximum material condition (MMC). Alternatively, they allow a least material modifier Ⓛ to indicate the specification is at the least material condition (LMC). This means that as the unrelated mating envelope size (or unrelated minimum material envelope size for LMC) deviates from the MMC (or LMC), additional tolerance or "bonus" tolerance is added to the tolerance in the feature control frame, yielding a total tolerance. For more information on this bonus tolerance, see "Evaluating Size with the Geometric Tolerance Command".

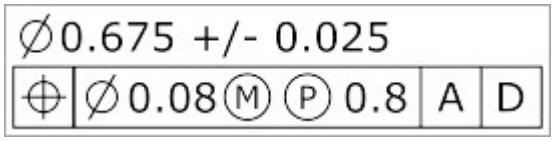
Tolerances referencing ISO 1101 allow additional Associated toleranced feature specification modifiers Ⓒ and Ⓖ for non-features of size. For features of size, Ⓒ, Ⓖ, Ⓝ, and Ⓧ are available. For details, see the "Deriving the Toleranced Feature" topic in the PC-DMIS Core documentation.

This example is in inches. Suppose a cylindrical hole has a position tolerance 0.08 at MMC, as shown here:



The size tolerance is 0.675 plus or minus 0.025, meaning the range of acceptable sizes is 0.650 to 0.700. The maximum material condition is then 0.650. If the unrelated measured mating envelope size is 0.661, then the bonus tolerance is 0.011, and the total tolerance is 0.091.

You can use a projected-zone modifier Ⓟ as shown here:



This projects (extrapolates) the measured feature axis as described in "Deriving the Toleranced Feature".

> **!** PC-DMIS only allows you to use projected tolerance zones on Auto Cylinder features. If you try to add a projected-zone modifier for any other feature type, the geometric tolerance command gives an error message stating that the feature type is invalid. This is because the projected tolerance zone needs to start at the nominal end-face of the cylinder. Measured cylinders and constructed cylinders typically do not place the nominal start point at the nominal end-face.

Tolerance Zone Shapes

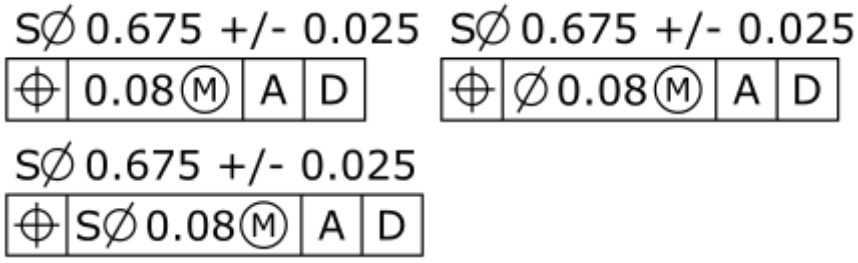
Different tolerance zone shapes are allowed for different types of features. For information about the feature command types that refer to different feature types, see "Feature Types With and Without Surface Data".

Point-like considered features

When the considered feature is point-like, the tolerance zone shape may be planar, diametrical, or spherical. These are point-like considered features:

- Sphere or 3D surfaceless point

From left to right, the pictures below show FCFs with a planar, diametric, and spherical tolerance zone when the considered feature is a sphere:



Planar and diametric tolerance zones on point-like considered features need a specified tolerance zone orientation, because the feature does not have enough information to orient the zone correctly. In these cases, the **Zone Orientation** button in the **Geometric Tolerance** dialog box becomes visible. For information on how to use this button to change the zone orientation, see "Zone Orientation" in the "Feature Control Frame Tab" topic.

If a position tolerance controls the X component of the position (planar tolerance zone), the tolerance zone surface normal vector should be X.

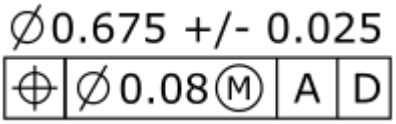
If a position tolerance controls the X and Y components of the position (diametric tolerance zone), the tolerance zone axis vector should be Z.

Axial Considered Features

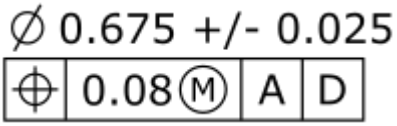
When the considered feature is axial, the tolerance zone may be planar, diametrical, radial arc, or right angle to radial. These are axial considered features:

Cylinder, circular cross section of a cylinder, cone, or surfaceless axis

A diametric tolerance zone is shown below, using the diametric zone symbol.



Planar zones, radial arc zones, and right angle to radial zones do not use any tolerance zone shape symbol and are shown below.



Planar tolerance zones on axial considered features need a specified tolerance zone orientation, because the feature does not have enough information to orient the zone correctly. In these cases, the **Zone Orientation** button in the **Geometric Tolerance** dialog box becomes visible. For information on how to use this button to change the zone orientation, see "Zone Orientation" in the "Feature Control Frame Tab" topic. This button also allows users to specify a radial arc or right angle to radial zone.

If a position tolerance controls the X component of the position, the tolerance zone surface normal vector should be X.

Plane-Like Considered Features

When the considered feature is plane-like, the tolerance zone is always planar and oriented parallel to the nominal surfaces. These are plane-like considered features:

Plane, surface line, width, slot, notch, surface point, or mid-point

You can have more than one considered feature, but those features must all be the same type.

Be careful with slots and notches.

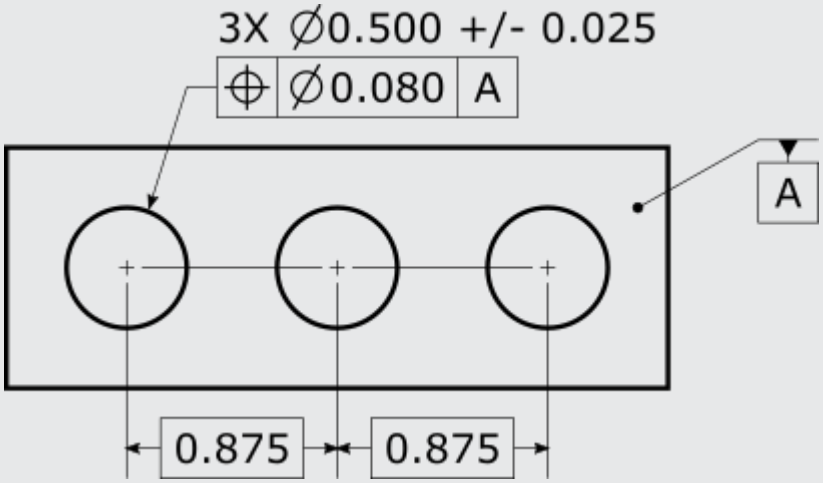
You should only use them if you already know that the form of the features is very good. If you suspect that the manufactured form error might be significant, do not use a slot or notch command. Instead, measure a scan around the perimeter of the feature and then tolerance the form, orientation, and location of the feature with a profile of a line tolerance.

Actual Value and Measured Value

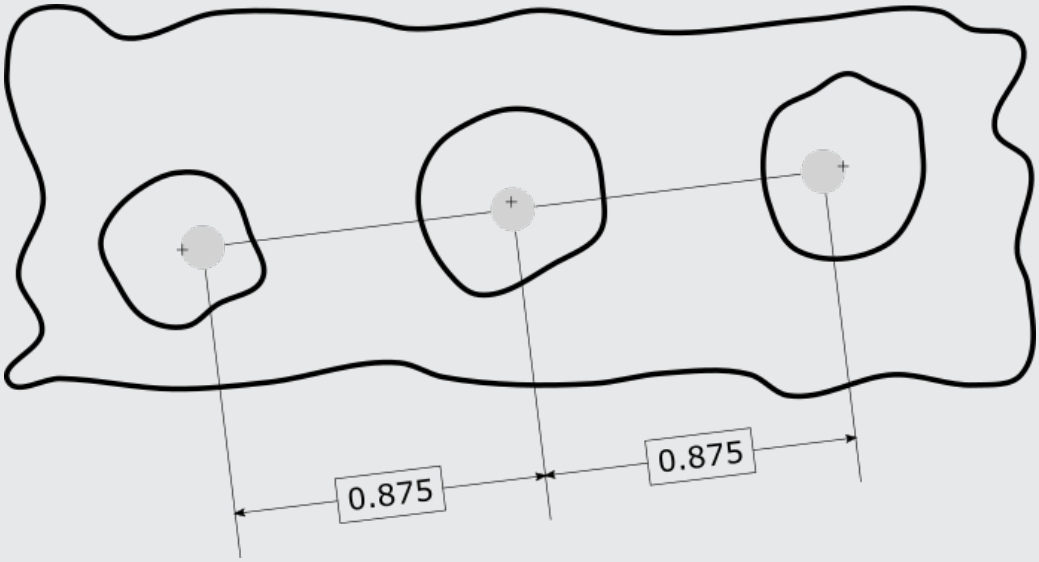
Actual Value:
Each considered feature has its own actual value. This is the size of the smallest tolerance zone that contains the actual toleranced feature. The zone is nominally oriented and located to each actual datum, with some exceptions detailed in "How PC-DMIS Solves Datums". When the position tolerance contains more than one considered feature, and the datum reference frame is not fully constrained, an optimization procedure must simultaneously fit all toleranced features in their respective tolerance zones if possible.

Measured Value:
Each considered feature has its own measured value. This is the size of the smallest tolerance zone that contains the measured toleranced feature. The zone is nominally oriented and located to each measured datum, with some exceptions detailed in "How PC-DMIS Solves Datums". When the position tolerance contains more than one considered feature, and the datum reference frame is not fully constrained, the PC-DMIS optimization procedure simultaneously fits all toleranced features into their respective tolerance zones in a proportional way, which guarantees all toleranced features will fit in their respective tolerance zones if at all possible.

Suppose you have this position specification:



With the above specification, the actual value looks like this:



The actual part surface uses the solid line, the actual toleranced features are the small crosses, and the smallest tolerance zones containing the actual toleranced features are shown in the shaded areas. The tolerance zones are nominally located and oriented with respect to each other and with respect to the datum.

Validity Rules

Considered features must have some nominal location and orientation to each datum feature.

All input features (considered and datum) must have the correct specified nominal values. This ensures that the measured values are calculated correctly, and that the tolerance command correctly identifies the optimizable degrees of freedom.

For a planar zone on axial features, the datum reference frame must fully constrain the tolerance zone orientation. The planar tolerance zone’s surface normal must be perpendicular to each considered feature's axis vector.

For radial arc and right angle to radial tolerance zones on axial features, follow these requirements:

- The datum reference frame must establish a clear polar origin and polar axis.
- The axial features must be nominally parallel to the polar axis.

Exposed Options

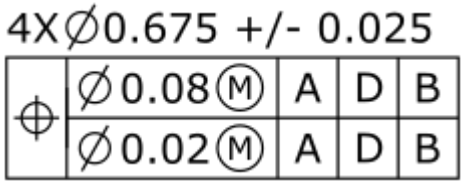
When the considered feature has surface data and the toleranced feature differs from the considered feature's surface data (spheres, cones, cylinders, circles, widths), the feature math type controls how to compute the tolerance feature from the considered feature's surface data. For information, see "Deriving the Toleranced Feature”.

When at least one datum feature has surface data, the datum math type controls how to compute the measured datums from the datum features' surface data. For more information, see "How PC-DMIS Solves and Uses Datums".

Slots can be considered in either a lengthwise or a widthwise fashion, as described in "Lengthwise versus Widthwise Slots".

Lower Segments of Composite Position

A position tolerance with multiple segments is called a “composite position”. Composite position tolerances are typically specified on a pattern of features. The first (or upper) segment of a composite position is the same as a single segment position as described in the preceding sections of this page. All lower segments of a composite position are subtly different. This is because the tolerance zones of the pattern have unlocked translation compared to the datum reference frame. However, the tolerance zones remain nominally located and oriented to each other.



The datum reference frames for the lower segments of a composite position follow these rules:

- Each datum reference frame must only use the same datums as the reference frame above it.
- The datums must be in the same order.

- The datums must have the same modifiers.
- A lower segment can have fewer datums than the segment above.

Suppose the upper segment has datums ABC. The lower segment then could reference no datums, datum A, datums AB, or datums ABC. But it could not reference datums BA nor AC nor ABD.

Here are some examples of allowed composite position tolerances:

4X∅0.675 +/- 0.025

⌖	∅0.08Ⓜ	A	B	C
	∅0.02Ⓜ	A	B	C

4X∅0.675 +/- 0.025

⌖	∅0.08Ⓜ	A	B	C
	∅0.02Ⓜ	A	B	

4X∅0.675 +/- 0.025

⌖	∅0.08Ⓜ	A	B	C
	∅0.02Ⓜ	A		

4X∅0.675 +/- 0.025

⌖	∅0.08Ⓜ	A	B	C
	∅0.02Ⓜ			

Here are some examples of not-allowed composite position tolerances:

4X∅0.675 +/- 0.025

⌖	∅0.08Ⓜ	A	B	C
	∅0.02Ⓜ	B	A	

4X∅0.675 +/- 0.025

⌖	∅0.08Ⓜ	A	B	C
	∅0.02Ⓜ	A	C	

4X∅0.675 +/- 0.025

⌖	∅0.08Ⓜ	A	B	C
	∅0.02Ⓜ	A	B	D

Report

Here is an example report for a position tolerance of two cylinders. The cylinders' size tolerance is in the upper label, and the diametric-zone position is in the lower label. The lower label includes information for the YZ positions of the cylinders, in the optimized frame (not in the current alignment).

FCFLOC1 Size	MM	Ø 8 +0.1/-0.1	DEFAULT	ASME Y14.5 2018

Feature	MEAS	NOMINAL	+TOL	-TOL	DEV	OUTTOL
CYL1	7.995	8.000	0.100	0.100	-0.005	0.000
CYL2	7.990	8.000	0.100	0.100	-0.010	0.000

FCFLOC1	MM	⌖ Ø0.2 Ⓜ A D E	DEFAULT	ASME Y14.5 2018

Feature	AX	MEAS	NOMINAL	+TOL	-TOL	DEV	OUTTOL	BONUS
CYL1 (END PT)	Y	-6.912	-7.000			0.088		
	Z	-27.992	-28.000			0.008		
	TP	0.176	0.000	0.200	0.000	0.176	0.000	0.095
CYL2 (END PT)	Y	7.092	7.000			0.092		
	Z	-27.989	-28.000			0.011		
	TP	0.184	0.000	0.200	0.000	0.184	0.000	0.090

In the lower label of the above illustration, the Y, Z, and TP rows for CYL1 and CYL2 summarize the position evaluation for each considered feature. The bottom row of each, labeled TP, behaves just like all of the reports for other geometric tolerances. For CYL2, the TP row includes the tolerance 0.200, the bonus 0.090, and the measured value 0.184.

In the lower label of the example report above, there are only three rows for each feature (Y, Z, and TP). For your reports, the axis column (AX) for your features might have some combination of several rows labeled X, Y, Z, PR, PA, and TP. When present, the X, Y, Z, PR, and PA rows give supplementary information as described below.

The Y and Z rows for CYL1 and CYL2 give supplementary information about the position evaluation. Those rows are intended to give a simplified representation of how the feature deviates from the ideal.

- The NOMINAL column of the supplementary information rows shows the nominal start point of the feature in question.
- The DEV column of those rows shows the worst deviation vector, among all of the toleranced feature's points.
- The MEAS column of those rows is the NOMINAL column plus the DEV column. In other words, it is the toleranced feature's worst point, after being projected to be as close as possible to the nominal start point, while preserving the worst deviation vector.

- Underneath the feature name, the report indicates which end or level of the cylinder was the worst. For example, it could say "(START PT)", "(END PT)", or "LEVEL#3".

The representation is simplified, because, as described in Deriving the Toleranced Feature, most feature types have more than one point in the toleranced feature. For example, cylinders typically have at least two points in the toleranced feature, the measured start point and the measured end point. By contrast, in some cases ISO cylinders have several points in the toleranced feature, one for each measured cross section.

If you turn on the textual analysis or graphical analysis, you can see all the points in the toleranced feature, together with their respective deviations. The supplementary information rows in the report has a MEAS column that does not necessarily appear in the textual analysis, because the supplementary information has been simplified to show deviation with respect to the nominal start point.

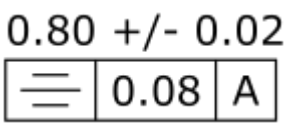
- Report

Introduction

When you select ASME Y14.5 – 2018 as the GDT standard, two past practices, use of concentricity and use of symmetry symbols, are no longer supported. For more detail, see the main foreword and sections A-5.3, A-8.4, D-3 and D4 of ASME Y14.5 - 2018.

A symmetry specification controls how much the feature can deviate from being symmetric about one or more datums.



For this geometric tolerance, these three aspects work together:

- Each considered feature and each resulting toleranced feature
- Each tolerance zone
- The datum features

To evaluate this tolerance, PC-DMIS converts each considered feature to a toleranced feature. You can find this described in "Deriving the Toleranced Feature".

PC-DMIS then optimizes each toleranced feature into its respective tolerance zone. The optimization process respects whatever constraints each datum imposes.

Allowed Feature Types

You can use these feature types:
widths, constructed mid planes, constructed mid lines, and constructed mid points

PC-DMIS constructs the toleranced feature differently based on the standard you use (ASME Y14.5 or ISO 1101).

ISO 1101 (or with a constructed mid feature or a 1D width):

PC-DMIS constructs the toleranced feature in the same ways as position toleranced features do.

ASME Y14.5 with a 2D or 3D width:

PC-DMIS provides an option to switch between MEDIAN_POINTS or AXIS:

AXIS - The software constructs the toleranced feature as the axis (center-plane) of the unrelated mating envelope (this is the same as position tolerances).

MEDIAN_POINTS - The software constructs the toleranced feature from all median points of the width. It does this according to paragraph 7.7.2 of ASME Y14.5 2009.

Allowed Modifiers

When the considered feature is a width, symmetry tolerances referencing ISO 1101 allow a maximum material modifier Ⓜ to indicate the specification is at the maximum material condition (MMC). Alternatively, they allow a least material modifier Ⓛ to indicate the specification is at the least material condition (LMC). This means that as the unrelated mating envelope size (or the unrelated minimum material envelope size for LMC) deviates from the MMC (or LMC), additional tolerance or "bonus" tolerance is added to the tolerance in the feature control frame, yielding a total tolerance. For more information on this bonus tolerance, see "Evaluating Size with the Geometric Tolerance Command".

Tolerances referencing ISO 1101 allow additional Associated toleranced feature specification modifiers Ⓒ and Ⓖ for non-features of size. For features of size, Ⓒ, Ⓖ, Ⓝ, and Ⓧ are available. For details, see the "Deriving the Toleranced Feature" topic in the PC-DMIS Core documentation.

Tolerance Zone Shapes

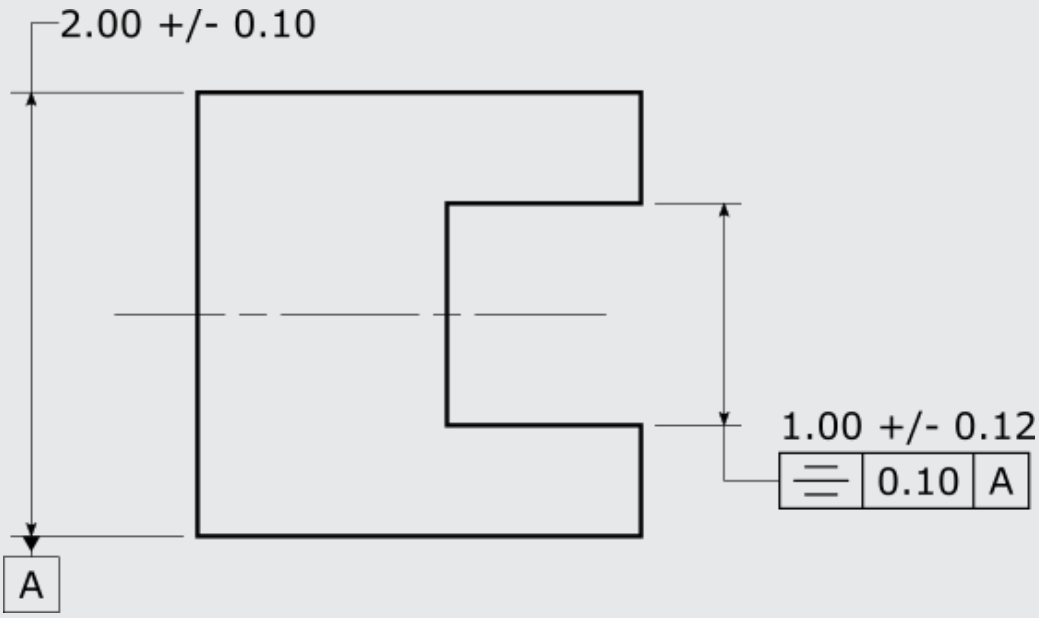
The tolerance zone shape is always planar. It is oriented parallel to the nominal surface or surfaces.

Actual Value and Measured Value

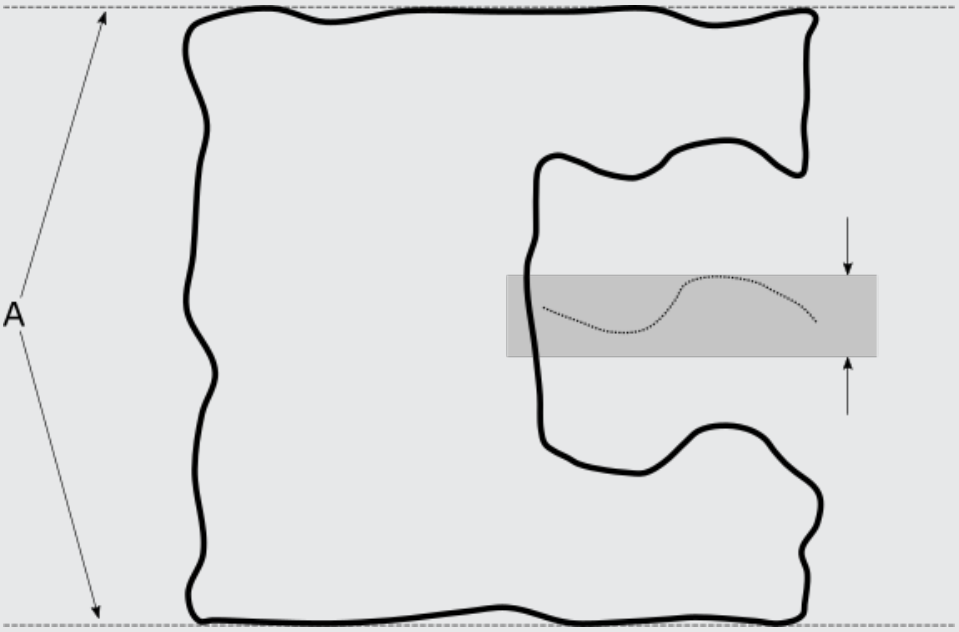
Actual Value:
This is the size of the smallest tolerance zone that contains the actual toleranced feature. The zone is nominally oriented and located to each actual datum.

Measured Value:
This is the size of the smallest tolerance zone that contains the measured toleranced feature. The zone is nominally oriented and located to each measured datum.

Suppose you have this symmetry specification:

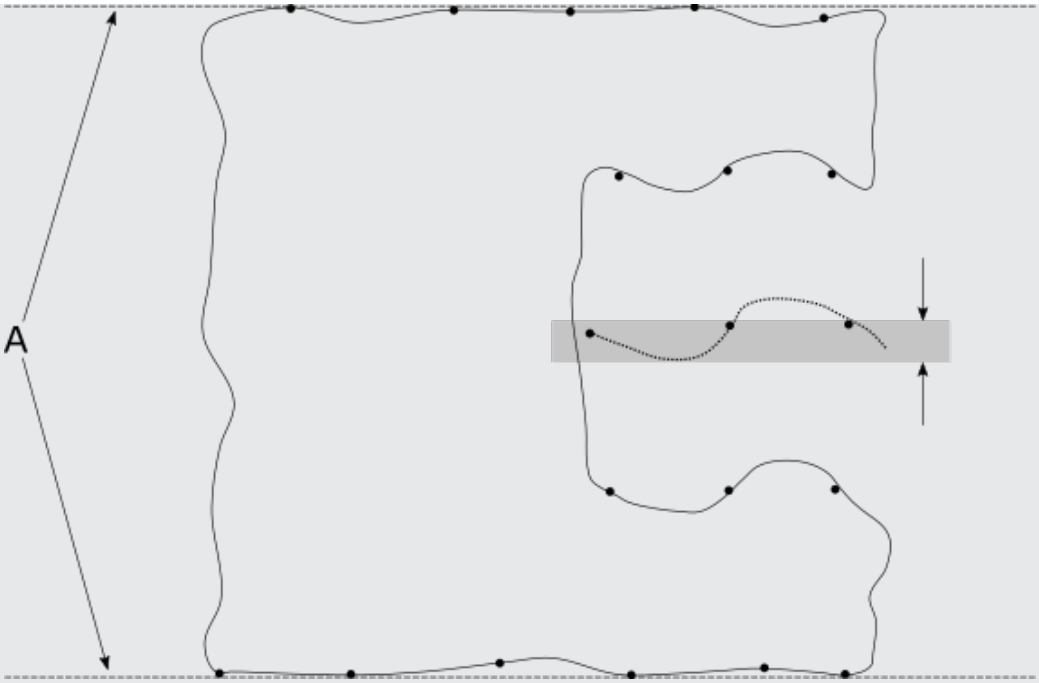


With the above specification, the actual value looks like this:



The actual part surface uses the solid line, the actual datum uses the dashed line, the toleranced feature uses the dotted line, and the smallest tolerance zone containing the actual toleranced feature is shown in the shaded area. The tolerance zone is exactly symmetric to the center-plane of the actual datum.

Finally, the measured value (with **DEFAULT** datum math) looks like this:



The measured tolerance zone is exactly symmetric to the center-plane of the measured datum. In this case, the measured points were not measured densely enough, and so the measured value is smaller than the actual value.

Validity Rules

All input features (considered and datum) must have the correct specified nominal values. This ensures that the measured values are calculated correctly, and that the tolerance command correctly identifies the optimizable degrees of freedom.

The considered feature surface or surfaces must be nominally symmetric with the datum reference frame.

Exposed Options

Symmetry tolerances have a feature math type when the considered feature is a width.

This math type controls how to compute the toleranced feature from the considered feature's surface data. For more information, see "Deriving the Toleranced Feature".

When at least one datum feature has surface data, the datum math type controls how to compute the measured datums from the datum features' surface data. For more information, see "How PC-DMIS Solves and Uses Datums".

Comparison to Past Practice

For many years, with PC-DMIS symmetry tolerances, you could input pairs of planes, pairs of lines, pairs of points, or pairs of sets. Originally, this was because PC-DMIS did not have a width command. Starting with PC-DMIS 2020 R2, these kinds of considered feature pairs are no longer allowed. Each considered feature has its own measured value, and that means the best way to use a symmetry command is with a width feature.

  - Report

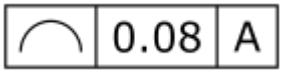
Introduction

A profile of a line specification controls how much the cross sections of features' surfaces can deviate from being the nominal shapes. These cross sections are located and oriented to zero or more datums.



For this geometric tolerance, these three aspects work together:

- Each considered feature's surface data
- Each considered feature's nominal shape and each resulting tolerance zone
- The datum features (if any are referenced)

To evaluate this tolerance, PC-DMIS optimizes each feature's surface data into its respective tolerance zone. The optimization process respects whatever constraints each datum imposes. With multiple considered features, the optimization process simultaneously considers those features. In this way it fits all the toleranced features into their tolerance zones at once.

Recommended Usage

Profile of a line specifications apply to surfaces. This means each cross section of the surface must have an actual value that is less than the specified tolerance. Each cross section should be considered separately from the others (rather than simultaneously).

For each surface that has a profile of a line specification, we recommend that you measure several cross sections:

- You need to have enough cross sections to adequately capture the entire surface's behavior.
- Place each cross section in a separate geometric tolerance command, so that the cross sections are considered and optimized separately. (If you put the cross sections into just one geometric tolerance command, they are considered simultaneously and your measured values will be overly large.)

Regarding Simultaneous Tolerance Command

Strictly speaking, it does not make sense to include a profile of a line specification in a simultaneous tolerance command. If you do this, the behavior of the profile of a line specification changes. Instead of considering each cross section individually, it considers all cross sections simultaneously. This is equivalent to profile of a surface. However, PC-DMIS does permit profile of a line specifications that have at least one datum to participate in a simultaneous tolerance command. In this case, PC-DMIS shows a warning message to indicate that the behavior has changed to match that of profile of a surface.

Allowed Feature Types

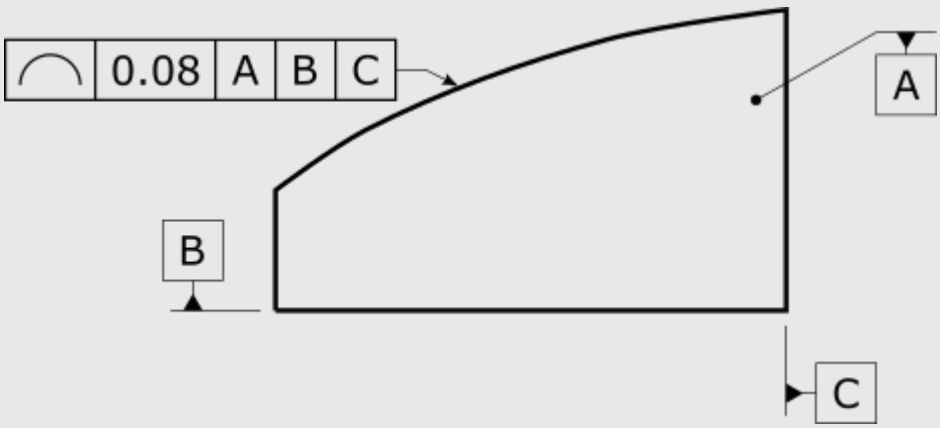
You can use these feature types to represent surface cross sections if they have surface data:

lines, circles, 2D and 1D widths, scans, ellipses, notches, slots, and sets.

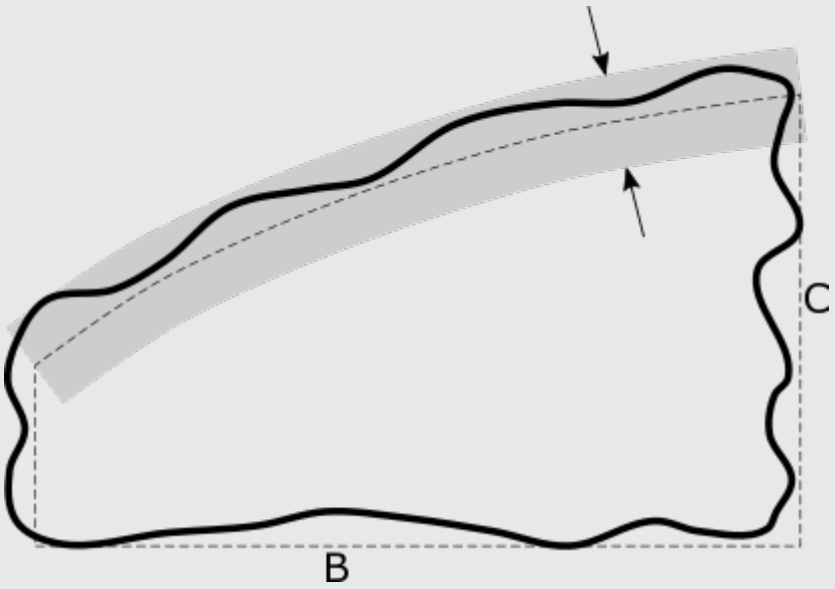
Tolerance Zones and Allowed Modifiers

The tolerance zone is based on the nominal surface of the feature. By default (without any modifiers), the tolerance zone is equal bilateral. This means that half of the tolerance value is on each side of the nominal surface:

Suppose you have this profile of a line specification:

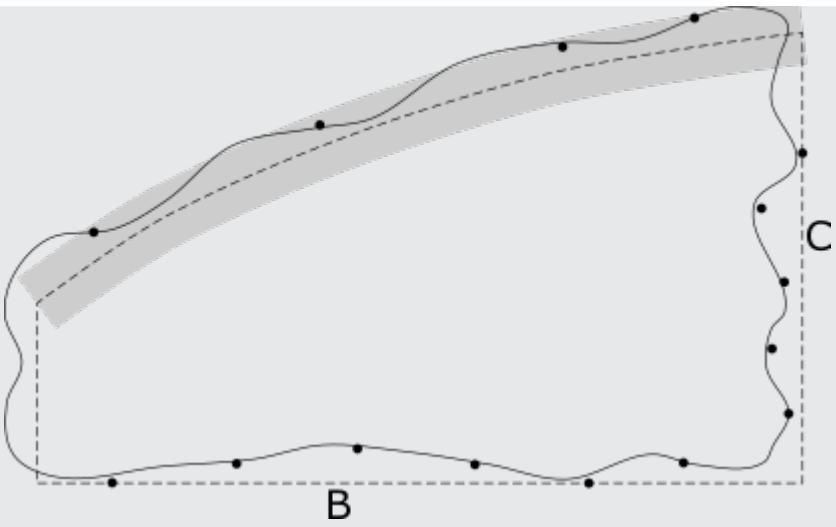


With the above specification, the actual value looks like this:



Since there are no modifiers, the tolerance zone is centered on the nominal surface, which is nominally oriented and located to each actual datum. The solid line indicates the actual surface, the dashed lines represent the nominal surfaces (including the actual datums) and the gray shaded area represents the minimum-size tolerance zone centered on the nominal surface containing the actual surface.

The measured value (with **DEFAULT** datum math) looks like this:



The measured tolerance zone center remains the nominal surface, which is nominally oriented and located to each measured datum. In this case, the measured points were not measured densely enough, and so the measured value is smaller than the actual value.

Modifiers may change the nature of the tolerance zone. Starting in ASME Y14.5 2009, PC-DMIS supports the Ⓤ modifier (unequally disposed profile) and, starting in ASME Y14.5 2018, PC-DMIS supports the △ modifier (dynamic profile). Under ISO 1101, PC-DMIS supports the UZ modifier (specified tolerance zone offset) and the OZ modifier (unspecified linear tolerance zone offset). While they are not equivalent, the Ⓤ and UZ modifiers have similar functionality. They offset the center of the tolerance zone from the nominal surface. Likewise, the △ and OZ modifiers have similar functionality. They allow the center of the tolerance zone to progress in the plus-material or minus-material direction. These modifiers did not exist in ASME Y14.5 1994 but it did support the concept of an unequally disposed tolerance zone. This was usually specified graphically on the print by dotted lines showing the extent of tolerance into and out of the material. Therefore, when selecting ASME Y14.5 1994 as the GDT standard for your PC-DMIS measurement routine, you must enter both the upper and lower tolerances when creating the feature control frame. PC-DMIS will then report the maximum and minimum deviations which are compared against the corresponding upper and lower tolerance values to assess conformance.

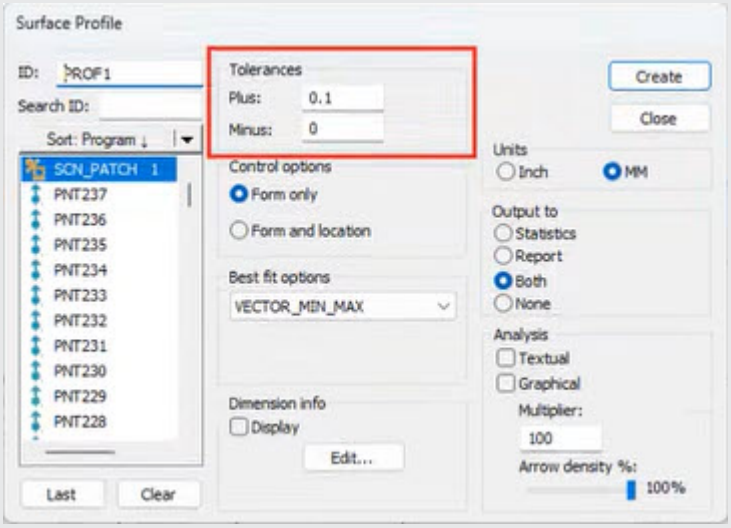
Legacy profile includes a “form only” option which only allows a single, positive tolerance to be entered. To achieve the same behavior using an ASME Y14.5 1994 geometric tolerance profile command, you must divide the total allowable tolerance in half and enter it as equal bilateral values.

The examples below show the differences between the Legacy Surface Profile and the Geometric Tolerance Profile of a Surface commands. Although the examples are for the Surface Profile, the rules are identical for the Line Profile.

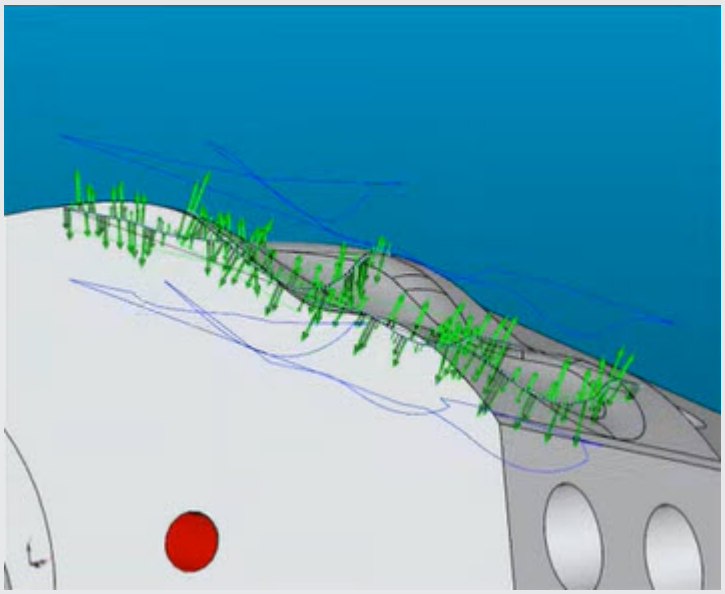
Click on the link below to show examples of the definition, result, and report for a Legacy Surface Profile:

Legacy Surface Profile, Form Only Example

The following example shows a Surface Profile dialog box with a Form only definition:



Example of a legacy Surface Profile dialog box defined for form only with an upper tolerance of 0.1 and a lower tolerance of 0.



Example of the results after the legacy command is executed.

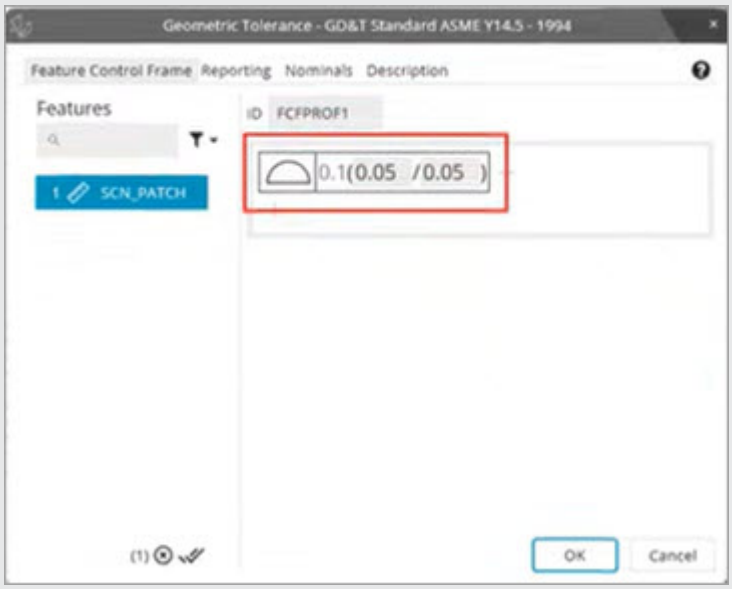
AX	NOMINAL	+TOL	-TOL	MEAS	MAX	MIN	OUTTOL
M	0.000000	0.100000	0.000000	0.071202	0.035601	-0.035601	0.000000

Example of what the legacy version of the report might look like.

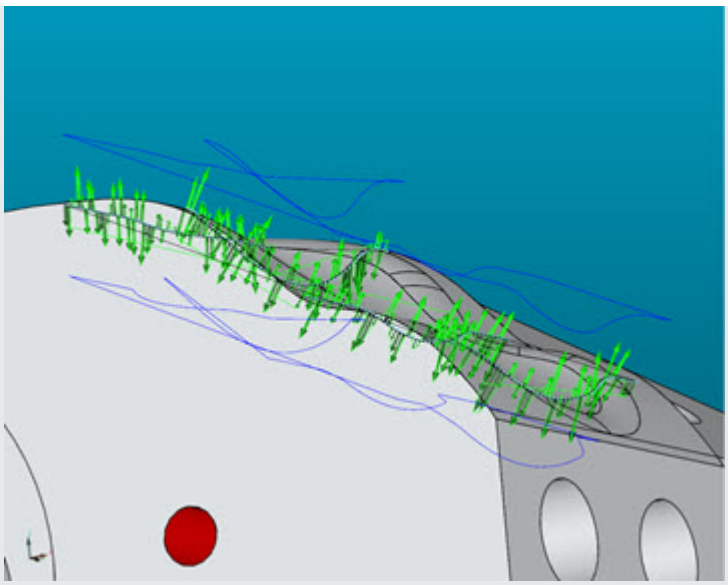
Click on the links below to show correct and incorrect examples of the definitions, results, and reports for a Geometric Tolerance Profile of a Surface:

ASME Y14.5 - 1994 Geometric Tolerance Profile of a Surface Correctly Defined Example

In this example, the Geometric Tolerance Profile of a Surface uses an equivalent upper and lower tolerance value of +/-0.05:



Example of a correctly defined Geometric Tolerance dialog box for a Profile of a Surface using the ASME Y14.5 - 1994 standard.



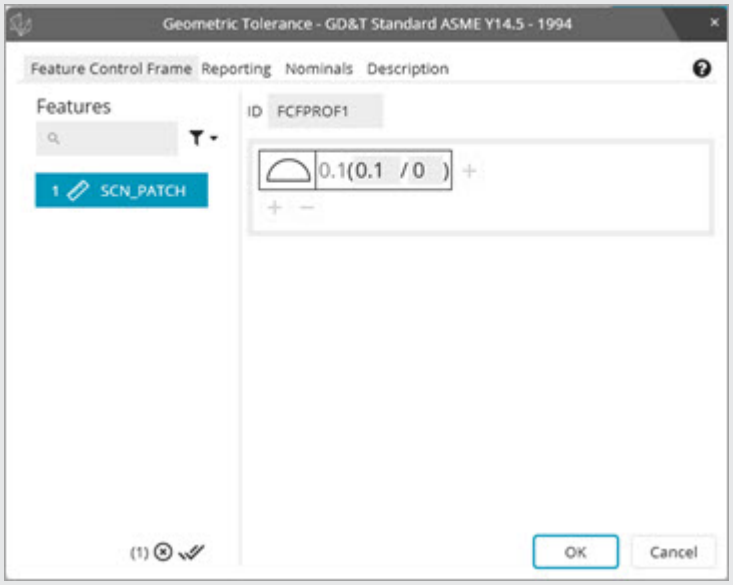
Example of the results after the Geometric Tolerance correctly defined command is executed.

FCFPROF1	MM	0.1	DEFAULT	ASME Y14.5 - 1994				
Feature	NOMINAL	+TOL	-TOL	MEAS	MAX	MIN	OUTTOL	
SCN_PATCH	0.000000	0.050000	0.050000	0.071202	0.035601	-0.035601	0.000000	

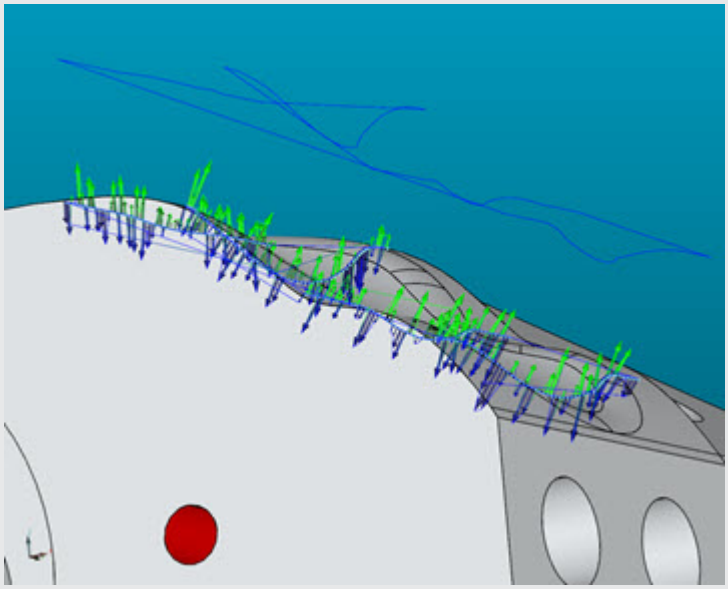
Example of what the Geometric Tolerance version of the report might look like for a correctly defined command.

ASME Y14.5 - 1994 Geometric Tolerance Profile of a Surface Incorrectly Defined Example

In this example, the Geometric Tolerance Profile of a Surface incorrectly uses a single upper tolerance value of 0.1. This results in an unequal tolerance zone causing all negative deviations to be out of tolerance.



Example of an incorrectly defined Geometric Tolerance dialog box for a Profile of a Surface using the ASME Y14.5 - 1994 standard.

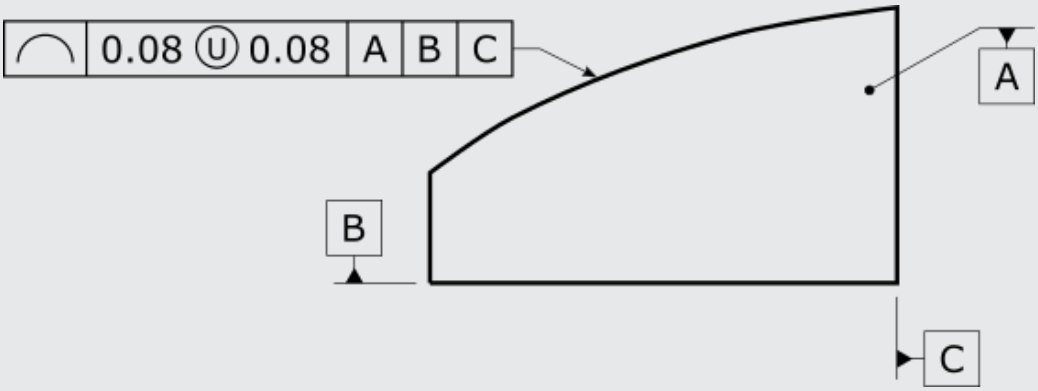


Example of the results after the Geometric Tolerance incorrectly defined command is executed.

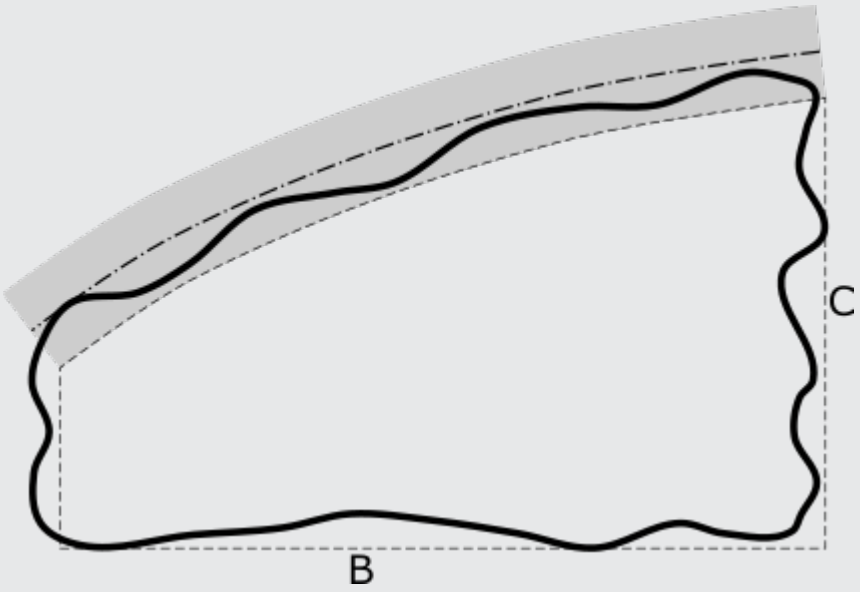
FCFPROF1	MM	0.1			DEFAULT		ASME Y14.5 - 1994
Feature	NOMINAL	+TOL	-TOL	MEAS	MAX	MIN	OUTTOL
SCN_PATCH	0.000000	0.100000	0.000000	0.086446	0.036446	-0.036446	0.000000

Example of what the Geometric Tolerance version of the report might look like for an incorrectly defined command.

Suppose you have the Ⓤ modifier specification shown below. The equivalent ISO specification would be 0.08 UZ+0.04.

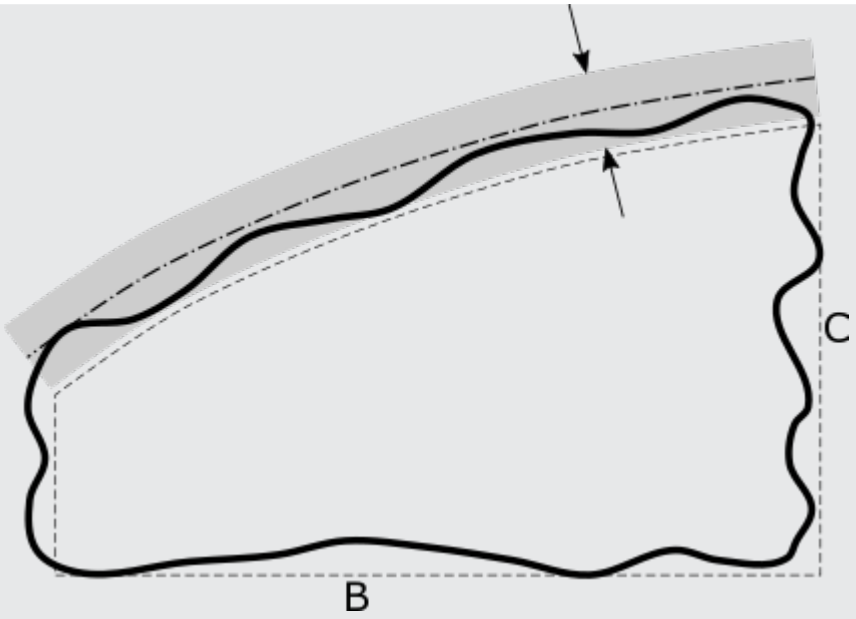


With the above specification, the specified tolerance zone looks like this:



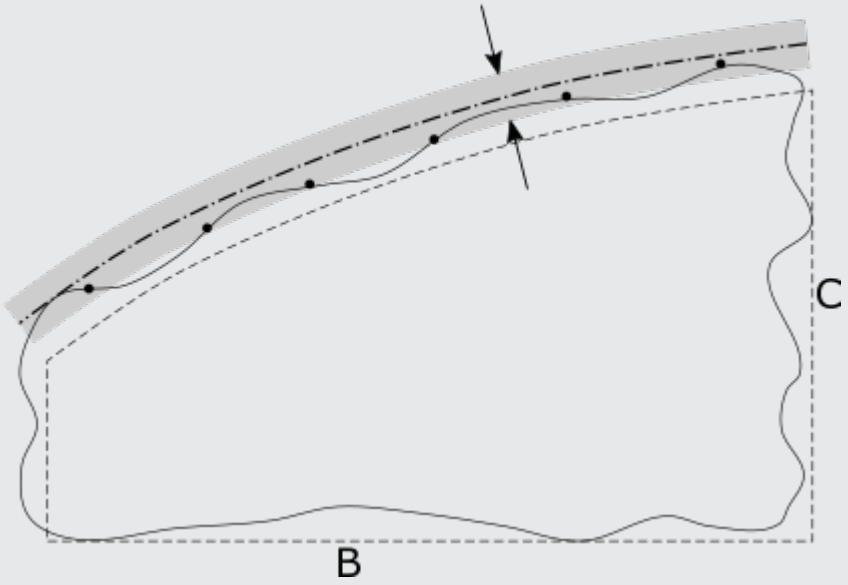
Because this is the specified tolerance zone, the tolerance zone is not minimized, and so it does not represent the actual value. The center of the tolerance zone is offset from the nominal surface and is shown in the dashed-dotted line.

The actual value looks like this:



The center of the tolerance zone stays the same (offset 0.04 from nominal in this case), but the zone is minimized until it just contains the actual surface.

The measured value (with **DEFAULT** datum math) looks like this:



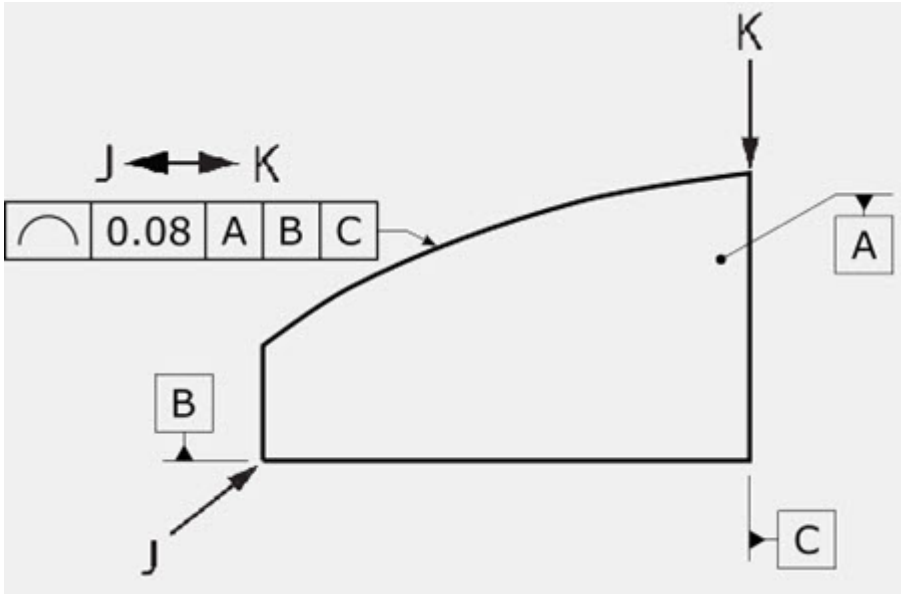
The center of the tolerance zone stays the same (offset 0.04 from nominal in this case) but the zone is minimized around that center until it just contains the measured surface points. In this case, the measured points were not measured densely enough, and so the measured value is smaller than the actual value.

You may find it helpful to remember that the measured value is equivalent to twice the absolute value of the worst deviation, measured from the center of the tolerance zone.

Profile In Between and Profile All Around

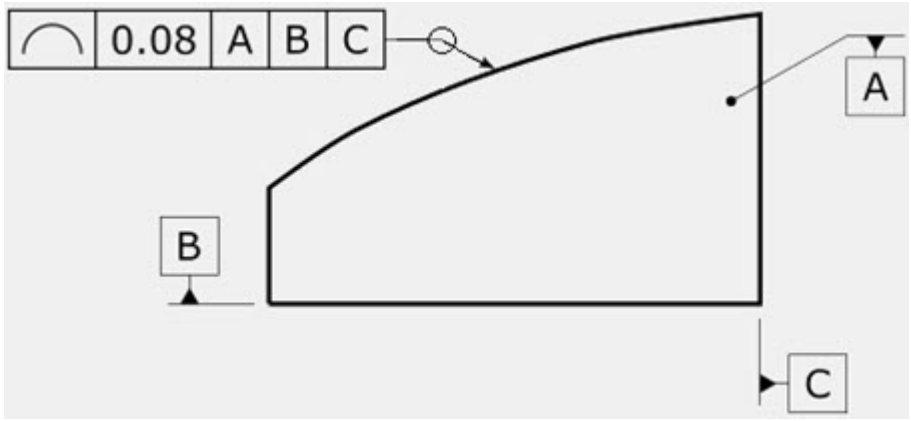
Profile In Between

The **In Between** symbol ⟷ is used between two uppercase letters to identify the extent of the toleranced surface. The surface consist of all points on the surface from the surface designated by the first letter (start) and ending with the surface designated by the second letter (end). This includes all the segments and areas between these letter-designated areas as shown below.



Profile All Around

Profile All Around is applied to the outlines of the cross-sections of a part or to all features represented by a closed outline. It is indicated by the **All Around** circle symbol ○ placed on the intersection of the leader line and the reference line of the tolerance indicator as shown below.



Summary

There is no way to select an **In Between** symbol ⟷ or an **All Around** symbol ○ in the feature control frame builder of the Geometric Tolerance command because they are not part of the feature control frame. Instead, to use the Geometric

Tolerance command to evaluate Profile In Between or Profile All Around, you must employ the correct measurement strategy yourself. To do this, you need to measure multiple cross sections which may need to span multiple surfaces. The easiest way to do this is with the Linear Open Scan command for Profile In Between or the Linear Closed Scan command for Profile All Around.

Another approach is to create multiple scans or a series of auto vector points and combine them into a constructed feature set.

- For Profile In Between, each linear open scan or constructed feature set would represent a single cross section that runs from the point indicated by the start letter to the point indicated by the end letter.
- For Profile All Around, each linear closed scan or constructed feature set would represent a single cross section that runs all around the part or closed outline.

You should evaluate each cross section using a separate profile of a line command and base your conformance decision on the worst value among all cross sections.

Actual Value and Measured Value

Profile tolerance zones have a defined center. They also have a mechanism to grow and shrink the zone around that center until it just envelops the actual surface.

Actual Value:
Each considered feature has its own actual value. This is the size of the smallest tolerance zone that contains the actual surface. The zone is nominally oriented and located to each actual datum, with some exceptions detailed in "How PC-DMIS Solves Datums".

If you have more than one considered feature, and the datum reference frame is not fully constrained, the optimization procedure must simultaneously fit all the features' surfaces in their respective tolerance zones, if possible.

Measured Value:
Each considered feature has its own measured value. This is the size of the smallest tolerance zone that contains the measured surface points. The zone is nominally oriented and located to each measured datum, with some exceptions detailed in "How PC-DMIS Solves Datums".

If you have more than one considered feature, and the datum reference frame is not fully constrained, the PC-DMIS optimization procedure simultaneously fits all features' surface points into their respective tolerance zones. It does this in a proportional way. This guarantees that all toleranced features will fit in their respective tolerance zones if possible.

ASME Y14.5-2009 and ASME Y14.5-2018 use the ASME Y14.5.1-2019 math standard which defines how to calculate an "actual value" of a profile tolerance. Section 8.3.1 (Uniform Tolerance Zones) of the Y14.5.1-2019 standard states, “This concept applies in the same way to equally disposed, unequally disposed and unilateral profile specifications" (see Figures 8-5 thru 8-7). "The actual value of a profile tolerance for a single feature is the value of t_0+2g for the enveloping zone to which the actual surface will conform." This results in the single measured value, equivalent to twice the farthest deviation from the centre of the tolerance zone that PC-DMIS reports.

ASME Y14.5 1994 uses the ASME Y14.5.1M-1994 math standard, which states, "For both unilateral and bilateral profile tolerances two actual values are necessarily calculated: one for surface variations in the positive direction and one for the negative direction. For each direction, the actual value of profile is the smallest intermediate tolerance to which the surface conforms. Note that no single actual value may be calculated for comparison to the tolerance value in the feature control frame, except in the case of unilateral profile tolerances." This means that when you select ASME Y14.5 1994 as your GD&T standard, you no longer get a single measured value, you get the minimum and maximum values instead. The only real difference is the way in which the information is presented, tolerance boundaries and conformance are unaffected. For more information, download the "ProfileReporting_Handout_V2" document from the PC-DMIS Knowledgebase repository.

Validity Rules

All input features (considered and datum) must have the correct specified nominal values and shapes. This ensures that PC-DMIS calculates the measured values correctly, and it ensures that the tolerance command correctly identifies the optimizable degrees of freedom.

Exposed Options

Several types of features expose an ITERATEANDREPIERCE option. These features are points, scans, ellipses, notches, slots, and sets (except for 2D profile vision auto-features and edge point features) when a CAD model is available. When available, PC-DMIS sets the ITERATEANDREPIERCE option to YES by default. It does this to ensure that the center of the tolerance zone is the CAD model surface. When the option is unavailable, or when NO is selected, those feature types create a separate planar tolerance zone for each measured point. The zone is defined by the theoretical point and vector associated with that measured point. This is called the "piecewise planar" approximation, which is excellent in many circumstances. It is poor in these cases:

- If the alignment used to find nominals is significantly different than the optimized datum reference frame

- If the measured data include sharp corners or radii

Due to the sometimes poor behavior of the piecewise-planar approximation, in most cases we recommend that you use a CAD model and keep the ITERATEANDREPIERCE option set to YES. In some circumstances, it makes sense to set this to NO if the computation time is too long. When you set it to NO, it usually improves computation speed, but you are responsible to ensure the piecewise planar approximation is a good approximation.

Lines, circles, and widths do not expose the ITERATEANDREPIERCE option because the geometric tolerance command internally represents the tolerance zones exactly. It is not possible to use the piecewise-planar approximation for those feature types. By contrast, 2D profile vision auto-features, edge point features, and scans made out of edge point features, and "adjust filter" constructed set features do not expose the ITERATEANDREPIERCE options because they always use the piecewise-planar approximation.

When no datums are referenced, the workplane option serves as a datum that defines the plane of the cross section, and defines the optimizable degrees of freedom. It can be set to ZPLUS, ZMINUS, XPLUS, XMINUS, YPLUS, or YMINUS.

When at least one datum feature has surface data, the datum math type controls how to compute the measured datums from the datum features' surface data.

For information, see "How PC-DMIS Solves and Uses Datums".

When there are no datum features, the tolerance zone math type controls how the measured surface points are optimized into their respective tolerance zones:

DEFAULT - This does a minimum-zone best fit (also called min-max). This best-fit finds the smallest tolerance zone that contains the surface points. Thus, the **DEFAULT** option produces the smallest measured value for evaluating profile of a line. It is also mathematically very similar to the specification, because if you measure points densely and with high accuracy, the measured value closely approximates the actual value.

LSQ - This does a least-squares best fit. It minimizes the sum of the squares of the deviations to the center of the zone. This option produces a larger measured value (it is more conservative than the **DEFAULT** option). But in general, this option computes more quickly.

Lower Segments of Composite Profile of a Line

A profile of a line tolerance with multiple segments is called a “composite profile of a line”. The first (or upper) segment of a composite profile of a line tolerance is the same as a single segment profile of a line as described above at the beginning of this topic. All lower segments of a composite profile of a line are subtly different. This is because the tolerance zones have unlocked translation compared to the datum

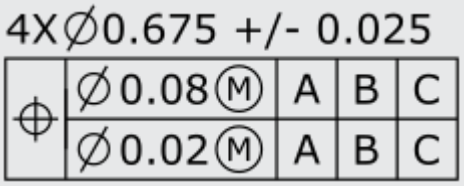
reference frame. However, the tolerance zones remain nominally located and oriented to each other.

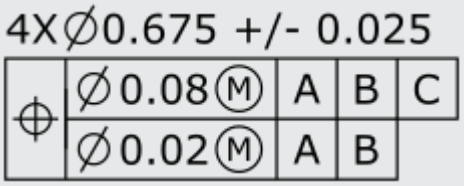
The datum reference frames for the lower segments of a composite profile of a line follow these rules:

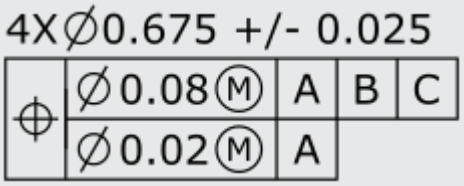
- Each datum reference frame must only use the same datums as the reference frame above it.
- The datums must be in the same order.
- The datums must have the same modifiers.
- A lower segment can have fewer datums than the segment above.

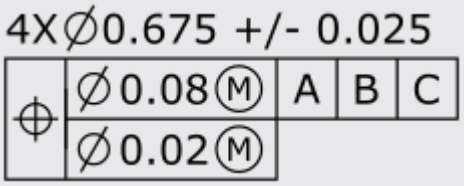
Suppose the upper segment has datums ABC. The lower segment then could reference no datums, datum A, datums AB, or datums ABC. But it could not reference datums BA nor AC nor ABD.

Here are some examples of allowed composite position tolerances:

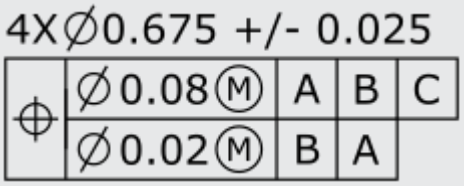


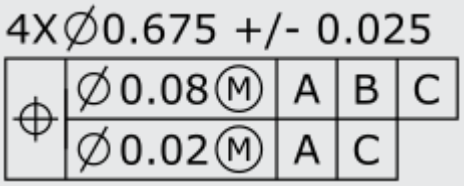


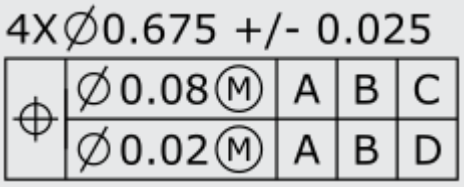




Here are some examples of not-allowed composite position tolerances:

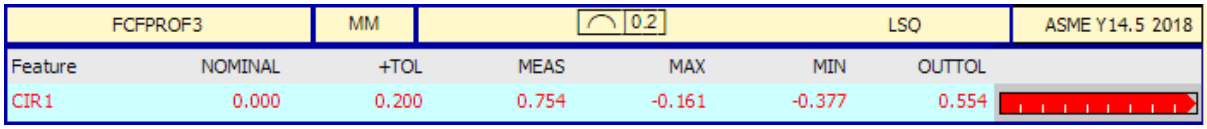






Report

Here is an example report for a profile of a line tolerance of a circle.



FCFPROF3	MM	⌒ 0.2			LSQ	ASME Y14.5 2018
Feature	NOMINAL	+TOL	MEAS	MAX	MIN	OUTTOL
CIR1	0.000	0.200	0.754	-0.161	-0.377	0.554

Profile of a Line Per Unit Tolerances

When the profile of a line tolerance has no datums, a **per unit** check box becomes visible. If you select this check box, profile of a line has two segments. The first (upper) segment is the overall profile of a line as described above. The lower segment is the per-unit profile of a line, which defines a unit length. The per-unit tolerances control the form of every possible unit of the toleranced feature.

Conceptually, the entire surface cross section is divided into an infinite number of overlapping unit lengths.

Actual Value:
Each of the infinite units has its own actual value. For the entire feature, this is the actual value of the worst unit.

Measured Values:
A very large number of overlapping units contain subsets of the measured points. For any given unit, the measured value is the maximum deviation minus the minimum deviation, where the deviations were calculated with the overall profile of a line. The measured value of the entire feature is the measured value of the worst unit.

Report

Here is an example report for a profile of a line per unit tolerance. The upper label is for the overall profile of a line, and the lower label is for the per unit profile of a line.

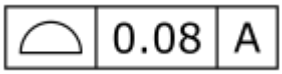
Introduction

A profile of a surface specification controls how much the features' surfaces can deviate from being the nominal shapes, which are located and oriented to zero or more datums.



For this geometric tolerance, these three aspects work together:

- Each considered feature's surface data
- Each considered feature's nominal shape and each resulting tolerance zone
- The datum features (if any are referenced)

To evaluate this tolerance, PC-DMIS optimizes each feature's surface data into its respective tolerance zone. The optimization process respects whatever constraints each datum imposes. With multiple considered features, the optimization process simultaneously considers those features. In this way it fits all the toleranced features into their tolerance zones at once.

Allowed Feature Types

You can use these feature types if they have surface data:

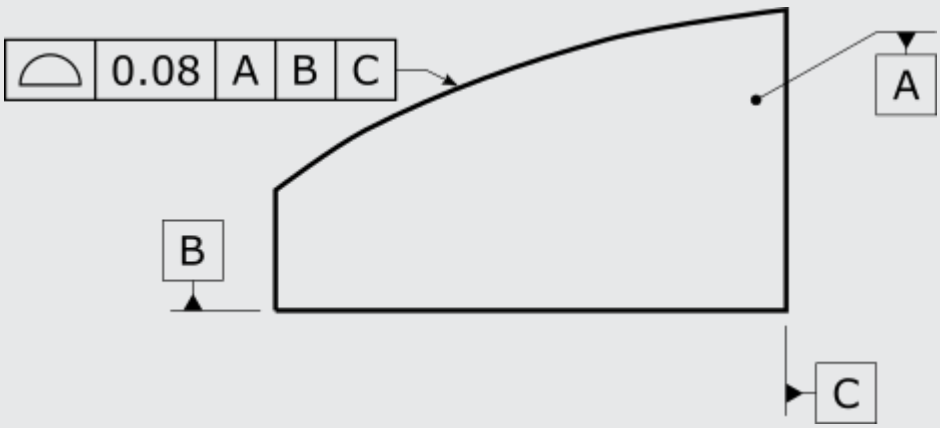
cylinders, spheres, 3D and 1D widths, scans, planes, cones, sets, and tori.

When no datums are referenced, there is no workplane option. Sometimes, the measured data were only measured in a single cross section. This is typically a case where profile of a surface to no datums was specified but the surface is too shallow to measure more than one cross section. In this case, the geometric tolerance command automatically detects the workplane of the cross section. It also uses that workplane as an invisible primary datum to restrict the degrees of freedom to that workplane.

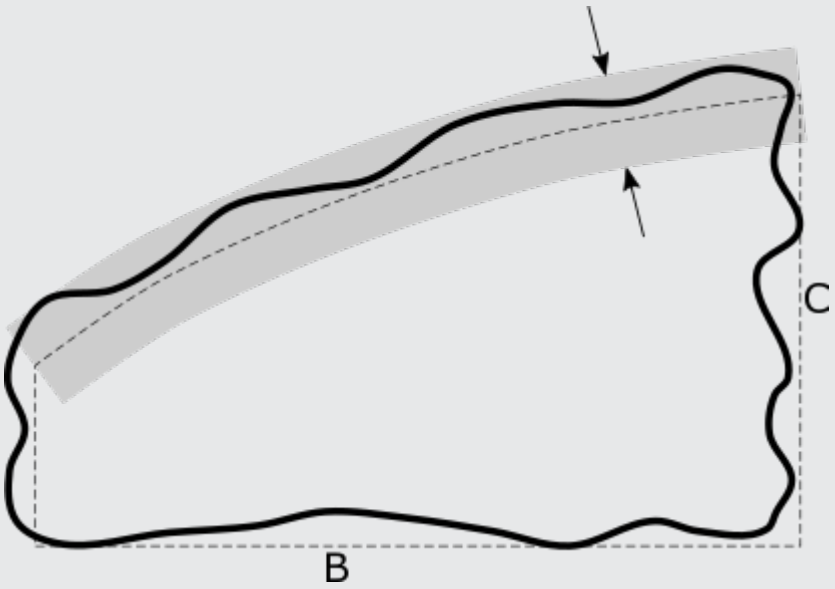
Tolerance Zones and Allowed Modifiers

The tolerance zone is based on the nominal surface of the feature. By default (without any modifiers), the tolerance zone is equal bilateral. This means that half of the tolerance value is on each side of the nominal surface:

Suppose you have this profile of a surface specification:

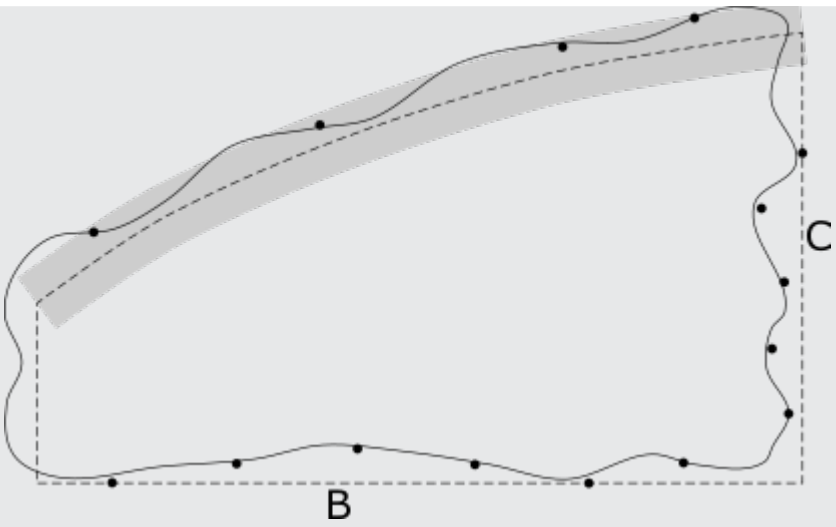


With the above specification, the actual value looks like this:



Since there are no modifiers, the tolerance zone is centered on the nominal surface, which is nominally oriented and located to each actual datum. The solid line indicates the actual surface, the dashed lines represent the nominal surfaces (including the actual datums) and the gray shaded area represents the minimum-size tolerance zone centered on the nominal surface that contains the actual surface.

The measured value (with **DEFAULT** datum math) looks like this:



The measured tolerance zone center remains the nominal surface, which is nominally oriented and located to each measured datum. In this case, the measured points were not measured densely enough, and so the measured value is smaller than the actual value.

Modifiers may change the nature of the tolerance zone. Starting in ASME Y14.5 2009, PC-DMIS supports the Ⓤ modifier (unequally disposed profile) and, starting in ASME Y14.5 2018, PC-DMIS supports the △ modifier (dynamic profile). Under ISO 1101, PC-DMIS supports the UZ modifier (specified tolerance zone offset) and the OZ modifier (unspecified linear tolerance zone offset). While they are not equivalent, the Ⓤ and UZ modifiers have similar functionality. They offset the center of the tolerance zone from the nominal surface. Likewise, the △ and OZ modifiers have similar functionality. They allow the center of the tolerance zone to progress in the plus-material or minus-material direction. These modifiers did not exist in ASME Y14.5 1994 but it did support the concept of an unequally disposed tolerance zone. This was usually specified graphically on the print by dotted lines showing the extent of tolerance into and out of the material. Therefore, when selecting ASME Y14.5 1994 as the GDT standard for your PC-DMIS measurement routine, you must enter both the upper and lower tolerances when creating the feature control frame. PC-DMIS will then report the maximum and minimum deviations which are compared against the corresponding upper and lower tolerance values to assess conformance.

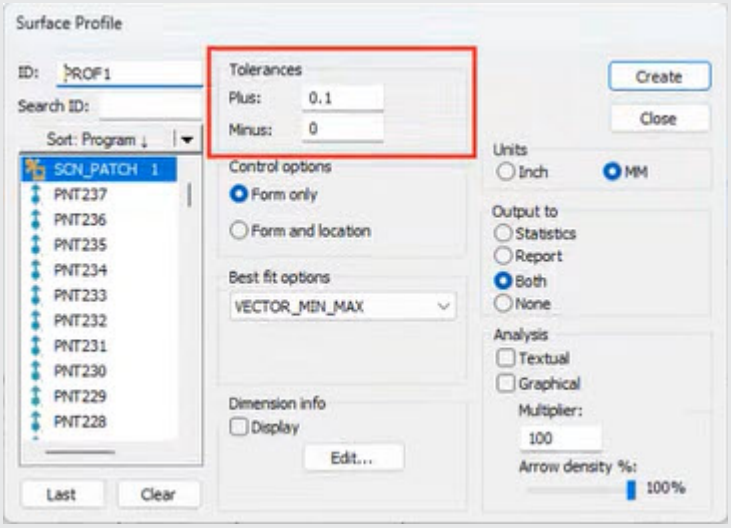
Legacy profile includes a “form only” option which only allows a single, positive tolerance to be entered. To achieve the same behavior using an ASME Y14.5 1994 geometric tolerance profile command, you must divide the total allowable tolerance in half and enter it as equal bilateral values.

The examples below show the differences between the Legacy Surface Profile and the Geometric Tolerance Profile of a Surface commands. Although the examples are for the Surface Profile, the rules are identical for the Line Profile.

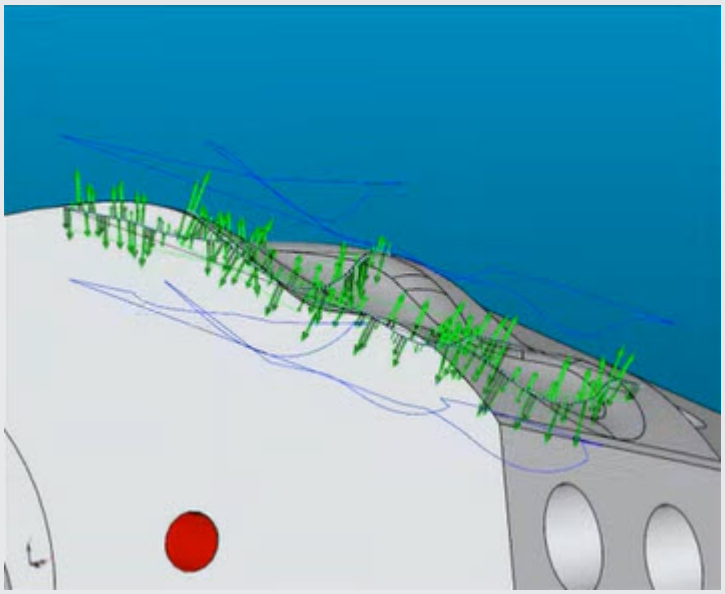
Click on the link below to show examples of the definition, result, and report for a Legacy Surface Profile:

Legacy Surface Profile, Form Only Example

The following example shows a Surface Profile dialog box with a Form only definition:



Example of a legacy Surface Profile dialog box defined for form only with an upper tolerance of 0.1 and a lower tolerance of 0.



Example of the results after the legacy command is executed.

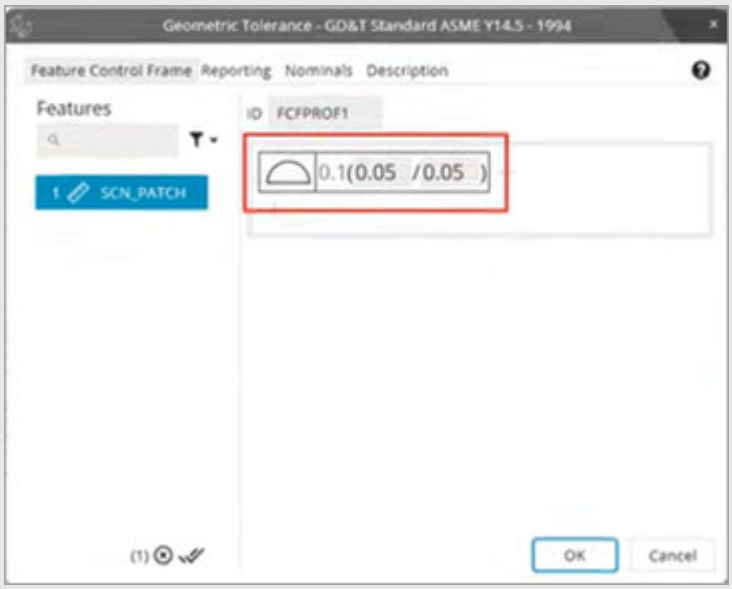
	MM	PROF1 - SCN_PATCH FORMONLY VECTOR_MIN_MAX					
AX	NOMINAL	+TOL	-TOL	MEAS	MAX	MIN	OUTTOL
M	0.000000	0.100000	0.000000	0.071202	0.035601	-0.035601	0.000000

Example of what the legacy version of the report might look like.

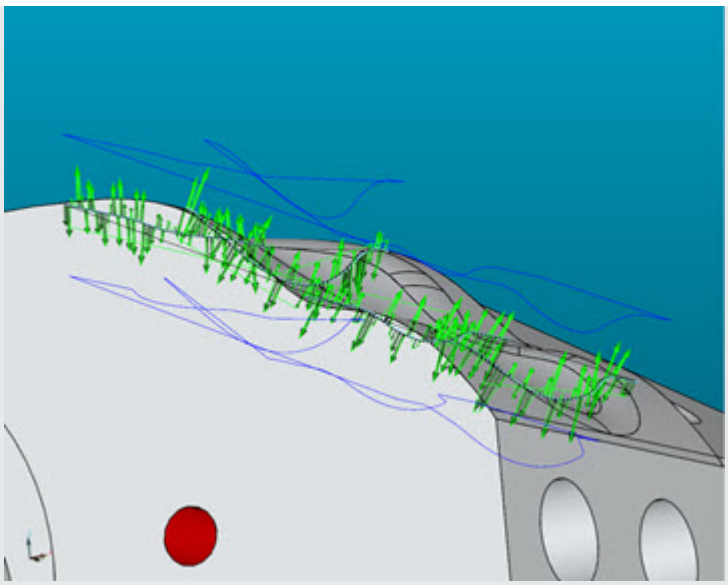
Click on the links below to show correct and incorrect examples of the definitions, results, and reports for a Geometric Tolerance Profile of a Surface:

ASME Y14.5 - 1994 Geometric Tolerance Profile of a Surface Correctly Defined Example

In this example, the Geometric Tolerance Profile of a Surface uses an equivalent upper and lower tolerance value of +/-0.05:



Example of a correctly defined Geometric Tolerance dialog box for a Profile of a Surface using the ASME Y14.5 - 1994 standard.



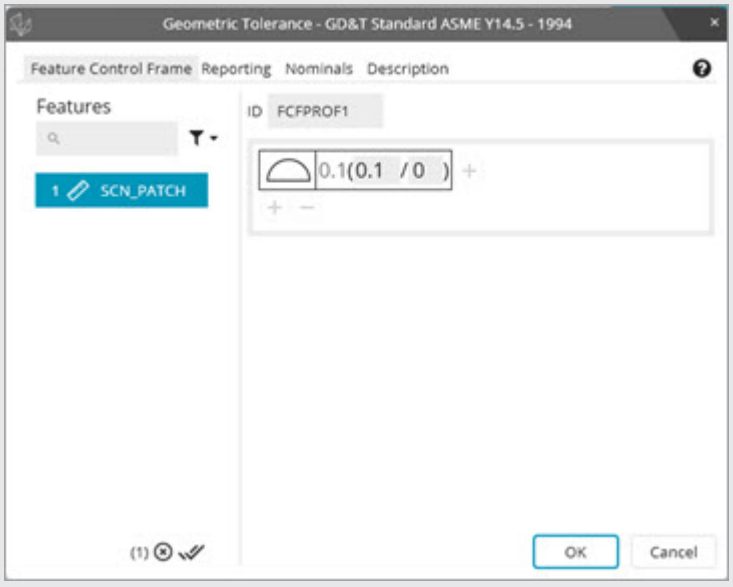
Example of the results after the Geometric Tolerance correctly defined command is executed.

FCFPROF1	MM	0.1	DEFAULT	ASME Y14.5 - 1994				
Feature	NOMINAL	+TOL	-TOL	MEAS	MAX	MIN	OUTTOL	
SCN_PATCH	0.000000	0.050000	0.050000	0.071202	0.035601	-0.035601	0.000000	

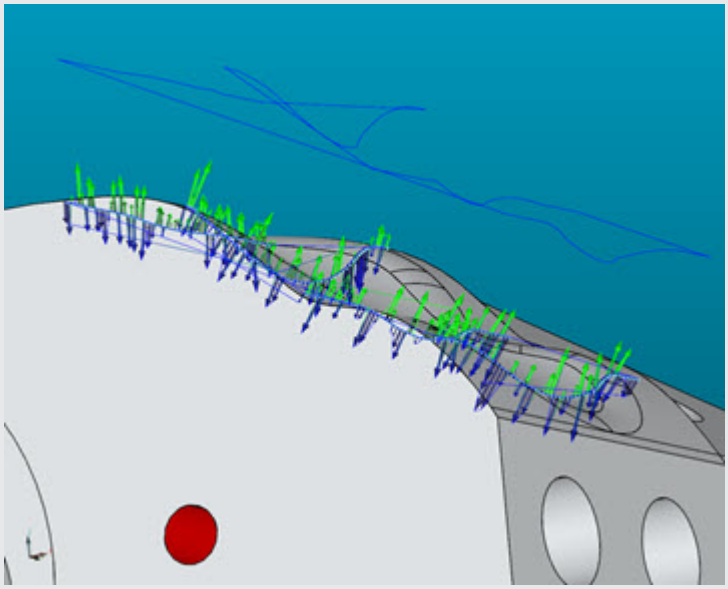
Example of what the Geometric Tolerance version of the report might look like for a correctly defined command.

ASME Y14.5 - 1994 Geometric Tolerance Profile of a Surface Incorrectly Defined Example

In this example, the Geometric Tolerance Profile of a Surface incorrectly uses a single upper tolerance value of 0.1. This results in an unequal tolerance zone causing all negative deviations to be out of tolerance.



Example of an incorrectly defined Geometric Tolerance dialog box for a Profile of a Surface using the ASME Y14.5 - 1994 standard.



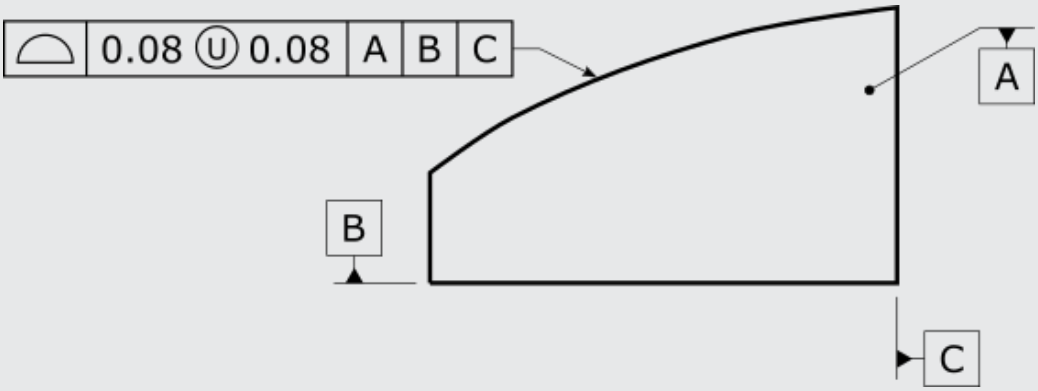
Example of the results after the Geometric Tolerance incorrectly defined command is executed.

FCFPROF1	MM	0.1	DEFAULT	ASME Y14.5 - 1994

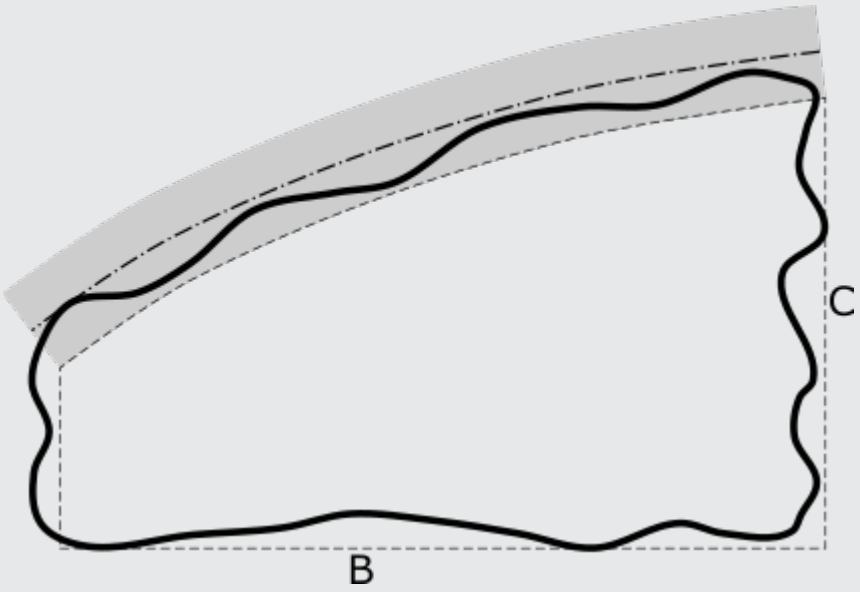
Feature	NOMINAL	+TOL	-TOL	MEAS	MAX	MIN	OUTTOL
SCN_PATCH	0.000000	0.100000	0.000000	0.086446	0.036446	-0.036446	0.000000

Example of what the Geometric Tolerance version of the report might look like for an incorrectly defined command.

Suppose you have the Ⓤ modifier specification shown below. The equivalent ISO specification would be 0.08 UZ+0.04.

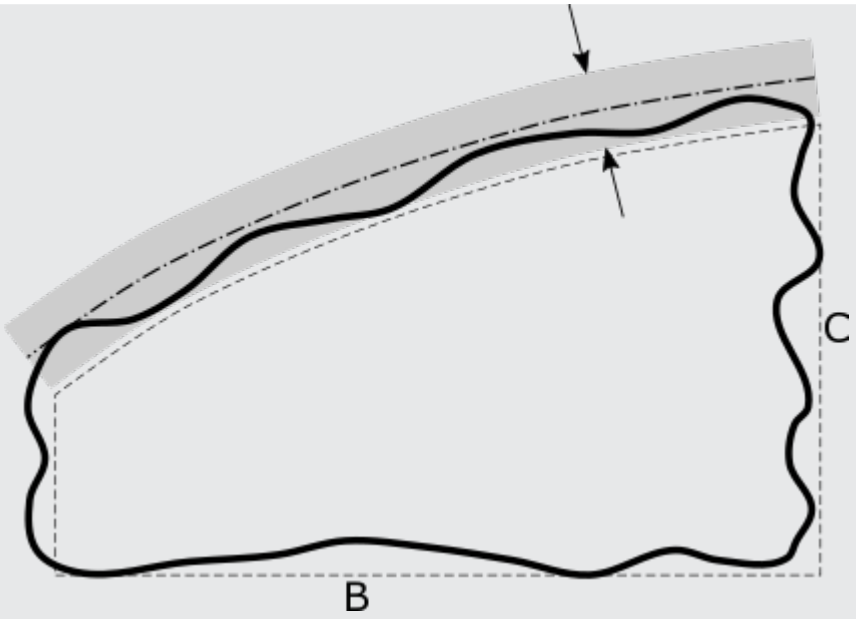


With the above specification, the specified tolerance zone looks like this:



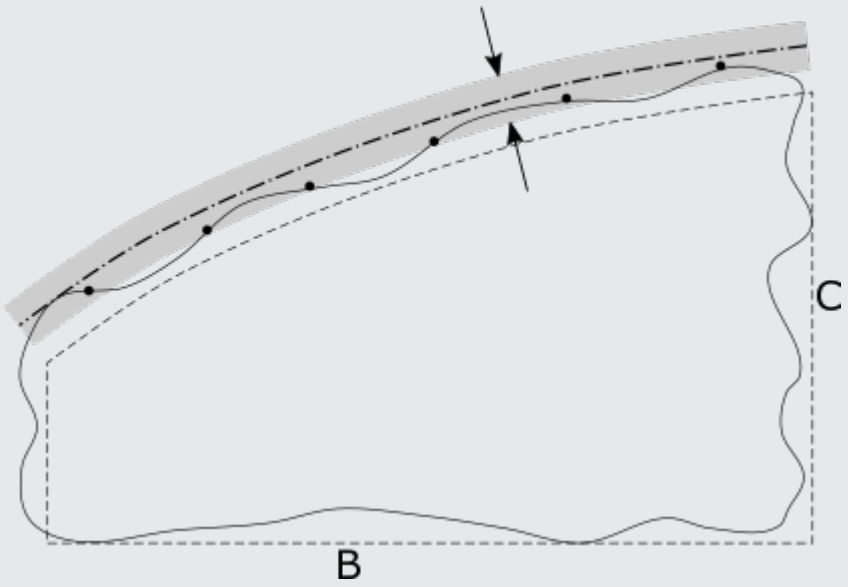
Because this is the specified tolerance zone, the tolerance zone is not minimized, and so it does not represent the actual value. The center of the tolerance zone is offset from the nominal surface and is shown in the dashed-dotted line.

The actual value looks like this:



The center of the tolerance zone stays the same (offset 0.04 from nominal in this case), but the zone is minimized until it just contains the actual surface.

The measured value (with **DEFAULT** datum math) looks like this:



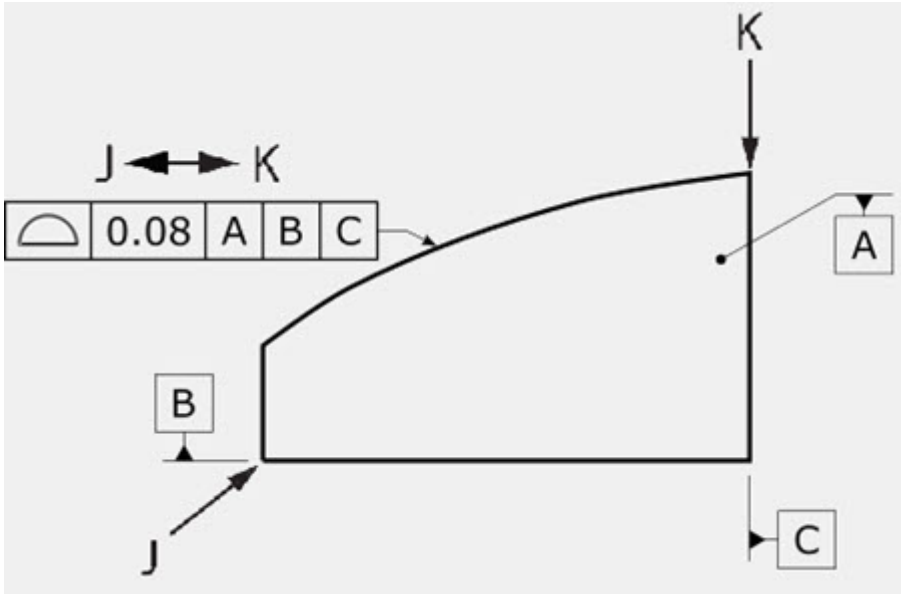
The center of the tolerance zone stays the same (offset 0.04 from nominal in this case) but the zone is minimized around that center until it just contains the measured surface points. In this case, the measured points were not measured densely enough, and so the measured value is smaller than the actual value.

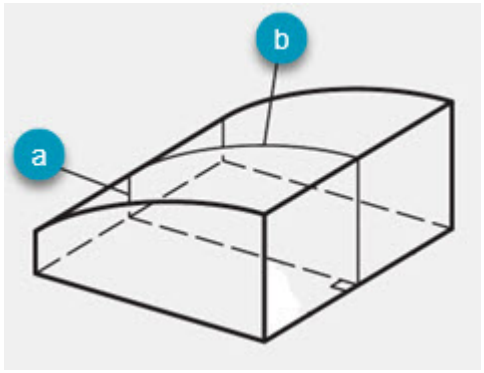
You may find it helpful to remember that the measured value is equivalent to twice the absolute value of the worst deviation, measured from the center of the tolerance zone.

Profile In Between, Profile All Around, and Profile All Over

Profile In Between

The **In Between** symbol ⟷ is used between two uppercase letters to identify the extent of the toleranced surface. The surface consist of all points on the surface from the surface designated by the first letter (start) and ending with the surface designated by the second letter (end). This includes all the segments and areas between these letter-designated areas as shown below.

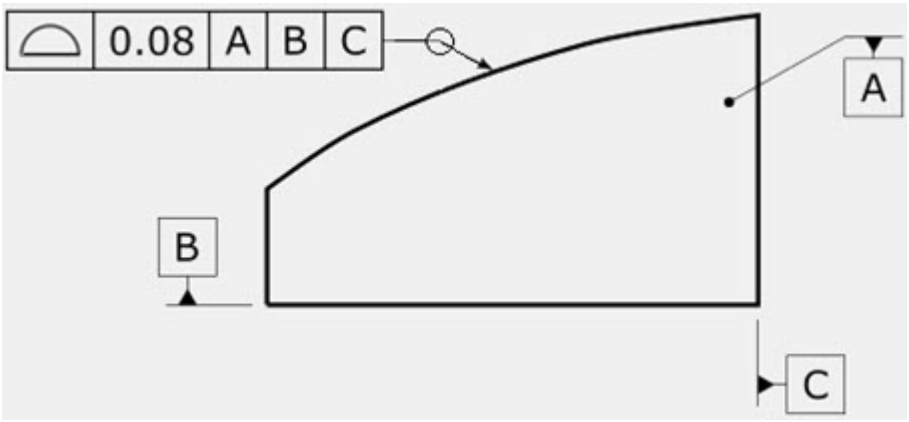


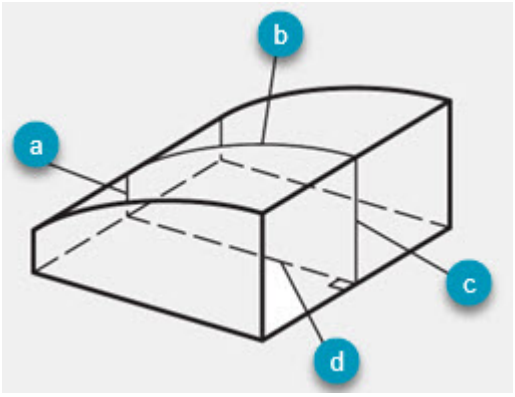


Profile In Between applies only to the surfaces indicated by the collection plane or view orientation, between the designated Start and End points.

Profile All Around

Profile All Around is applied to the outlines of the cross-sections of a part or to all features represented by a closed outline. It is indicated by the **All Around** circle symbol ○ placed on the intersection of the leader line and the reference line of the tolerance indicator as shown below.

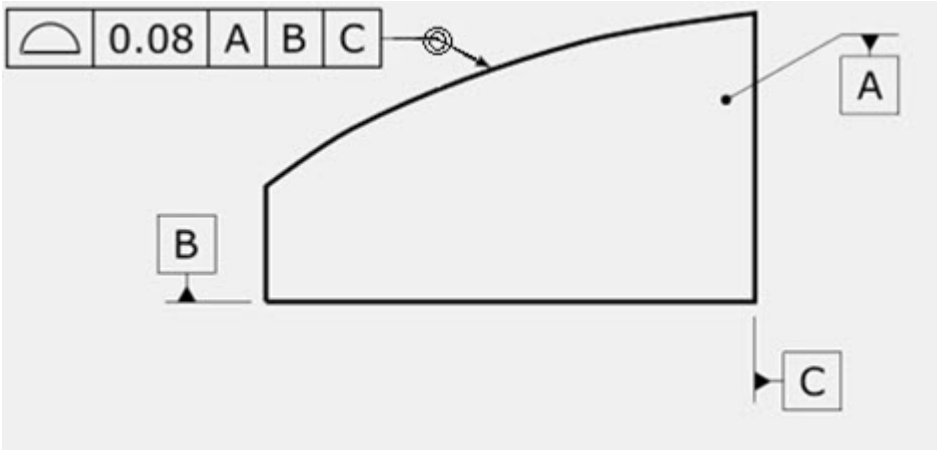


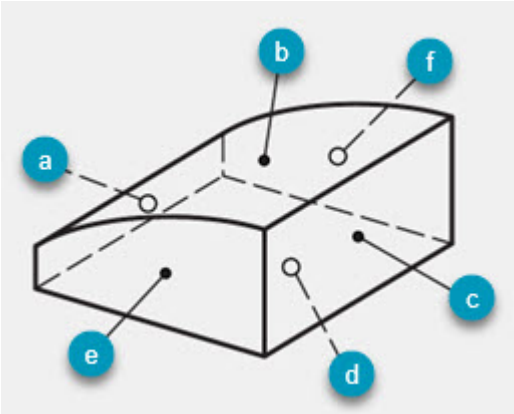


Profile All Around only applies to the surfaces identified by the collection plane or view orientation, not to the entire workpiece.

Profile All Over

Profile All Over is applied to all integral features of a workpiece and is indicated by a two concentric circle symbol ◎ placed on the intersection of the leader line and the reference line of the tolerance indicator as shown below.





Profile All Over applies to all surfaces of the entire workpiece and is three-dimensional.

Summary

There is no way to select a Profile In Between, Profile All Around, or Profile All Over symbol in the feature control frame builder of the Geometric Tolerance command because they are not part of the feature control frame. Instead, to use the Geometric Tolerance command to evaluate Profile In Between, Profile All Around, or Profile All Over, you must employ the correct measurement strategy yourself. You need to measure all the applicable surfaces such that they are treated as a single feature. The easiest way to do this is with a series of Linear Open Scan commands for Profile In Between or a series of Linear Closed Scan commands for Profile All Around or Profile All Over.

Another approach is to create a series of auto features (one for each individual surface). All the scans or auto features that pertain to the surfaces under evaluation must then be combined into a single constructed feature set.

- For Profile In Between, the constructed feature set would represent the entire extent of all surfaces that run from the point indicated by the start letter to the point indicated by the end letter.
- For Profile All Around, the constructed feature set would represent the entire extent of all surfaces that run all around the part or closed outline.
- For Profile All Over, the constructed feature set would represent the entire extent of all outer surfaces of the entire part.

You should use a single profile of a surface command that references the constructed feature set as the considered feature to evaluate any of these requirements.

Actual Value and Measured Value

Profile tolerance zones have a defined center. They also have a mechanism to grow and shrink the zone around that center until it just envelops the actual surface.

Actual Value:
Each considered feature has its own actual value. This is the size of the smallest tolerance zone that contains the actual surface. The zone is nominally oriented and located to each actual datum, with some exceptions detailed in "How PC-DMIS Solves Datums".

If you have more than one considered feature, and the datum reference frame is not fully constrained, the optimization procedure must simultaneously fit all the features' surfaces in their respective tolerance zones, if possible.

Measured Value:
Each considered feature has its own measured value. This is the size of the smallest tolerance zone that contains the measured surface points. The zone is nominally oriented and located to each measured datum, with some exceptions detailed in "How PC-DMIS Solves Datums".

If you have more than one considered feature, and the datum reference frame is not fully constrained, the PC-DMIS optimization procedure simultaneously fits all features' surface points into their respective tolerance zones. It does this in a proportional way. This guarantees that all toleranced features will fit in their respective tolerance zones if possible.

ASME Y14.5-2009 and ASME Y14.5-2018 use the ASME Y14.5.1-2019 math standard which defines how to calculate an "actual value" of a profile tolerance. Section 8.3.1 (Uniform Tolerance Zones) of the Y14.5.1-2019 standard states, “This concept applies in the same way to equally disposed, unequally disposed and unilateral profile specifications" (see Figures 8-5 thru 8-7). "The actual value of a profile tolerance for a single feature is the value of t_0+2g for the enveloping zone to which the actual surface will conform." This results in the single measured value, equivalent to twice the farthest deviation from the centre of the tolerance zone that PC-DMIS reports.

ASME Y14.5 1994 uses the ASME Y14.5.1M-1994 math standard, which states, "For both unilateral and bilateral profile tolerances two actual values are necessarily calculated: one for surface variations in the positive direction and one for the negative direction. For each direction, the actual value of profile is the smallest intermediate tolerance to which the surface conforms. Note that no single actual value may be calculated for comparison to the tolerance value in the feature control frame, except in the case of unilateral profile tolerances." This means that when you select ASME Y14.5 1994 as your GD&T standard, you no longer get a single measured value, you get the minimum and maximum values instead. The only real difference is the way in which the information is presented, tolerance boundaries and conformance are unaffected. For more information, download the "ProfileReporting_Handout_V2" document from the PC-DMIS Knowledgebase repository.

Validity Rules

All input features (considered and datum) must have the correct specified nominal values and shapes. This ensures that PC-DMIS calculates the measured values correctly, and it ensures that the tolerance command correctly identifies the optimizable degrees of freedom.

Exposed Options

Several types of features expose an ITERATEANDREPIERCE option. These are points, scans, sets, and torii (except for 2D profile vision auto-features and edge point features) when a CAD model is available. When available, the option is set to YES by default, because that ensures the center of the tolerance zone is the CAD model surface. When the option is unavailable, or when NO is selected, those feature types create a separate planar tolerance zone for each measured point, defined by theoretical point and vector associated with that measured point. This is called the "piecewise planar" approximation, which is excellent in many circumstances. It is poor in these cases:

- If the alignment used to find nominals is significantly different than the optimized datum reference frame
- If the measured data include sharp corners or radii

Due to the sometimes-poor behavior of the piecewise-planar approximation, in most cases we recommend that you use a CAD model and keep the ITERATEANDREPIERCE option set to YES. In some circumstances, it makes sense to set it to NO if the computation time is too long. When you set it to NO in this way, it usually improves computation speed, but you are responsible to ensure that the piecewise planar approximation is a good approximation.

Cylinders, spheres, widths, planes, and cones do not expose the ITERATEANDREPIERCE option because the geometric tolerance command internally represents the tolerance zones exactly. It is not possible to use the piecewise-planar approximation for those feature types. By contrast, 2D profile vision auto-features, edge point features, scans made out of edge point features, and "adjust filter" constructed set features do not expose the ITERATEANDREPIERCE options because they always use the piecewise-planar approximation.

When at least one datum feature has surface data, the datum math type controls how to compute the measured datums from the datum features' surface data.

For information, see "How PC-DMIS Solves and Uses Datums".

When there are no datum features, the tolerance zone math type controls how the measured surface points are optimized into their respective tolerance zones:

DEFAULT - This does a minimum-zone best fit (also called min-max). This best-fit finds the smallest tolerance zone that contains the surface points. Thus, the **DEFAULT** option produces the smallest measured value for evaluating profile of a

surface. It is also mathematically very similar to the specification, because if you measure points densely and with high accuracy, the measured value closely approximates the actual value.

LSQ - This does a least-squares best fit. It minimizes the sum of the squares of the deviations to the center of the zone. This option produces a larger measured value (it is more conservative than the **DEFAULT** option). But in general, this option computes more quickly.

Lower Segments of Composite Profile of a Surface

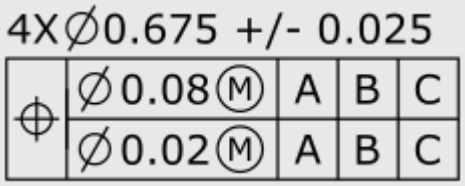
A profile of a surface tolerance with multiple segments is called a “composite profile of a surface”. The first (or upper) segment of a composite profile of a surface tolerance is the same as a single segment profile of a surface as described above at the beginning of this topic. All lower segments of a composite profile of a surface are subtly different. This is because the tolerance zones have unlocked translation compared to the datum reference frame. However, the tolerance zones remain nominally located and oriented to each other.

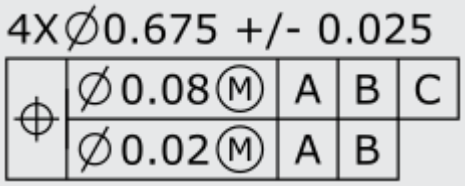
The datum reference frames for the lower segments of a composite profile of a surface follow these rules:

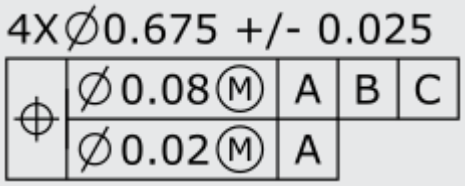
- Each datum reference frame must only use the same datums as the reference frame above it.
- The datums must be in the same order.
- The datums must have the same modifiers.
- A lower segment can have fewer datums than the segment above.

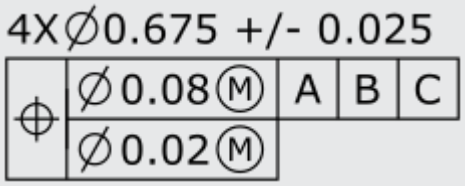
Suppose the upper segment has datums ABC. The lower segment then could reference no datums, datum A, datums AB, or datums ABC. But it could not reference datums BA nor AC nor ABD.

Here are some examples of allowed composite position tolerances:









Here are some examples of not-allowed composite position tolerances:

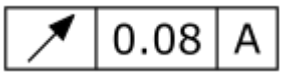
Introduction

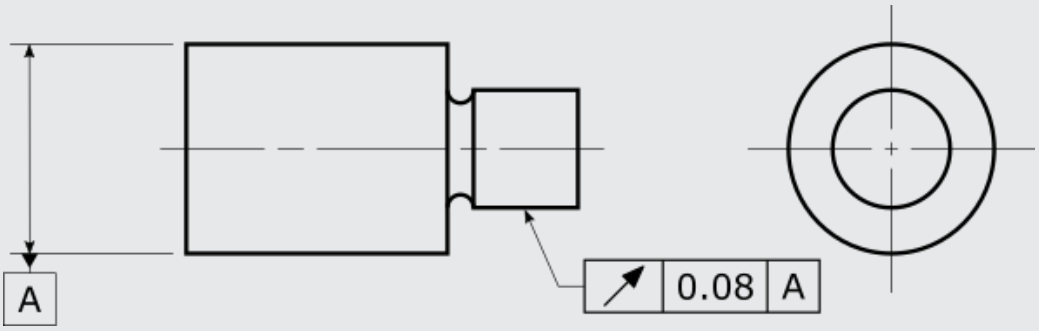
A circular runout specification controls how much the feature's surface cross sections can deviate from being perfect circles centered on some datum axis.



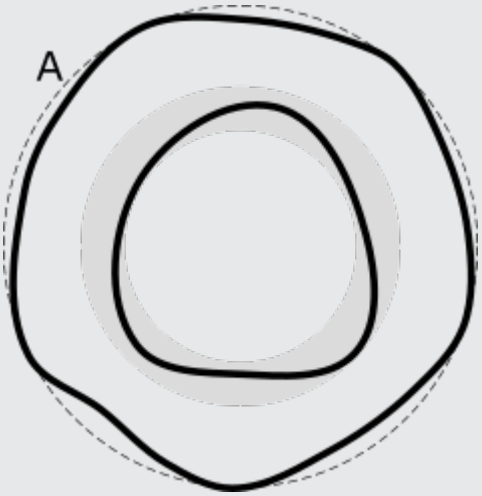
Actual Value:
For a cross section, this is the minimum distance between two circles. These circles are centered on and oriented perpendicular to the datum axis. They contain the entire cross section between them.

For a whole feature, this is the worst actual value of all the cross sections.

Suppose you had this circular runout specification:

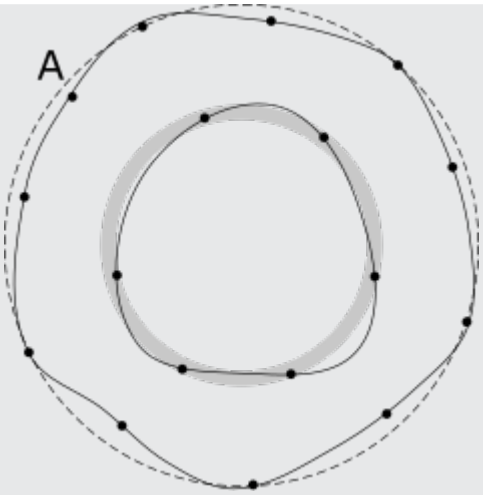


With the above specification, the actual value for one of the cross sections looks like this:



The actual part surface uses the solid line, the actual datum uses the dashed line, and the smallest tolerance zone containing the cross section's surface is shown in the shaded area. The tolerance zone is exactly coaxial to the actual datum axis. The actual value for the whole feature is the worst actual value of all the cross sections.

Finally, the measured value (with DEFAULT datum math) for one of the cross sections looks like this:



The measured tolerance zone is exactly coaxial to the measured datum axis. In this case, the measured points were not measured densely enough, and so the measured value is smaller than the actual value. The measured value for the whole feature would be the worst measured value of all the cross sections.

Allowed Feature Types

You can use circular, cylindrical, conical, or planar features that have surface data. For details on the circles, cylinders, cones, and planes that have surface data, refer to "Feature Types With and Without Surface Data". These features must be nominally concentric with the datum axis.

Circular Features

This geometric tolerance interprets circular features as a single cross section.

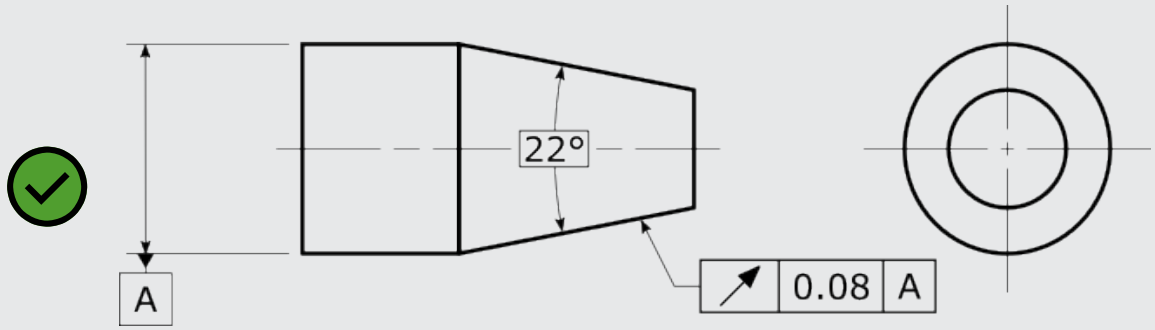
Measured Value:
This is the distance between two circles. The circles contain all the measured points between them. The circles are centered on and perpendicular to the datum axis.

Usually, the two circles are coplanar. This means the surface has zero conical angle. However, the "cone half angle" option in the command lets you specify a conical surface. In that case, PC-DMIS angles the two circles so that the tolerance zone is perpendicular to the nominal surface. The cone half angle represents the angle of the nominal surface, not the tolerance zone.

- For outer circles, positive angles mean the circle vector points towards the cone vertex, and negative angles mean the circle vector points away from the cone vertex.
- For inner circles, positive angles mean the circle vector points away from the cone vertex, and negative angles mean the circle vector points towards the cone vertex.

These inner and outer conventions were chosen to represent typical defaults. Most of the time, outer circle vectors point toward the cone vertex—the positive angle case. Also, most of the time, inner circle vectors point away from the cone vertex—the positive angle case.

Suppose you have the following specification, and you decide to measure the cone as a series of circles (even though we recommend using a cone feature):



In that case, the circles are outer circles, which means if the circle's vector points to the right (towards the cone vertex), the cone half angle should be set to +11°. If the circle's vector points to the left (away from the cone vertex), the cone half angle should be set to -11°.

Cylindrical Features

This geometric tolerance divides up the data from a cylindrical feature into multiple cross sections. The tolerance evaluates the runout on each cross section. To maximize your chances of finding the worst actual cross section, we recommend that you measure the cylinder with many cross sections.

Measured Value:
Across the entire feature, this is the measured value of the worst cross section. If you didn't measure the measured data in cross sections, PC-DMIS gives you an error.

Conical Features

This geometric tolerance divides up the data from a conical feature into multiple cross sections. The tolerance evaluates the runout on each cross section. It orients each tolerance zone perpendicular to the nominal surface. To maximize your chances of finding the worst actual cross section, we recommend that you measure the cone with many cross sections.

Measured Value:
Across the entire feature, this is the measured value of the worst cross section. If you didn't measure the measured data in cross sections, PC-DMIS gives you an error.

Planar Features

This geometric tolerance divides up the data from a planar feature into one or more circular sections around the datum axis. The tolerance orients each tolerance zone perpendicular to the nominal surface. To maximize your chances of finding the worst actual circular section, we recommend that you measure the plane with many circular sections.

Measured Value:
Across the entire feature, this is the measured value of the worst circular section. If you didn't measure the measured data in circular sections that surround the datum axis, PC-DMIS gives you an error.

Validity Rules

The datum reference frame must establish a clear datum axis.

Allowed Modifiers

None. This geometric tolerance does not allow modifiers.

Exposed Options

For circular features, the "cone half angle" option allows the circle to represent a cross section of a conical surface, instead of a cylindrical surface. This adjusts the orientation of the tolerance zone. Both positive and negative cone half angles make sense, which allows you to control whether the nominal cone opening direction is parallel or antiparallel to the nominal circle's vector.

For inner circles with positive cone half angles, the circle vector points from smaller cone diameters to larger cone diameters. Negative cone half angles are the reverse. This convention was chosen because it makes positive angles be the most common case for most users.

For outer circles with positive cone half angles, the circle vector points from larger cone diameters to smaller cone diameters. Negative cone half angles are the reverse. This convention was chosen because it makes positive angles be the most common case for most users.

When at least one datum feature has surface data, the datum math type controls how to compute the measured datums from the datum features' surface data. For more information, see "How PC-DMIS Solves and Uses Datums".

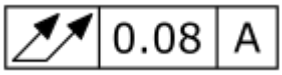
Introduction

A total runout specification controls how much the feature can deviate from having perfect form centered on some datum axis.



Allowed Feature Types

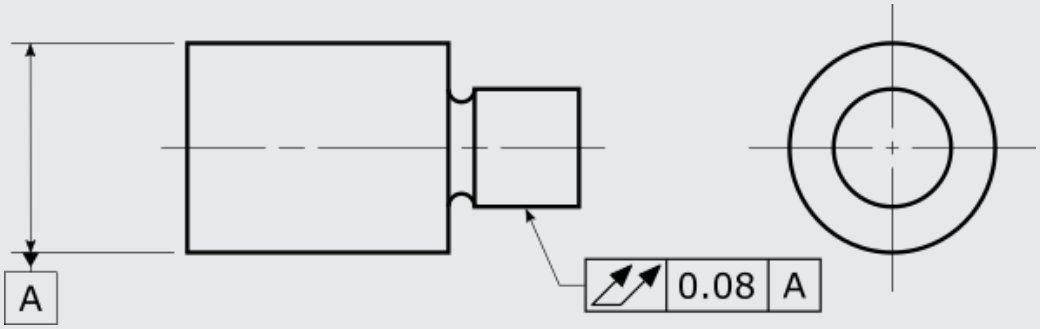
You can use cylindrical, conical, or planar features that have surface data. For details on the cylinders, cones, and planes that have surface data, refer to "Feature Types With and Without Surface Data". They must be nominally concentric with the datum axis.

Cylindrical Features

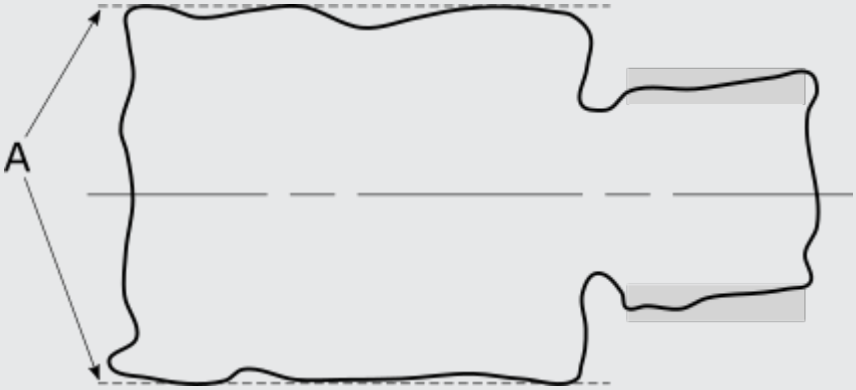
Actual Value:
This is the minimum distance between two concentric cylinders that contain the actual surface between them. The cylinders are concentric with the actual datum axis.

Measured Value:
This is the minimum distance between two concentric cylinders that contain all the measured points between them. The cylinders are concentric with the measured datum axis.

Suppose you had this total runout specification:

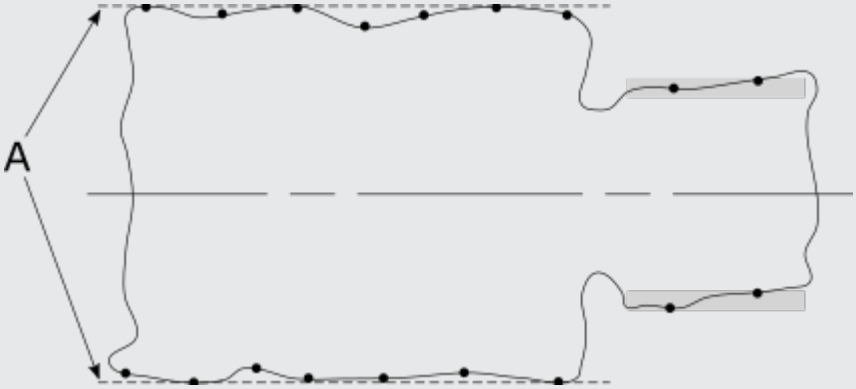


With the above specification, the actual value look like this:



The actual part surface uses the solid line, the actual datum uses the dashed line, and the smallest tolerance zone containing the actual feature surface is shown in the shaded area. The tolerance zone is exactly coaxial to the actual datum axis.

Finally, the measured value (with **DEFAULT** datum math) looks like this:



The measured tolerance zone is exactly coaxial to the measured datum axis. In this case, the measured points were not measured densely enough, and so the measured value is smaller than the actual value.

Conical Features

Actual Value:
This is the minimum distance between two concentric cones that contain the entire actual surface between them. The cones are concentric with the actual datum axis. They also have the same cone angle as the nominal cone surface.

Measured Value:
This is the minimum distance between two concentric cones that contain all the measured points between them. The cones are concentric with the measured datum axis. They also have the same cone angle as the nominal cone surface.

Planar Features

Actual Value:
This is the minimum distance between two parallel planes that contain the entire actual surface between them. The planes are perpendicular to the actual datum axis.

Measured Value:
This is the minimum distance between two parallel planes that contain all the measured points between them. The planes are perpendicular to the measured datum axis.

Validity Rules

The datum reference frame must establish a clear datum axis.

Allowed Modifiers

None. This geometric tolerance does not allow modifiers.

Exposed Options

When at least one datum feature has surface data, the datum math type controls how to compute the measured datums from the datum features' surface data. For more information, see "How PC-DMIS Solves and Uses Datums".

Introduction

Many geometric tolerances reference one or more datums. Datums serve to align the actual surfaces with the nominal geometry so that position, perpendicularity, runout, and other tolerances, can be evaluated with respect to those datums.

First, PC-DMIS best-fits all of the actual primary datum surfaces to their respective datum simulators.

Second, PC-DMIS best-fits the actual secondary datum surfaces to their datum simulators while preserving the relationship (interaction) between the actual primary datum surfaces and their datum simulators.

Third, PC-DMIS best-fits the actual tertiary datum surfaces to their datum simulators, while preserving the relationship (interaction) between the actual primary and secondary datum surfaces and their datum simulators.

Finally, all toleranced features are optimized into their tolerance zones, preserving the relationship (interaction) between the datum surfaces and their simulators.

This process is much like using a functional gage:

First, the part is brought to the gage and the actual primary datum surface is aligned to the gage's primary datum simulator.

Second, the actual secondary datum surface is aligned to the gage's secondary datum simulator, keeping the actual primary datum surface aligned to the gage's primary datum simulator.

Third, the actual tertiary datum surface is aligned to the gage's tertiary datum simulator, keeping the actual primary and secondary datum surfaces aligned.

Finally, the considered features are evaluated, using gage pins or something similar.

Terminology Note: There are several phrases used in the GDT standards to describe the concept of a datum simulator:

- ASME Y14.5 - 1994 and 2009 uses "datum simulator".
- ASME Y14.5 - 2018 uses "true geometric counterpart".
- ISO 5459 uses "associated datum feature".

These phrases are approximately equivalent. This document uses the phrase "datum simulator" for brevity.

There are two ways to think about the datum reference frame process, which are equivalent to each other.

The gage point of view.

The actual part can be aligned to the nominal geometry as described above. The nominal geometry (or gage) is fixed and the actual part is aligned to it.

The part point of view

The actual part is fixed and the nominal geometry (or gage) is aligned to it. Under the part point of view, PC-DMIS best-fits the datum simulators to the actual part. You can use either point of view to describe how geometric tolerances and datums are solved in PC-DMIS.

The remainder of this topic uses the part point of view to describe how PC-DMIS solves datums.

The ASME Y14.5.1 2019 math standard introduced the first mathematical definition for datums. Prior to this, ASME Y14.5.1M 1994 used the "candidate datum set" concept. The geometric tolerance command's DEFAULT Datum Math always yields a valid candidate datum. Therefore, the PC-DMIS behavior described in this section is the same for all versions of ASME Y14.5 (1994, 2009, and 2018).

Comparison to Past Practice

Prior to PC-DMIS 2020 R2, with the XactMeasure command, datum reference frames were handled rather like a PC-DMIS alignment, with a level feature, a rotate feature, and one or more origin features. All of these features you selected from the datum features. Starting with version 2020 R2, the geometric tolerance command does not use any alignment concepts for datum reference frames. Instead, it uses gage concepts for the datum reference frames. This enables support for more unusual datum reference frames that cannot be represented by the level-rotate-origin framework.

Degrees of Freedom Constrained by a Datum Reference Frame

A geometric tolerance without any datum references has no degrees of freedom constrained: all three degrees of translation and all three degrees of orientation are free. Each successive datum constrains more degrees of freedom. Specifically, after a datum has been solved, any translations and rotations are not allowed to alter the datum simulator. For example, after a primary datum plane is solved, the secondary and tertiary datums are not allowed to move the primary datum plane. That means translations within the primary datum plane are allowed, and rotations within the primary datum plane are allowed, but rotation or translation out of plane are not allowed.

These constraints are mathematically defined in terms of invariance classes. Each invariance class is defined below, with some examples of datums exhibiting the invariance class. The examples are not exhaustive: many more examples exist that are not listed.

- **Spherical invariance:** the spherical invariance class constrains three translation degrees of freedom and leaves unconstrained all 3 rotations about a center-point. This includes both spherical features and surfaceless 3D points.
- **Planar invariance:** the planar invariance class constrains rotation about two directions orthogonal to the surface normal, and translation along the surface normal. It leaves unconstrained the rotation about the surface normal and translation along the two directions orthogonal to the surface normal. This includes planes, plane cross sections (lines on a surface) referenced as a secondary or tertiary datum, plane samples (points on a surface), and all width types.
- **Cylindrical invariance:** the cylindrical invariance class constrains rotation about the two directions orthogonal to the axis vector, and translation along the two directions orthogonal to the axis vector. It leaves unconstrained the rotation about the axis, and translation along the axis. This includes cylinders, circles referenced as a secondary or tertiary datum, surfaceless axes, and conical surfaces which are treated as axis-only (see the subtopics on cones below).
- **Revolute invariance:** the revolute invariance class constrains rotation about the two directions orthogonal to the axis vector, and all three translation degrees of freedom. It leaves unconstrained the rotation about the axis. This includes circles referenced

as a primary datum (see "Datum Cylinder Cross Sections" below) and patterns of two non-concentric spheres.

- **Prismatic invariance:** the prismatic invariance class constrains all three orientation degrees of freedom, and translation along two directions orthogonal to the translation vector. It leaves unconstrained translation along the translation vector. This includes plane cross sections (lines on a surface) referenced as a primary datum (see "Datum Plane Cross-Sections" below) and patterns of parallel non-coaxial cylinders.
- **Complex invariance:** the complex invariance class constrains all degrees of freedom. This includes patterns of non-parallel cylinders and patterns of three non-coaxial spheres. Datum reference frames with complex invariance are often called fully-constrained datum reference frames.

When more than one datum is referenced, the invariance class of each datum must be combined so that none of the datum simulators are allowed to move.

Example 1: A primary datum plane combined with a secondary datum circle in that plane yields a revolute invariance class. The primary datum plane constrains three degrees of freedom, and the secondary datum circle constrains two more degrees of freedom (translation in the plane).

Example 2: A primary datum plane, a secondary datum line on a surface, and a tertiary datum point on a surface yields a complex invariance class. The primary datum constrains three degrees of freedom yielding a planar invariance class. Adding the secondary datum constrains two more degrees of freedom, yielding a prismatic invariance class. Adding the tertiary datum constrains the remaining translation degree of freedom, yielding a complex invariance class.

Example 3: A primary datum sphere combined with a secondary datum sphere (not concentric with the primary) has a revolute invariance class. The primary datum sphere constrains three degrees of translation, and the secondary datum sphere constrains two degrees of orientation. The line between the two spheres is the axis of the revolute invariance class.

Comparison to Past Practice

Starting in PC-DMIS 2020 R2, the geometric tolerance command analyzes the datum reference frame in terms of invariance classes. This enables correct handling of unusual datum reference frames where the vectors are not square to each other. For example, a primary datum plane with a secondary datum plane at a 30-degree angle to the primary has a prismatic invariance class. Prior to this version, PC-DMIS did not fully support these unusual datum reference frames.

Datum Math Types under ASME Y14.5

As discussed in "Specification Versus Verification" in "Introduction to Geometric Tolerances and Feature Control Frames", we offer multiple math types for datum computation. PC-DMIS provides two ways to compute an ASME measured datum simulator using measured surface data. These are the two datum math types available:

DEFAULT - This does a void filtration (planar surfaces only) and a constrained least squares best fit. This algorithm is extremely similar to the actual simulator definition and so it is a good choice when the measurement uncertainty of each point is much less than the form error of the surface.

LSQ - This does a plain least squares best fit to the surface data. No void filtering is done. This algorithm is mathematically rather different than the actual simulator definition, but it is a better choice than **DEFAULT** when the measurement uncertainty of each point is much larger than the form error of the surface and much larger than the orientation error of the surface to higher precedence datums.

In between the two extremes, where the measurement uncertainty of each point is at least on the same order of magnitude as the form error, and at most on the order of magnitude as the orientation error, it can be difficult to predict which math type will yield a closer measured approximation to the actual datum simulator. The only way to be sure which type is the better choice is to do a careful study:

First, use a collection of manufactured parts that represent the range of manufacturing errors to control.

Second, measure the parts densely, using lots of cross sections. Use high-end equipment with much lower measurement uncertainty of each point than the form error. Compute the datums with the **DEFAULT** datum math type described above.

Finally, measure the parts with the actual equipment and measurement strategies used in production.

You can experiment with the two math types to see which one is closer to the high-accuracy result.

For any datum math option, we recommend that you measure the datum surface densely to maximize how well the measured datum simulator approximates the actual datum simulator.

Datum Math Types under ISO 1101

As discussed in the "Specification Versus Verification" subtopic in "Introduction to Geometric Tolerances and Feature Control Frames", we offer multiple math types for datum computation. PC-DMIS provides three ways to compute an ISO measured datum simulator using measured data. These are the three datum math options available:

DEFAULT - This does a void filtration (all surface types) and a constrained min max, maximum inscribed, or minimum circumscribed best fit (depending on feature type, whether the surface is inner or outer, and the material modifier). This algorithm is extremely similar to the actual simulator definition, and so it is a good choice when the measurement uncertainty of each point is much less than the form error of the surface.

LSQ - This does a plain least squares best fit to the surface data. No void filtering is done. This algorithm is mathematically rather different than the actual simulator definition, but it is a better choice than **DEFAULT** when the measurement uncertainty of each point is much larger than the form error of the surface and much larger than the orientation error of the surface to higher precedence datums.

In between the two extremes, where the measurement uncertainty of each point is at least on the same order of magnitude as the form error, and at most on the order of magnitude as the orientation error, it can be difficult to predict which math type will yield a closer measured approximation to the actual datum simulator. The only way to be sure which type is the better choice is to do a careful study:

First, use a collection of manufactured parts that represent the range of manufacturing errors to control.

Second, measure the parts densely, using lots of cross sections. Use high-end equipment with much lower measurement uncertainty of each point than the form error. Compute the datums with the **DEFAULT** datum math type described above.

Finally, measure the parts with the actual equipment and measurement strategies used in production.

You can experiment with the two math types to see which one is closer to the high-accuracy result.

CL2 - This does a void filtration (all surface types) and a constrained least squares best fit. Like the **DEFAULT** datum math option, this option requires the measurement uncertainty of each surface point to be much less than the form error of the surface. This option deviates from ISO 5459 - 2011; reasons for doing so might include:

- Stability: The constrained least squares algorithm gives a more stable result than constrained min max, maximum inscribed, or minimum circumscribed best fits.
- Comparison to physical inspection methods: The constrained least squares algorithm is a closer approximation to a surface plate than constrained min max.
- Comparison to assembly: The constrained least squares algorithm is a closer approximation to the assembled state than constrained min max.

- Support future standards: The past several unpublished drafts of ISO 5459 have specified constrained least squares as the default, and so it seems likely the next edition of ISO 5459 will do the same.

For any datum math option, we recommend that you measure the datum surface densely to maximize how well the measured datum simulator approximates the actual datum simulator.

Modifiers for Datums

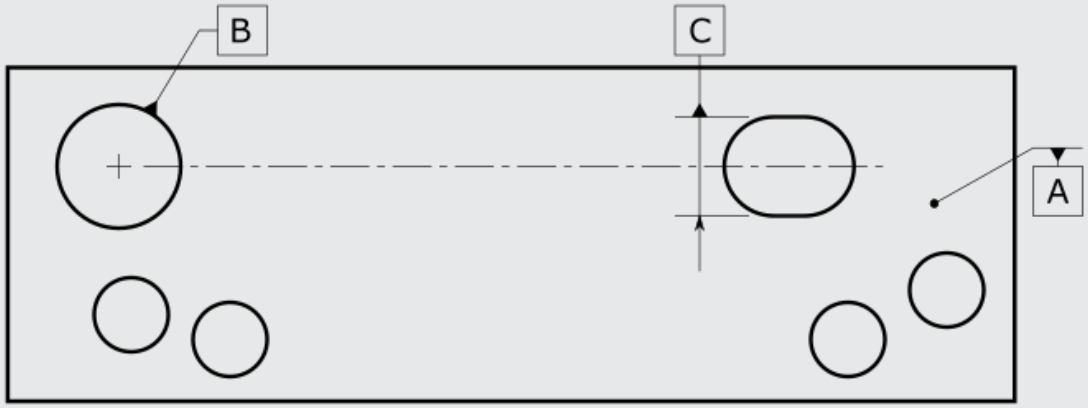
Datums can have several types of modifiers. The most common types are the material modifiers Ⓜ and Ⓛ. These modifiers are described in "Datums with a Material Modifier". When you mark the **Advanced Modifiers** check box, additional modifiers become accessible, including the translation modifier for ASME and the [DF] modifier for ISO.

The [DF] Modifier

The [DF] modifier is not standardized. This means it is not in any published ISO standard. The modifier has been introduced in some unpublished drafts of ISO 5459. In those drafts, [DF] stands for "Distance Fixed". This means the datum location is constrained to any higher-precedence datum or datums, overriding the default variable distance. Even though this modifier is not part of the standard, we found that this modifier is necessary to support several ISO functional requirements, especially plane-circle-width datum reference frames (and width variations like slots and mid-lines).

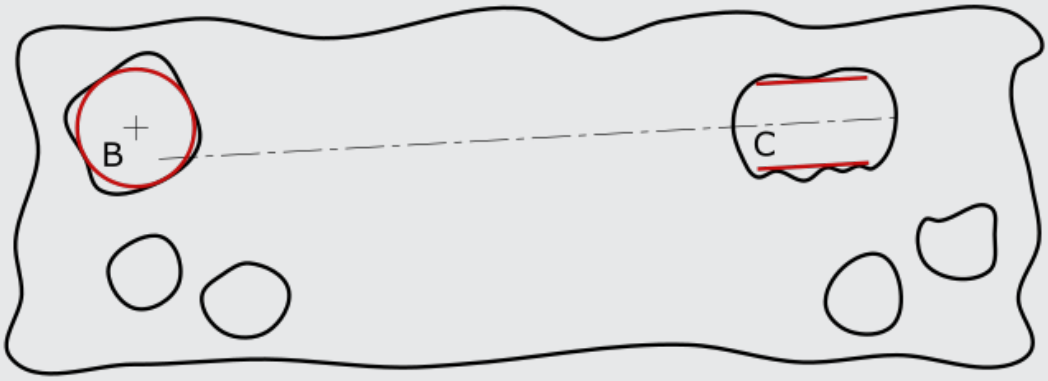
- Without the modifier, the orientation of the slot fully controls the in-plane rotation angle. This gives unstable, non-functional results (especially when the slot is short).
- With the modifier, the actual angle from the circle to the slot controls the in-plane rotation angle. This is the functional intent.

Suppose you have the following ISO specification, where the primary datum is A, the secondary datum is B, and the tertiary datum is C:



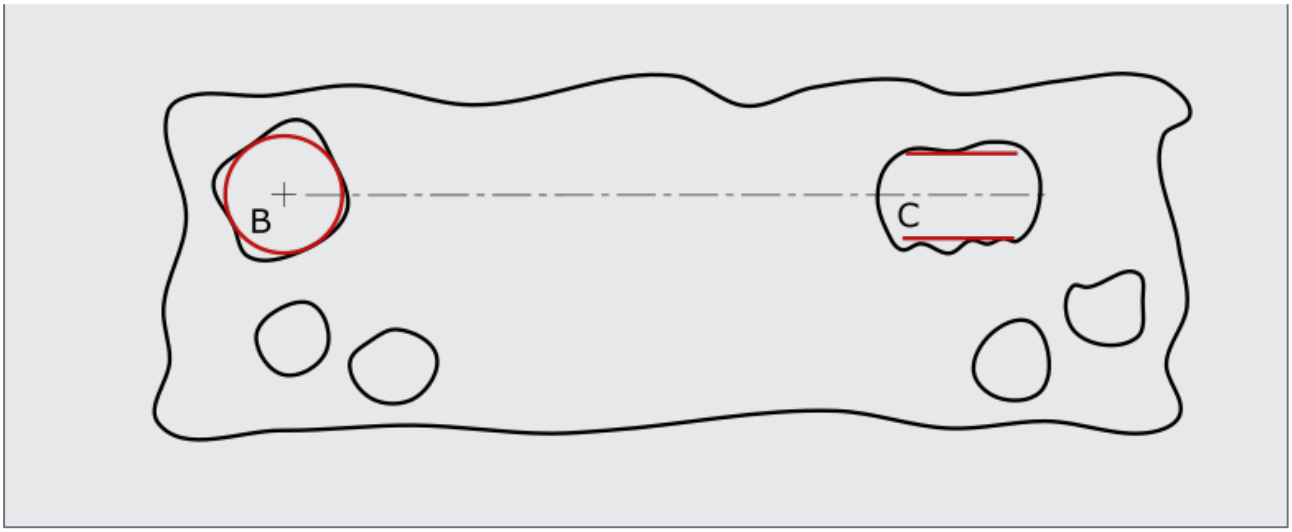
With No Modifiers

Of course, the real part has location, orientation, and form errors on the real surface. With no modifiers, the datum reference frame looks like the image below. The in-plane rotation angle comes completely from the orientation of datum C. Often, this makes the in-plane rotation angle unstable. This is because small variations in C lead to large changes in the in-plane rotation angle:



With the [DF] Modifier

For this datum reference frame, usually datum C needs a [DF] modifier. The modifier constrains the datums' relative location. This constraint makes datum C coplanar with datum B. This matches the typical functional intent and makes the datum reference frame more stable:



Datum Planes with Surface Data under ASME Y14.5

For planes, the actual datum plane simulator is defined by ASME Y14.5.1 - 2019. The actual surface is filtered to remove dents and other voids, and then a perfect plane is fitted to the filtered surface using constrained least squares. This fit makes the simulator external to the material while it maximizes contact and stability. In cases where the actual surface would rock, the constrained least squares definition produces a stabilized solution.

Secondary and tertiary actual datum plane simulators are nominally constrained in orientation to higher-precedence datum simulators. Secondary and tertiary datum planes are not restricted in location compared to higher-precedence datum simulators. This means that a translation modifier on a datum plane is the same thing as no translation modifier.

When datum planes have surface data, PC-DMIS computes a measured approximation to the actual datum using that surface data and using the chosen datum math option. For details on planes that have surface data, refer to "Feature Types With and Without Surface Data".

Datum Planes with Surface Data under ISO 1101

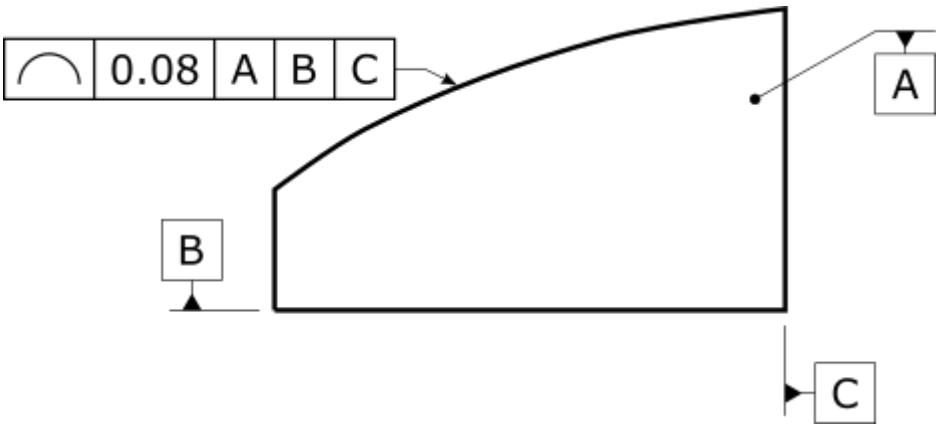
For planes, the actual datum plane simulator is defined by ISO 5459 - 2011, using the phrase "associated datum feature." The actual surface is filtered to remove dents and other voids, and then a perfect plane is fitted to the filtered surface using constrained min max. This fit makes the simulator external to the material, with the low points of the filtered surface as close as possible to the actual datum simulator.

Secondary and tertiary actual datum plane simulators are nominally constrained in orientation to higher-precedence datum simulators. They are not restricted in location compared to higher-precedence datum simulators unless the datum has a [DF] modifier. When the datum has a [DF] modifier, the simulators are nominally constrained in orientation and location to the higher-precedence datum simulators.

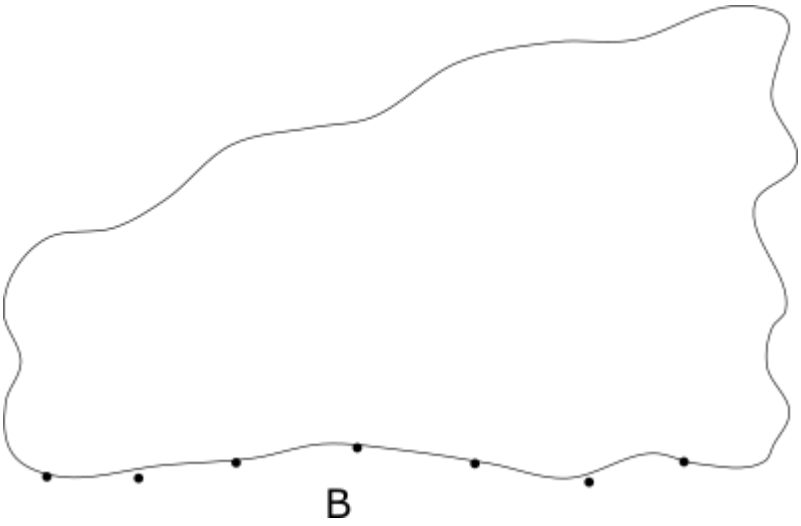
When datum planes have surface data, PC-DMIS computes a measured approximation to the actual datum using that surface data and using the chosen datum math option. For details on planes that have surface data, refer to "Feature Types With and Without Surface Data".

Illustrations of Datum Planes: Filtration, Best Fitting, and Orientation Constraints

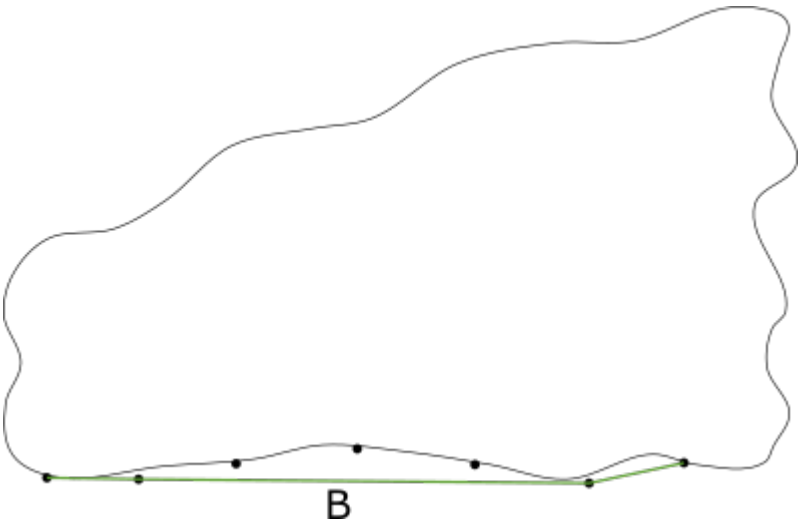
As an example of the best-fitting process, suppose you had the following specification:



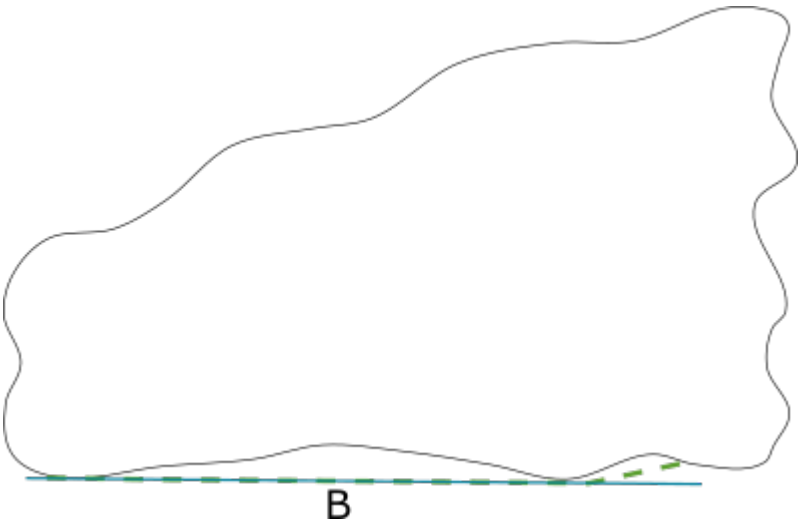
It's easier to illustrate void filtering and best fitting in 2D than 3D, so let's suppose datum B was measured as a line instead of as a plane (even though we recommend that you measure it as a plane). The measured points might look like this:



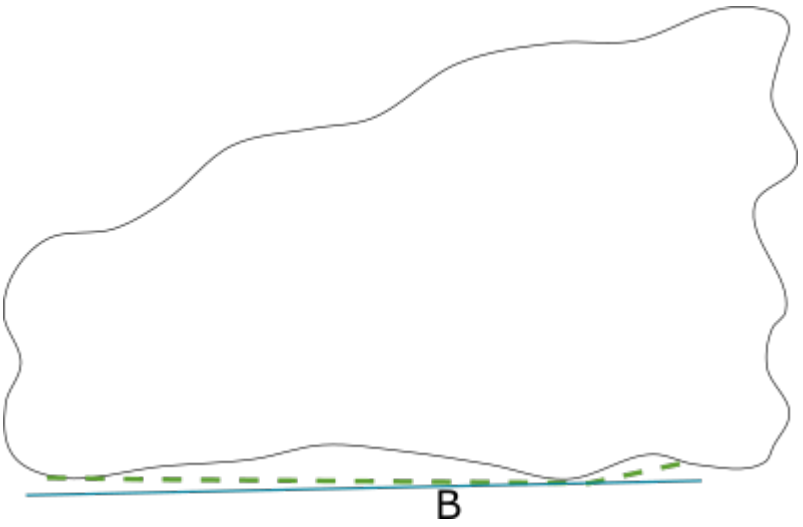
Then the void-filtered surface would look like shown below in green:



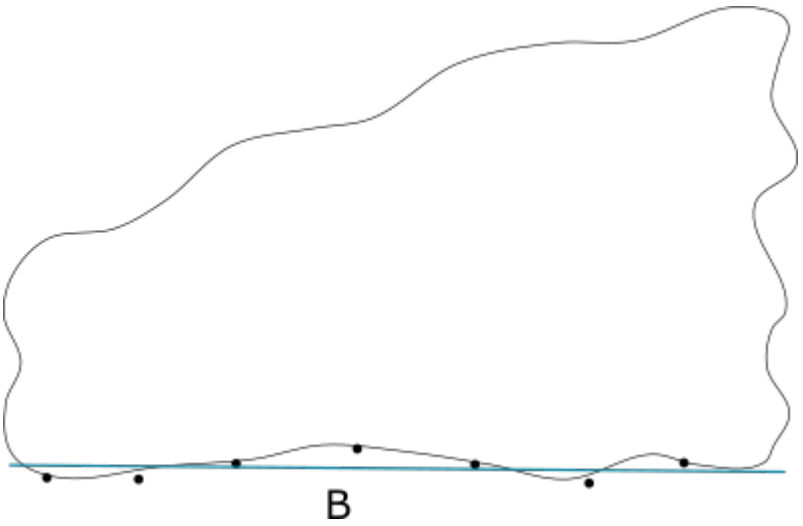
Then the best-fitted constrained least squares line (the result of the **DEFAULT** datum math option for ASME, or the **CL2** datum math option for ISO) is best fitted to the filtered surface, and looks like this shown in blue:



By contrast, the best-fitted constrained min max line (the result of the **DEFAULT** datum math option for ISO) is best-fitted to the filtered surface, and looks like this shown in blue:

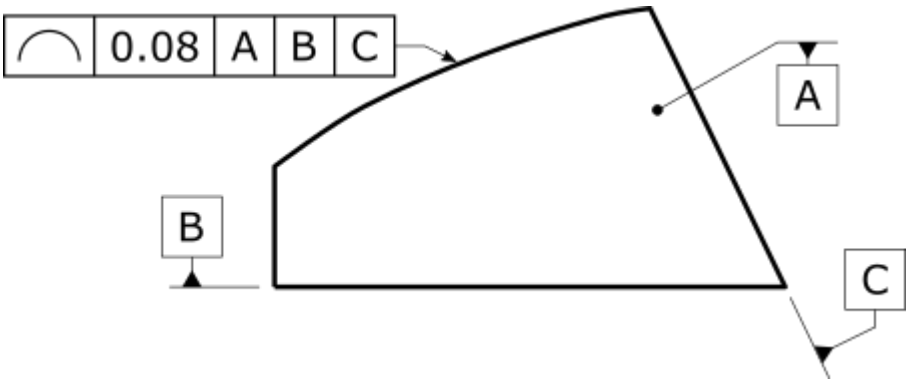


Meanwhile, the (unconstrained) least squares line (the result of the **LSQ** datum math option) is best-fitted to the original measured points, and looks like this shown in blue:

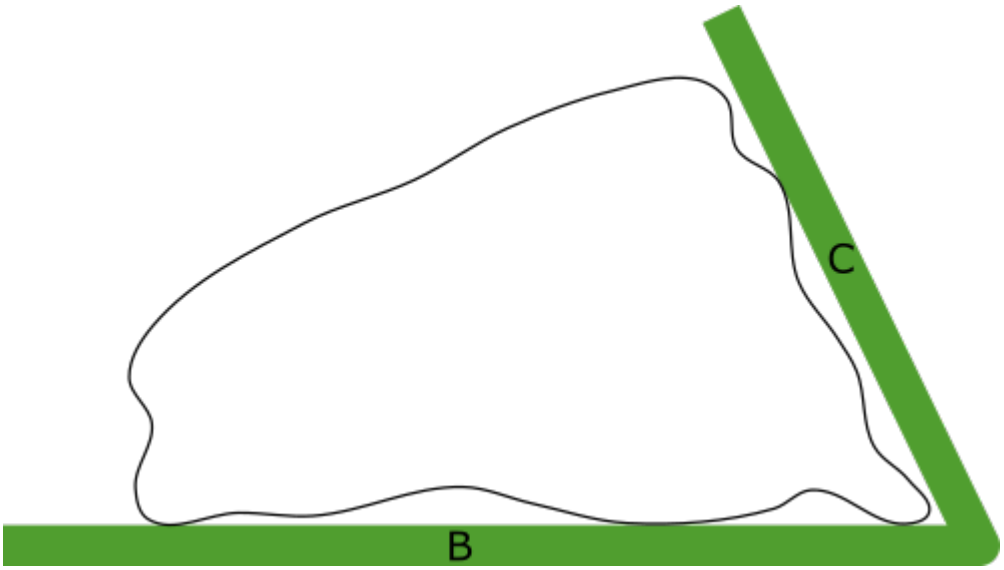


In this particular case, the **DEFAULT** datum math option is a better approximation to the actual datum than the **LSQ** datum math option. However, as seen in "Introduction to Geometric Tolerances and Feature Control Frames", the **LSQ** datum math option is a better approximation to the actual datum when the measurement uncertainty of each measured point is larger. Meanwhile, the **CL2** math type under ISO gives a better approximation to the assembled behavior of the datum, but a poorer approximation to the actual (specified) datum.

As an example of orientation constraints, suppose you had the following specification:



Then the actual (specified) datums for a realistic part might look like this:



Note that actual datum simulator C has the nominal angle to actual datum simulator B. Also note that the datum simulator C contacts the actual surface in exactly one point.

Datum Planes without Surface Data

In rare applications, a datum plane is defined that does not have a surface. For example, a plane that contacts three spheres. PC-DMIS supports applications like this by allowing for datum feature types that do not have surface data.

When a primary datum plane does not have surface data, the geometric tolerance command uses the MEAS values of the plane as the datum simulator.

When a secondary or tertiary datum plane does not have surface data, the geometric tolerance command constructs a measured plane that is as close as possible to the MEAS plane while being nominally oriented to the higher-precedence datum simulators. As seen above, ASME and ISO secondary and tertiary datum planes are not nominally located to higher-precedence datums (unless there is a [DF] modifier).

As discussed in "Structuring your Measurement Routine for Geometric Tolerances", in most cases we do not recommend using datum planes without surface data, because you

are taking over phases 2 and 3 of the conceptual evaluation process. If you do so, it is your responsibility to construct the feature according to appropriate standards.

For details on planes that do not have surface data, refer to "Feature Types With and Without Surface Data".

Datum Plane Cross Sections

Datum line features can be either a cross section of a planar surface (see "Feature Types With and Without Surface Data") or a surfaceless axis. This subtopic here discusses the cross section case. The surfaceless axis is discussed in "Datum Cylinders without Surface Data, and Surfaceless Axes".

Because these types of line features represent a cross section of a planar surface, the above sections on datum planes apply here. For example, the actual datum simulator is an entire planar surface. By contrast, the measured datum simulator is a cross section of a planar surface because only a cross section of the surface was measured. This means we recommend that you do not use line features that represent a plane cross section as a primary datum. You should only use these line features as a datum if higher precedence datums have already defined the workplane of the line. However, PC-DMIS still allows these lines to be used as a primary datum. In that case PC-DMIS levels to the view of the line before it considers the datum line itself:

The view of a measured line or best-fit line is its workplane.

The view of an auto-line is its nominal surface vector.

Because lines are not recommended as a primary datum, PC-DMIS shows a warning message, as discussed in "Troubleshooting error messages and warnings". It may seem counter intuitive, but a primary datum line on a surface constrains five degrees of freedom (prismatic invariance class), while a primary datum plane constrains only three degrees of freedom (planar invariance class). This means if you measure less data, you are actually constraining more degrees of freedom. This is because you are requiring the line's view to become an implicit datum that is higher precedence than any datums in your feature control frame.

If you use a line on a surface as a primary datum, the warning cannot be turned off. This is because we strongly recommend that you do not use surface lines as primary datums. However, PC-DMIS supports this case for legacy applications. Instead, we recommend that you measure the datum plane first, and use that as the primary datum. Then measure a plane or line as the secondary datum.

Most line features referenced as a datum are on a surface—they have surface data. While it is possible in PC-DMIS to measure a line on a non-planar surface, the geometric tolerance command always handles lines on surfaces as coming from a planar surface. Because the measured datum simulator is only a cross section of the planar surface, the

measured algorithms (void filtering and fitting) are all two-dimensional instead of three-dimensional.

We do not recommend that you use lines representing cross sections of planar surfaces for datum features unless you already know that the orientation error is very small between higher precedence datums and the planar surface represented by the line. Instead, we recommend that you use plane features to represent the secondary or tertiary planar surface whenever possible.

PC-DMIS handles datum lines that represent a planar cross section that do not have surface data somewhat like datum planes that do not have surface data. The geometric tolerance command constructs a measured plane cross section that is as close as possible to the MEAS plane cross section while being nominally oriented to the higher-precedence datum simulators. As discussed in "Structuring your Measurement Routine for Geometric Tolerances", in most cases we do not recommend using datum features without surface data, because you are taking over phases 2 and 3 of the conceptual evaluation process. If you do so, it is your responsibility to construct the feature according to appropriate standards.

The measured surface normal of a line is parallel to the cross product of its line vector and its workplane vector.

For details on lines that represent a plane cross section and that have surface data, refer to "Feature Types With and Without Surface Data"

Datum Plane Samples

The geometric tolerance command treats most point types as a single sample of a planar surface. While it is possible in PC-DMIS to measure a point on a non-planar surface, the geometric tolerance command always handles datum points on a surface as if they come from a planar surface. Therefore, the above sections on datum planes apply here. For example, the actual datum simulator is an entire planar surface. By contrast, the measured datum simulator is a single sample of a planar surface. This is because only a sample of the surface was measured. That means void filtering does not take place. The orientation of the planar surface must be completely constrained by higher-precedence datums (no fitting takes place). You can only use a sample of a planar surface as a tertiary datum.

We do not recommend that you use points on a surface for datum features unless you already know that the orientation error is very small between higher precedence datums and the planar surface represented by the point. Instead, we recommend that you use plane features to represent the tertiary planar surface whenever possible.

For details on the points that represent a sample of a planar surface, refer to "Feature Types With and Without Surface Data"

Datum Cylinders with Surface Data under ASME Y14.5

For cylinders, the actual datum simulator is defined by ASME Y14.5.1 - 2019. A perfect cylinder is fitted to the actual surface using constrained least squares.

There is no void filtration. This fit makes the simulator external to the material while it maximizes contact and stability. In cases where the actual surface would rock, the constrained least squares definition produces a stabilized solution.

Secondary and tertiary actual datum cylinder simulators are nominally constrained in orientation and location to higher-precedence datum simulators. When a translation modifier is present, secondary or tertiary datum cylinders are not restricted in location compared to higher-precedence datum simulators, but they remain constrained in orientation.

When datum cylinders have surface data, PC-DMIS computes a measured approximation to the actual datum using that surface data and using the chosen datum math option. For details on the cylinders that have surface data, refer to "Feature Types With and Without Surface Data".

Datum Cylinders with Surface Data under ISO 1101

For cylinders, the actual datum simulator is defined by ISO 5459 - 2011, using the phrase "associated datum feature." The actual surface is filtered to remove dents and other voids, and then a perfect cylinder is fitted to the filtered surface using a maximum-inscribed (inner cylinders) or minimum-circumscribed (outer cylinders) formula. This fit makes the simulator external to the material and can be considered a mating envelope.

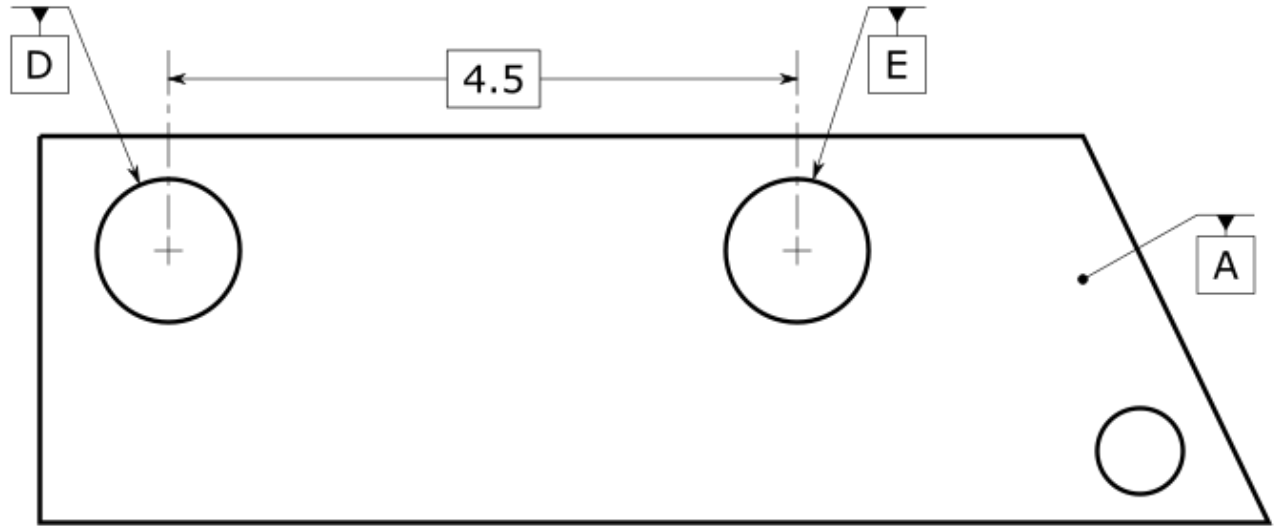
Unfortunately, inscribed and circumscribed algorithms are notoriously unstable, and so PC-DMIS, with the **DEFAULT** datum math type, uses a constrained least squares algorithm to inscribe or circumscribe this type of datum feature. The constrained least squares algorithm produces almost the same diameter as a pure inscribing or circumscribing, but the algorithm is much more stable. Therefore, **DEFAULT** and **CL2** datum math types are the same for this type of datum feature.

Secondary and tertiary actual datum cylinder simulators are nominally constrained in orientation to higher-precedence datum simulators. They are not restricted in location compared to higher-precedence datum simulators unless the datum has a [DF] modifier. When the datum has a [DF] modifier, the simulators are nominally constrained in orientation and location to the higher-precedence datum simulators.

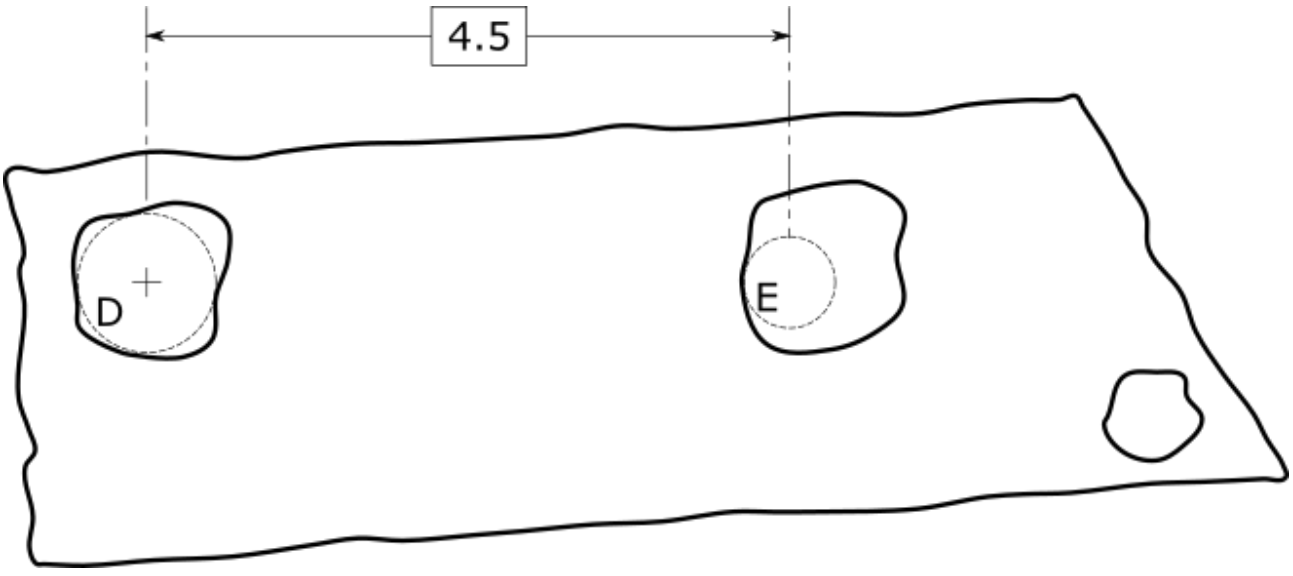
When datum cylinders have surface data, PC-DMIS computes a measured approximation to the actual datum using that surface data and using the chosen datum math option. For details on the cylinders that have surface data, refer to "Feature Types With and Without Surface Data".

Illustrations of Datum Cylinders: Location Constraints and No Location Constraints

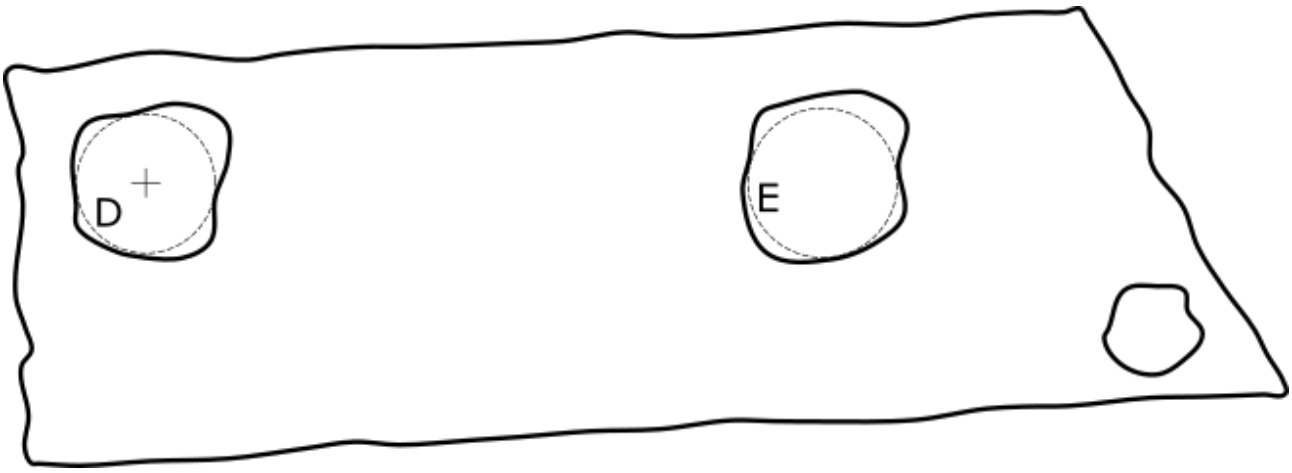
A frequently seen datum reference frame is the primary datum plane, followed by a secondary datum cylinder, followed by a tertiary datum cylinder. Here's an illustration of a specification, where the primary datum plane is A, the secondary datum cylinder is D, and the tertiary datum cylinder is E:



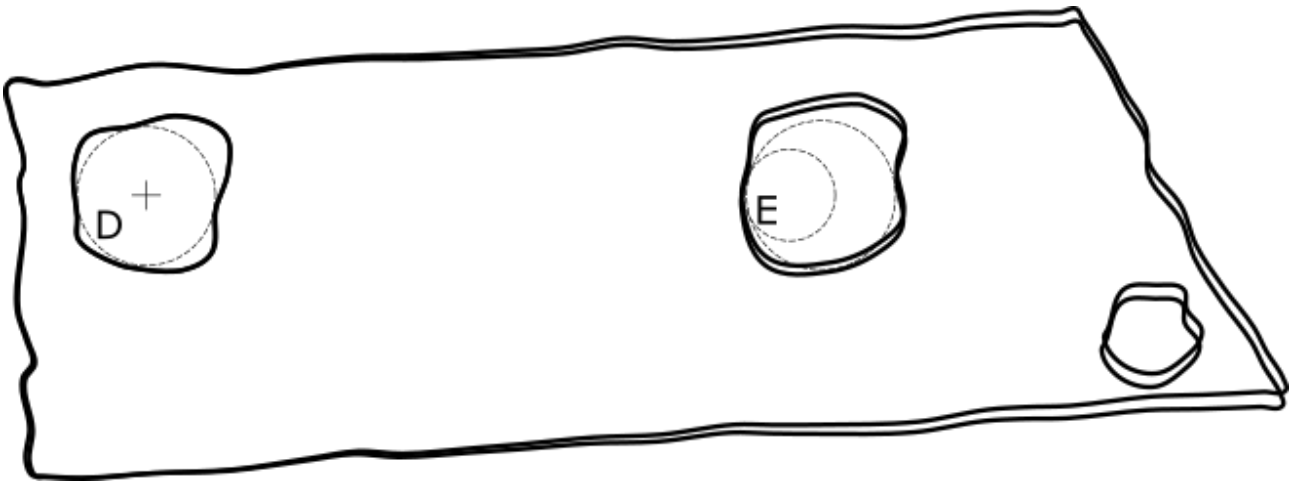
Under ASME (or under ISO with a [DF] modifier on the tertiary datum), the secondary and tertiary datums are nominally located with respect to each other. This results in the following datum reference frame:



Under ISO (or under ASME with a translation modifier on the tertiary datum), there are no location constraints between the secondary datum D and the tertiary datum E. This results in the following datum reference frame, which has a different rotation:



The difference between the two datum reference frames is easier to see when they are superimposed on each other:



Datum Cylinders without Surface Data, and Surfaceless Axes

In rare applications, a datum cylinder or axis is defined that does not have a surface. For example, a datum cylinder that circumscribes three pins. PC-DMIS supports applications like this by allowing for datum feature types that do not have surface data.

When a primary datum cylinder or axis does not have surface data, the geometric tolerance command uses the MEAS values of the cylinder or axis as the datum simulator.

When a secondary or tertiary datum cylinder or axis does not have surface data, the geometric tolerance command constructs a measured axis that is as close as possible to the MEAS axis while being nominally constrained to the higher-precedence datum simulators.

- For ASME datum cylinders or axes without surface data that do not have a translation modifier, and for ISO datum cylinders or axes without surface data

that have a [DF] modifier, the datum simulator is nominally located and oriented to the higher-precedence datum simulators.

- For ASME datum cylinders or axes without surface data that have a translation modifier, and for ISO datum cylinders or axes without surface data, the datum simulator is nominally oriented to the higher-precedence datum simulators (unless a [DF] modifier is present).

As discussed in "Structuring your Measurement Routine for Geometric Tolerances", in most cases we do not recommend using datum cylinders or axes without surface data, because you are taking over phases 2 and 3 of the conceptual evaluation process. If you do so, it is your responsibility to construct the feature according to appropriate standards.

For details on the cylinders that have and do not have surface data, and the feature types that represent surfaceless axes, refer to "Feature Types With and Without Surface Data".

Datum Cylinder Cross Sections

The geometric tolerance command treats datum circles as a cross section of a cylindrical surface. While PC-DMIS can measure a circle on a non-cylindrical surface, the geometric tolerance command always handles datum circles as coming from a cylindrical surface. Therefore, the above sections on datum cylinders apply here. For example, the actual datum simulator is an entire cylindrical surface. By contrast, the measured datum simulator is a cross section of a cylindrical surface. This is because only a cross section of the surface was measured. That means the measured algorithms (void filtering and fitting) are all two-dimensional instead of three-dimensional (surface data are filtered for ISO datum circles, not ASME ones). This also means it is not recommended to use a circle as a primary datum. More precisely, you should not use a circle as a datum until higher precedence datums have defined the vector of the cylindrical axis.

However, PC-DMIS allows circles to be used as a primary datum, in the which case PC-DMIS levels to the view of the circle before considering the datum circle itself. The view of a circle is its nominal vector. Because circles are not recommended as a primary datum, you will get a warning, as discussed in "Troubleshooting error messages and warnings". It may seem counter intuitive, but a primary datum circle constrains five degrees of freedom (revolute invariance class) while a primary datum cylinder constrains only four degrees of freedom (cylindrical invariance class). This means if you measure less data, you are actually constraining more degrees of freedom. This is because you are requiring the circle's view to become an implicit datum that is higher precedence than any datums in your feature control frame.

If you use a circle as a primary datum, the warning cannot be turned off. This is because we strongly recommend that you do not use circles as primary datums. However, PC-DMIS supports this case for legacy applications. Instead, we recommend that you measure the datum plane first, and use that as the primary datum. Then measure a cylinder or circle as the secondary datum.

For the reasons discussed in "Datum Cylinders with Surface Data under ISO 1101", datum circles in the geometric tolerance command that reference ISO 1101 are the same for **DEFAULT** and **CL2** datum math types.

We do not recommend that you use circles for datum features unless you already know that the orientation error is very small between higher precedence datums and the cylindrical surface represented by a circle. Instead, we recommend that you use cylinder features to represent the cylindrical surface whenever possible.

PC-DMIS handles datum circles without surface data somewhat similarly to datum cylinders without surface data. The geometric tolerance command constructs a measured cylinder cross section that is as close as possible to the MEAS cylinder cross section while being nominally constrained to the higher-precedence datum simulators.

- For ASME datum circles without surface data that do not have a translation modifier, and for ISO datum circles without surface data that have a [DF] modifier, the datum simulator is nominally located and oriented to the higher-precedence datum simulators.

- For ASME datum circles without surface data that have a translation modifier, and for ISO datum circles without surface data that do not have a [DF] modifier, the datum simulator is nominally oriented to the higher-precedence datum simulators.

As discussed in "Structuring your Measurement Routine for Geometric Tolerances", in most cases we do not recommend using datum circles without surface data, because you are taking over phases 2 and 3 of the conceptual evaluation process. If you do so, it is your responsibility to construct the feature according to appropriate standards.

For details on the circles that have and do not have surface data, refer to "Feature Types With and Without Surface Data".

Datum Widths under ASME Y14.5

For widths, the actual datum simulator is defined by ASME Y14.5.1 - 2019. A perfect width is fitted to the actual surface using constrained least squares.

There is no void filtration. This fit makes the simulator external to the material while it maximizes contact and stability. In cases where the actual surface would rock, the constrained least squares definition produces a stabilized solution.

Secondary and tertiary actual datum width simulators are nominally constrained in orientation and location to higher-precedence datum simulators. When a translation modifier is present, secondary or tertiary datum widths are not restricted in location compared to higher-precedence datum simulators, but they remain constrained in orientation.

All widths in PC-DMIS have surface data. PC-DMIS computes a measured approximation to the actual datum using that surface data and using the chosen datum math option.

When possible, use the 3D width type. This is because it represents the entire width surface. When the width is too shallow to measure as a 3D width, you can use a 2D width as a secondary or tertiary datum. You should not use a 2D width as a datum until higher precedence datums have defined the workplane of the 2D width. 2D widths as datums have the same cautions as described in "Datum Plane Cross-Sections".

When the width is too small to use even as a 2D width, you can use a 1D width as a tertiary datum. Higher precedence datums must have completely defined the orientation of the 1D width surface. 1D widths have the same cautions as described in "Datum Plane Samples".

Datum Widths under ISO 1101

For widths, the actual datum simulator is defined by ISO 5459 - 2011, using the phrase "associated datum feature." The actual surface is filtered to remove dents and other voids, and then a perfect width is fitted to the filtered surface using a maximum-inscribed (inner widths) or minimum-circumscribed (outer widths) formula. This fit makes the simulator external to the material and can be considered a mating envelope.

Unfortunately, inscribed and circumscribed algorithms are notoriously unstable, and so PC-DMIS, with the **DEFAULT** datum math type, uses a constrained least squares algorithm to inscribe or circumscribe this type of datum feature. The constrained least squares algorithm produces almost the same diameter as a pure inscribing or circumscribing, but the algorithm is much more stable. Therefore, **DEFAULT** and **CL2** datum math types are the same for this type of datum feature.

Secondary and tertiary actual datum widths simulators are nominally constrained in orientation to higher-precedence datum simulators. They are not restricted in location compared to higher-precedence datum simulators unless the datum has a [DF] modifier. When the datum has a [DF] modifier, the simulators are nominally constrained in orientation and location to the higher-precedence datum simulators.

All widths in PC-DMIS have surface data. PC-DMIS computes a measured approximation to the actual datum using that surface data and using the chosen datum math option.

When possible, use the 3D width type. This is because it represents the entire width surface. When the width is too shallow to measure as a 3D width, you can use a 2D width as a secondary or tertiary datum. You should not use a 2D width as a datum until higher precedence datums have defined the workplane of the 2D width. 2D widths as datums have the same cautions as described in "Datum Plane Cross-Sections".

When the width is too small to use even as a 2D width, you can use a 1D width as a tertiary datum. Higher precedence datums must have completely defined the orientation of the 1D width surface. 1D widths have the same cautions as described in "Datum Plane Samples".

Datum Slots and Notches

In some cases, it makes sense to use a slot or notch command as a secondary or tertiary datum. The geometric tolerance command treats datum slots and notches like 2D widths without any surface data. While slot and notch commands typically do have surface data, they do not collect enough surface data in the right places to use that surface data in a geometric tolerance context. Therefore, the geometric tolerance command treats slots and notches as 2D widths without surface data.

When you use slots and notches as a datum without any modifier, PC-DMIS treats them like a mid-line: a datum plane cross section that does not have surface data. When you use them as a datum with a material modifier Ⓜ or Ⓛ, PC-DMIS treats slots and notches much like a 2D width without surface data would be treated. For more information, see "Datums with a Material Modifier".

Be careful with datum slots and notches.

You should only use them if you already know that the form of the features is very good. If you suspect that the manufactured form error might be significant, do not use a slot or notch command. Instead, measure a scan around the perimeter of the feature and then tolerance the form, orientation, and location of the feature with a profile of a line tolerance.

If you need to reference the feature as a datum, instead of a slot or notch, use a constructed 2D or 3D width (with surface data).

Datum Cones with Surface Data under ASME Y14.5

For cones, the actual datum simulator is incompletely defined by ASME Y14.5.1 - 2019. A perfect cone is fitted to the actual surface using constrained least squares.

There is no void filtration. This fit makes the simulator external to the material while it maximizes contact and stability. In cases where the actual surface would rock, the constrained least squares definition produces a stabilized solution.

ASME Y14.5 specifies that primary datum cones constrain five degrees of freedom: three degrees of translation and two of rotation. Only a single degree of rotation is left (rotation about the cone axis). Unfortunately, ASME Y14.5 and Y14.5.1 are ambiguous in how translation along the axis is constrained (there are multiple possible interpretations, each yielding a different constrained translation along the axis). Furthermore, in our experience most drawings that reference datum cones are intended to use only the axis of the cone as the datum. Therefore, the PC-DMIS geometric tolerance command treats all datum cones as axis-only. This means they constrain at most four degrees of freedom (not translation along the cone).

Under ASME Y14.5, the geometric tolerance command fits datum cones such that both the central diameter and cone angle are optimized.

Secondary and tertiary actual datum cone simulators are nominally constrained in orientation and location to higher-precedence datum simulators. When a translation modifier is present, secondary or tertiary datum cones are not restricted in location compared to higher-precedence datum simulators, but they remain constrained in orientation.

When datum cones have surface data, PC-DMIS computes a measured approximation to the actual datum using that surface data and using the chosen datum math option. For details on the cones that have surface data, refer to "Feature Types With and Without Surface Data".

Datum Cones with Surface Data under ISO 1101

For cones, the actual datum simulator is defined by ISO 5459 : 2011. A perfect cone is fitted to the actual surface using constrained min max. The actual surface is filtered to remove dents and other voids, and then a perfect cone is fitted to the filtered surface using constrained min max. This fit results in the simulator being external to the material, with the low points of the filtered surface as close as possible to the actual datum simulator. ISO 5459 : 2011 further specifies that the cone angle is fixed at nominal (not optimized).

ISO 5459 specifies that primary datum cones constrain five degrees of freedom: three degrees of translation and two of rotation. Only a single degree of rotation is left (rotation about the cone axis). Unfortunately, this gives an unstable translation along the cone axis. This is because small changes in actual cone diameter frequently yield large changes in the defined translation along the cone axis. Furthermore, in our experience most drawings referencing datum cones are intended to use only the axis of the cone as the datum. Therefore, the PC-DMIS geometric tolerance command treats all datum cones as axis-only: they only constrain at most four degrees of freedom (translation along the cone is free). This is equivalent to PC-DMIS assuming that the [SL] modifier is present on all datum cones (either implicitly or explicitly).

Secondary and tertiary actual datum cone simulators are nominally constrained in orientation to higher-precedence datum simulators. They are not restricted in location compared to higher-precedence datum simulators unless the datum has a [DF] modifier. When the datum has a [DF] modifier, the simulators are nominally constrained in orientation and location to the higher-precedence datum simulators.

When datum cones have surface data, PC-DMIS computes a measured approximation to the actual datum using that surface data and using the chosen datum math option. For details on the cones that have surface data, refer to "Feature Types With and Without Surface Data".

Datum Cones without Surface Data

When a cone without surface data is referenced as a datum, because cones are treated as axis-only, the behavior is the same as described above in "Datum Cylinders without Surface Data, and Surfaceless Axes". As discussed in "Structuring your Measurement Routine for Geometric Tolerances", in most cases we do not recommend using datum cones without surface data, because you are taking over phases 2 and 3 of the conceptual evaluation process. If you do so, it is your responsibility to construct the feature according to appropriate standards.

For details on the cones that do not have surface data, refer to "Feature Types With and Without Surface Data".

Datum Spheres with Surface Data under ASME Y14.5

For spheres, the actual datum simulator is defined by ASME Y14.5.1 - 2019. A perfect sphere is fitted to the actual surface using constrained least squares.

There is no void filtration. This fit makes the simulator external to the material while it maximizes contact and stability. In cases where the actual surface would rock, the constrained least squares definition produces a stabilized solution.

Secondary and tertiary actual datum sphere simulators are nominally constrained in location to higher-precedence datum simulators unless a translation modifier is present. This is because spheres have no orientation and so are not constrained in orientation to higher precedence datums.

When datum spheres have surface data, PC-DMIS computes a measured approximation to the actual datum using that surface data and using the chosen datum math option. For details of what spheres have surface data, refer to "Feature Types With and Without Surface Data".

Datum Spheres with Surface Data under ISO 1101

For spheres, the actual datum simulator is defined by ISO 5459 - 2011, using the phrase "associated datum feature." The actual surface is filtered to remove dents and other voids, and then a perfect sphere is fitted to the filtered surface using a maximum-inscribed (inner-spheres) or minimum-circumscribed (outer-spheres) formula. This fit makes the simulator external to the material and can be considered a mating envelope.

Unfortunately, inscribed and circumscribed algorithms are notoriously unstable, and so PC-DMIS, with the **DEFAULT** datum math type, uses a constrained least squares algorithm to inscribe or circumscribe this type of datum feature. The constrained least squares algorithm produces almost the same diameter as a pure inscribing or circumscribing, but the algorithm is much more stable. Therefore, **DEFAULT** and **CL2** datum math types are the same for this type of datum feature.

Secondary and tertiary actual datum spheres are not restricted in location or orientation compared to higher-precedence datum simulators, unless the datum has a [DF] modifier. This is because spheres have no orientation and so are not constrained in orientation to higher precedence datums. When the datum has a [DF] modifier, the simulators are nominally constrained in location to the higher-precedence datum simulators.

When datum spheres have surface data, PC-DMIS computes a measured approximation to the actual datum using that surface data and using the chosen datum math option. For details on the spheres that have surface data, refer to "Feature Types With and Without Surface Data".

Datum Spheres without Surface Data, and Surfaceless 3D Points

In rare applications, a datum sphere or 3D point is defined that does not have a surface. For example, a datum sphere that circumscribes three spheres. PC-DMIS supports applications like this by allowing for datum feature types that do not have surface data.

When a primary datum sphere or surfaceless 3D point does not have surface data, the geometric tolerance command uses the MEAS values of the sphere as the datum simulator.

When a secondary or tertiary datum sphere or surfaceless 3D point does not have surface data, the geometric tolerance command uses the MEAS values of the sphere as the datum simulator. For ASME datum spheres or surfaceless 3D points without surface data that do not have a translation modifier, and for ISO datum spheres with a [DF] modifier, a re-location is done in a way that minimally translates the centroid and ensures the datum simulator is nominally located to higher-precedence datum simulators.

As discussed in "Structuring your Measurement Routine for Geometric Tolerances", in most cases we do not recommend using datum spheres or surfaceless 3D points without surface data, because you are taking over phases 2 and 3 of the conceptual evaluation process. If you do so, it is your responsibility to construct the feature according to appropriate standards.

For details on the spheres that do not have surface data, and the feature types that represent surfaceless 3D points, refer to "Feature Types With and Without Surface Data".

Datum Patterns

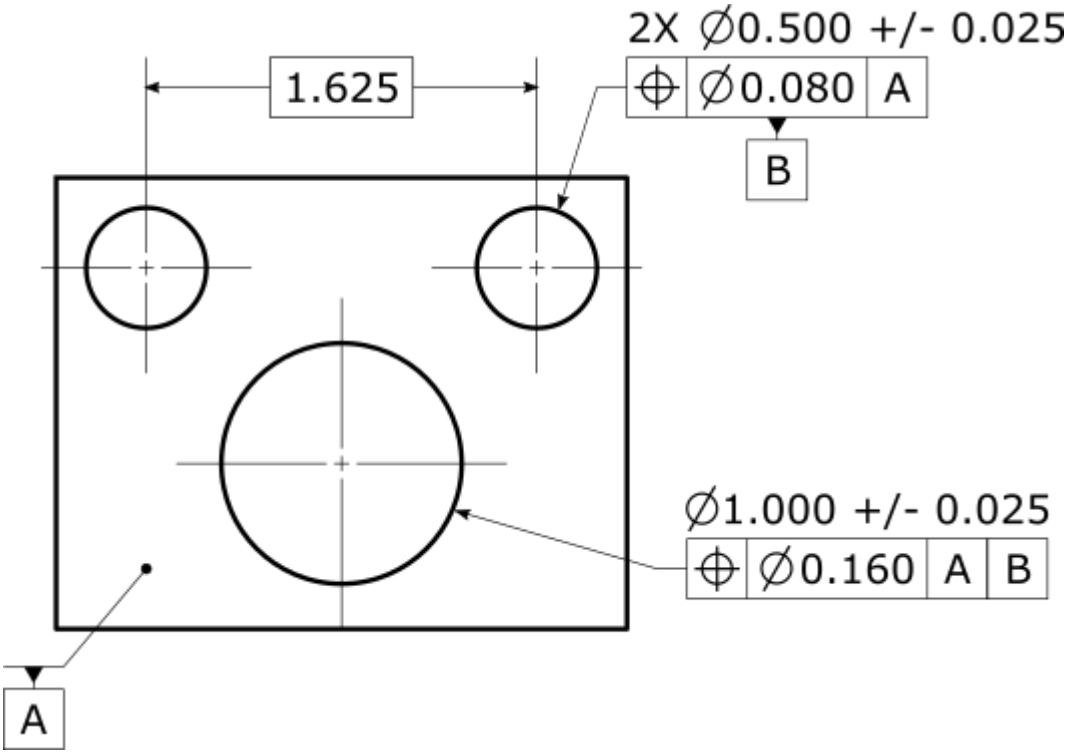
Datum patterns consist of features of size (cylinders, circles, widths, and spheres) that have the same nominal size, size tolerance, and are all inner or all outer. The datum simulators for the pattern are nominally oriented and located with respect to each other.

Under ASME Y14.5, the sizes of the simulators match each other because the nominal sizes and size tolerances and the in and out options are all the same. This is because paragraph 7.12.4 of ASME Y14.5 2018 states that the simulators must grow and shrink simultaneously. The set of actual datum simulators is defined by a constrained least squares fit. The fit is applied to the features' surfaces simultaneously, keeping the nominal location and orientation between each simulator as well as keeping the sizes matched. There is no void filtration.

ISO 5459 does not clearly state whether the simulators must have matched sizes or independent sizes. In our interpretation, the sizes are independent for ISO datum simulators within a pattern. See the example after paragraph 6.2.3 of ISO 5459 : 2011, as well as Figure A.8 which informed our interpretation. The set of actual datum simulators is defined by a constrained min max fit. The fit is applied to the features' void-filtered surfaces simultaneously, keeping the nominal location/orientation between each simulator, but allowing the sizes to vary independently.

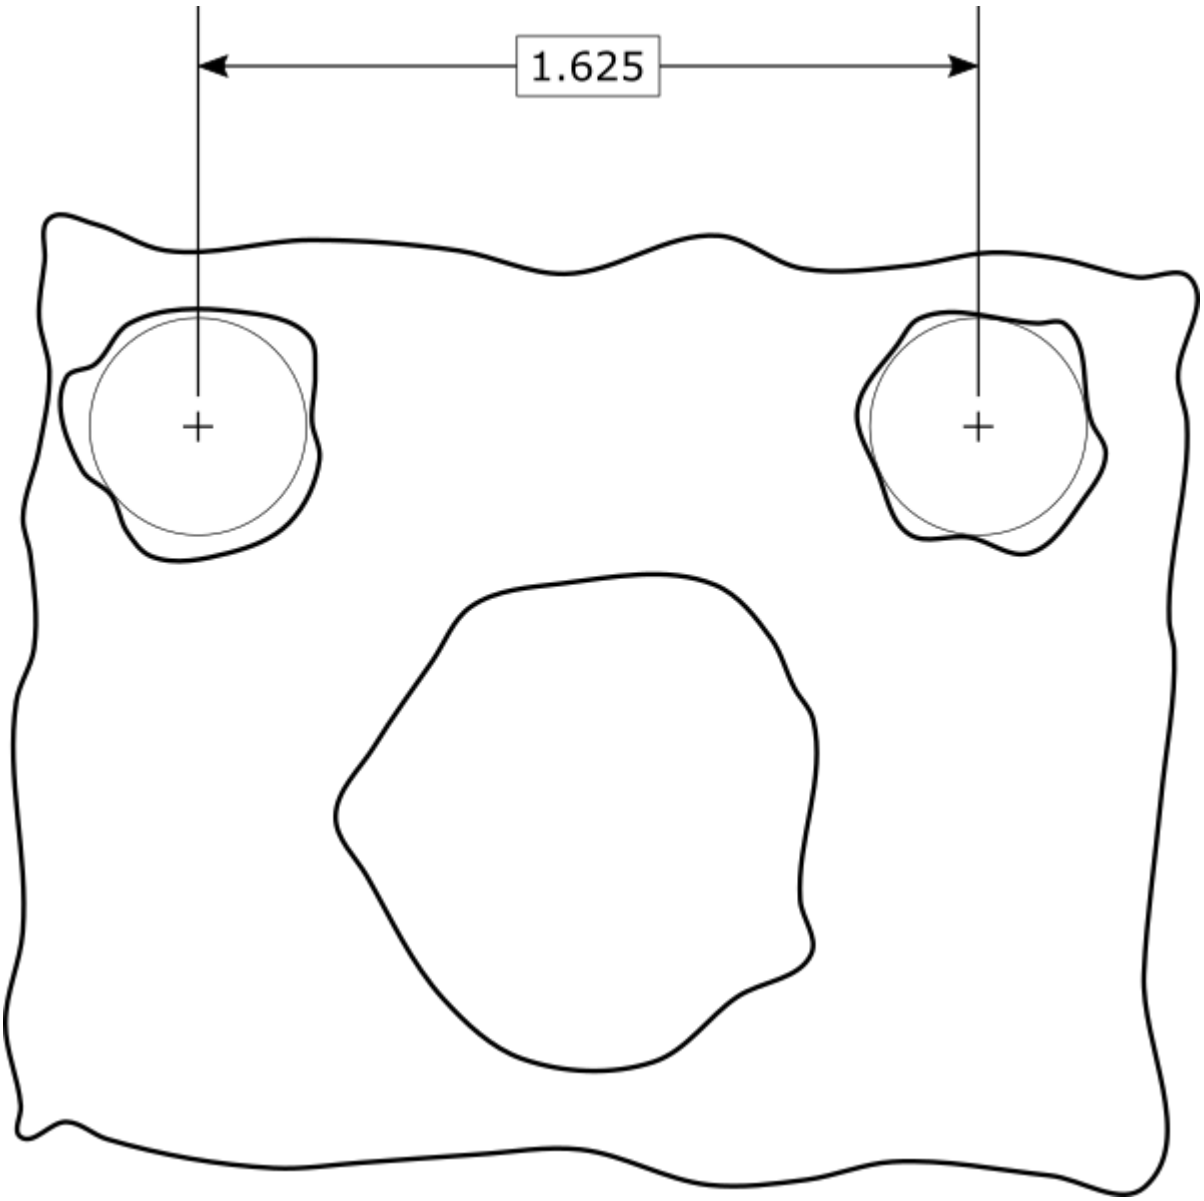
Illustrations of Datum Patterns

Suppose you had the following specification:



ASME

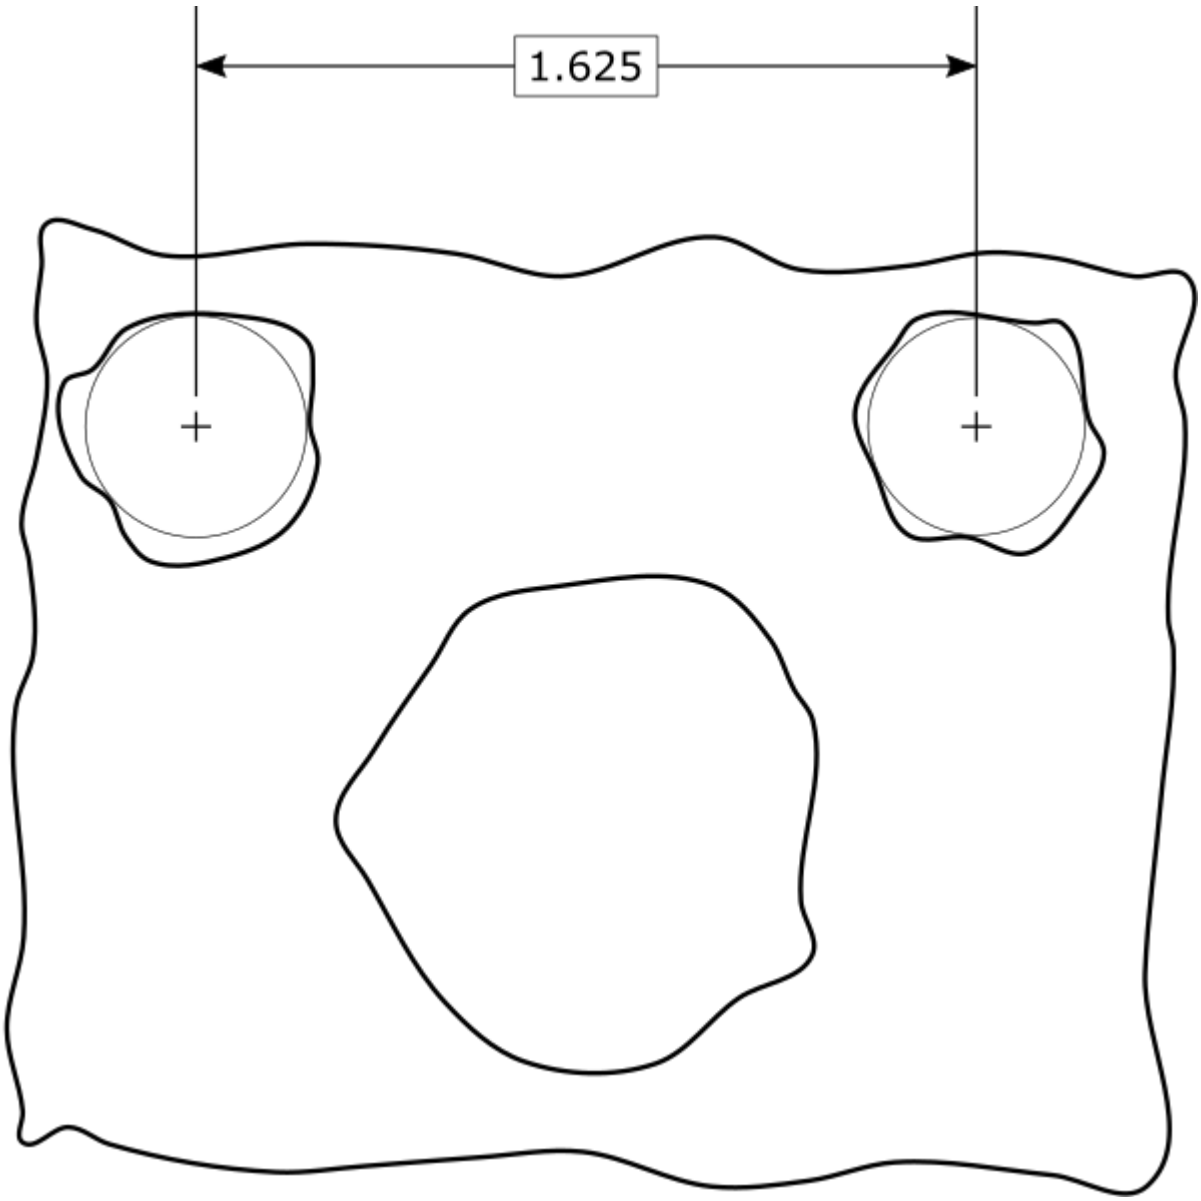
Given the above specification, the actual A | B datum reference frame under ASME is fully constrained, and looks like this:



Notice that the pattern's datum simulators are nominally located with respect to each other and have the same size.

ISO

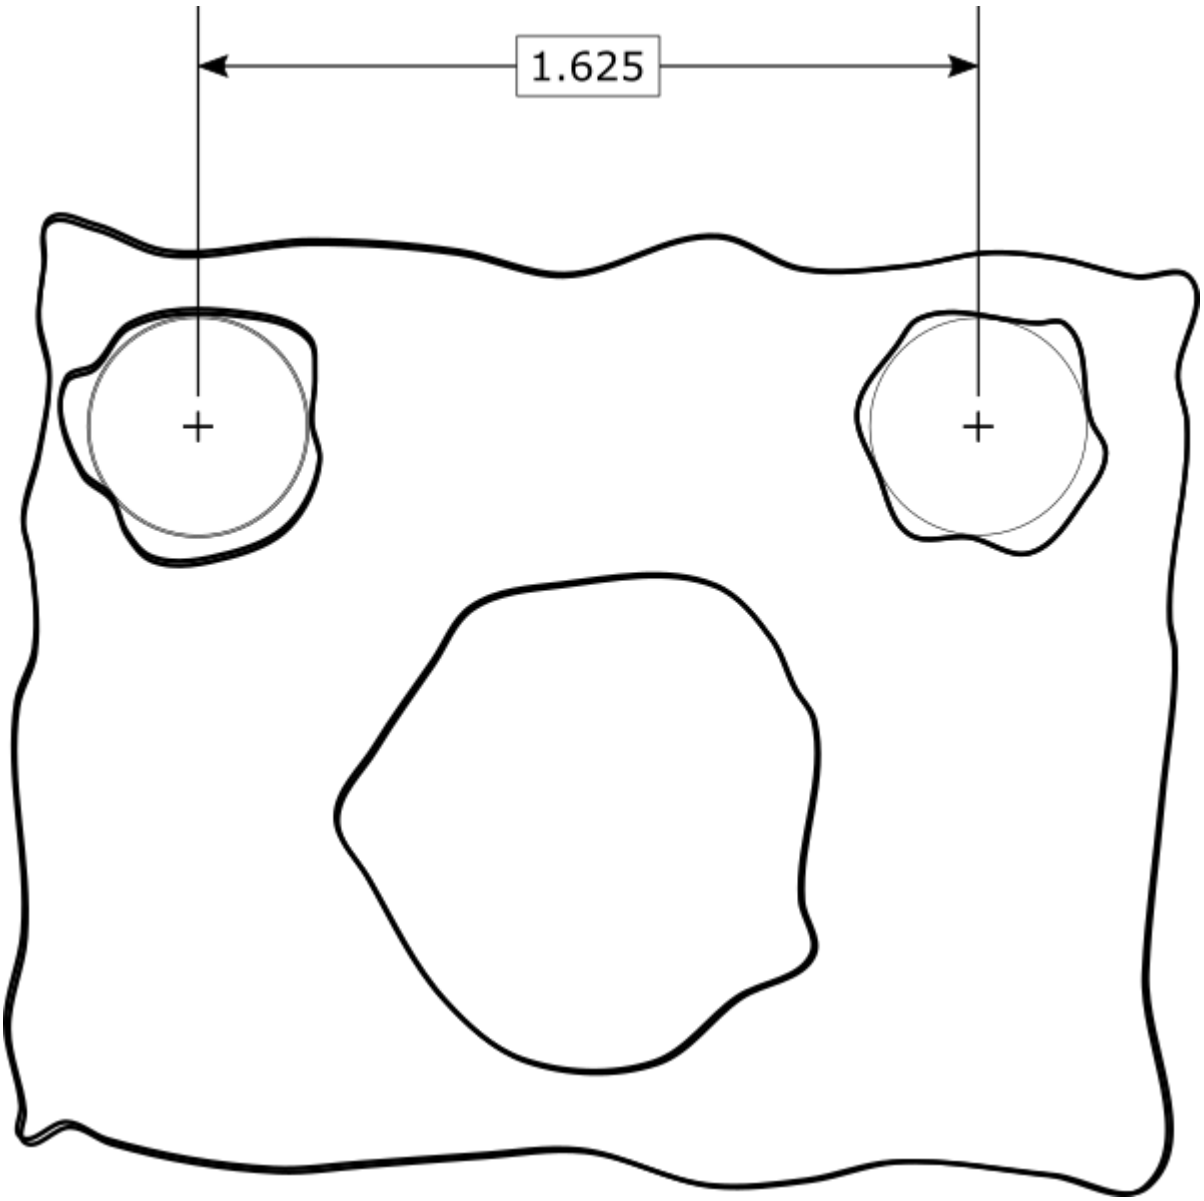
Given the above specification, the actual A | B datum reference frame under ISO is also fully constrained, and looks like this:



Notice that the pattern's datum simulators are nominally located with respect to each other, but do not have the same size. The overall rotation is different between ASME and ISO since the datum sizes are different.

ASME and ISO Superimposed

It's easier to see the difference between ASME and ISO when the two above images are superimposed:



Common Datums: Coaxial Cylinders

A common datum of multiple coaxial cylinders uses a hyphen in the datum reference, for example A-B or A-D-F. Typically, these items will differ between the cylinders: the nominal sizes, the size tolerance, or the in or out state. The datum simulators for the pattern are nominally oriented and located with respect to each other. This means the simulators will be coaxial.

Under ASME Y14.5, the sizes of the simulators are related to each other but typically do not match each other. Paragraph 7.12.4 of ASME Y14.5 2018 states that the simulators must grow and shrink simultaneously from their respective MMBs to their LMBs. The set of actual datum simulators is defined by a constrained least squares fit to the features' surfaces simultaneously. The fit also keeps these: the nominal location and orientation between each simulator and the sizes related by the simultaneous growing or shrinking from the maximum material boundary (MMB) to the least material boundary (LMB). There is no void filtration.

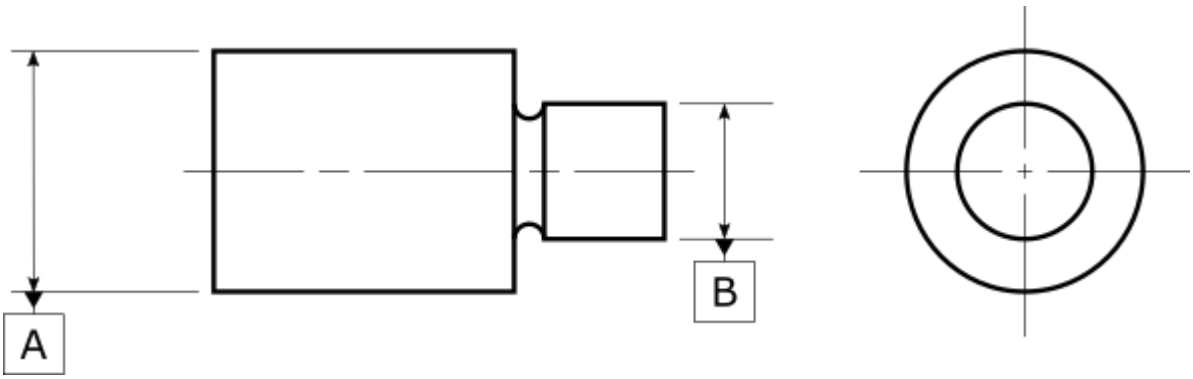
In order for PC-DMIS to correctly grow or shrink the simulator sizes simultaneously, you must create the size tolerances and geometric tolerances on datums *before* you allow any geometric tolerances to reference those datums. That is, the tolerances on the datum must be earlier in the measurement routine than the geometric tolerances referencing the datum.

If you later edit any size tolerance on a datum, you must ensure that all subsequent geometric tolerances that reference that datum have the correct size tolerance information for the datum.

ISO 5459 does not clearly state whether the simulators must have related sizes or independent sizes. In our interpretation, the sizes are independent for ISO datum simulators within a common datum. See the example after paragraph 6.2.3 of ISO 5459 : 2011, as well as Figure A.8 which informed our interpretation. The set of actual datum simulators is defined by a constrained min max fit to the features' void-filtered surfaces simultaneously. This fit also keeps the nominal location and orientation between each simulator, but it allows the sizes to vary independently.

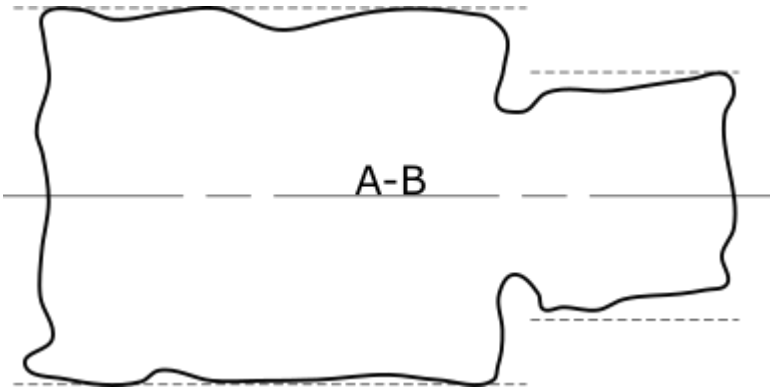
Illustrations of Coaxial Datums

Suppose you had the following specification:



ASME

In that case, the A-B common datum under ASME would look this:



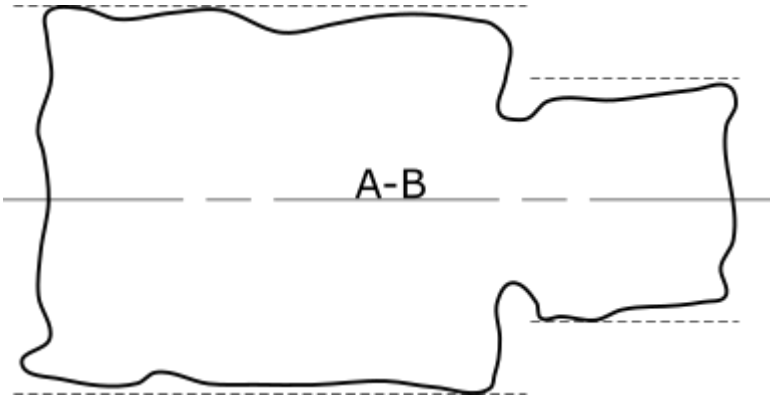
Notice that the A and B simulators are exactly coaxial.

ISO

With the above specification, the A-B common datum under ISO would be different, for two reasons:

1. The less-important reason is that the ISO one has independent sizes.
2. The more-important reason is that the ISO association for common datums is constrained min-max by default. This minimizes the distance between the low points of the filtered datum surfaces and the simulators.

The ISO common datum looks like this:



Common Datums: Offset Parallel Planes

A common datum of offset parallel planes uses a hyphen in the datum reference, for example A-B or A-D-F. The datum simulators for the pattern are nominally oriented and located with respect to each other. This means the simulators will be parallel and offset by their nominal distances.

Under ASME Y14.5, the set of actual datum simulators is defined by a constrained least squares fit to the features' void-filtered surfaces simultaneously. This fit also keeps the nominal location/orientation between each simulator.

Under ISO 1101, the set of actual datum simulators is defined by a constrained min max fit to the features' void-filtered surfaces simultaneously, keeping the nominal location and orientation between each simulator.

Datums with a Material Modifier

Datum cylinders, circles, spheres, widths, slots, and notches may have material modifiers Ⓜ or Ⓛ. A material modifier makes the geometric tolerance command handle the datum differently than datums that don't have them.

Without a material modifier, the datum completely constrains the normal degrees of freedom.

With a material modifier, the datum merely requires that a material boundary fits inside the feature surface or that the feature surface fits inside a material boundary.

The behavior is much like a functional gage. For example, in a typical case, the physical datum simulator on the gage is a pin, and it must fit in the hole on the actual part, but it is allowed to wiggle within the hole. Thus, the normal degrees of freedom are not completely constrained.

The geometric tolerance command approximates the interaction between the boundary and the measured surface. It does this with an axis-in-zone approximation. First, a surface envelope is computed. Then, the axis of the surface envelope is constrained to be within a perfect-form zone. The surface envelope size and the material boundary size determine the size of the zone. The zone is nominally oriented and located to higher-precedence datums. The zone is like the feature itself: spherical for spherical features, diametric for cylindrical and circular features, and planar for width, slot, and notch features. Here, we use the "axis of the surface envelope" concept rather loosely:

For a datum sphere, it is a single point.

For a datum cylinder, it is the axis.

For a datum width, it is the center-plane.

This axis-in-zone approximation is typically conservative unless the orientation error of the mating envelope is extreme. It is also typically an excellent approximation unless the form error of the surface is extreme. The conservative nature of the approximation means that even if the form error of the surface is extreme, the geometric tolerance command will not accept nonconforming parts, so long as the orientation error of the mating envelope is not extreme. PC-DMIS uses this approximation for two main reasons: (1) computation times are much faster, and (2) it does not require a densely measured datum surface (although we always recommend that you measure datum surfaces densely).

With surface data, the datum math type is available. For the **DEFAULT** datum math type (and the **CL2** datum math type under ISO), with a maximum material modifier, PC-DMIS computes the surface envelope externally to the material. It uses constrained least squares (it is a mating envelope). With a minimum material modifier, the surface envelope

is internal to the material, but PC-DMIS still uses constrained least squares (it is a minimum material envelope). ISO datums with the **DEFAULT** or **CL2** datum math option void-filter the surface before the fit, but ASME datums do not. For the **LSQ** datum math type, regardless of the material modifier, the surface envelope uses plain unfiltered least squares.

When there is no surface data, the MEAS feature is used as the surface envelope. See the "Feature Types With and Without Surface Data" topic for lists of the feature types that do not have surface data. As discussed in "Structuring your Measurement Routine for Geometric Tolerances", in most cases we do not recommend using datum features without surface data, because you are taking over phases 2 and 3 of the conceptual evaluation process. If you do so, it is your responsibility to construct the feature according to appropriate standards.

The rules to compute the size of the material boundary are complicated; please see "Determining the Size of the Material Boundary". A print rarely specifies a material boundary size. When specified, it overrides the rules that compute the size of the material boundary. The geometric tolerance command supports this: first you click **Advanced Modifiers**, and then you type a material boundary size.

In order for PC-DMIS to correctly determine the size of the material boundary, you must create the size tolerances and geometric tolerances on datums *before* you allow any geometric tolerances to reference those datums. That is, the tolerances on the datum must be earlier in the measurement routine than the geometric tolerances that reference the datum.

If you later edit any size tolerance on a datum, you must ensure that all subsequent geometric tolerances that reference that datum have the correct size tolerance information for the datum.

Once PC-DMIS compute the surface envelope and the size of the material boundary, the size of the zone is the difference between the surface envelope size and the size of the material boundary:

For inner features with a maximum material modifier and for outer features with a minimum material modifier, this is the surface envelope size minus the material boundary size.

For outer features with a maximum material modifier and for inner features with a minimum material modifier, this is the material boundary size minus the surface envelope size.

The datum surface envelope axis must stay in the zone for all lower-precedence datums and for tolerance zone calculations that use this datum. However, the axis is not optimized in the zone. The axis is only required to be in the zone.

A zone size of zero or negative implies that the datum violates its size tolerance. In the functional gage world, in a case like this, the gage's pin would not fit in its actual part hole. In this case, the geometric tolerance command does not fail the position or profile tolerance just because the datum is out of tolerance, but it lets the datum's size tolerance fail the datum. Instead of failing the position or profile tolerance, the datum is re-evaluated without a material modifier.

In some cases, a secondary or tertiary datum with a material modifier has translation available to it. This is always true under ISO and is also the case under ASME when a translation modifier is present. In this case, the tolerance zone is allowed to move relative to higher-precedence datums until it optimally contains the surface envelope axis. After that, its position is fixed relative to higher precedence datums. The orientation of the zone is still nominal relative to higher precedence datums.

The extent of the "axis of the mating envelope" is defined in the following way:

For datum spheres, it is the center-point of the surface envelope.

For datum cylinders, the axis of the surface envelope, is extrapolated to the end-faces in the same way as the toleranced feature is extrapolated. For information, see "Deriving the Toleranced Feature".

For datum circles, it is the center-point of the surface envelope.

For datum widths, the measured surface points are projected to the center-plane of the surface envelope, and the axis of the mating envelope is the minimal convex polygon that contains all the projected points.

For datum slots, the measured mid-line is extrapolated to the length of the slot.

For datum notches, the measured mid-line is extrapolated to the width of the notch.

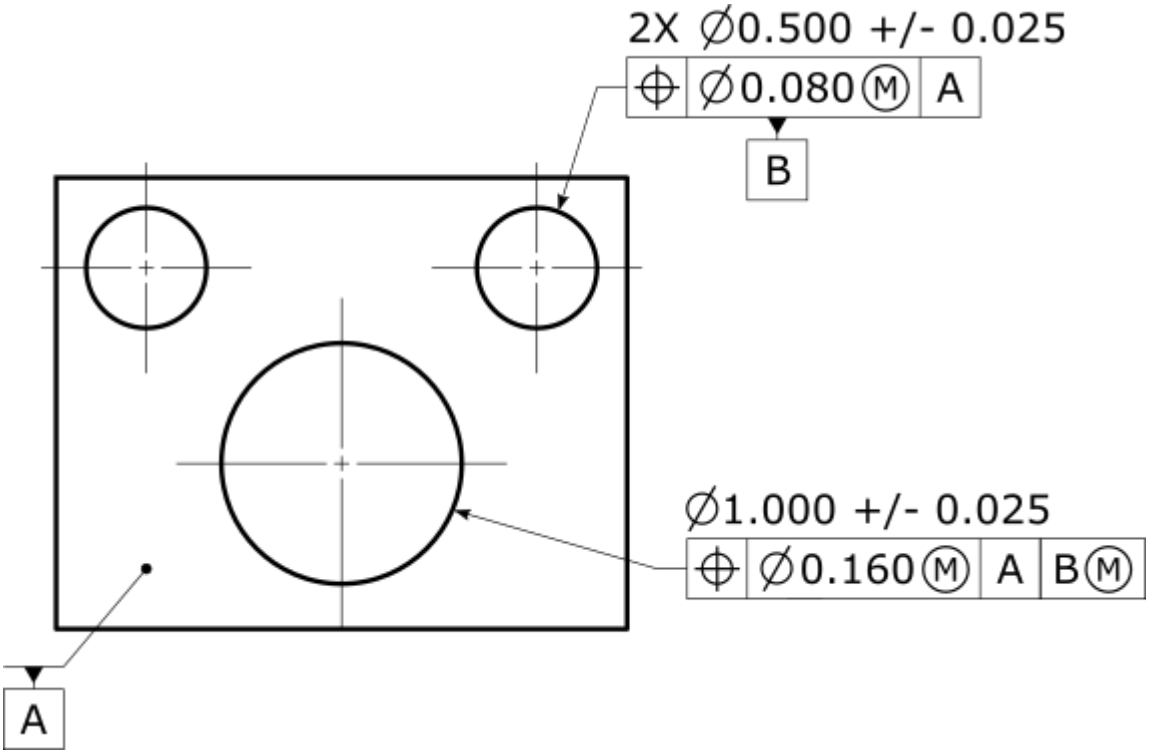
Datum patterns and common datums of coaxial cylinders are also allowed to have a material modifier. In this case, each surface envelope and zone size is calculated independently. This maximizes the accuracy of the axis-in-zone approximation. The zones are nominally oriented and located with respect to each other.

When translation is not available (ASME without a translation modifier), the zones are nominally oriented and located with respect to higher-precedence datums.

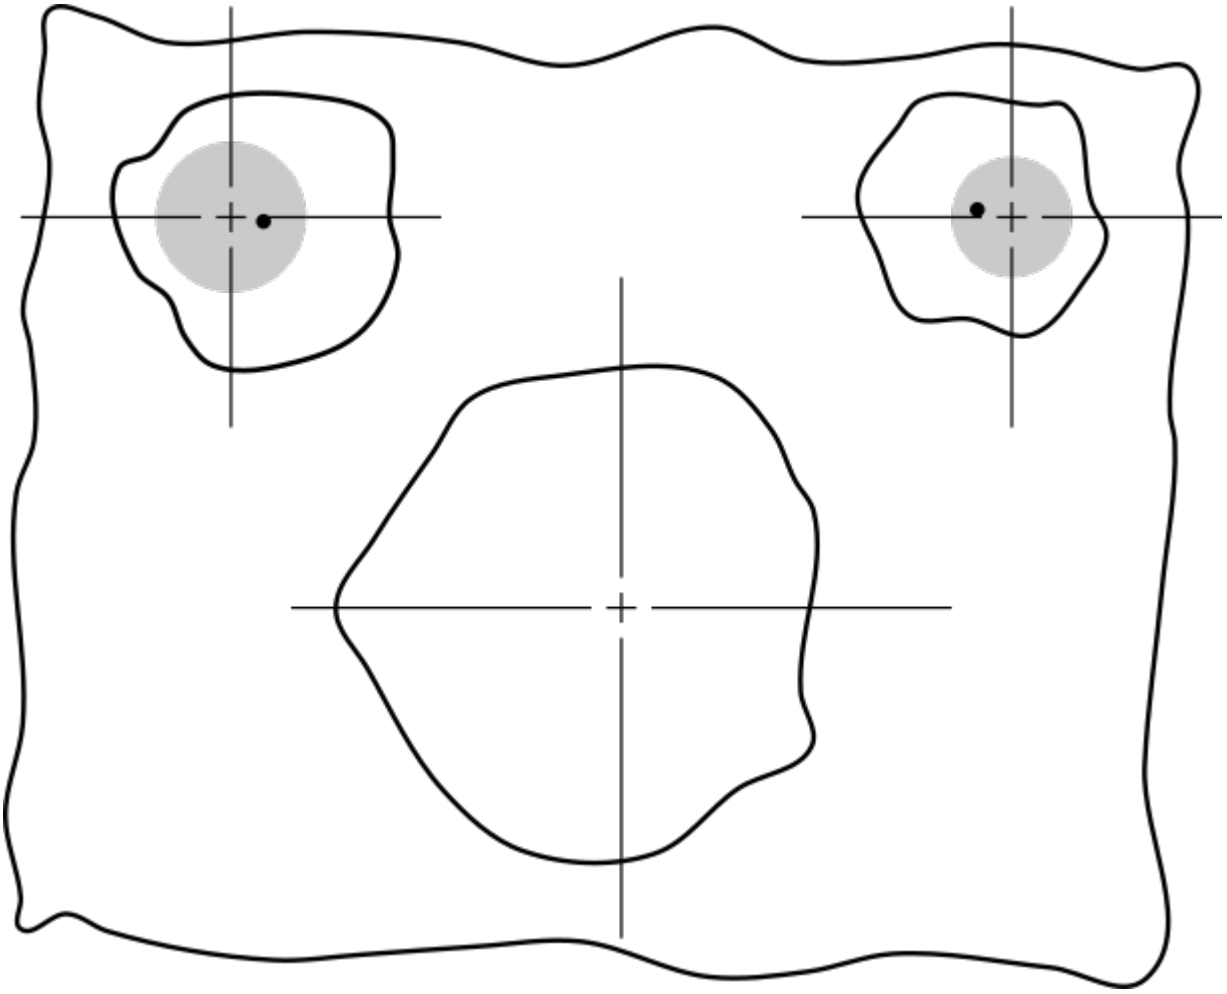
When translation is available (whether ASME with a translation modifier or ISO), the tolerance zones may translate together until they optimally contain the surface envelope axes. However, the zones remain nominally oriented and located with respect to each other, and they remain nominally oriented to higher precedence datums.

Illustrations of Datums with a Material Modifier

Suppose you had the following specification, using a secondary datum pattern referenced at maximum material boundary (MMB):

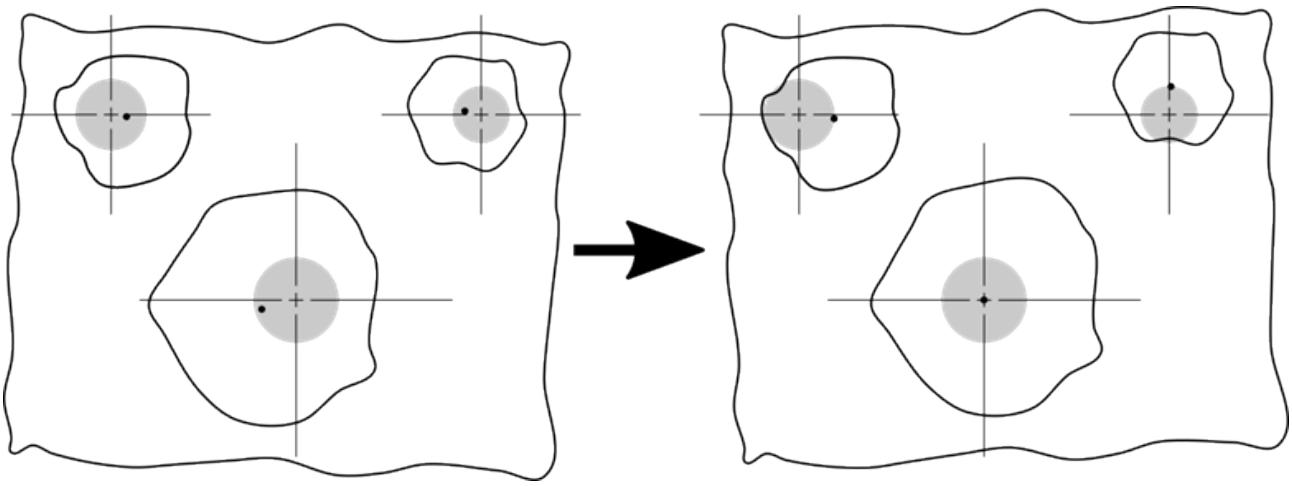


Solving the datum reference frame might result in this illustration:



The solid lines are the actual surface, the gray shaded areas represent the datum zones, and the small dots represent the datum axis that must be in the zone. The left datum has a bigger zone because the left actual datum hole is larger. The sizes of the zones are exaggerated to show how things work.

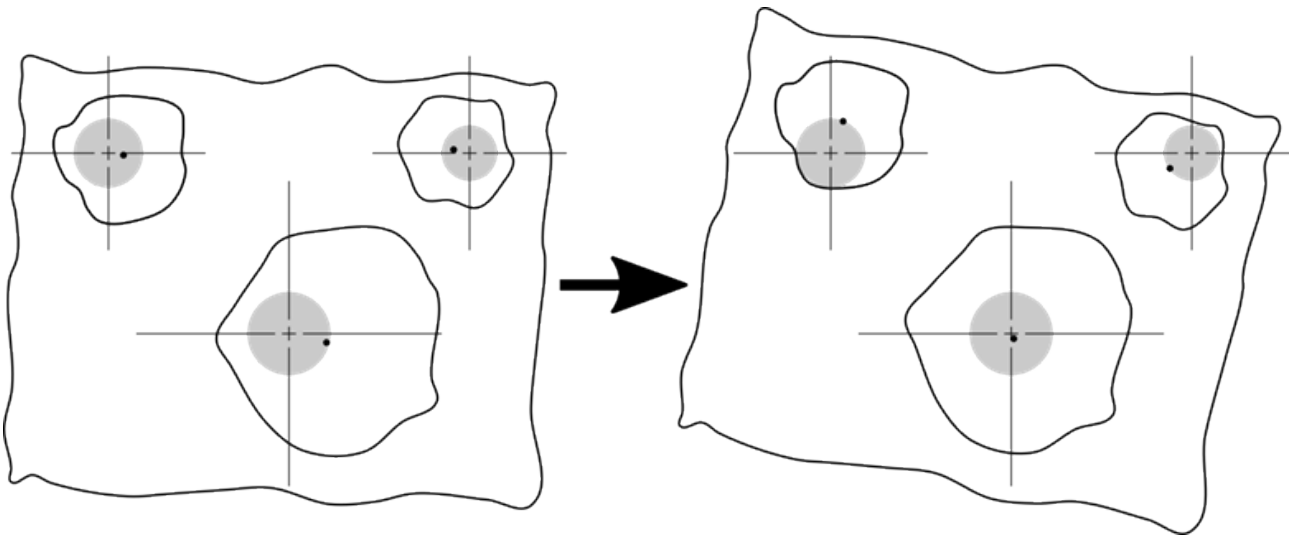
Since the datum axes are allowed to move within the datum zones (but not go outside them), that means the actual value for the position tolerance can be zero. Here is an illustration of how this works:



On the left is before optimization, showing the axis and tolerance zone of the big hole. On the right is after optimization, where the axis of the big hole is optimized to perfect location (yielding zero actual value) while the datum axes are forced to remain inside their zone but are not optimized.

The surfaces are shown to aid understanding, but they do not participate in the optimization. The optimization only uses the zones and the axes.

However, if the big hole has a large enough position error, the measured value will not be zero. Below is an illustration of such a case:



The big hole's actual value is optimized to be as small as possible, but the datums need to stay in their zones and so the actual value isn't zero.

Determining the Size of the Material Boundary

When you reference a datum with a material boundary modifier, the geometric tolerance command needs to compute the size of the material boundary unless the material

boundary size is specified. The material boundary size is based on the size tolerance of the datum feature and the applicable geometric tolerances.

For datums with a maximum material modifier, you start with the maximum material condition size. This is the upper limit of size for outer features, and the lower limit of size for inner features. Then you adjust this size by the applicable geometric tolerance.

For datums with a least material modifier, you start with the least material condition size. This is the lower limit of size for outer features, and the upper limit of size for inner features. Then you adjust this size by the applicable geometric tolerance.

For material boundaries that contain the feature surface, the applicable geometric tolerance increases the size of the material boundary. This is for outer features with a maximum material modifier and for inner features with a least material modifier.

For material boundaries that are contained by the feature surface, the material boundary size is decreased by the applicable geometric tolerance. This is for inner features with a maximum material modifier and for outer features with a least material modifier.

Rules to Determine Geometric Tolerance

The rules that determine which geometric tolerance to apply, if any, are complicated. They are described in ISO 2692:2014 (section 4) and described in ASME Y14.5-2018 (section 7.9). The PC-DMIS rules are shown below. In the ISO case, the rules are adapted to the tolerance types that PC-DMIS supports.

Primary Datums Under ISO 1101

For primary datums with ISO, we adjust the material boundary by the form tolerance at the same material condition, if it exists:

If the primary datum is a cylinder, we use the axis straightness at the same material condition, if it exists.

If the primary datum is a sphere or width, we ignore the form tolerance and do not adjust the material boundary.

If the primary datum is A Ⓜ and datum cylinder A is a shaft and has an axis straightness at Ⓜ, the maximum material boundary (MMB) is the maximum size of the shaft plus the axis straightness tolerance.

Secondary Datums Under ISO 1101

For secondary datums with ISO, we adjust the material boundary by the orientation or location tolerance at the same material condition that references the same primary datum, with the same datum modifiers, and that does not have any secondary datum. All other tolerances are ignored. If more than one such tolerance exists, the material boundary adjustment uses the smallest such tolerance.

Tertiary Datums Under ISO 1101

For tertiary datums with ISO, we adjust the material boundary by the orientation or location tolerance at the same material condition that references the same primary datum, with the same datum modifiers, and that references the same secondary datum, with the same datum modifiers, and that does not have any tertiary datum. All other tolerances are ignored. If more than one such tolerance exists, the material boundary adjustment uses the smallest such tolerance.

Primary Datums Under ASME Y14.5

For primary datums with ASME, we adjust the material boundary by the axis straightness form tolerance, if it exists. We do not adjust the material boundary for spheres and widths.

If the primary datum is A Ⓜ and datum cylinder A is a shaft and has an axis straightness, the maximum material boundary is the maximum size of the shaft plus the axis straightness tolerance.

In rare cases, a pattern is used as a primary datum with a material boundary modifier. In such cases, we first look for a position tolerance on the pattern without datums. If the position tolerance exists, PC-DMIS adjusts the material boundary by the position tolerance value. If no such position exists, then we look for an axis straightness tolerance.

Secondary Datums Under ASME Y14.5

For secondary datums with ASME, we adjust the material boundary by the orientation or position tolerance on the secondary datum.

- for a single datum, we use the orientation tolerance of the datum to the primary datum
- if no such orientation tolerance exists, we use the position tolerance of the datum pattern to the primary datum with the same datum modifiers
- for a datum pattern, we use the position tolerance of the datum pattern to the primary datum with the same datum modifiers

- for a common datum, we use the simultaneous position tolerances of the common datum features to the primary datum with the same datum modifiers
- the only geometric tolerances that are considered are specified at the same material condition as the secondary datum in question, and have no secondary datum

Tertiary Datums Under ASME Y14.5

For tertiary datums with ASME, we adjust the material boundary by a position tolerance on the tertiary datum (not orientation). The position tolerance must reference the same primary and secondary datums, with the same datum modifiers, without any tertiary datum. The position tolerance must be at the same material condition as the tertiary datum in question. If no such position tolerance is found, the material boundary is not adjusted by any geometric tolerance. For a single datum, the position tolerance must reference that feature. For a datum pattern, the position tolerance must reference the pattern. For a common datum, there must be simultaneous position of the common datum features.

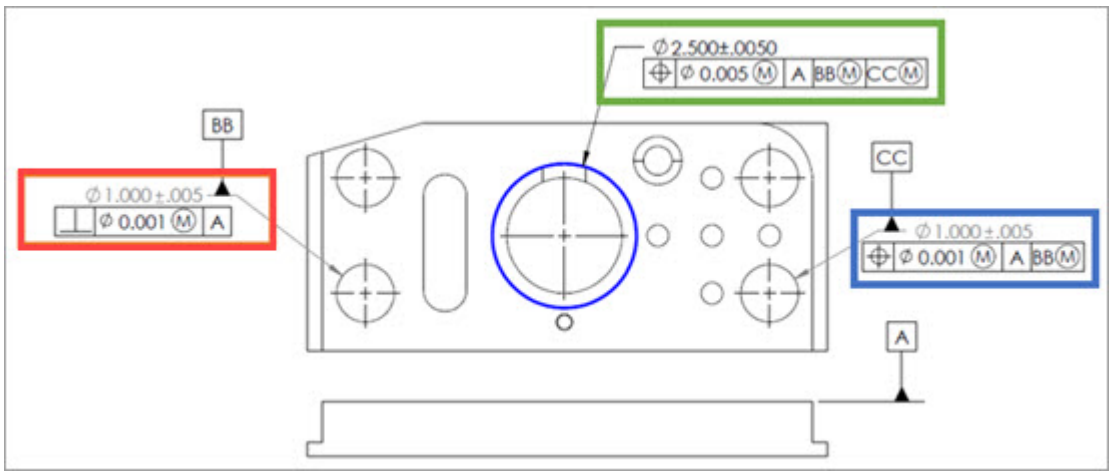
Datum Reference Messages

When you reference a datum with a modifier, PC-DMIS shows this message in the **Geometric Tolerance** dialog box:

> *Datums referenced at MMB/LMB must have been previously toleranced at MMC/LMC to their higher precedence datums. Where no such tolerance is found, zero at MMC/LMC will be applied.*

This is to remind you that the applicable Geometric Tolerance command(s) should have already been created for any datum feature(s) with a material condition modifier. If you have not created the applicable Geometric Tolerances for the referenced datum with a material condition modifier, PC-DMIS uses a Geometric Tolerance of 0.0 MMC to determine the MMB/LMB (Maximum/Least Material Boundary) value.

This reminder message cannot be turned off or disabled.



In this example, the position callout to evaluate is:

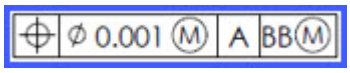
Example of the geometric tolerance for a position feature.

In addition to the feature's modifier, the secondary and tertiary datums also have modifiers.

Per the secondary datum rules, datum BB has an Applicable Geometric Tolerance to datum A:

Example of the geometric tolerance for datum BB.

Per the tertiary datum rules, datum CC has an applicable geometric tolerance to datums A and BB:

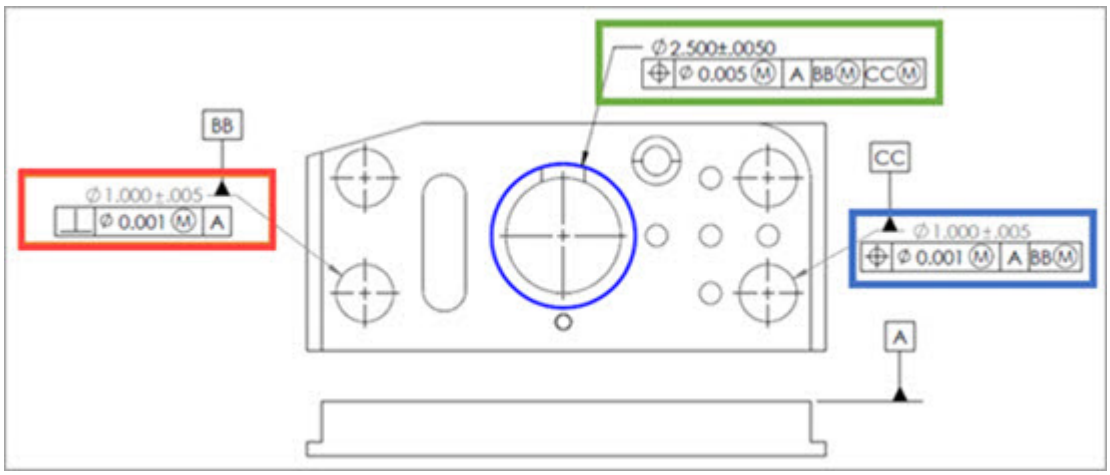


Example of the geometric tolerance for datum CC.

You must add the geometric tolerance for datum BB to the measurement routine ***first***. Once that geometric tolerance has been added, you can then add the geometric tolerance for datum CC.

Once you have defined the geometric tolerances for those datums, you can then add the geometric tolerance for the position feature to the measurement routine. PC-DMIS uses the geometric tolerances for datums BB and CC (applicable geometric tolerances) to determine the clearance (datum shift).

When you create the geometric tolerance for the position feature above for example, PC-DMIS reads up in the measurement routine to locate the applicable geometric tolerances for the datums with material condition modifiers. If PC-DMIS does not find any, it uses 0.0 @ MMC for the secondary and tertiary datums.



When PC-DMIS uses 0.0 @ MMC, in many cases you might see that PC-DMIS applies a limited datum shift. If the drawing specifies no applicable geometric tolerance, it may be a design or drawing error.

Even though PC-DMIS applies 0.0 @ MMC tolerance(s) to determine a conservative calculation for datum shifts, they do not appear in PC-DMIS reports. To confirm if the datums conform to these conservative tolerances, you can add the tolerance(s) to the measurement routine.

Using Modifiers on Datums and Their Reported Measurement Results

When you use modifiers on datums, PC-DMIS evaluates the available clearance in the datum reference frame (DRF) by using the applicable tolerances provided on the datums. When this occurs, it resolves to one of these two possible outcomes:

Result #1

The DRF **conforms** to the tolerances and PC-DMIS determines that there is clearance available in the DRF.

In this case, PC-DMIS optimizes the fit of the DRF, it applies the datum shift, and provides the measurement results.

Result #2

The DRF **does not conform** to the tolerances and PC-DMIS determines that there is **no clearance available** in the DRF.

If you attempt to use a functional gage for the part, **it would not fit**. This leaves PC-DMIS with two reporting options:

Report Option #1: PC-DMIS could generate a report with an error message but no measurement results.

Report Option #2 : PC-DMIS could generate a report with a conservative measurement solution without the datum shift.

PC-DMIS utilizes Report Option #2 and still evaluates the Geometric Tolerance ***without*** using modifiers on the datums:

- PC-DMIS uses the original position tolerance 
and evaluates this tolerance by removing the modifiers from the datum features. PC-DMIS would then complete the final evaluation as:

- PC-DMIS would not apply a datum shift

> PC-DMIS still indicates the original position tolerance requirement in the report:
>
> >

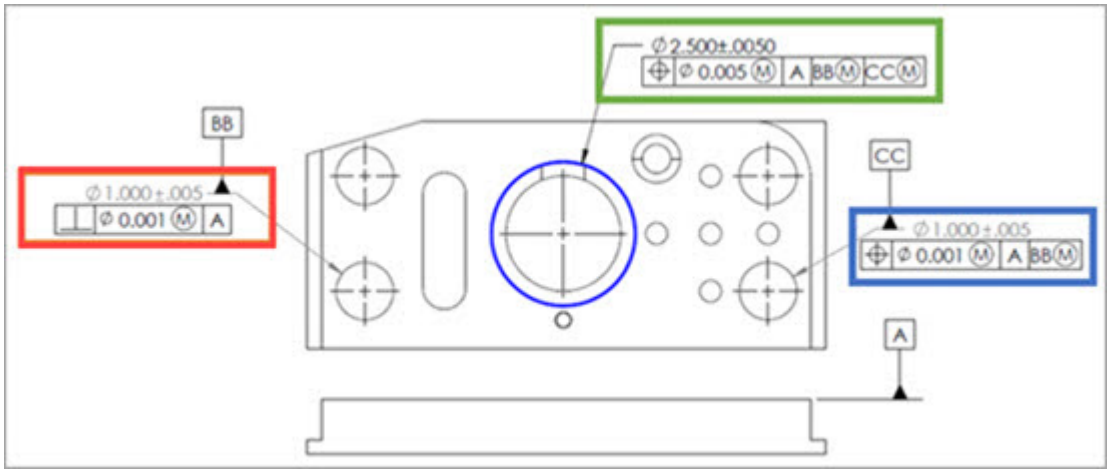
> Both results are possible even when no applicable geometric tolerances are found and PC-DMIS uses 0.0 @ MMC for the applicable geometric tolerances. For additional information, see the "Rules to Determine Geometric Tolerance" in this chapter of the PC-DMIS Core documentation.

Consider this example again:



If the datums conform to their applicable geometric tolerances, then PC-DMIS evaluates the tolerance 
and reports the measurement results after the datum shifts as described in **Result #1** above.

However, if any of the datums do not conform to their applicable geometric tolerances, then PC-DMIS evaluates the original tolerance 
without the modifiers on any of the datums as

. PC-DMIS reports the measurement results ***without*** datum shift as described in **Result #2** above.

With Result #2, a review of the applicable geometric tolerances for the datums will show at least one of them as non-conforming. In this example, the non-conforming tolerances would either be

on datum BB or 
on datum CC.

Datums with Unconstrained Location Compared to Higher-Precedence Datums

An ASME datum with a translation modifier, or an ISO datum without a [DF] modifier, has unrestricted translation compared to higher-precedence datum simulators. Both the ASME and ISO standards are unclear about what this means when there are any datums referenced with a material modifier.

For these reasons we make the following recommendations:

- For ASME standard, when you use a modifier on a datum, we do not recommend using the translation modifier in the datum reference frame (DRF).
- For ISO standard, when you use a modifier on datum, we recommend that you always use the [DF] modifier in the DRF.

If you choose to ignore these recommendations, PC-DMIS solves the DRF as noted below and the PC-DMIS simulated gage fitting will most likely always have available clearance in the DRF.

Suppose we take a primary datum plane, a secondary datum circle at maximum material, and a tertiary datum circle without a material modifier but with translation allowed. There are two possible interpretations:

1. We could evaluate the datum reference frame independent of the position tolerance; we optimize the B-C distance so that B is optimally centered in its hole, and then we keep that distance constant while evaluating the position tolerance.
2. We could evaluate the datum reference frame simultaneously with the position tolerance; while optimizing the position tolerance we allow the B-C distance to vary until the position tolerance measured value is as small as possible.

In PC-DMIS, we use the first interpretation because it is more conservative (the measured values are larger).

Optimized Shift

Starting in PC-DMIS 2026.2, you can report optimized shift for the following position or profile tolerance cases, for both ISO 1101 and ASME Y14.5:

- Single-segment tolerances or the first segment of multi-segment tolerances whose datum reference frame (DRF) is fully constrained and includes a material condition modifier. ASME Y14.5 2018 section 7.11.11 calls this case "Datum feature Shift/ Displacement". In ISO GPS, you can consider the optimized shift as decomposition. The goal of decomposition is to translate measurement results into parameter values that you can use to adjust the manufacturing process (see ISO 20170:2019).

  The reported optimized shift information is relative to the datum reference frame's gage-centered pose (see below). The optimized shift values are always in the datum reference frame display coordinates.

- Lower segments of multi-segment tolerances.

  The reported optimized shift information is relative to the first segment's solved datum reference frame, in the datum reference frame display coordinates.

The Gage-Centered Pose

A pose is the combined position and orientation of the datum reference frame — the three translations and three rotations that appear in the report as Shift X, Shift Y, Shift Z, Rotation X, Rotation Y, and Rotation Z.

A datum feature referenced at maximum material boundary (MMB) or least material boundary (LMB) typically has play (movement) inside its gage. The gage-centered pose centers the datum features in their gages so that the gage clearance is as large as it can be, shared evenly when more than one gage competes for it.

The gage-centered pose is not the same as the pose the same datums produce with every material modifier removed, meaning all datums at regardless of material boundary (RMB) under ASME or no material requirement under ISO.

Enabling Optimized Shift

You can enable or disable optimized shift for each segment. Either select the applicable check box on the **Reporting** tab of the **Geometric Tolerance** dialog box, or toggle `SHOW_OPT_SHIFT` to `ON` in the applicable segment section of the command in Command Mode, as shown below:

When you enable optimized shift, the report in the Report window adds different optimized shift information, depending on the circumstances:

	This symbol means that optimized shift is not available. You see this symbol for unsupported cases, or for cases where PC-DMIS cannot display meaningful information (RMB cases, for example).
	This symbol means that the axis is locked. You see this symbol when optimization is available, but the degree of freedom for this axis cannot move or shift.
	This symbol means that the axis is unlocked. You see this symbol when an axis is fully free to optimize by any amount necessary. For example, this often occurs with a lower segment of composite callouts where a degree of translation can move (Z direction), but because the cylinder vectors are in the Z direction, this has no effect on the measurement results.
	Where explicit optimized shift data is available, you see a number that represents the amount of linear shift. These numbers are in the same units as the geometric tolerance command (mm or inches).
	Where explicit optimized shift data is available, you see a number that represents the amount of angular rotation. These numbers are in the measurement routine's angular units (decimal degrees or degrees minutes and seconds) for rotations (see "Display Angle Degrees").
INTERFERENCE	This appears in the final "Optimized Fit" column for cases where any of the datum features violate their material condition boundary (MMB or LMB). It means that there is interference between the datum simulator and the actual datum feature(s) – if you check the part using a physical gage, that gage does not fit.

Single-Segment Examples

Datum A is a plane (+Z), Datum E is a cylinder (+Z), and Datum CC is a plane (-X). We have a position dimension with two cylinders off location, with deviation values of 0.020 mm in two directions.

This is a fully constrained DRF, so there is no optimized shift and PC-DMIS displays the symbol:

FCFLOC1_EX1 Size	MM	Ø 16.4 ± 0.2	DEFAULT	ASME Y14.5 - 2018

Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
CYL8	16.400	0.200	-0.200	16.400	0.000	0.000

Optimized Shift	Shift X	Shift Y	Shift Z	Rotation X	Rotation Y	Rotation Z
Segment 1						

However, if the print has a modifier added to Datum E ⌖ Ø0.005Ⓜ A EⓂ CC, we have the potential for optimized shift. The Geometric Tolerance command only allows optimized shift if the Datum E cylinder does not violate its MMB.

In the example below, our datum violates its MMB boundary, so the last column (Optimized Fit) appears and reports "Interference". The report also includes the datum size for clarity, which shows how the size violates the boundary. The Optimized Shift values for this case all show "locked" because we remove the MMB and report the RMB solution.

Optimized Shift	Shift X	Shift Y	Shift Z	Rotation X	Rotation Y	Rotation Z
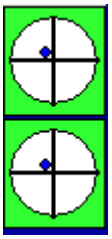
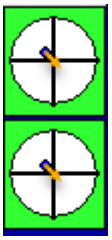
Segment 1	0.020	-0.020	🔒	🔒	🔒	🔒

Direction of the Reported Shift Values

You can use different perspectives when reporting the Optimized Shift values. PC-DMIS takes the approach of having the simulated gage fixed in place and the part moving. As a result, if you look at the original position values (Dim FCFLOC_EX1) for CYL8 and CYL9, the position error is in this direction (viewing from +Z):



As we gain clearance, the part moves to the right and down on the simulated gage (see yellow arrows):



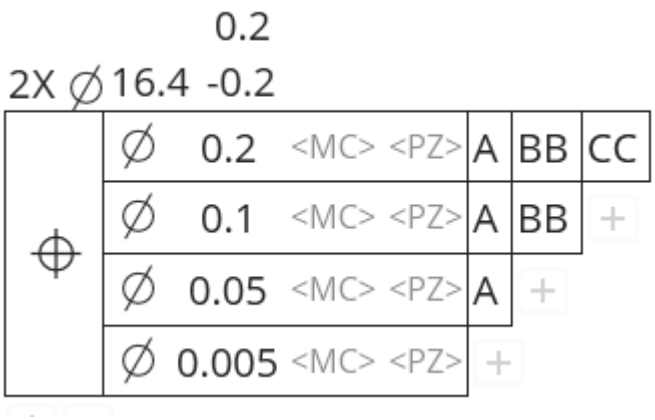
Our final result is a position whose deviation values are exactly at 0.0, with Optimized Shift values of X +0.020, Y -0.020.

When there is a modifier on the datum (MMB or LMB), PC-DMIS reports the optimized shift this way because the datum feature has play (movement) inside its gage. The starting point (coordinate system) is always the gage-centered pose.

Composite Callout Examples

Composite requirements for position and profile can get complicated. The example below shows datums without modifiers. If your first segment has MMB or LMB modifiers, PC-DMIS reports the optimized shift for that segment similar to the single segment considered above. Some of the report screenshots below show only a partial section of the entire report. The shift values reported in any lower segments compare the DRF for that segment to the DRF in the first segment.

Datum A is a plane (+Z), Datum BB is a plane (-Y), and Datum CC is a plane (-X). Consider the overall requirement for this example:



FCFLOC1_EX5 Size	MM	⌀ 16.4 ± 0.2	DEFAULT	ASME Y14.5 - 2018

Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
CYL8	16.400	0.200	-0.200	16.400	0.000	0.000
CYL9	16.400	0.200	-0.200	16.400	0.000	0.000

FCFLOC1_EX5	MM	⌖ ⌀0.2 A BB CC	DEFAULT	ASME Y14.5 - 2018

Feature	AX	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL	BONUS
CYL8 (START PT)	X	80.000			79.980	-0.020		
	Y	101.000			101.020	0.020		
	TP	0.000	0.200	0.000	0.057	0.057	0.000	0.000
CYL9 (END PT)	X	80.000			79.980	-0.020		
	Y	19.000			19.020	0.020		
	TP	0.000	0.200	0.000	0.057	0.057	0.000	0.000

Optimized Shift	Shift X	Shift Y	Shift Z	Rotation X	Rotation Y	Rotation Z
Segment 1						

For Segment 1, PC-DMIS does not allow or report optimized shift.

FCFLOC1_EX5	MM	⌖ ⌀0.1 A BB	DEFAULT	ASME Y14.5 - 2018

Feature	AX	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL	BONUS
CYL8 (END PT)	X	80.000			80.000	0.000		
	Y	101.000			101.000	0.000		
	TP	0.000	0.100	0.000	0.000	0.000	0.000	0.000
CYL9 (END PT)	X	80.000			80.000	-0.000		
	Y	19.000			19.000	0.000		
	TP	0.000	0.100	0.000	0.000	0.000	0.000	0.000

Optimized Shift	Shift X	Shift Y	Shift Z	Rotation X	Rotation Y	Rotation Z
Segment 2	0.020	-0.020				

For Segment 2:

- The datums lock and control the rotational degrees of freedom
- PC-DMIS does not report a specific Shift Z because it can move infinitely for this case . It has no effect on the position calculation because the cylinder vectors are in the Z direction.

- SHIFT X and SHIFT Y have reported values. The shift values compare the DRF from Segment 2 to the DRF on Segment 1.

FCFLOC1_EX5	MM	⌖ Ø0.05 A			DEFAULT	ASME Y14.5 - 2018		
Feature	AX	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL	BONUS
CYL8 (END PT)	X	80.000			80.000	0.000		
	Y	101.000			101.000	-0.000		
	TP	0.000	0.050	0.000	0.000	0.000	0.000	0.000

Introduction

The geometric tolerance command has detailed rules for feature types with surface data, for features types without surface data, and for features types that you cannot use in a geometric tolerance command at all. Unfortunately, some feature types are only allowed to be used with a few tolerance types, and that information is not detailed here. Also, there are a few exceptions to the rules detailed here that were omitted for clarity but are rare enough that we did not document them.

There are several types of features that you can use with the geometric tolerance command:

- Plane
- Cross section of a plane (surface line)
- Sample of a plane (surface point)
- Cylinder
- Cross section of a cylinder (surface circle)
- Surfaceless axis
- Width
- Cone
- Sphere
- Surfaceless 3D point

- Freeform

The documentation below talks about each PC-DMIS feature type and illustrates the kinds of PC-DMIS features that belong to the geometric tolerance command types.

For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points).

For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

Planes

With Surface Data

Plane feature types with surface data include:

Measured planes, auto planes (any measurement strategy), constructed BF planes, and constructed BFRE planes

No Surface Data

Plane feature types without surface data include:

Alignment planes, cast planes, mid-planes, perpendicular planes, parallel planes, primary datum planes, offset planes, translated planes, and generic planes

Only Allowed for Datums

Some plane types you can use only as datums, but not as considered features. These features include:

Alignment planes, cast planes, perpendicular planes, parallel planes, primary datum planes, offset planes, translated planes, and generic planes

Lines

The Geometric Tolerance dialog box has an interpretation message whenever you use a constructed line as a constructed feature or as a datum, letting you know whether the constructed line is being treated as a line on a surface (cross section of a planar surface) or as an axis of revolution (surfaceless axis).

With Surface Data

The geometric command always treats a line feature on a surface as a cross section of a planar surface. While you can measure a line on a non-planar surface in PC-DMIS, the geometric tolerance command always handles lines on surfaces as coming from a planar surface. These line types have surface data. They include these features:

Measured lines, auto lines (any measurement strategy), constructed 2D BF lines, constructed BFRE lines, and scan segment lines

Constructed 3D BFRE lines frequently have incorrect nominal values, even when you program your routine from a CAD model. Specifically, the nominal workplane of the constructed 3D BFRE line contains both the nominal surface normal and the nominal line vector. It is often nominally misaligned with the drawing. If you use this as a datum, it can frequently cause the following error message:

"Datum feature <feature name> is 2D. It needs a higher-precedence datum to constrain its workplane."

In most cases, we recommend using constructed 2D BFRE lines instead of constructed 3D BFRE lines so the nominal workplane of the line is correct.

For information on how PC-DMIS handles line surface vectors for constructed 2D and 3D lines, see the "Constructed Line Surface Vectors" section of the "Migration from Prior Versions of PC-DMIS" topic of the PC-DMIS Core documentation.

No Surface Data

Some line features are cross sections of a plane, but they do not have surface data. These include:

Mid-lines, projected lines, and secondary datum lines

Some line features are surfaceless axes. These represent some axis of revolution and do not have a surface. These do not have surface data. These line features include:

Alignment lines, constructed 3D BF lines, cast lines, intersection lines, parallel lines, perpendicular lines, offset lines, and generic lines

Special Cases

Some line features deviate from the above interpretation in these special cases:

- Constructed 3D BF lines and offset lines are cross sections of a plane and have surface data when they are constructed from points measured on a surface.
- Parallel lines and perpendicular lines are cross sections of a plane, but do not have surface data when the resulting nominal surface normal matches the location reference (the second input to the construction).

Points

With Surface Data

A point feature on a surface is always treated as a sample of a planar surface. While you can measure a point on a non-planar surface in PC-DMIS, the geometric tolerance command always handles points on surfaces as coming from a planar surface. These point types have surface data. These point features include:

Measured points, vector points (default strategy, not the self-centering one), surface points, edge points, high points, mid-points, and tertiary datum points

No Surface Data

Some point features do not have a surface and are constrained in 3 dimensions just like the center-point of a sphere. These are surfaceless 3D points. These point features include:

Cast points, corner points, drop points, generic points, intersection points, offset points, origin points, projection points, and vector distance points

A pierce point is constrained in two dimensions, so it is a surfaceless axis having a length of zero. For information on surfaceless axes, see the "Lines" above.

Not Allowed

PC-DMIS does not allow auto angle point features as inputs to the geometric tolerance command, either as considered features or as datums.

Cylinders

With Surface Data

Cylinder feature types with surface data include:

Measured cylinders, auto cylinders (any measurement strategy), constructed BF cylinders, and constructed BFRE cylinders

No Surface Data

Cylinder feature types without surface data include:

Cylinders and generic cylinders

Not Allowed

Projection cylinders are not allowed as inputs to the geometric tolerance command, neither as considered features nor datums.

Circles

With Surface Data

Circle features are treated as a cross section of a cylindrical surface. While you can measure a circle on a non-cylindrical surface in PC-DMIS, the geometric tolerance command always handles circles as coming from a cylindrical surface (with one exception detailed in "Circular Runout").

Circle feature types with surface data include:

Measured circles, auto circles (except the gage scan calibration measurement strategy), constructed BF circles, constructed BFRE circles, and scan segment circles

No Surface Data

Circle feature types that do not have surface data include:

Intersection circles, projection circles, cylinder circles, cone circles, sphere circles, cast circles, tangent 2 lines circles, tangent 3 lines circles, tangent 3 circles, scan minimum circles, and generic circles

Not Allowed

Some circle feature types are not allowed as inputs to the geometric tolerance command, neither as considered features nor datums. These include:

Auto circles with the gage scan calibration measurement strategy

Additionally, sphere circles are allowed as a considered feature but are not allowed as a datum.

Widths

All width features have surface data.

Slots and Notches

With Surface Data

Slots and notches have surface data when you use them in a profile of a line tolerance.

No Surface Data

Slots and notches do not have surface data when you use them in a position tolerance or as a datum.

Be careful with slot and notch features.

You should only use them if you already know that the form of the features is very good. If you suspect that the manufactured form error might be significant, do not use a slot or notch command. Instead, measure a scan around the perimeter of the feature and then tolerance the form, orientation, and location of the feature with a profile of a line tolerance.

Cones

With Surface Data

Cone features with surface data include:

Measured cones, auto cones (any measurement strategy), constructed BF cones, and constructed BFRE cones

No Surface Data

Cast cones represent a conical surface but do not have surface data.

Generic cones don't have a diameter in PC-DMIS, and so they represent a surfaceless axis and do not have surface data.

Not Allowed

Projection cones are not allowed as inputs to the geometric tolerance command, neither as considered features nor as datums.

Spheres

With Surface Data

Sphere features with surface data include:

Measured spheres, auto spheres, constructed BF spheres, and constructed BFRE spheres

No Surface Data

Sphere features without surface data include:

Cast spheres and generic spheres

Not Allowed

Projection spheres are not allowed as inputs to the geometric tolerance command, neither as considered features nor as datums.

Freeform Feature Types

The geometric tolerance command allows Freeform features as considered features for profile tolerances. These features have a number of measured points with matching nominal points and nominal vectors.

When there is no CAD model present, or when you don't use the iterate and re-pierce option, PC-DMIS calculates the deviations simply as the vector deviation of the measured point to the nominal planar surface defined by the nominal point and the nominal vector. This is the "piecewise planar" approximation.

When your measurement routine uses a CAD model, and you use iterate and re-pierce, PC-DMIS calculates the deviations to the CAD model (there is no piecewise planar approximation). For more information, see "Profile of a Line" and "Profile of a Surface".

PC-DMIS considers these feature types as considered freeform features:

Scan commands, constructed sets, constructed filtered sets, constructed adjust filter objects, auto Profile2D features (vision), and tori

Possible Surface Data

PC-DMIS considers some polygons as freeform features (with surface data) when you use them in a profile tolerance, but it considers them as circle features (lacking surface data) when you use them in a position tolerance. These feature types aren't really designed for position tolerances, but they are included as circles (lacking surface data) for migration purposes.

PC-DMIS considers slots and notches as freeform features (with surface data) when you use them in a profile tolerance, but it considers them as width features (lacking surface data) when you use them in a position tolerance.

Not Allowed

These features or types of features are not allowed as inputs to the geometric tolerance command, neither as considered features nor as datums:

Measured sets, area scans, projected ellipses, projected notches, projected slots, auto blobs, flush and gap features, load fixture features, face features,

object features, constructed curve features, constructed surface features, and gage features

Reverse Features

Several types of features are "reverse" features. These include:

Reverse planes, reverse cylinders, and so on

Possible Surface Data

Reverse features might have surface data. It depends on the input to the reverse feature. If the input has surface data, so does the reverse feature.

Possibly Allowed

You might be able to use reverse features as a considered feature or datum feature. It depends on the input to the reverse feature. The surface handling of the reverse feature is the same as the input feature. For example, a reverse line may be a surfaceless axis or a plane cross section. It depends on the input to the reverse feature.

Not Allowed

You cannot use reverse features that are constructed out of a different type of feature than the reverse feature as inputs to the geometric tolerance command, neither as considered features nor as datums. For example, you cannot use a reverse line constructed from a cylinder as an input to the geometric tolerance command.

Evaluating Size with the Geometric Tolerance Command

Many geometric tolerance commands contain a size tolerance. This page describes how the geometric tolerance command computes measured size values and measured local size values.

Size Specifications

The geometric tolerance command supports only a few size specifications. There is a separate size command for more complicated size specifications. For information, see "" in the PC-DMIS Core documentation.

Under ASME, the geometric tolerance command uses the following size specification. The unrelated actual mating envelope (UAME) controls the feature surface in the plus-material direction, and the local sizes control the feature surface in the minus-material direction. The local sizes are opposed-point sizes unless the feature is a cylinder, and you have the

`CIRCULAR_ELEMENTS` local size option. That said, the geometric tolerance command does not report local sizes unless you turn on local size reporting, because many measurement systems have insufficient accuracy to verify that the local sizes comply with the size tolerance.

Under ISO, starting with PC-DMIS 2025.1, size math and feature math are independent of each other (for details, see the "Comparison to Past Practice - ISO Math Types" section in the "Structuring your Measurement Routine for Geometric Tolerances" topic of the PC-DMIS Core documentation). Most ISO size tolerances are envelope sizes as defined in ISO 14405-1. This means the plus-material direction is controlled by a mating envelope size, and the minus-material direction is controlled by opposed-point local sizes. However, when ISO 17450-3 applies, as discussed in "Deriving the Toleranced Feature", then the size tolerance is a no-modifiers (default) size. This means the size tolerance does not control any mating envelope, and the only sizes are the two-point local sizes.

Global Size

Anytime the size specification includes a mating envelope size, the size tolerance has a global size. ISO tolerances call this GLOBAL SIZE in the Edit window, while ASME tolerances call this UAME in the Edit window. The only time the size tolerance does not have a global size is when ISO 17450-3 applies as discussed above, or when you select an ISO (LP) size modifier.

If your considered feature does not have surface data, the global size is the `MEAS` size of the input feature. ISO size modifiers are not available for features that do not have surface data.

If your considered feature has surface data, and your ISO size math or the ASME feature math option is **LSQ** (least squares), the global size is the size of the (unconstrained) least squares best fit.

If your considered feature has surface data, and your ISO size math or ASME feature math option is **DEFAULT**, the global size is the size of the inscribed or circumscribed best fit, whichever of the two is external to the material. Since traditional inscribed and circumscribed fits are notoriously unstable, PC-DMIS uses a constrained least squares algorithm to compute the inscribed or circumscribed fit in a stable way.

As discussed in "Specification Versus Verification" section of the "Introduction to Geometric Tolerances and Feature Control Frames" topic in the PC-DMIS Core documentation, PC-DMIS offers both **LSQ** and **DEFAULT** feature math options because different measurement systems have different amounts of measurement uncertainty. If your measurement system is precise and accurate enough to measure the feature's form error—if the measurement uncertainty is much smaller than the form error—then it makes sense to use **DEFAULT** math. If the measurement uncertainty is larger than the form error, then you should use **LSQ** math. For more information, see "Specification Versus Verification".

Local Size

If ISO 17450-3 applies as discussed above, then the size specification is the default ISO size specification (no modifiers), meaning there are only local sizes and no global size. The geometric tolerance command reports both the maximum and the minimum local size.

If ISO 17450-3 does not apply, and if your considered feature has surface data, you have the option to report local sizes. This is primarily useful when your feature math option is **DEFAULT**, because the geometric tolerance command reports only the *worst* local size in the internal to material direction. When combined with **DEFAULT** size math, the global size controls the surface in the external to material direction while the local size controls the surface in the internal to material direction. By contrast, the **LSQ** size math has a least-squares global size, which does not control the surface deviations in either direction. In this case, the surface will be uncontrolled in the external to material direction.

For ISO size tolerances, and for ASME size tolerances on spheres and widths, the local sizes are evaluated using opposed points. Each local size is essentially a two-point caliper measurement. Please ensure your measured points all have a directly opposed point, or the measurement accuracy may suffer. This is especially challenging on spheres.

For ASME size tolerances on cylinders, you have a choice of using the `OPPOSED_POINTS` interpretation or the `CIRCULAR_ELEMENTS` interpretation. These interpretations are specified in ASME Y14.5.1 - 2019. The opposed points interpretation behaves as just described.

The circular elements interpretation requires that the surface data was measured in circular cross sections. It best-fits a circle to each cross section; the sizes of the circles are the local sizes. When the feature math type is **LSQ**, the circles are computed using least squares. When the feature math type is **DEFAULT**, the circles are inscribed or circumscribed, whichever of the two is internal to the material. Since traditional inscribed and circumscribed fits are notoriously unstable, PC-DMIS uses a constrained least squares algorithm to compute the inscribed or circumscribed fit in a stable way.

It does not make sense to report local sizes unless your measurement system is precise and accurate enough to measure the feature's form error.

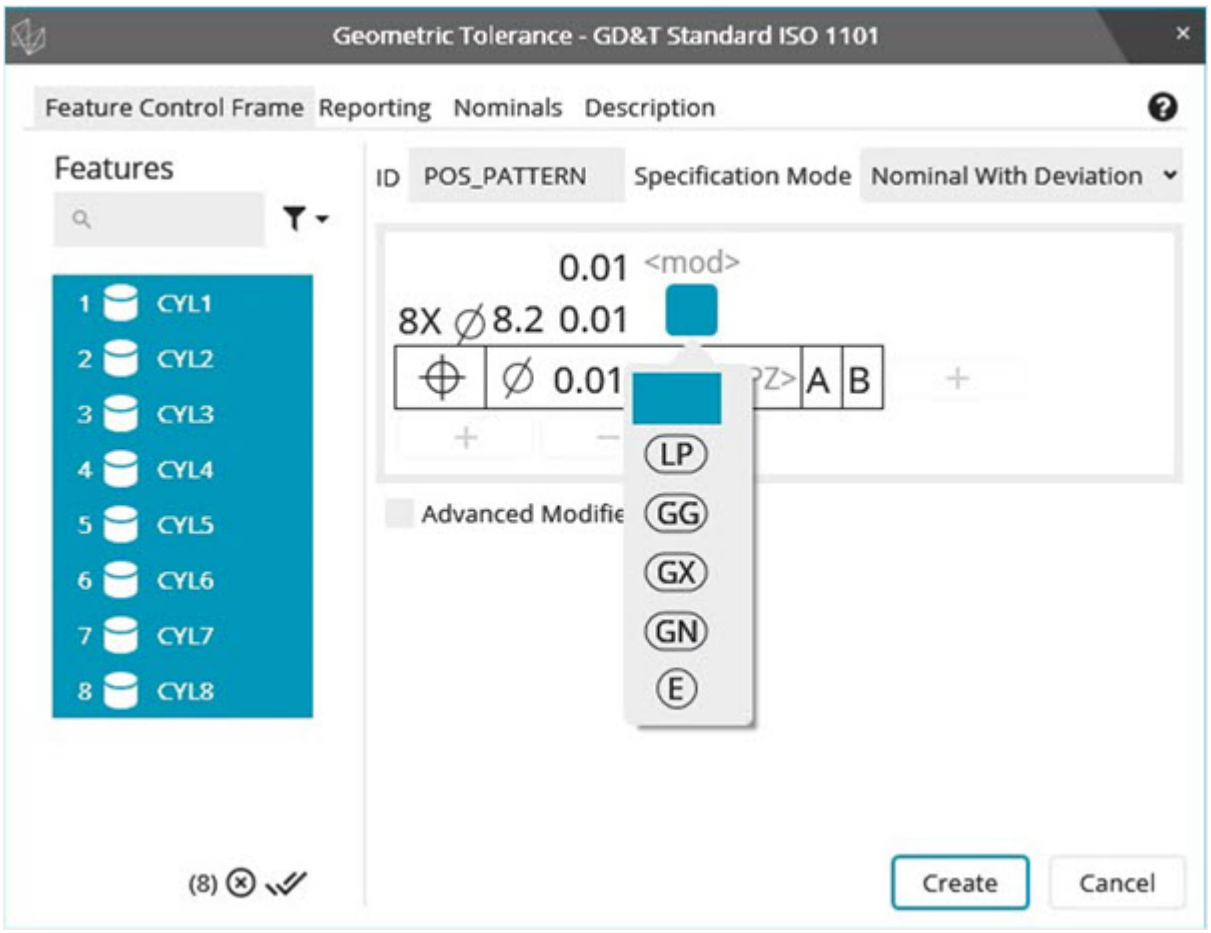
ISO Size Modifiers

Starting with PC-DMIS 2025.1, the Geometric Tolerance command supports some of the more common ISO 14405-1 size modifiers, such as:

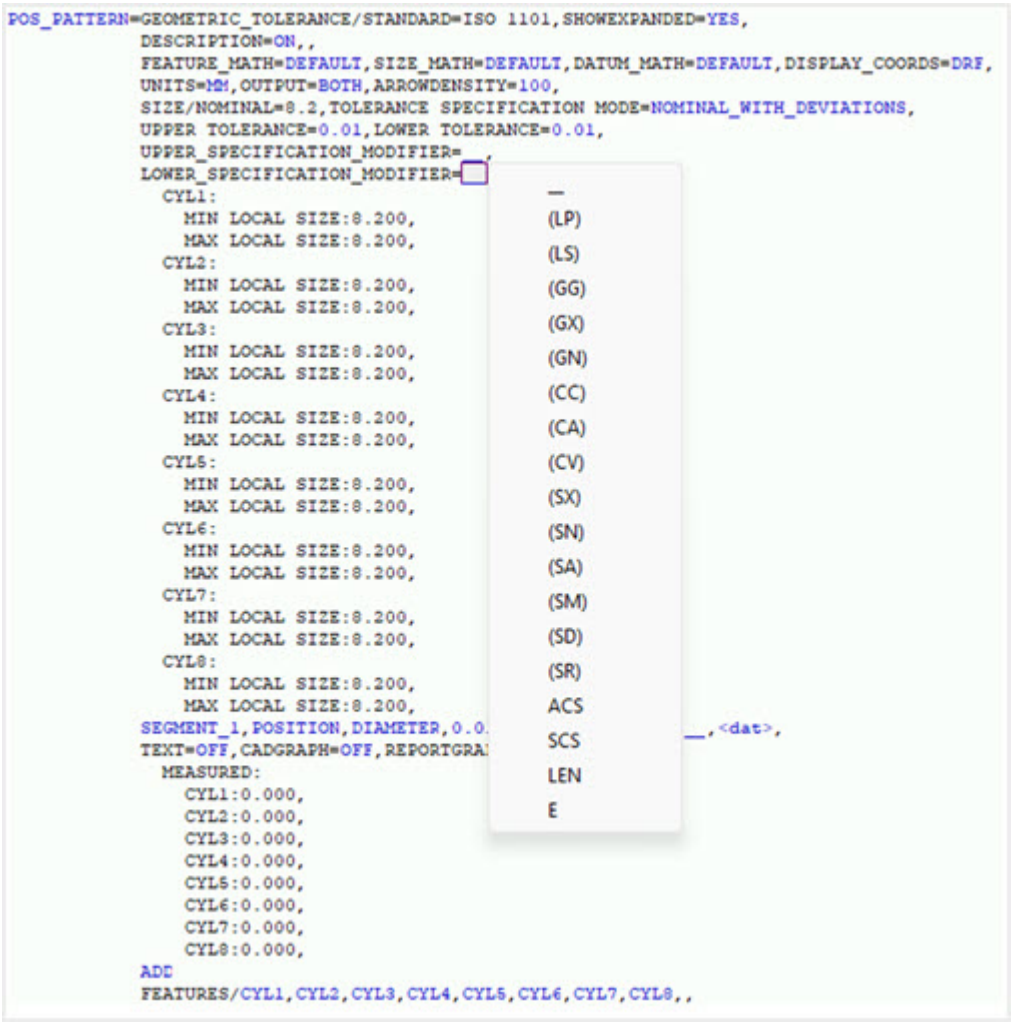
- (LP) - Two-point Size
- (GG) - Least-squares Association Criterion
- (GX) - Maximum Inscribed Association Criterion
- (GN) - Minimum Circumscribed Association Criterion

- (E) - Envelope Requirement

These modifiers are available from the **Geometric Tolerance** dialog box.



You can also add or remove size modifiers directly in the Edit window. You can either type it in or select it from a list as shown below:



Because the geometric tolerance command's Edit window `UPPER_SPECIFICATION_MODIFIER` and `LOWER_SPECIFICATION_MODIFIER` list is shared with the size command, all ISO size modifiers are shown. This doesn't mean, however, that they are all available for selection. You can only add modifiers which the geometric tolerance command supports. If you try to add an unsupported modifier, PC-DMIS ignores your selection and retains the applicable `LOWER_SPECIFICATION_MODIFIER` or `UPPER_SPECIFICATION_MODIFIER` 's existing selection.

You can see a typical example of how the information appears in the Edit window command and in the report when you select the option to report size modifiers:

```
FCFLOC1     =GEOMETRIC_TOLERANCE/STANDARD=ISO 1101,SHOWEXPANDED=YES,

CYL2 (LEVEL # 1)	TP	0.000000	0.500039	0.000000	0.015947	0.015947	0.000000	0.000000

Bonus Calculations

Some geometric tolerances have a maximum material condition modifier Ⓜ (MMC) or least material condition modifier Ⓛ (LMC). This means that as the unrelated mating envelope size (or unrelated minimum material envelope size for LMC) deviates from the MMC (or LMC), additional tolerance or "bonus" tolerance is added to the tolerance in the feature control frame, yielding a total tolerance. For the **DEFAULT** feature math, the measured bonus tolerance is the difference between an inscribed or circumscribed best fit and one of the limits of size. Since traditional inscribed and circumscribed fits are notoriously unstable, PC-DMIS uses a constrained least squares algorithm to compute the inscribed or circumscribed fit in a stable way. For the **LSQ** feature math, the measured bonus tolerance is the difference between the least squares global size and one of the limits of size.

Measured bonus tolerance is calculated in the following way.

- For MMC tolerances on outer features, the bonus is the upper limit of size (the MMC size) minus the circumscribed size (external to material envelope) or the least squares size (depending on the feature math type).
- For MMC tolerances on inner features, the bonus is the inscribed size (external to material envelope) or the least squares size (depending on the feature math type) minus the lower limit of size (the MMC size).
- For LMC tolerances on outer features, the bonus is the inscribed size (internal to material envelope) or the least squares size (depending on the feature math type) minus the lower limit of size (the LMC size).

- For LMC tolerances on inner features, the bonus is the upper limit of size (the LMC size) minus the circumscribed size (internal to material envelope) or the least squares size (depending on the feature math type).

In every case, the bonus is limited so it is never negative, and never exceeds the total size tolerance (the upper boundary of size minus the lower boundary of size).

The selection of ISO size modifiers does not affect the bonus calculation. Bonus values are always calculated as described above.

Report

Without Local Size

When you are not reporting local size, the size label of the report looks like this:

FCFLOC5 Size		MM	SØ 31.75 +0.025/-0.025		LSQ	ASME Y14.5 2018
Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
SPH1	31.750000	0.025000	-0.025000	31.751629	0.001629	0.000000
SPH2	31.750000	0.025000	-0.025000	31.748836	-0.001164	0.000000

The header bar shows the dimension ID of the tolerance, the dimension units (MM or IN), the size specification, the math type (**LSQ** in this case), and the standard (ASME Y14.5 in this case). The table below shows the measured sizes of each sphere.

With Global and Local Sizes

When you are reporting global sizes and local sizes, the size label has extra rows, with LS added as a suffix for the worst local sizes. For example, "SPH1 - LS". For ASME tolerances on cylinders, the header bar also says whether the local size interpretation is OPPOSED or CIRCULAR. When reporting global sizes and local sizes, the report looks like this:

FCFLOC5 Size		MM	SØ 31.75 +0.025/-0.025 OPPOSED		LSQ	ASME Y14.5 2018
Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
SPH1	31.750000	0.025000	-0.025000	31.751629	0.001629	0.000000
SPH1 - LS	31.750000	0.025000	-0.025000	31.731449	-0.018551	0.000000
SPH2	31.750000	0.025000	-0.025000	31.748836	-0.001164	0.000000
SPH2 - LS	31.750000	0.025000	-0.025000	31.734986	-0.015014	0.000000

Without Global Size

When ISO 17450-3 applies, there is no global size reported. Instead, MIN and MAX are added as a suffix for the worst local sizes in both directions. The report looks like this:

LOC12 Size		MM	Ø 152.4 +/- 5		DEFAULT	ISO 1101
Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
CYL2 - MIN	152.400	5.000	-5.000	152.477	0.077	0.000
CYL2 - MAX	152.400	5.000	-5.000	152.830	0.430	0.000
CYL3 - MIN	152.400	5.000	-5.000	152.490	0.090	0.000
CYL3 - MAX	152.400	5.000	-5.000	152.848	0.448	0.000

With ISO 14405 Size Modifiers

When ISO 14405 size modifiers are applied, the details are listed in the header with the appropriate suffix added to the feature name as shown below:

FCFLOC3 Size		MM	Ø 30 [+0.1 LP] - [-0.1 GX]		MODIFIER	ISO 1101
Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
CYL1 - LP	30.000000	0.100000	0.100000	29.957540	-0.042460	0.000000
CYL1 - GX	30.000000	0.100000	0.100000	29.919873	-0.080127	0.000000

Introduction

For most specification types, the toleranced feature is the considered feature's surface data. However, with location and orientation geometric tolerances (position, concentricity, symmetry, perpendicularity, parallelism, and angularity) the toleranced feature is derived from the considered feature's surface data. This applies to circles, cones, cylinders, notches, slots, spheres, and widths. This also applies to the tangent plane modifier planar features. Each type of considered feature is handled differently. This topic covers features that have surface data, features without surface data (including mid-planes and mid-lines),

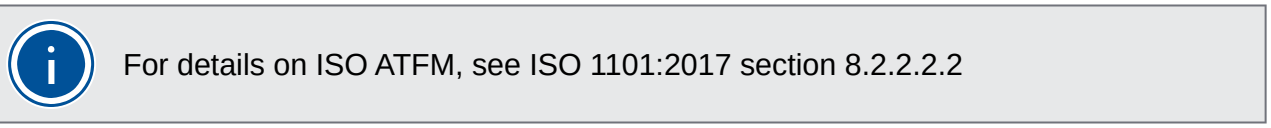
and finally the tangent plane modifier. For information on the command types that have and do not have surface data, see "Feature Types With and Without Surface Data".

In several places below, we discuss the sample plane. Circle, cone, and cylinder Auto features can have a sample plane:

- When the feature has a sample feature, the sample feature is the sample plane.
- When the feature has one sample hit, the sample plane passes through that hit and is nominally oriented to the measured datums.
- When the feature has three or more sample hits, the sample plane is the least squares plane for those sample hits.
- When the feature has no sample hits nor sample feature selected, there is no sample plane.

When there is a sample plane, there is also a start plane that intersects the axis at the start point. The nominal sample plane is allowed to be offset from the nominal start plane, because the nominal sample plane might not intersect the nominal axis at the start point. The measured start plane is parallel to the measured sample plane and is nominally offset from it.

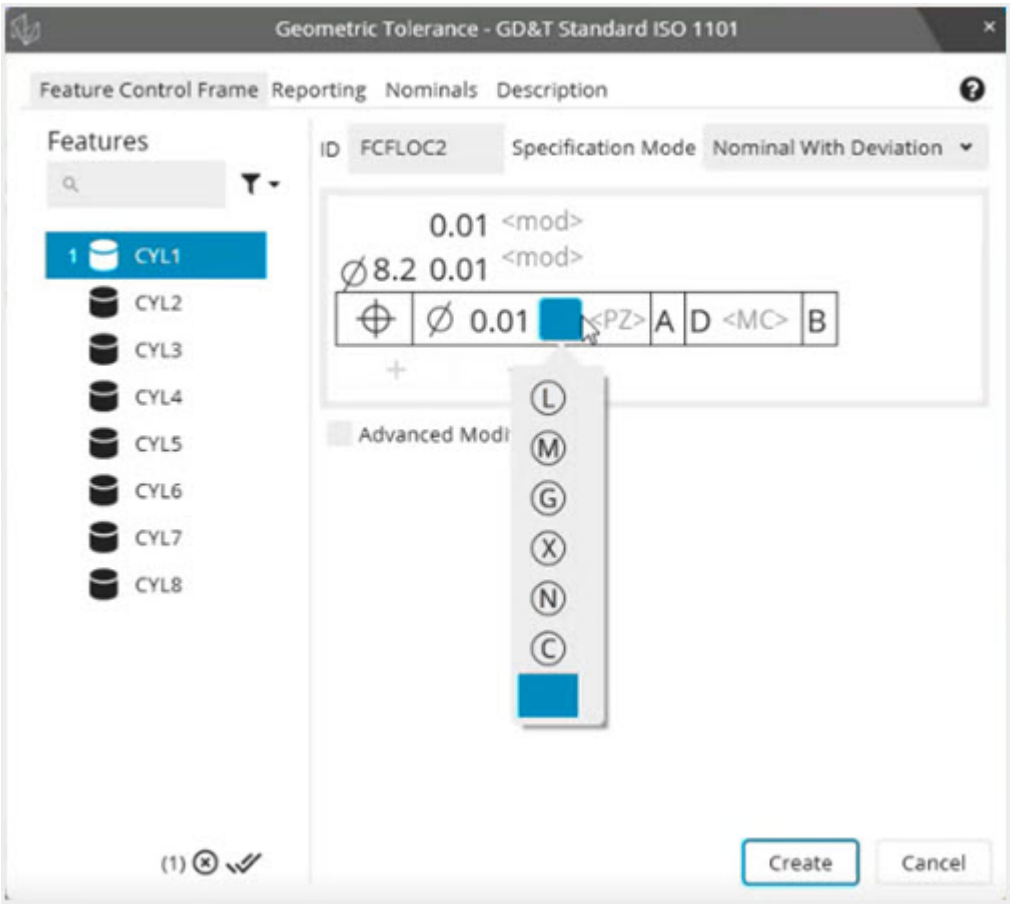
ISO Associated Toleranced Feature Modifiers (ATFM)



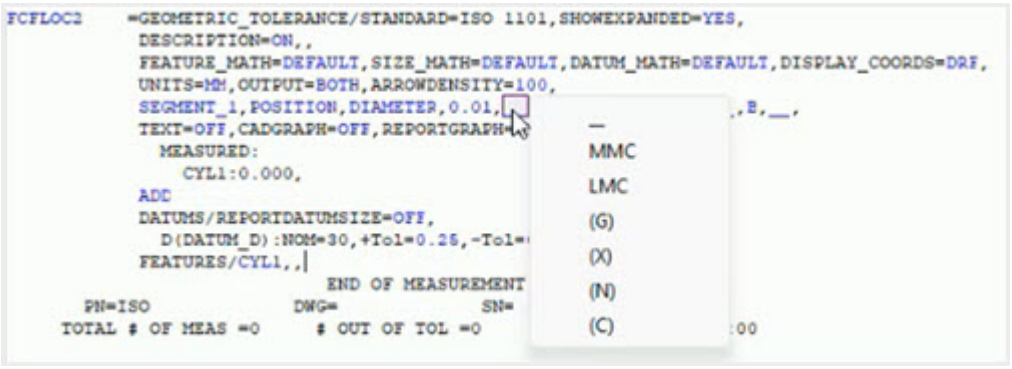
Starting with PC-DMIS 2025.1, the geometric tolerance command supports these ISO Associated Toleranced Feature Modifiers (ATFM):

- Ⓒ **MinMax (Chebyshev)** feature modifier - This feature modifier is available for circle, cone, cylinder, line, plane, and width considered feature types.
- Ⓖ **Least Squares (Gaussian)** feature modifier - This feature modifier is available for circle, cone, cylinder, line, plane, and width considered feature types.
- Ⓝ **Minimum Circumscribed** feature modifier - This feature modifier is available for circle, cylinder, line, plane, and width considered feature types.
- Ⓧ **Maximum Inscribed** feature modifier - This feature modifier is available for circle, cylinder, line, plane, and width considered feature types.
- Ⓣ **Tangent** feature modifier - This feature modifier is only available for plane considered feature types.

You can add the associated tolerance feature modifier to the tolerance section of the Feature Control Frame in the **Geometric Tolerance** dialog box.



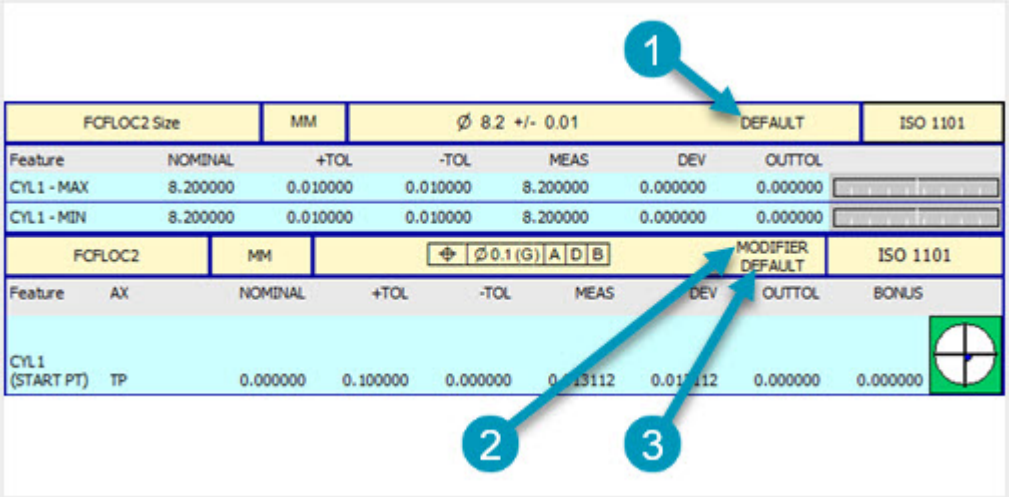
You can also select the associated tolerance feature modifier in the Edit window when in Command Mode:



When you select the modifier from the Edit window, the FEATURE_MATH shows "MODIFIER_SELECTED", and the selected modifier overrides the usual **DEFAULT** or **LSQ** feature fitting.

> **!** You cannot combine an associated toleranced feature modifier with a material condition modifier (MMC or LMC).

The resulting report shows the selected modifiers and applicable math types:



1. *SIZE Math Type*
2. *FEATURE Math Type (indicating a modifier was selected)*
3. *DATUM Math Type*

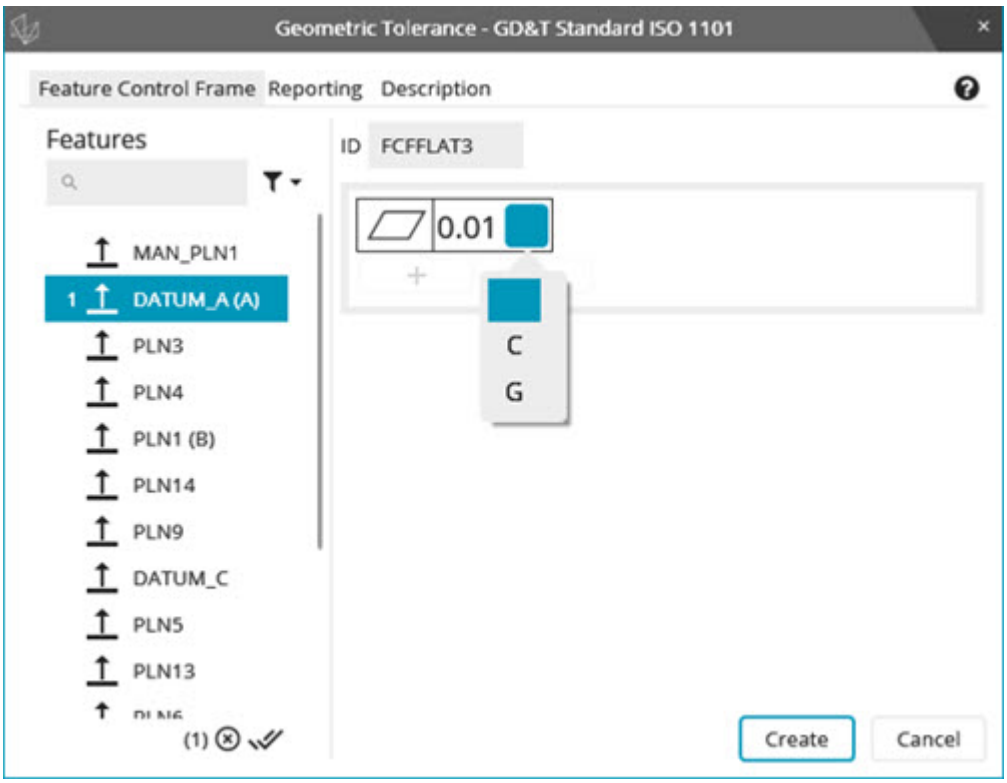
ISO Reference Feature Association Modifiers (RFAM)

> For details on the ISO Reference Feature Association Modifiers (RFAM), see ISO 1101:2017 section 8.2.2.3.1.

Starting with PC-DMIS 2025.1, the Geometric Tolerance command supports these ISO Reference Feature Association Modifiers (RFAM):

- **C** - **MinMax (Chebyshev)** feature without Constraint: This reference feature association modifier is available for circularity, cylindricity, flatness, and surface straightness tolerances.
- **G** - **Least Squares (Gaussian)** feature without Constraint: This reference feature association modifier is available for circularity, cylindricity, flatness, and surface straightness tolerances.

ISO RFAM are not applicable for straightness of an axis. You can add an RFAM to the tolerance section of the Feature Control Frame in the **Geometric Tolerance** dialog box as shown here:

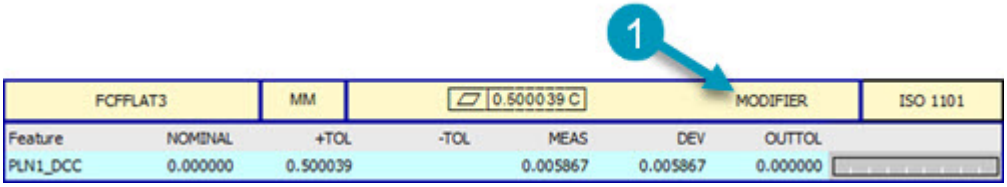


You can also select the associated RFAM in the Edit window when in Command Mode:

When you select the modifier from the Edit window, the TOLERANCE_ZONE_MATH shows "MODIFIER_SELECTED", and the selected modifier overrides the usual **DEFAULT** or **LSQ** feature fitting.

> **!** You cannot combine a reference feature modifier with a material condition modifier (MMC or LMC).

The resulting report shows the selected modifiers and applicable math types:



1. *TOLERANCE_ZONE_MATH (indicating a modifier was selected)*

Feature Math Types

As discussed in the "Specification Versus Verification" section of the "Introduction to Geometric Tolerances and Feature Control Frames" topic, we offer multiple math types for toleranced feature computation. PC-DMIS provides two such math types for features having measured surface data: **DEFAULT** and **LSQ**. What they do is detailed below. For the most part, **DEFAULT** is a good choice when the measurement uncertainty of the surface data is much less than the form error of the surface, because the mathematics is similar to the specification.

The **LSQ** feature math option does a plain least squares best fit to the surface data. This algorithm is mathematically quite different than the specification, but it is a better choice than **DEFAULT** when the measurement uncertainty of each point is much larger than the form error of the surface.

For more details, see "Specification Versus Verification".

Spherical Features With Surface Data

The toleranced feature is a 3D point when the considered feature is a sphere. When the spherical feature has surface data, the toleranced feature is constructed in the following way:

A fit type is selected, based on the feature math type (**DEFAULT** or **LSQ**) and based on the material modifier. The **LSQ** math type always does a least-squares best fit. The **DEFAULT** math type does an inscribed or circumscribed best fit. When the material modifier is RFS (no material modifier) or MMC, the inscribed or circumscribed fit is chosen to be external to the material. When the material modifier is LMC, the inscribed or circumscribed fit is chosen to be internal to the material. Thus, the DEFAULT math type usually produces the unrelated actual mating envelope (UAME) unless the modifier is LMC. In that case, the math type produces the unrelated actual minimum material envelope (UAMME). Since traditional inscribed and circumscribed fits are notoriously unstable, PC-DMIS uses a constrained least squares algorithm to compute the inscribed or circumscribed fit in a stable way.

The center-point of the fitted sphere is the toleranced feature.

Cylindrical Features with Surface Data under ASME Y14.5

The toleranced feature is an axis when the considered feature is a cylinder. Under ASME Y14.5, when a cylindrical feature has surface data, the toleranced feature is constructed in the following way:

First, a fit type is selected, based on the feature math type (**DEFAULT** or **LSQ**) and on the material modifier. The **LSQ** math type always does a least-squares best fit. The **DEFAULT** math type does an inscribed or circumscribed best fit. When the material modifier is RFS (no material modifier) or MMC, the inscribed or circumscribed fit is chosen to be external to the material. When the material modifier is LMC, the inscribed or circumscribed fit is

chosen to be internal to the material. Thus, the **DEFAULT** math type usually produces the unrelated actual mating envelope (UAME) unless the modifier is LMC. In that case, the math type produces the unrelated actual minimum material envelope (UAMME). Since traditional inscribed and circumscribed fits are notoriously unstable, PC-DMIS uses a constrained least squares algorithm to compute the inscribed or circumscribed fit in a stable way.

Second, an extrapolation is selected. It is based on whether a sample plane is available and whether a projected-zone modifier is present:

- When there is no sample plane, and there is no projected zone modifier, the best-fit axis is extrapolated to the nominal end-faces of the cylinder. The nominal end-faces of the cylinder are nominally oriented and located to the measured datums. If there is a projected zone modifier, the extrapolation starts at the nominal start-face of the cylinder. It continues away from the end-face, until it hits the nominal projection plane parallel to the start plane at the projected distance away from it.

- When there is a sample plane, the extrapolation starts at the measured start plane.

The extrapolated best-fitted axis is the toleranced feature.

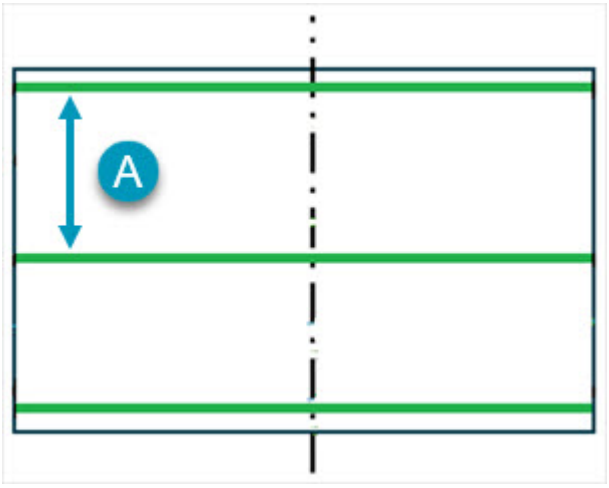
Cylindrical Features with Surface Data under ISO 1101

The toleranced feature is an axis when the considered feature is a cylinder. Under ISO 1101, when a cylindrical feature has surface data, the toleranced feature is constructed in the following way:

First, PC-DMIS determines whether ISO 17450-3 : 2016 applies or not. To PC-DMIS, it applies when there is no material modifier, no associated tolerance feature modifier, no projected-zone modifier, and the feature math type is **DEFAULT**.

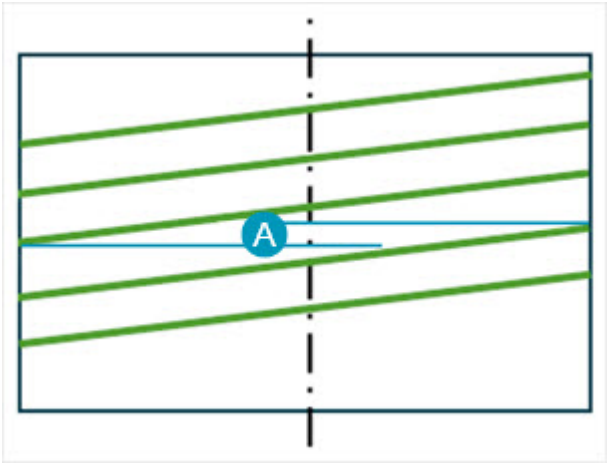
When ISO 17450-3 applies, and the surface data were measured in cross sections, the toleranced feature is an imperfect axis. Each cross section has a least-squares circle fitted to it. The vector of each circle is the vector of the least-squares axis of the entire cylinder. The center-points of the circles form the toleranced feature. This process matches closely with the specification in ISO 17450-3. When the surface data were not measured in cross sections, PC-DMIS attempts to automatically section the data in the following way:

- If the cylinder was measured in clean cross sections, meaning multiple distinct levels with an easily detectable gap between each level, then PC-DMIS uses those clean cross sections.



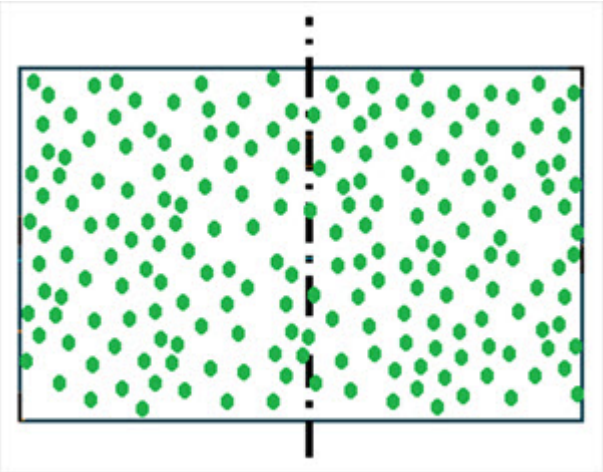
***A** - Gap*
Easily detectable gap between the end of one level and the start of the next. Three cross sections are returned.

- If the cylinder was not measured in clean cross sections, but the data follows a clean spiral pattern, then PC-DMIS divides the spiral into several cross sections, equal to the number of revolutions in the spiral (so long as the spiral has more than two revolutions).



***A** - No Gap*
You can see in this example one continuous spiral or overlapping start and end points. Five cross sections are returned.

- If the cylinder was not measured in either clean cross sections or a clean spiral pattern, then PC-DMIS performs a best effort to divide the data into cross sections.



You can see in this example that there is no discernible pattern. The number of returned cross sections depends on the point distribution and density.

After PC-DMIS divides the cylinder into cross sections, it rejects any section that has less than 90 degrees of arc. The corresponding circle center is not included in the toleranced feature.

In some cases, the above procedure produces no circle centers. For example, spiral scans with two or fewer revolutions or all cross sections were found to have less than 90 degrees of arc. In such cases, it is not possible to adhere so closely to the description in ISO 17450-3, and so PC-DMIS employs an approximation. Specifically, the toleranced feature is the axis of the least-squares cylinder, extrapolated to the endpoints of the measured surface data.

When ISO 17450-3 does not apply, a fit type is selected, based on the feature math type (**DEFAULT** or **LSQ**) and based on the material modifier. The LSQ math type always does a least-squares best fit. The **DEFAULT** math type does an inscribed or circumscribed best fit. When the material modifier is RFS (no material modifier) or MMC, the inscribed or circumscribed fit is chosen to be external to the material. When the material modifier is LMC, the inscribed or circumscribed fit is chosen to be internal to the material. Since traditional inscribed and circumscribed fits are notoriously unstable, PC-DMIS uses a constrained least squares algorithm to compute the inscribed or circumscribed fit in a stable way.

When ISO 17450-3 does not apply, and after a fit has been computed, an extrapolation is selected. The extrapolation is based on whether a sample plane is available, and based on whether a projected-zone modifier is present:

- When there is no sample plane, and there is no projected zone modifier, the best-fit axis is extrapolated to the nominal end-faces of the cylinder. The nominal end-faces of the cylinder are nominally oriented and located to the measured datums. If there is a projected zone modifier, the extrapolation starts at the nominal start-face of the cylinder. It continues away from the end-face, until it hits the nominal projection plane parallel to the start plane at the projected distance away from it.
- When there is a sample plane, the extrapolation starts at the measured start plane.

The extrapolated best-fitted axis is the toleranced feature.

Circular Features with Surface Data under ASME Y14.5

The toleranced feature is a 2D point when the considered feature is a circle. Under ASME Y14.5, when a circular feature has surface data, the toleranced feature is constructed in the following way:

First, a fit type is selected, based on the feature math type (**DEFAULT** or **LSQ**) and on the material modifier. The **LSQ** math type always does a least-squares best fit. The **DEFAULT** math type does an inscribed or circumscribed best fit. When the material modifier is RFS (no material modifier) or MMC, the inscribed or circumscribed fit is chosen to be external to the material. When the material modifier is LMC, the inscribed or circumscribed fit is chosen to be internal to the material. Thus, the **DEFAULT** math type usually produces the unrelated actual mating envelope (UAME) unless the modifier is LMC. In that case, the math type produces the unrelated actual minimum material envelope (UAMME). Since traditional inscribed and circumscribed fits are notoriously unstable, PC-DMIS uses a constrained least squares algorithm to compute the inscribed or circumscribed fit in a stable way.

Second, a projection is selected, based on whether there is a sample plane:

- When there is no sample plane, the best-fit center-point is projected to the nominal start-plane of the circle. The nominal start-plane is nominally oriented and located to the measured datums.
- When there is a sample plane, the best-fit center-point is projected to the measured start plane.

The projected point is the toleranced feature.

Circular Features with Surface Data under ISO 1101

The toleranced feature is a 2D point when the considered feature is a circle. Under ISO 1101, when a circular feature has surface data, the toleranced feature is constructed in the following way:

All of the possibilities involve fitting a circle.

First, PC-DMIS determines whether ISO 17450-3 : 2016 applies or not. To PC-DMIS, it applies when there is no material modifier, no associated tolerance feature modifier, and the feature math type is **DEFAULT**.

When ISO 17450-3 applies, the toleranced feature is the center-point of the least-squares circle.

When ISO 17450-3 does not apply, a fit type is selected, based on the feature math type (**DEFAULT** or **LSQ**) and on the material modifier. The **LSQ** math type always does a least-squares best fit. The **DEFAULT** math type does an inscribed or circumscribed best fit.

When the material modifier is MMC, the inscribed or circumscribed fit is chosen to be external to the material. When the material modifier is LMC, the inscribed or circumscribed fit is chosen to be internal to the material. Since traditional inscribed and circumscribed fits are notoriously unstable, PC-DMIS uses a constrained least squares algorithm to compute the inscribed or circumscribed fit in a stable way.

The axis vector of the best-fit circle is nominally oriented to the measured datums. If there is a sample plane, it controls the axis vector of the best-fit circle to the extent that the measured datums do not control the axis vectors.

Next, a projection is selected, based on whether there is a sample plane:

- When there is no sample plane, the best-fit center-point is projected to the nominal start-plane of the circle. The nominal start-plane is nominally oriented and located to the measured datums.
- When there is a sample plane, the center-point is projected to the measured start plane. The orientation of the measured start plane depends on the number of sample hits taken. If there is only one sample hit, the measured start plane inherits the nominal orientation. If there are three or more sample hits, the measured start plane inherits its orientation from the measured sample plane.

The projected point is the toleranced feature.

Conical Features With Surface Data under ASME Y14.5

The toleranced feature is an axis when the considered feature is a cone. Under ASME Y14.5, when a conical feature has surface data, the toleranced feature is constructed in the following way:

First, a fit type is selected, based on the feature math type (**DEFAULT** or **LSQ**). The **LSQ** math type always does a least-squares best fit. The **DEFAULT** math type does an inscribed or circumscribed best fit, chosen to be external to the material. Thus, the **DEFAULT** math type produces the unrelated actual mating envelope (UAME). Since traditional inscribed and circumscribed fits are notoriously unstable, PC-DMIS uses a constrained least squares algorithm to compute the inscribed or circumscribed fit in a stable way. In all of these fits, the cone angle is allowed to optimize from the nominal angle.

Second, an extrapolation is selected. It is based on whether sample hits are available:

- When there is no sample plane, the best-fit axis is extrapolated to the nominal end-faces of the cone. The nominal end-faces of the cone are nominally oriented and located to the measured datums.
- When there is a sample plane, the extrapolation starts at the measured start plane.

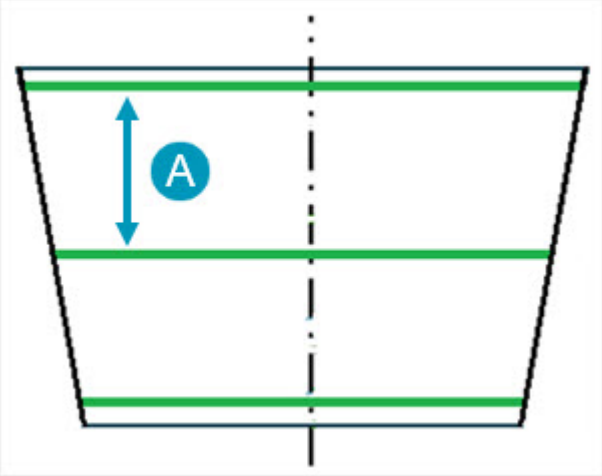
The extrapolated best-fitted axis is the toleranced feature.

Conical Features with Surface Data under ISO 1101

The toleranced feature is an axis when the considered feature is a cone. Under ISO 1101, when a cylindrical feature has surface data, the toleranced feature is constructed in the following way:

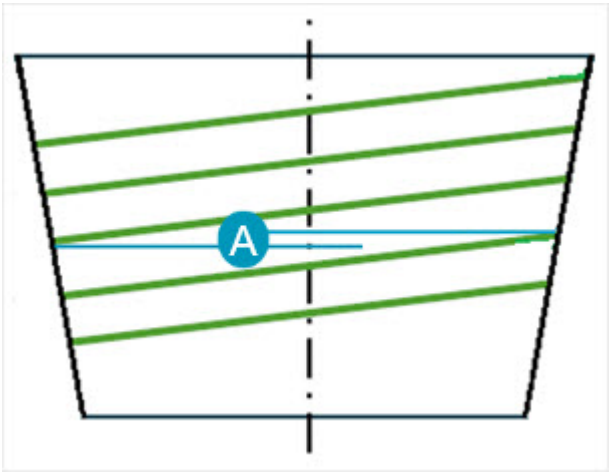
When the feature math type is **DEFAULT**, PC-DMIS decides that a generalization of ISO 17450-3 : 2016 applies so the toleranced feature is an imperfect axis derived from multiple cross sections. Each cross section has a least-squares circle fitted to it. The vector of each circle is the vector of the least-squares axis of the entire cone. The center-points of the circles form the toleranced feature. This process matches closely with the specification in ISO 17450-3. PC-DMIS determines the cross sections in the following way:

- If the cone was measured in clean cross sections, meaning multiple distinct levels with an easily detectable gap between each level, then PC-DMIS uses those clean cross sections.



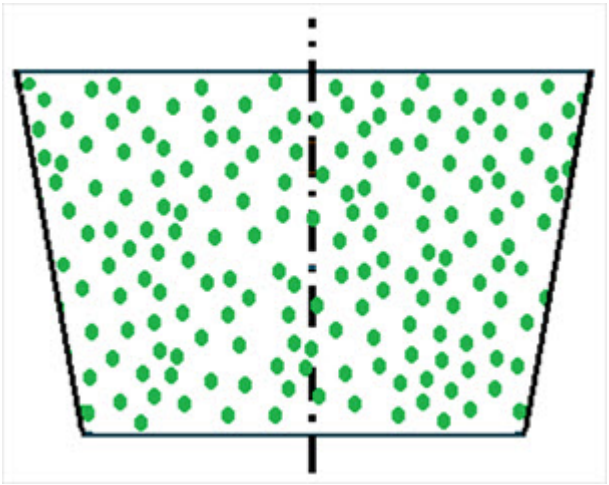
A *- Gap*
Easily detectable gap between the end of one level and the start of the next. Three cross sections are returned.

- If the cone was not measured in clean cross sections, but the data follows a clean spiral pattern, then PC-DMIS divides the spiral into several cross sections, equal to the number of revolutions in the spiral (so long as the spiral has more than two revolutions).



A *- No Gap*
You can see in this example one continuous spiral or overlapping start and end points. Five cross sections are returned.

- If the cone was not measured in either clean cross sections or a clean spiral pattern, then PC-DMIS performs a best effort to divide the data into cross sections.



You can see in this example that there is no discernible pattern. The number of returned cross sections depends on the point distribution and density.

After PC-DMIS divides the cone into cross sections, it rejects any section that has less than 90 degrees of arc. The corresponding circle center is not included in the toleranced feature.

In some cases, the above procedure produces no circle centers. For example, spiral scans with two or fewer revolutions or all cross sections were found to have less than 90 degrees of arc. In such cases, it is not possible to adhere so closely to the description in ISO 17450-3, and so an approximation is employed. Specifically, the toleranced feature is the axis of the least-squares cone, extrapolated to the endpoints of the measured surface data.

When the feature math type is **LSQ**, PC-DMIS decides that ISO 17450-3 : 2016 does not apply. A least-squares fit is computed to produce a least-squares axis. The cone angle is

allowed to optimize from the nominal angle. Next, an extrapolation is selected, based on whether sample hits are available:

- When there is no sample plane, the best-fit axis is extrapolated to the nominal end-faces of the cone. The nominal end-faces of the cone are nominally oriented and located to the measured datums.
- When there is a sample plane, the extrapolation starts at the measured start plane.

The extrapolated best-fitted axis is the toleranced feature.

Width Features with Surface Data under ASME Y14.5

The toleranced feature is a plane when the considered feature is a width. Please note that all PC-DMIS width features have surface data. Under ASME Y14.5, when the considered feature is a width, the toleranced feature is constructed in the following way:

First, a fit type is selected, based on the feature math type (**DEFAULT** or **LSQ**) and on the material modifier. The **LSQ** math type always does a least-squares best fit. The **DEFAULT** math type does an inscribed or circumscribed best fit. When the material modifier is RFS (no material modifier) or MMC, the inscribed or circumscribed fit is chosen to be external to the material. When the material modifier is LMC, the inscribed or circumscribed fit is chosen to be internal to the material. Thus, the **DEFAULT** math type usually produces the unrelated actual mating envelope (UAME) unless the modifier is LMC. In that case, the math type produces the unrelated actual minimum material envelope (UAMME). Since traditional inscribed and circumscribed fits are notoriously unstable, PC-DMIS uses a constrained least squares algorithm to compute the inscribed or circumscribed fit in a stable way.

Second, the surface points are all projected to the center-plane of the fitted width. The toleranced feature is then the convex polygon that describes the perimeter of those projected surface points. Mathematically, the toleranced feature is the convex hull of the projected surface points.

Width Features with Surface data under ISO 1101

The toleranced feature is a plane when the considered feature is a width. Please note that all PC-DMIS width features have surface data. Under ISO 1101, when the considered feature is a width, the toleranced feature is constructed in the following way:

First, PC-DMIS decides whether ISO 17450-3 : 2016 applies or not. To PC-DMIS, ISO 17450-3 : 2016 applies when there is no material modifier and the feature math type is **DEFAULT**.

When ISO 17450-3 applies, the toleranced feature is an imperfect plane. The toleranced feature is the center-points of the opposed two point sizes as described in ISO 17450-3 and ISO 14405-1. This process matches closely with the specification in ISO 17450-3.

When ISO 17450-3 does not apply, a fit type is selected, based on the feature math type (**DEFAULT** or **LSQ**) and on the material modifier. The **LSQ** math type always does a least-squares best fit. The **DEFAULT** math type does an inscribed or circumscribed best fit. When the material modifier is RFS (no material modifier) or MMC, the inscribed or circumscribed fit is chosen to be external to the material. When the material modifier is LMC, the inscribed or circumscribed fit is chosen to be internal to the material. Since traditional inscribed and circumscribed fits are notoriously unstable, PC-DMIS uses a constrained least squares algorithm to compute the inscribed or circumscribed fit in a stable way.

When ISO 17450-3 does not apply, and after a fit has been computed, the surface points are all projected to the fitted plane. The toleranced feature is then the convex polygon that describes the perimeter of those projected surface points. Mathematically, the toleranced feature is the convex hull of the projected surface points.

Features without Surface Data

Several types of considered features do not have surface data (for information, see "Feature Types With and Without Surface Data"). When the considered feature does not have surface data, the feature math type is unavailable in the geometric tolerance command. In most cases, you should not use features that do not have surface data. This is because the geometric tolerance command is unable to construct the toleranced feature from the surface data in a way that complies with the ASME Y14.5 or ISO 1101. Instead, you are responsible to define the toleranced feature according to any applicable standards.

For axial or linear features without surface data, the toleranced feature is the line segment from the measured start point to the measured end point. For circular, spherical, and point features without surface data, the toleranced feature is the measured centroid of the feature.

3D constructed BF lines have more complex handling. PC-DMIS interprets them as features without surface data. Instead, it interprets the input points as circle centers of circular cross sections. Under ISO 1101, this interpretation complies with ISO 17450-3 : 2016, and the toleranced feature is the set of centroids. However, under ASME Y14.5, PC-DMIS interprets 3D constructed BF lines in the same way as other axial or linear features without surface data. In that case, the toleranced feature is the start-to-end line segment (except for straightness of an axis tolerances which use all the input centroids).

The mid-plane is the only planar feature without surface data that is allowed as a considered feature. For the most part, you should use 3D widths instead of mid-planes (and 2D widths instead of mid-lines, and 1D widths instead of mid-points). The mid-plane command is still supported so that old programs continue to work after they migrate to PC-DMIS 2020 R2 or later. Since PC-DMIS still supports mid-plane for these legacy applications, its interpretation in the geometric tolerance command is similar to XactMeasure's interpretation. Specifically, PC-DMIS interprets mid planes to have four

corners that lie in the mid-plane, and the toleranced feature consists of the rectangle between those four corners.

Slots and Notches

Slots and notches are treated as 2D widths without surface data. That is, the toleranced feature is a line centered on the feature's centroid. For slots, users can choose whether the slot is considered widthwise or lengthwise, as discussed in "Lengthwise versus Widthwise Slots":

> For a widthwise slot, the size of the slot is the slot's width, and the tolerance zone controls the position in the width direction. That means the toleranced feature line is parallel to the slot's length and is as long as the slot's length.
>
> For a lengthwise slot, the size of the slot is the slot's length, and the tolerance zone controls the position in the length direction. That means the toleranced feature line is parallel to the slot's width and is as long as the slot's width.
>
> For notches, the size of the notch is the notch's length, and the tolerance zone controls the position in the length direction. That means the toleranced feature line is parallel to the notch's width and is as long as the notch's width.

Tangent plane modifier

Most of the time, for plane-type considered features, the toleranced feature is the considered feature's surface data. However, the tangent plane modifier makes the toleranced feature different from the surface data. Angularity, parallelism, perpendicularity, and position tolerances on planes are allowed to use the tangent plane modifier. The toleranced feature is derived in the following way.

First, an external-to-material constrained least squares plane is fitted in a way that removes the influence of surface voids. This is the same way that primary datum planes are fitted under ASME Y14.5 with **DEFAULT** datum math, and the same way primary datum planes are fitted under ISO 1101 with **CL2** datum math. We use this math because (1) it is external to the material, (2) it mimics the behavior of a surface plate quite well, and (3) it is stable compared to other external-to-material fits.

Next, the surface points are all projected to the constrained least squares plane. The toleranced feature is then the convex polygon that describes the perimeter of those projected surface points. Mathematically, the toleranced feature is the convex hull of the projected surface points.

Simultaneous Tolerances

Many geometric tolerances are meant to be considered simultaneously. For example, when position and/or profile of a surface specifications reference the same partially

constrained datum reference frame, you should usually consider them simultaneously. For more details, see the following standards:

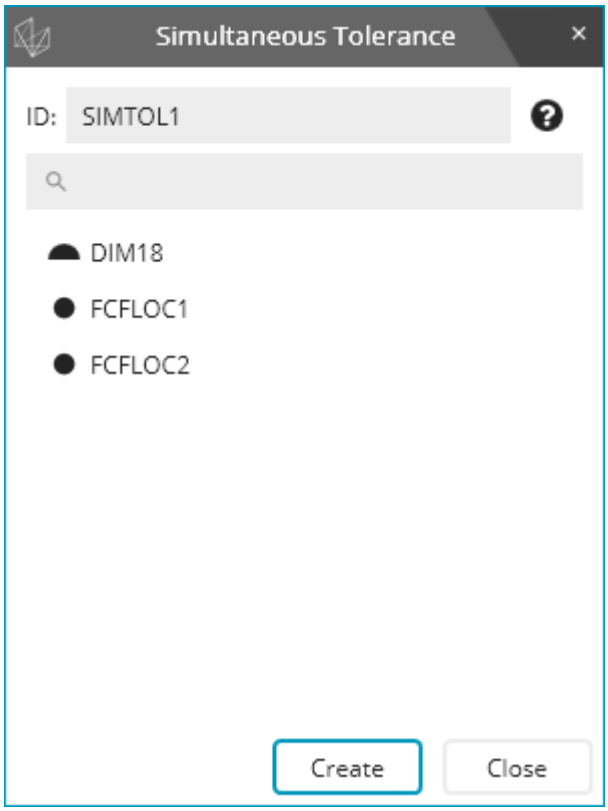
- ASME Y14.5 - 1994 sections 4.5.12 and 5.3.6
- ASME Y14.5 - 2009 section 4.19
- ASME Y14.5 - 2018 section 7.19
- ISO 5458 - 1998

You are responsible to choose which geometric tolerances to consider simultaneously. To do this, you create a simultaneous tolerance command for each set of simultaneous geometric tolerances.

PC-DMIS can consider profile of a line specifications simultaneously so long as they have at least one datum, but this is not recommended. For more details, see "Profile of a Line".

Defining a Simultaneous Tolerance

1. From the menu, choose **Insert | Dimension | Simultaneous Tolerance** to open the **Simultaneous Tolerance** dialog box:



2. Modify the dimension ID if needed.
3. Select which geometric tolerance commands belong to the simultaneous tolerance.

4. After you select a geometric tolerance command, the list filters itself so you only see dimensions with the same datum reference frame as the first tolerance command you selected.

Command Mode Syntax

In the Edit window, the Command Mode syntax looks like this:

```
SIMTOL2 =SIMULTANEOUS_TOLERANCE/
FCFLOC2,FCFLOC5,FCFPROF12,,
```

As in the dialog box, the only controls in the Edit window are for the dimension ID and which geometric tolerance commands belong to the simultaneous tolerance.

Behavior

Consider the simultaneous tolerance command as an annotation or directive. Nothing happens if you execute it. It also does not appear in the report. Instead, the simultaneous tolerance command changes how the geometric tolerances are evaluated.

During execution, the geometric tolerance commands know that they belong to the simultaneous tolerance command. They also know which of the other geometric tolerance commands are also part of the simultaneous tolerance command. If you've measured all of the inputs to all of the simultaneous tolerances (so the tolerance is ready to evaluate), the simultaneous calculation takes place. If you haven't measured all the input features, then the tolerance is not ready to evaluate. In this case, PC-DMIS temporarily shows a "Waiting for evaluation" message in all of the geometric tolerance commands in the simultaneous set. The message identifies which geometric tolerance is causing the delay, and any unmeasured features. Your report temporarily shows "Waiting" as well, instead of a measured value. Once you measure all input features, PC-DMIS updates the Edit window and report with the measured values.

The report for a tolerance that belongs in a simultaneous set looks like this:

FCFLOC8		MM	⌖ ∅0.1Ⓜ D NⓂ OⓂ : SIMTOL2 LSQ					ASME Y14.5 2018
Feature	AX	NOMINAL	+TOL	-TOL	MEAS	DEV	BONUS	OUTTOL
	X	57.150000			57.211490	0.061490		
	Z	101.600000			101.529825	-0.070175		
DAT_Y1_Z1	TP	0.000000	0.100000	0.000000	0.186606	0.186606	0.024326	0.062280
	X	-209.550000			-209.559500	-0.009500		
	Z	-25.400000			-25.493130	-0.093130		
DAT_Y2	TP	0.000000	0.100000	0.000000	0.187227	0.187227	0.024740	0.062487

The report is essentially the same as any other geometric tolerance. PC-DMIS shows the label in the report in the same place it would be if there were no simultaneous tolerance. You can know if a tolerance was considered simultaneously by the text in the header of the

label. For example, in the image above, SIMTOL2 is that text. It indicates which simultaneous tolerance command the geometric tolerance command belongs to.

PC-DMIS does not consider lower segments of composite position or profile tolerances simultaneously. The upper segment is simultaneous with other tolerance commands, but PC-DMIS considers any lower segments independently of everything else.

Measurement Routine Structuring Recommendations

Be aware that during execution, when PC-DMIS executes each geometric tolerance in the simultaneous set, it displays a temporary "Waiting" message until all tolerances belonging to the simultaneous set have been executed. The easiest way to avoid this temporary "Waiting" message is to measure all your features first, then put all your tolerances after all your features. This ensures that all tolerances are ready to evaluate, and you never get a "Waiting" message.

If you use expressions with your geometric tolerance commands, place them late enough in your measurement routine so that you don't get a "Waiting" message.

Finally, while your measurement routine does not need any special structure to use simultaneous tolerances, it is safest to have the same “active alignment” for all the individual Geometric Tolerance commands and the “Simultaneous Tolerance” command. Where possible, place the “Simultaneous Tolerance” command directly after the final Geometric Tolerance command for that group of FCFs (don’t wait until the end of the measurement routine). If there are alignment changes in the measurement routine, measured values will be unaffected, but it may be necessary to add “Recall Alignment” commands to prevent problems with the XYZ summary information.

Comparison to Past Practice

PC-DMIS 2020 R2 introduced the simultaneous tolerance (`SIMULTANEOUS_TOLERANCE`) command. This command works with the new geometric tolerance command. Prior to this, PC-DMIS had the simultaneous evaluation (`SIMULTANEOUS_EVALUATION`) command. It was designed to work with the XactMeasure command. The new simultaneous tolerance command works differently from the simultaneous evaluation command:

Simultaneous Evaluation (2020 R1 and Earlier Behavior)	Simultaneous Tolerance (2020 R2 and Later Behavior)
XactMeasure tolerances were unmarked for execution (blue in the Command mode edit window).	Geometric tolerances are marked for execution (white in the Edit window in Command mode).
XactMeasure tolerances had nothing in the report.	Geometric tolerances report as usual, and a small note in the report states that they belong to a simultaneous set.
The simultaneous evaluation report had all of the results from all of the tolerances in the simultaneous set.	Simultaneous tolerance produces nothing in the report

Migration

If you open a program from version 2020 R1 or earlier, PC-DMIS does the following:

- Converts any simultaneous evaluation commands to simultaneous tolerance commands
- Converts XactMeasure tolerances to geometric tolerance commands
- Marks the geometric tolerance commands for execution (white in the Edit window in Command mode)
- If any profile of a line specifications are included in a simultaneous evaluation command, that do not reference any datums, PC-DMIS converts them to profile of a surface.

For additional information on migration, see "Migration from Prior Versions of PC-DMIS".

Outputting Results from Geometric Tolerances

There are many ways to output results from geometric tolerance commands.

Statistical Data

Statistical data is one of the most common ways to access results from geometric tolerances. For more information, see the "Tracking Statistical Data" chapter.

Only the `STATS/ON,Datapage+` or `STATS/ON,QDAS` methods of statistical output support Geometric Tolerance commands.

Excel Output

Excel output is another common way to access results from geometric tolerances. For more information, see "Output to an Excel File" in the "Using Basic File Options" chapter of the PC-DMIS Core documentation.

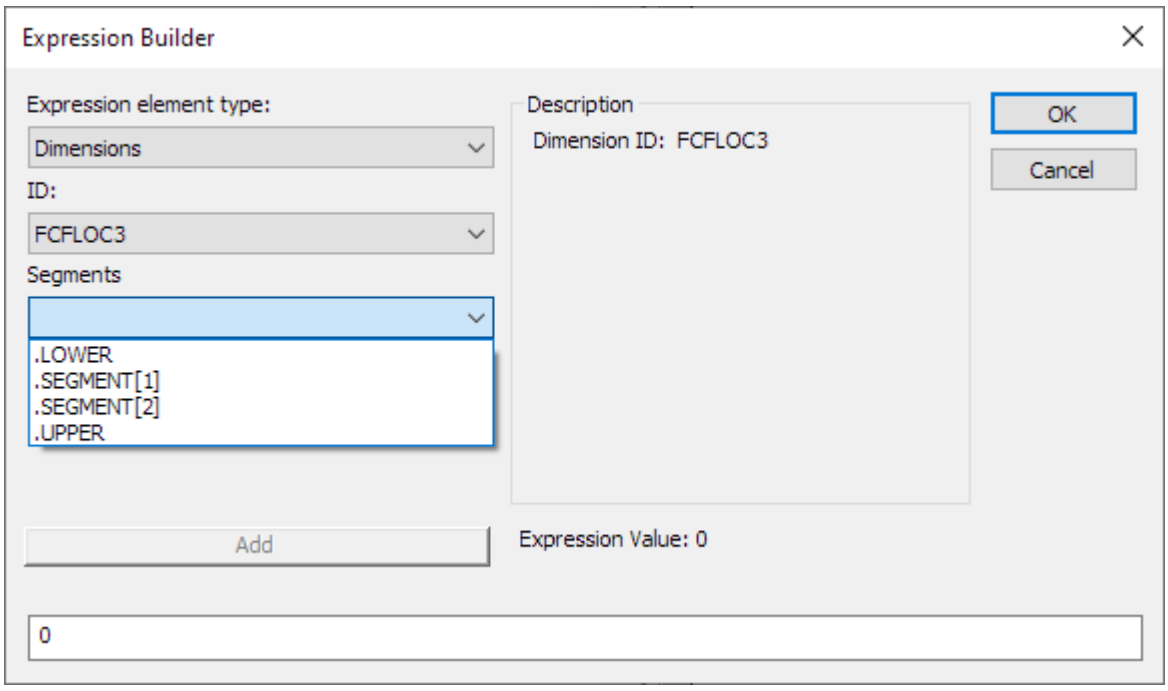
You can also export content with the Excel Form Report (**Insert | Report Command | Excel Form Report**). For details, see "Using the Excel Form Report Command" section of the PC-DMIS Toolkit Modules documentation.

Expressions

Expressions are also a common way to access results from geometric tolerances. For a general overview of how expressions work, see the "Using Expressions and Variables" chapter.

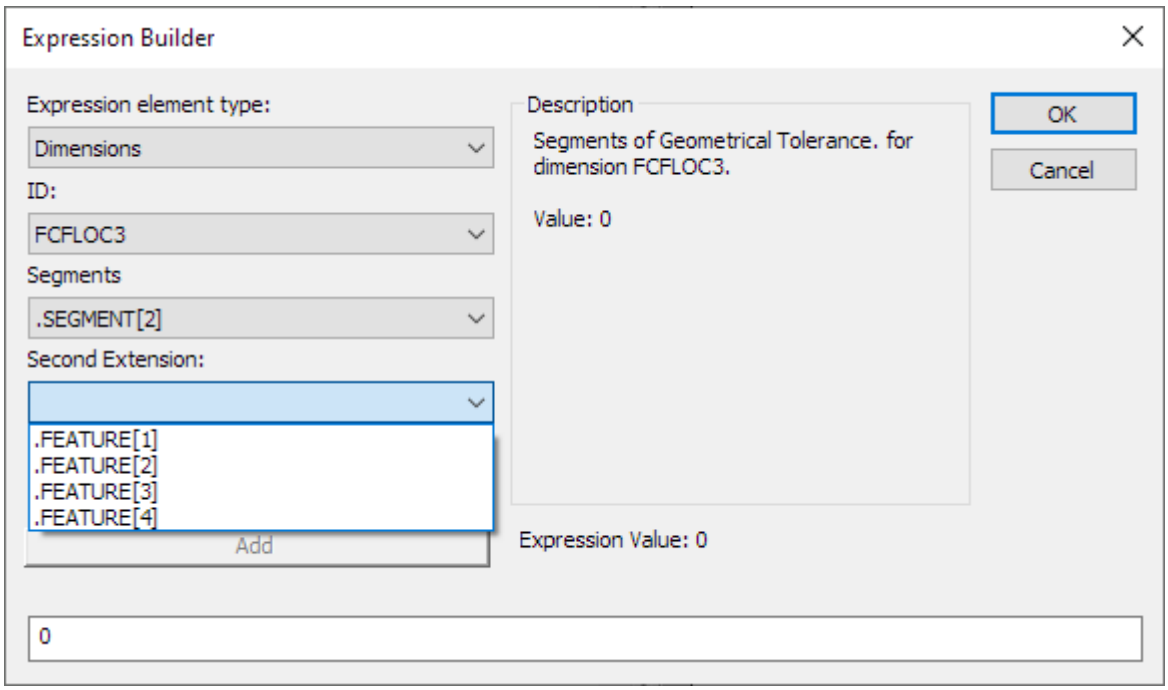
The easiest way to construct an expression that references a geometric tolerance is with the **Expression Builder** dialog box.

1. Choose the **Edit | Expression** menu option to access the **Expression Builder** dialog box. If the menu option is not visible, your Edit window cursor must be on a field that can accept an expression, such as the value of a variable assignment.
2. From the **Expression element type** list, select **Dimensions**.
3. From the **ID** list, select the dimension's ID name.
4. From the **Segments** list, select the segment to use in your expression. You will see all of the geometric tolerance command's segments listed here:



- **.LOCAL_SIZE** accesses the local size
- **.UAME** accesses the unrelated mating envelope size
- **.SEGMENT[1]** accesses the first segment
- **.SEGMENT[2]** accesses the second segment

5. After you select your segment, the **Second Extension** list appears. From that list, choose the feature you want to know the results from:



PC-DMIS shows all of the geometric tolerance command's features listed here.

6. After you choose your feature, the **Extension** list appears. From that list, choose the extension.

   For information on these extensions and what information they contain, see "Valid Extensions for Dimension Reference of Type Double by Example" in "References of Type Double" in the "Using Expressions and Variables" chapter.

7. Click **OK** to insert the expression into the Edit window.

Notes on Geometric Tolerance Report Labels

GEOTOL_SUMMARY labels

Due to the design of the Geometric Tolerance GEOTOL_SUMMARY labels (GEOTOL_SUMMARY.lbl, GEOTOL_SUMMARY1.lbl, GEOTOL_SUMMARY2.lbl, GEOTOL_SUMMARY3.lbl, and GEOTOL_SUMMARY4.lbl), you should not customize the vertical and horizontal alignment.

The reason you should not customize GEOTOL_SUMMARY labels is that they use a single row for each feature. Because of this, the content (for example, X, Y, Z, PR, PA, and TP) uses non-trimmable carriage returns to define each row of data. If you try to set a horizontal alignment to the GEOTOL_SUMMARY label, it only affects the first row. If you try to set a vertical alignment to the GEOTOL_SUMMARY label, it produces a stair step report since +Tol and -Tol are not shown for X, Y, Z, PR, and PA.

SIZE_GEOTOLERANCE.LBL label

The Geometric Tolerance SIZE_GEOTOLERANCE.LBL labels are individual rows but they are unique in that they group the upper and lower sizes for each feature. For this reason, you should not customize the SIZE_GEOTOLERANCE.LBL label.

Text Mode Dimension Reporting does not support Geometric Tolerance commands. For details on editing text in Geometric Tolerance reports, see "Edit Text Reporting" in the "Changing the Report Window's Content" section of the PC-DMIS Core documentation.

Migration from Prior Versions of PC-DMIS

In this Topic Hide

Introduction

When you open a measurement routine from a prior version, PC-DMIS attempts to migrate the commands. Depending on the version the routine was previously saved as, the types of Geometric Tolerance commands it contains and the features they reference, you may encounter a migration report. The migration report details any errors that were encountered, and any changes that needed to be applied to make your routine compatible with PC-DMIS 2026.2.

Prior to migration, when you open your routine in this version of PC-DMIS, the software creates a backup of your measurement routine in this folder:

C:\Users\Public\Documents\Hexagon\PC-DMIS\2026.2\MigrationBackup

Never open this measurement routine from this backup location. If you want to use the backed-up measurement routine, copy it to another folder first.

If you click the **Cancel** button on the migration report, PC-DMIS discards the migrated measurement routine and automatically restores the original version.

You can control whether PC-DMIS creates a backup of the measurement routine or not with the Settings Editor `MigrationBackup` setting. This setting is set to **True** by default. If you set this to **False**, PC-DMIS still presents you with a migration report, but it does not create a backup of the measurement routine. Because of this, PC-DMIS does not show the **Cancel** option on the migration report since no backup is available to perform a restore.

For details on the `MigrationBackup` setting, see the "MigrationBackup" topic in the "FileMan" section of the PC-DMIS Settings Editor documentation.

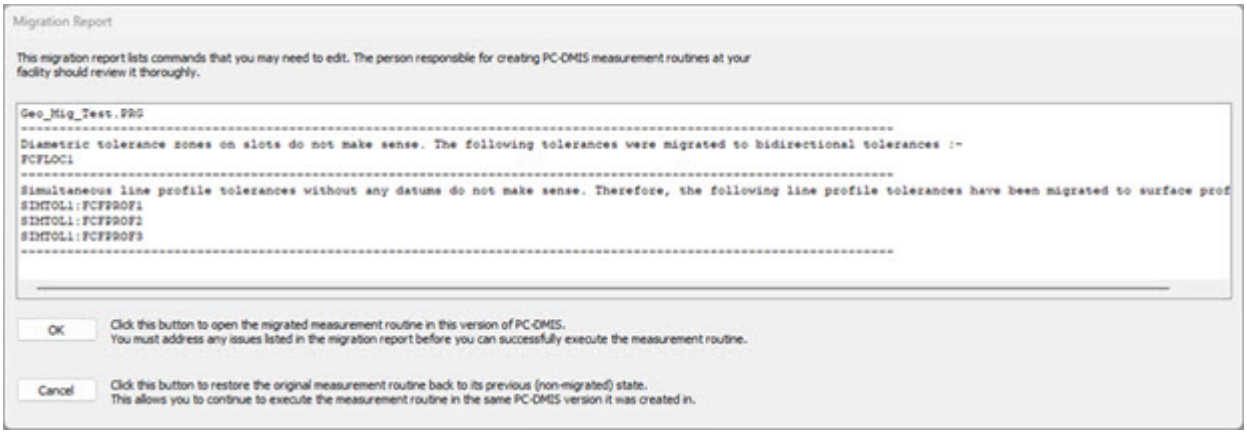
Suggested Workflow

Migration is mostly automatic, but in some cases, you may need to customize the migration to your needs. You can use some options to control how the migration takes place. We suggest the following workflow to migrate your PC-DMIS measurement routines from a prior version:

- Back up your old measurement routines to a safe place and never open them with 2020 R2 or later.
- Make a copy of your backup measurement routines in a folder you are willing to experiment with.
- Open the experimental copies of your measurement routines in this version of PC-DMIS.
- Carefully examine the results of the migration. Verify that the migration worked as desired and that the new measured values fit your needs.
- In rare cases, a migration might not work for you in a small number of places. In these cases, manually edit those places in your program to update the commands.
- In rare cases, the migrated math types might not work for you in a large number of places. If this happens, adjust your migration options, make new copies from your backup measurement routines, and place the copies in the experimental folder. Then open these new copies with this version.
- Repeat this workflow until all your measurement routines are working for you.

Migration Report

When PC-DMIS encounters issues during migration, the migration tool creates a report in a **Migration Report** dialog box. The migration report looks like this:



Migration Report dialog box with a migration report.

PC-DMIS automatically saves the migration report in the same location as the measurement routine with the same name as the measurement routine but with _migratedReport.txt appended to it.

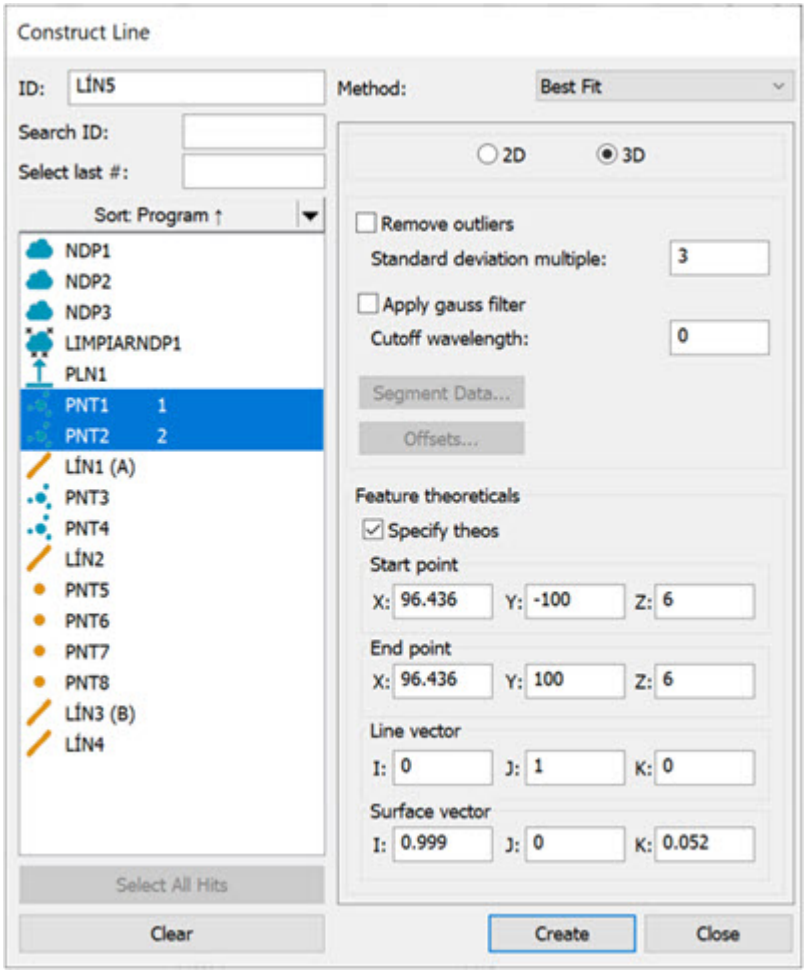
Most migration reports are much simpler than the example in the image above. In the image above, the report conveys these main pieces of information:

- PC-DMIS changed FCFLOC1 from a single, diametric position of a slot to two separate planar positions of the slot – one for the slot's length-wise orientation and one for the slot's width-wise orientation. This is because support for diametric position of slots was removed in PC-DMIS 2020 R2 SP1.
- PC-DMIS detected multiple profile of a line tolerances to no datums were previously being evaluated simultaneously. Support for simultaneous line profile tolerances without any datums was removed in PC-DMIS 2022.1 and the following service packs: 2020 R2 SP11, 2021.1 SP8, and 2021.2 SP3. For details, see the "Simultaneous Profile of a Line Tolerances" section in this topic.

Important Notes

Constructed Line Surface Vectors

All constructed BF and BFRE lines have a line vector and a surface vector which are important to the geometric tolerance command. However, while you can see and edit the line vector in the edit window when in Command mode, the surface vector information is only accessible through the **Specify Theos** section of the line's **Construct Line** dialog box.



If you manually edit the line vector, PC-DMIS automatically adjusts the Surface vector so that it remains orthogonal. In older versions of PC-DMIS, this was not always the case, and the surface vector may have been incorrect (where THEO line vectors had been corrected in the edit window after manually teaching points on the machine or when a measurement routine was created without a CAD model for example). XactMeasure did not use the line's surface vector, so this was previously not a problem. For the Geometric Tolerance command however, correct surface vectors are important in many cases. Therefore, starting with PC-DMIS version 2024.1, PC-DMIS now checks for lines with non-orthogonal line and surface vectors when it opens measurement routines. If any error is found, PC-DMIS automatically normalizes the surface vector and informs you with a warning message in the migration report.

Simultaneous Profile of a Line Tolerances

If a set of profile of a line tolerances are part of a simultaneous evaluation command, and if those profile of a line tolerances do not reference any datums, then they are migrated to profile of a surface. This is because it does not make sense (from a standards compliance perspective) to simultaneously evaluate profile of a line tolerances. The Migration Report announces the migration when it happens. For more details, see "Profile of a Line" and "Simultaneous Tolerances".

Options to Control Migration

When you migrate measurement routines from earlier versions of PC-DMIS that contain Geometric Tolerance commands, PC-DMIS attempts to automatically select the appropriate GD&T standard using the following rules:

- If the combined total of ISO Size and Geometric Tolerance commands ***is greater*** than the combined total of ASME Size and Geometric Tolerance commands, then ***all*** of the migrated Size and Geometric Tolerance commands use ISO 1101 (see note).
- If the combined total of ISO Size and Geometric Tolerance commands ***is less*** than the combined total of ASME Size and Geometric Tolerance commands, then ***all*** of the migrated Size and Geometric Tolerance commands use ASME Y14.5, subject to additional rules for selecting the year (see note).
- If the combined total of ISO Size and Geometric Tolerance commands ***is equal to*** the combined total of ASME Size and Geometric Tolerance commands, then ***all*** of the migrated Size and Geometric Tolerance commands use the GDTStandard entry in the Dimensions section of the PC-DMIS Settings Editor. For details, see "GDTStandard" in the PC-DMIS Settings Editor documentation (see note).

Additional rules for determining which year of ASME Y14.5 a routine should migrate to:

- If the ASME Geometric Tolerance commands include concentricity or symmetry tolerances, the migrated measurement routine will use ASME Y14.5 – 2009.
- If the ASME Geometric Tolerance commands do not include any concentricity or symmetry tolerances, the migrated measurement routine will use ASME Y14.5 – 2018.

Starting with PC-DMIS version 2023.2, you cannot have different GD&T standards in a single measurement routine. Therefore, PC-DMIS does not allow you to migrate a 2023.2 (or newer) measurement routine from ISO to ASME or vice vera.

ASME Y14.5 – 1994 does not allow the use of the translation modifier, dynamic profile modifier, customized datum reference frames or a specified material boundary size. It also uses the older, two-value definition of profile (see ASME Y14.5.1M – 1994).

ASME Y14.5 – 2009 does not allow the use of the dynamic profile modifier.

ASME Y14.5 – 2018 does not allow the use of concentricity or symmetry.

In some cases, you may not want to use the standard that PC-DMIS chooses during migration. You can control which migrated standard to apply. To do this, create a file named fcfMigrationPreferences.json and place it in "*C:\ProgramData\Hexagon\PC-DMIS\2026.2*" folder. Note that the C:\ProgramData\ folder is hidden by default.

The "*fcfMigrationPreferences.json*" file must be in the JSON format (see https://en.wikipedia.org/wiki/JSON).

Here is an example file:

```
{
"default standard migrates to":"ASME Y14.5-2018"
}
```

"default standard migrates to" is the only valid key for the "*fcfMigrationPreferences.json*" file. When the "*fcfMigrationPreferences.json*" file does not exist (or it exists but it is not valid a valid JSON file), then PC-DMIS selects the migrated math options according to the rules described above. When the "*fcfMigrationPreferences.json*" file exists, and PC-DMIS determines that it is a valid JSON file, and it has the valid key and values for controlling the migration, then PC-DMIS uses the math options defined by the "*fcfMigrationPreferences.json*" file.

Invalid keys in the "*fcfMigrationPreferences.json*" file are allowed, but they are ignored. If the "*fcfMigrationPreferences.json*" file exists, and PC-DMIS determines that it is a valid JSON file, but that it lacks the valid key or value, then the behavior for that key is the same as if there were no "*fcfMigrationPreferences.json*" file.

The valid values for the "default standard migrates to" key for the "*fcfMigrationPreferences.json*" file are:

- "ASME Y14.5-1994"
- "ASME Y14.5-2009"
- "ASME Y14.5-2018"
- "ISO 1101"

The valid keys and values in the "*fcfMigrationPreferences.json*" file must be in English.

Dimensioning Size

The Size command (**Insert | Dimension | Size**) facilitates computing and reporting of local and global sizes per the ISO 14405-1 or ASME Y14.5 standards. The ISO 14405-1 and the ASME Y14.5 standards define local and global actual sizes.

For ASME Y14.5, the allowed features are cylinders, opposed parallel planes (also known as 3D widths), spheres, circles (cylinder cross sections), 2D widths (3D width cross sections). ASME Y14.5 defines the unrelated actual mating envelope and the local size.

For ISO 14405-1, the allowed features are cylinders, 3D widths, and their cross sections. Over twenty modifiers are defined in ISO 14405-1. You can combine these modifiers in various ways to create a specification operator for size. Separate specification operators are allowed for the upper and lower size limits. This means that thousands of different kinds of size calculations exist.

Command Modes

The Size command defines four different modes. These modes allow you to enter, calculate, and report different kinds of size calculations:

1. **ASME Y14.5**

   The Size command in this mode does the following:

   - It records a nominal size, an upper deviation limit, and a lower deviation limit.
   - It calculates the unrelated actual mating envelope. The command also calculates a long list of local sizes.
   - It reports the actual mating envelope. The command also reports the worst of the local sizes.

2. **ISO 14405-1, Nominal with Deviation**

   The Size command in this mode records a nominal size, an upper deviation limit, and a lower deviation limit.

   - If there is a single specification operator, the operator applies to both limits.
   - If there are two specification operators, each operator only applies to one limit.
   - If a specification operator is a global size, that global size is computed, and the report compares the global size to the applicable limit or limits.
   - If a specification operator is a local size, a long list of those local sizes is computed, and the worst local size is reported for each applicable limit.

3. **ISO 14405-1, ISO Code**

   The Size command in this mode records a nominal size and an ISO code. This information, together with ISO 286-1, define the limits of size.

   The ISO 286-1 standard defines hundreds of tolerance codes that look somewhat like "E9" and "H7". These tolerance codes are all supported by the size command. Reporting is much like the ISO nominal-with-deviations mode.

4. **ISO 14405-1, Range of Sizes**

You should use this mode with the range of sizes modifier defined by ISO 14405-1 (the text SR enclosed in an oval).

The Size command in this mode does the following:

- It only records one specification operator.
- It does not record a nominal size, nor limits on deviations.
- It records a single tolerance value, because the range of sizes modifier produces specification operators that are similar to form tolerances. For an example, see Figure 17 in the ISO 14405-1 standard. Reporting in this mode is similar to reporting for form tolerances.

Input Features

The Size command allows only one input feature at a time.

In the ASME Y14.5 and ISO 14405-1 modes, the valid input feature types are 1D widths, 2D widths, 3D widths, circles, cylinders, and spheres.

Any input features that you use with the Size command should contain enough points to represent well the actual surface. To best mimic the intent of the standards, those points should be opposing points.

Limits on Input Features for Section Sizes

Several ISO specification operators for size are referred to as "section sizes". For example, "(GG) ACS" and "(LP) ACS (SX)" are section sizes. Section sizes are local sizes where each cross-section of the cylinder or of the 3D width has a size. Then, the worst section size is reported for each applicable limit.

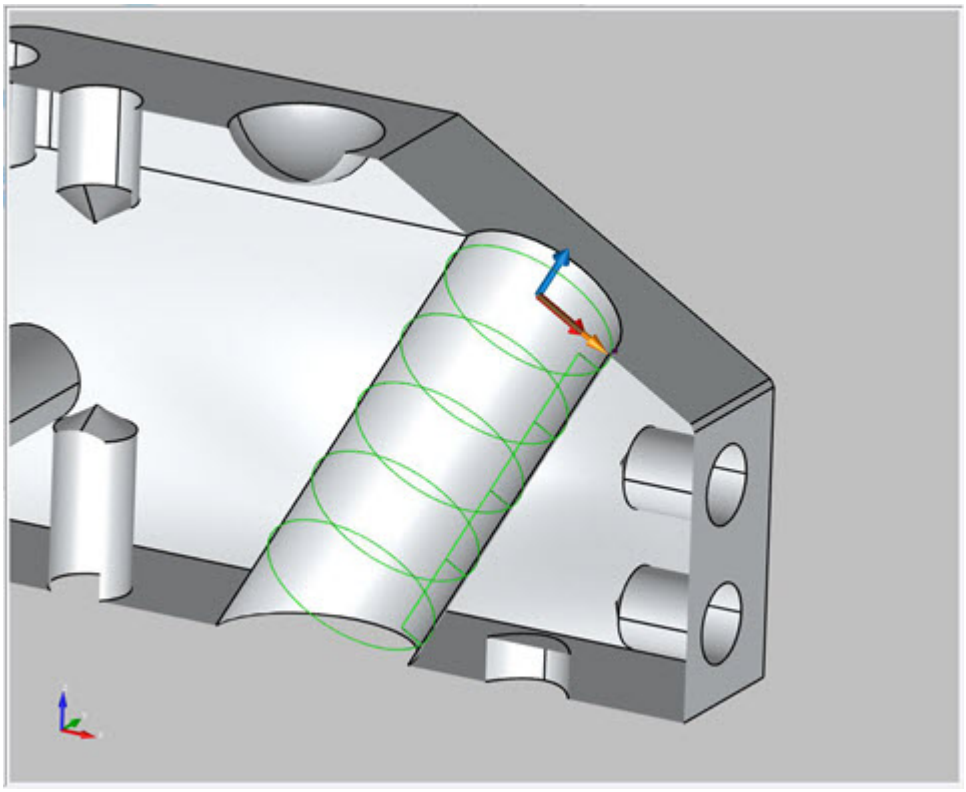
One possibility for producing data in sections is to use 2D cross section features like circles and 2D widths. The other possibility is to use a measurement strategy that produces data in sections, such as "Default PC-DMIS Measurement Strategy" or "Adaptive Cylinder Concentric Circle Scan". For more information on measurement strategies, see the "Working with Measurement Strategies" topic in the "PC-DMIS CMM" documentation.

When evaluating the section sizes, the command partitions the data into sections, according to these rules:

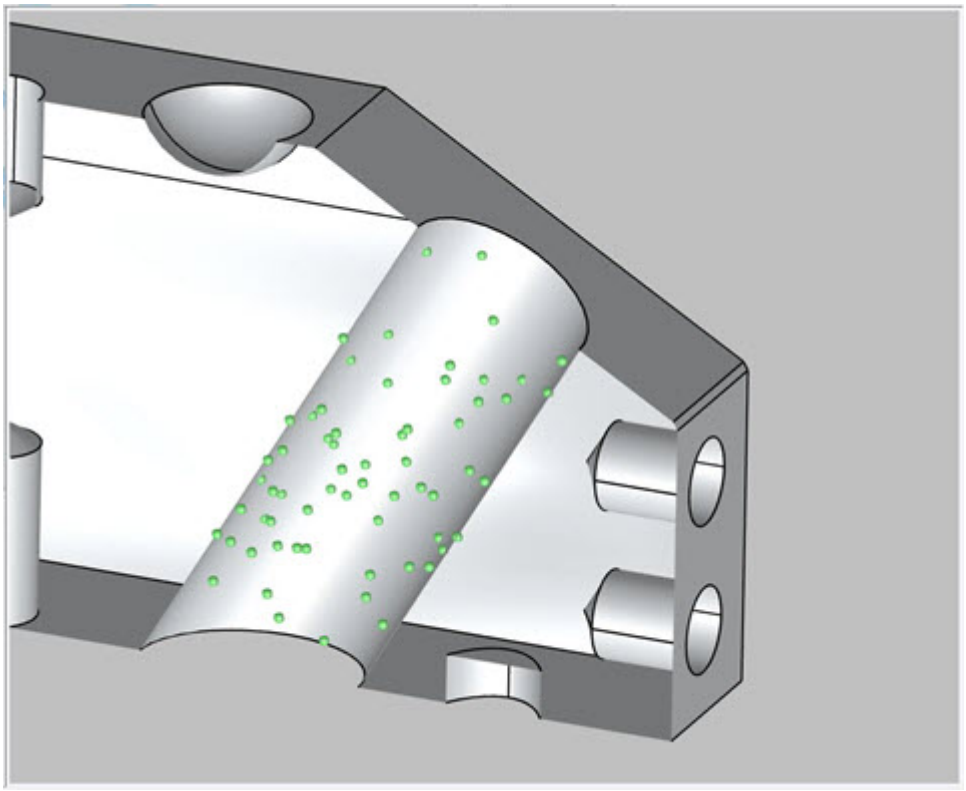
- For circle features and 2D widths, the command uses the data without partitioning, because the feature is already a cross section.
- For cylinders, the command attempts to partition the data into circular cross sections. The data must be arranged in circles or the command will fail.
- For 3D widths, the command fails.

When partitioning cylindrical data, the command first projects the points onto the cylinder's axis. It then identifies clusters of projected points as belonging to the same cross section.

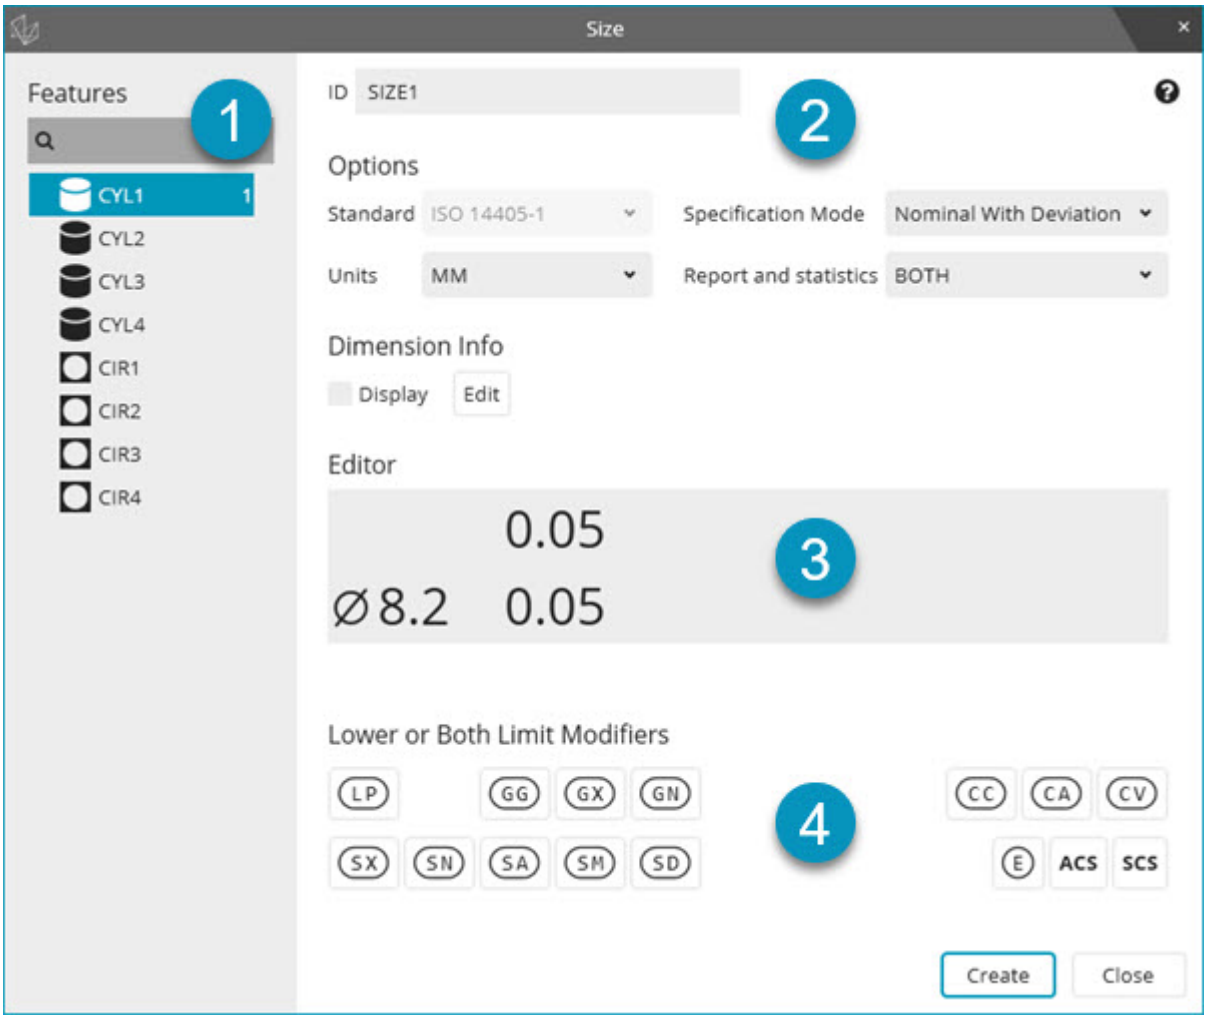
Example of Good Inputs



Example of Bad Inputs



To Dimension a Feature Using the SIZE Option



The main components of the Dimension Size dialog box are:

- ***1** - Feature List area*
- ***2** - Options area*
- ***3** - Editor area*
- ***4** - Limit Modifier area*

For information on how to display dimensional information, see the "Display Dimension Information" topic in the PC-DMIS Core documentation.

To dimension a feature using the SIZE option, do this:

1. Select **Insert | Dimension | Size** to show the **Size** dialog box.
2. The **Standard** list in the **Options** area shows the current standard to use in the tolerance. It should match the standard used in your print. PC-DMIS supports prints based on ASME Y14.5 and ISO 1101.
3. From the **Options** area, choose your options:
    a. The **Standard** list, select the standard to use to calculate the size.

b. If you use the ISO 14405-1 standard, from the **Specification Mode** list, select the Command mode. For information, see "Command Modes". The print requirement determines the selection to use.

c. If you use the ASME Y14.5 standard, a **Local Size options** list appears where **Specification Mode** is. Choose the type of local size, either **Opposed Points** or **Circular elements** (default).

You can find details on the Opposed Points and Circular Elements interpretations of Local Size in the "Local Size" section of the "Evaluating Size with the Geometric Tolerance Command" topic in the PC-DMIS Core documentation.

d. Set the **Units** and **Report and Statistics** as needed. For information on these options, see the "Common Dimension Dialog Box Options" topic in the "Using Legacy Dimensions" chapter.

4. In the **Editor** area, use the steps below to define the tolerance.

The **Editor** area adjusts to fit the mode requirements that you choose from the **Standard** and **Specification** lists. This means any existing changes you made to the dialog box are lost when you select a new specification mode.

a. Select the region you want to edit and type in the value.

b. To add an upper specification operator, click on the upper tolerance value. From the **Lower or Both Limit Modifiers** area, you can then click the modifier buttons to add modifiers into the upper specification operator.

c. To add a lower specification operator, click on the lower tolerance value. From the **Lower or Both Limit Modifiers** area, you can then click the modifier buttons to add modifiers into the lower specification operator. When there's only one specification operator, put the modifiers in the lower specification operator.

d. To remove a modifier, select the button again to clear the highlight.

Example showing selected modifiers.

5. Click the **Create** button to create the Size command in the Edit window.

Reading the Report

ISO 14405-1 : Nominal with Deviations

With the NOMINAL_WITH_DEVIATIONS mode, PC-DMIS compares the upper specification operator measured size against the upper limit of size. It also compares the lower specification operator measured size against the lower limit of size. Therefore, the Size command generates two measured values for a given feature of size:

SIZE1-CYL1			MM		Ø 25.4 [+0.15 GN] - [-0.15 GX]	
MODIFIER	MEAS	NOMINAL	+TOL	-TOL	DEV	OUTTOL
GN	25.500	25.400	0.150		0.100	0.000
GX	25.300	25.400		0.150	-0.100	0.000

ISO 14405-1 : Tolerance Codes

With the TOLERANCE_CODE mode, the PC-DMIS report mimics NOMINAL_WITH_DEVIATIONS mode, except that it displays the tolerance code in the dimension header:

SIZE2-CYL1			MM		Ø 25.4 JS14 [GN] - [GX]	
MODIFIER	MEAS	NOMINAL	+TOL	-TOL	DEV	OUTTOL
GN	25.500	25.400	0.260		0.100	0.000
GX	25.300	25.400		0.260	-0.100	0.000

ISO 14405-1 Range of Sizes

With the RANGE_OF_SIZES mode, PC-DMIS compares a maximum measured size against a minimum measured size and reports the difference. This mode requires a single measured value. The software compares that measured value against an upper tolerance.

SIZE3-CYL1			MM		Ø 0.25 SR	
MODIFIER	MEAS	NOMINAL	+TOL	-TOL	DEV	OUTTOL
SR	0.200	0.000	0.250		0.200	0.000

ASME Y14.5 - Local Size

With ASME Y14.5, two size characteristics are reported, the Unrelated Actual Mating Envelope (UAME) and Local Size.

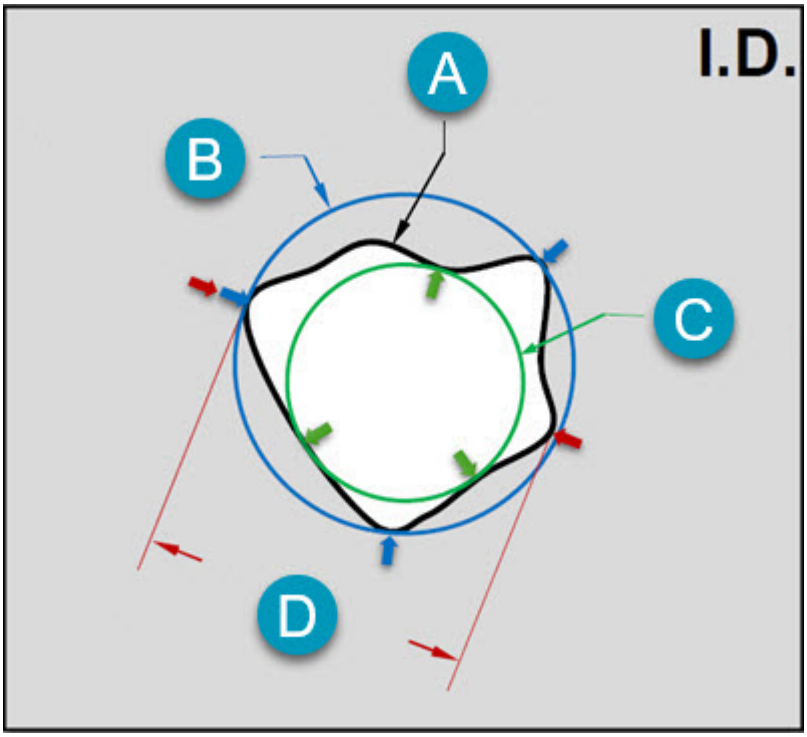
The UAME is the minimum circumscribed size for external features (e.g. pin) and the maximum inscribed size for internal features (e.g. hole).

Local Size:

1. **Circular Elements** (default) report the smallest circumscribed circular element (internal feature/ hole) or largest inscribed circular element (external feature/pin) amongst all local sizes.
2. **Opposed Points** reports the largest opposed point distance (internal feature/hole) and smallest opposed point distance (external feature/pin) amongst all local sizes.

SIZE4-CYL1			MM		Ø 25.4 +0.15/-0.15 OPPOSED POINTS	
MODIFIER	MEAS	NOMINAL	+TOL	-TOL	DEV	OUTTOL
UAME	25.300	25.400	0.150	0.150	-0.100	0.000
Local Size	25.500	25.400	0.150	0.150	0.100	0.000

ASME Y14.5 Local Size Example



A. **True shape of the feature's cross section**

B. **Local Size (Circular Elements) - ⌀ 44.2659**

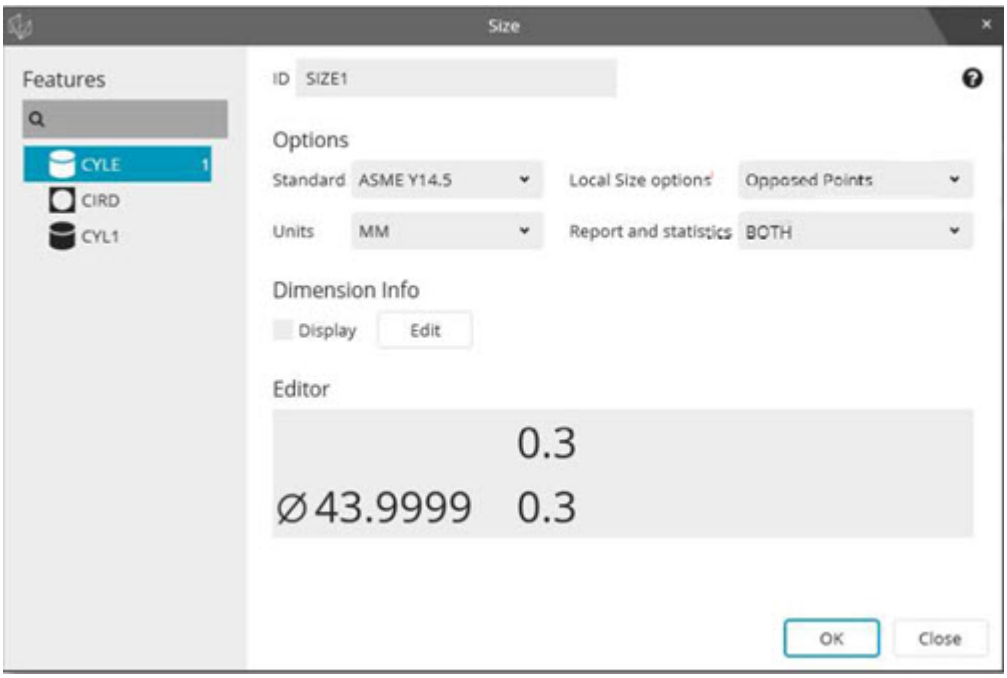
C. **UAME - ⌀ 43.8849**

D. **Local Size (Opposed Points) - ⌀ 44.2656**

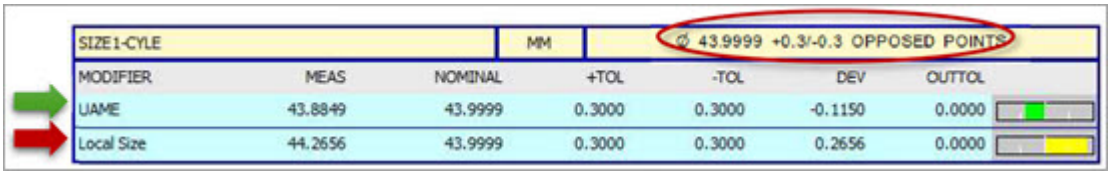
> The symbol "⌀" denotes **Diameter**.

For an inner diameter (ID) feature using the ASME Y14.5 standard, you can see from the above image that:

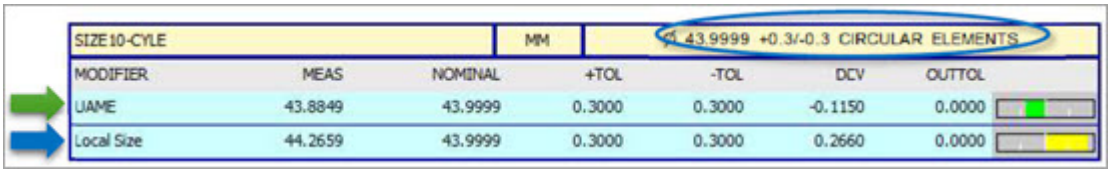
- The Unrelated Actual Mating Envelope (UAME) is the largest possible inscribed circle.
- The Local Size is based on which option you select from the **Local Size options** list of the Geometric Tolerance **Size** dialog box (see descriptions above).



If you select **Opposed Points** from the **Local Size options** list as shown in the Geometric Tolerance **Size** dialog box image above, PC-DMIS reports the result as:



If you select the **Circular Elements** option, PC-DMIS reports the feature as:

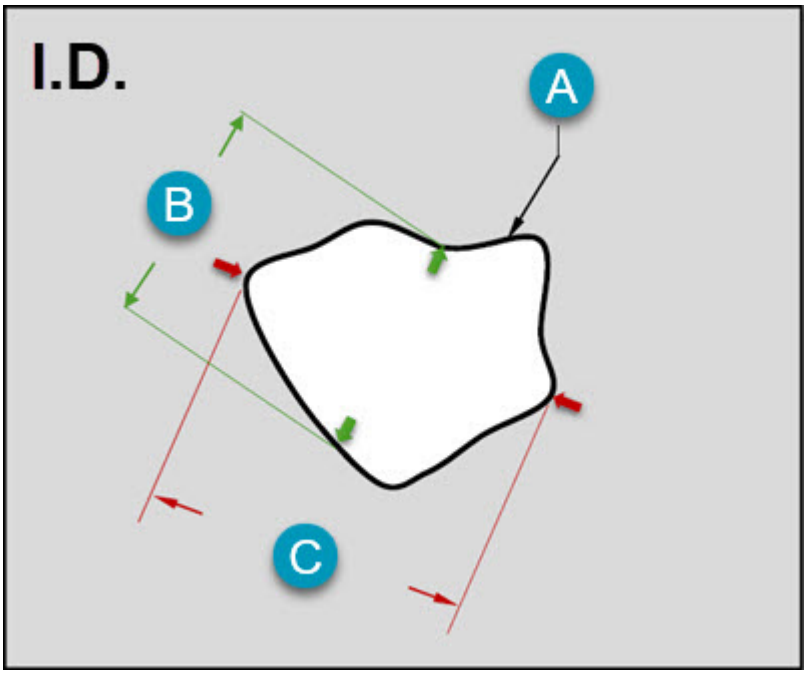


SIZE 10-CYLE		MM	Ø 43.9999 +0.3/-0.3 CIRCULAR ELEMENTS			
MODIFIER	MEAS	NOMINAL	+TOL	-TOL	DCV	OUTTOL
UAME	43.8849	43.9999	0.3000	0.3000	-0.1150	0.0000
Local Size	44.2659	43.9999	0.3000	0.3000	0.2660	0.0000

In all cases where details related to the ASME standards are concerned, you should consult the primary source at The American Society of Mechanical Engineers (ASME) website.

ISO 1101 - Local Size

When PC-DMIS reports Size using the ISO standard, it is based on Local Size only. Because of the Independency Rule, it is not based on the unrelated or related mating envelope. For details on the ISO Independency Rule, see ISO 8015: 2011 section 5.5 “Principle of Independence”.

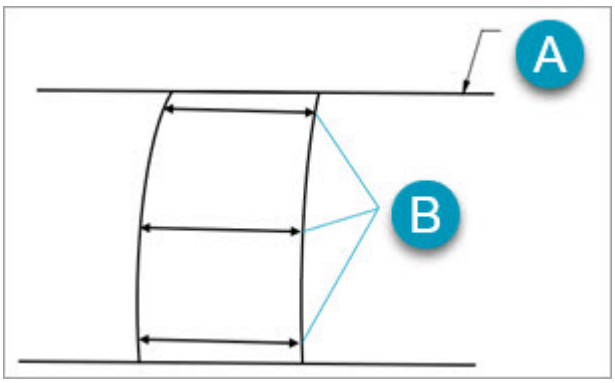


A. ***True shape of the feature's cross section***

B. ***Minimum Local 2-Point Size***

C. ***Maximum Local 2-Point Size***

For example, when you measure a cylinder feature at multiple levels, PC-DMIS evaluates each cross section individually and then reports the Maximum and Minimum 2-point size, similar to performing a caliper check.



A. *Datum feature simulator of datum feature A (Plane)*

B. *Actual local sizes (Any individual distance at any cross section of a feature of size)*

> **!** In all cases where details related to the ISO 1101 standards are concerned, you should consult the primary source at The International Organization for Standardization (ISO) website.

Supported ISO 14405-1 Modifiers

The Size command supports the following modifiers that are defined in the ISO 14405-1 standard:

- (LP) - Two-point size
- (GG) - Least-squares association criterion
- (GX) - Maximum inscribed association criterion
- (GN) - Minimum circumscribed association criterion
- (CC) - Circumference diameter (calculated size)
- (CA) - Area diameter (calculated size)
- (CV) - Volume diameter (calculated size)
- (SX) - Maximum size
- (SN) - Minimum size
- (SA) - Average size
- (SM) - Median size
- (SD) - Mid-range size
- (SR) - Range of sizes
- (E) - Envelope requirement
- ACS - Any cross section or sections
- SCS - Specific fixed cross section or sections

Using GD&T Selection Modes to Create FCFs

PC-DMIS provides these ways to get Feature Control Frames (FCFs) into PC-DMIS from GD&T tolerances in other sources:

GD&T Selection Mode (from CAD) ( ) - This enables you to import GD&T callouts embedded in your CAD model. In this mode you can box select or click on callouts to import them. For more information on this option, see "Using GD&T Selection Mode (from CAD)".

> You can access **GD&T Selection Mode (from CAD)** From the **Graphic Modes** toolbar or the **QuickMeasure** toolbar.

GD&T Selection Mode (from File) ( ) - PC-DMIS lets you import a drawing and decide what GD&T tolerances to import. This process uses Optical Character Recognition (OCR). For information on this option, see "Using GD&T Selection Mode (From File)". For more information, see "About Optical Character Recognition (OCR) to Create FCFs" below.

You can access **GD&T Selection Mode (from File)** from one of these:

- **Graphic Modes** toolbar
- **QuickMeasure** toolbar
- **File | Import** menu

Using GD&T Selection Mode (from CAD)

GD&T Selection Mode (from CAD) ( ) imports selected GD&T callouts from CAD models that contain them as dynamically-generated Geometric Tolerance dimensions or datum definitions.

For information on how to do this, see the "Importing CAD GD&T Callouts" heading within the "Working with CAD GD&T Callouts" topic of the "Editing the CAD Display" chapter.

Using GD&T Selection Mode (from File)

PC-DMIS can recognize and import GD&T tolerances on blueprints into your measurement routine with the **GD&T Selection Mode (from File)** ( ) option.

PC-DMIS uses Optical Character Recognition (OCR) to import the GD&T tolerances. PC-DMIS can import a .pdf file or an image file.

You can find sample blueprint .pdf files that correspond to the Hexagon demo-block CAD models, in the **Training** subfolder where you installed PC-DMIS.

When you import a blueprint file, the software parses the content of the file. It then shows the **GD&T from Capture** window and applies an orange highlight to all the supported items that you can import.

You then decide what supported items to import:

- One item at a time - To do this, click on an orange-colored tolerance.
- Multiple items - To do this, box-select multiple orange-colored tolerances.
- All items on a page - To do this, from the toolbar on the **GD&T from capture** window, click the **Process whole page** ( ) option.

If you choose to process multiple supported items or all supported items on a page, the software opens the OCR widget and cycles through each GD&T tolerance from the selection.

Be aware that OCR recognition does not handle every item in your file. For information on what items are supported and unsupported, see the "About Optical Character Recognition (OCR) to Create FCFs" topic in the PC-DMIS Core documentation.

PC-DMIS also parses measurement units and default tolerances from the title block and applies a light-blue highlight to them. For more information on the title block see, "About Optical Character Recognition (OCR) to Create FCFs". If PC-DMIS does not correctly determine the default tolerance values from the title block, you can use the pause button on the widget and manually fix a tolerance on any created item. For information on how to use the pause button, see "OCR Widget".

Procedure

This procedure explains how to import one or more callouts.

1. From the **Graphic Modes** toolbar, or the **QuickMeasure** toolbar, click the **GD&T Selection Mode (from File)** ( ) option.
2. Import a CAD model into the Graphic Display window that corresponds with your blueprint.

3. From the **Open** dialog box, navigate to an electronic blueprint file. This can be an image file or a .pdf file. OCR detection works best with an image that has at least 300 DPI. Lower resolutions may produce less accurate results.

4. Select the file, and click **Open** to parse the file and show all the recognized contents as orange-highlighted items in the **GD&T from Capture** window.

> Note that with this window open, the Edit window is not initially available for selection. This means you cannot delete features that you create unless you create them with the OCR widget or unless you click the pause button on the widget to pause the import process.

5. Do one of the following to import one or more items into PC-DMIS and to show the OCR widget:

   - Click on a single callout. This can be a GD&T tolerance or a basic linear distance, angle distance, or location dimension.
   - Box-select multiple callouts on the page.
   - From the toolbar on the GD&T from capture window, click **Process whole page** ( ).

6. Follow the instructions in the OCR widget.

> During the procedure, you need to pick features for datums or input features for the geometric tolerances. You can create these features with QuickFeatures. You can also select existing features from the Graphic Display window if you click on their feature IDs. PC-DMIS does not support clicking in the Edit window to select features.

Characteristic IDs

If your imported file has characteristic IDs, and you enabled the **Use Characteristic ID** check box from the **General** tab of the **Setup Options** dialog box, PC-DMIS automatically assigns an ID in the OCR widget that matches the characteristic ID. Any features that you then define with the OCR widget for the callout next to that ID use this naming convention:

<BalloonID>__1, <BalloonID>__2, and so on.

For example, if you have a characteristic ID of 3 in your file, and you need to create two features for the tolerance with that ID, PC-DMIS gives the feature that you create the IDs of 3__1 and 3__2.

If a callout has a multiplier, such as a callout for a bolt-hole pattern, PC-DMIS assigns the characteristic ID for the first feature or dimension in the pattern. Any other features or dimensions in that pattern follow the default naming convention for that feature or dimension.

Datums Target Definition

If the OCR widget asks you to define datum target points, follow this procedure:

1. Press Ctrl + Shift and click on the CAD to create a vector point QuickFeature for each target.
2. As you define each datum target, the vector point feature appears in the Edit window.
3. Once you define the targets for a datum feature, it shows "Completed" for that datum feature. The OCR parsing of the file may not determine the number of targets needed. If that happens, you can create additional vector point features even if the targets for a datum feature show "Completed".
4. When you're done creating all the points for a target, click **Next** to go to the next set of datum targets.
5. Continue to define datum targets until the text on the widget says "Datum Target Definition Complete".
6. At this point, you can use the **Pause** button ( ) on the widget to pause the GD&T import process so that you can work with PC-DMIS to finish defining the datums. This can be a complex process that involves alignments, constructed features, or doing other work in PC-DMIS.
7. Use the Edit window, and press F9 on each Datum Definition (DATDEF command in Command Mode) to show the **Datum Definition** dialog box.
8. Link the datum targets to the datum letter.
9. Once you use PC-DMIS to define any datums from the targets, click **Resume** ( ) on the widget.

Datums Definition

If the OCR widget shows **Datums definition**, you need to use QuickFeatures to create datum features for those Geometric Tolerance commands. (If you've already created a datum feature, you can click on its feature ID from the Graphic Display window to select it.)

1. Create or select a datum feature or click **Skip current feature definition** ( ) if you want to skip over single datum definition for now.
2. Click **Next** and select additional datum features.

3. Continue repeating the above steps until the widget shows "Datums Definition Completed".

4. Then click **Apply** to define the remaining GD&T information.

Tolerances Definition

If the OCR widget shows **GEOTOL1**, you need to define the remaining GD&T information. If you skipped any datum definitions from the previous procedure, the widget asks you to define them now during the GD&T definition.

1. Once datums are completely defined, you need to create or select the actual considered feature or features. Use QuickFeatures to create the minimum number of features from the CAD model for the current step. (If you've already created a considered feature, you can click on its feature ID from the Graphic Display window to select it).

2. If you don't want to import a GD&T tolerance, click **Skip GEOTOL1** ( ). You can go back to a skipped item with the **Back** button ( ) as long as it is not on an earlier .pdf page.

3. Once you define a feature or features from the CAD model for a step, from the widget, click **Next** ( ). This continues with the next step of the GD&T definition. The **Next** button becomes enabled once you've defined the minimum number of features.

4. Once you define the features, and the widget informs you that the tolerances definition is completed, click **Apply** ( ). This accepts your changes and moves onto the next GD&T tolerance in the GD&T from Capture window.

5. Continue repeating the above steps until you have defined all selected GD&T tolerances.

Basic Linear Distance, Angle Distance, or Location Definitions

When you import basic dimensions, such as linear distance, angle distance, or location, you need to select or create features as usual to fulfill the definition requirements for these basic dimensions.

For the linear distance or angle distance dimensions, this can be a complex process that involves alignments, constructed features, or doing other work in PC-DMIS. In those cases, use the available **Pause** button to help you. Here's the procedure for those:

1. For those two dimension types, select the distance or angle features.

2. On the widget, click **Next** ( ). This continues with the next step of the definition and the widget says "Tolerances definition completed".
3. At this point, if you need to do something in PC-DMIS to fulfill the definition, click the small **Pause** button ( ) on the OCR widget. This temporarily stops the import process and gives you nearly full control over PC-DMIS.
4. Do whatever work you need to do in PC-DMIS to fulfill the callout definition.
5. On the widget, click the **Resume** button ( ) to resume the import process and click **Apply** ( ) to accept the definition. If the callouts have tolerance values defined in the blueprint, those values are also parsed and assigned to any created dimension in the Edit window.

Best Practices

OCR detection works best with an image that has at least 300 DPI. Lower resolutions may produce less accurate results.

When you have imported the desired GD&T tolerances, double-check the geometric tolerance commands that PC-DMIS generated.

Related Topics:

[About Optical Character Recognition (OCR) to Create FCFs]

[GD&T from Capture Window]

[OCR Widget]

About Optical Character Recognition (OCR) to Create Geometric Tolerances

The **GD&T Selection Mode (from File)** ( ) method uses OCR to identify the GD&T tolerance information to import.

For more information, see the "[Using GD&T Selection Mode (from File)]" topic.

Resolution

OCR detection works best with an image that has at least 300 DPI. Lower resolutions may produce less accurate results.

Supported Geometric Tolerance Types

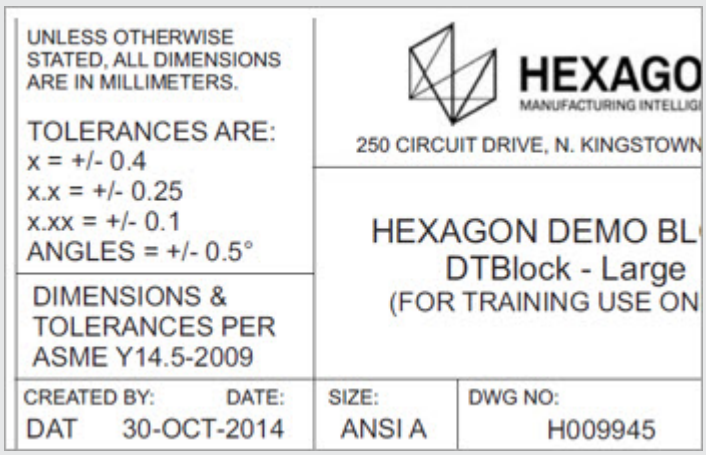
The described OCR methods support these Geometric Tolerance types:

- The 14 characteristic symbols
- The Diameter symbol

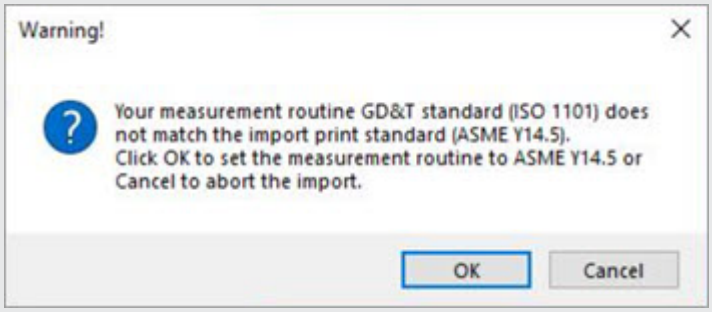
- M, L, P, and other modifier symbols bounded by circles
- Data within the boxes and size data above boxes
- Single-line tolerances, multi-line non-composite tolerances, composite tolerances
- Linear, Angular, and Location dimensions

PC-DMIS highlights supported items you can interact with in orange.

When you import GD&T through OCR, PC-DMIS checks the title block text to see if a GD&T standard is declared.



If there is, PC-DMIS compares it to what is defined in the measurement routine. If the standards do not match, PC-DMIS displays a warning message asking if you want to continue or cancel the import.

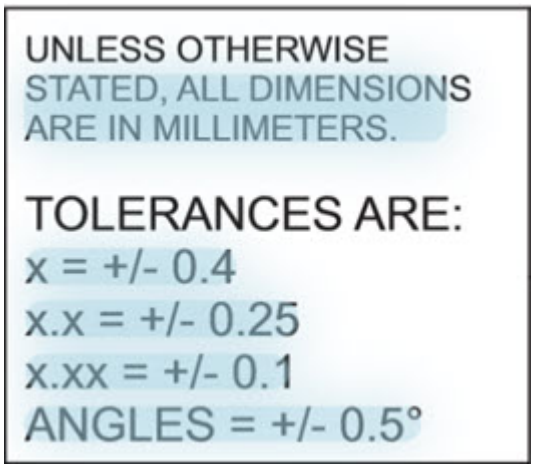


Example Warning message showing mismatch between current and imported GD&T standards

- If you click **OK**, PC-DMIS applies the GD&T standard called out in the title block and sets all existing Geometric Tolerance commands in the measurement routine to be invalid. You can use the invalid commands to recreate new versions of the commands based on the updated GD&T standard. You can then delete the invalid commands after you recreate the new commands.
- If you click **Cancel**, PC-DMIS cancels the import, and nothing changes in your measurement routine.

Other Supported Items

- OCR detection also parses some default tolerances and measurement units from the title block. This happens automatically, and PC-DMIS visually indicates that it has been parsed by highlighting the title block text in a light blue color, like this:



Example of a title block with parsed text (Highlighted in blue).

PC-DMIS compares the measurement units on the blueprint against the measurement units of the routine. If they are different, PC-DMIS converts the blueprint's tolerance values into the units used by the routine. If the blueprint doesn't clearly state the measurement units, PC-DMIS assumes that the tolerances match the measurement units of the routine. PC-DMIS applies the parsed default tolerances to any dimension on the drawing that doesn't have tolerances already explicitly defined.

- OCR detection can also support characteristic IDs. For that to work, you need to enable the **Use characteristic ID naming** check box from the **General** tab of the **Setup Options** dialog box prior to performing the OCR detection. For more information on that check box, see "Use Characteristic ID Naming" in the "Setting Your Preferences" chapter. For information on OCR detection of characteristic IDs, see "Using GD&T Selection Mode (from File)" where the topic discusses characteristic IDs.

Unsupported Items

The OCR methods above do not support some complex elements. These include items like square brackets, extended characters, double-headed arrows, and so on.

FAQ

Question: What happens if my measurement routine already has a datum defined with the same label as a datum defined in the drawing?

Answer: If a datum definition with the same name already exists in your measurement routine, PC-DMIS does not request that you to create a new datum feature of the same name. Instead, PC-DMIS uses the existing datum feature from your measurement routine.

Question: Do I need to use OCR to recognize a datum all by itself?

Answer: No. Since datums are always defined for a GD&T tolerance, the OCR does not recognize them as separate GD&T notes. You only need define the GD&T tolerances and PC-DMIS prompts you to select the datum features as needed.

Question: What happens if there is size text immediately above the GD&T tolerance?

> *Answer: PC-DMIS parses this additional line and assigns the data to the created Geometric Tolerance.*

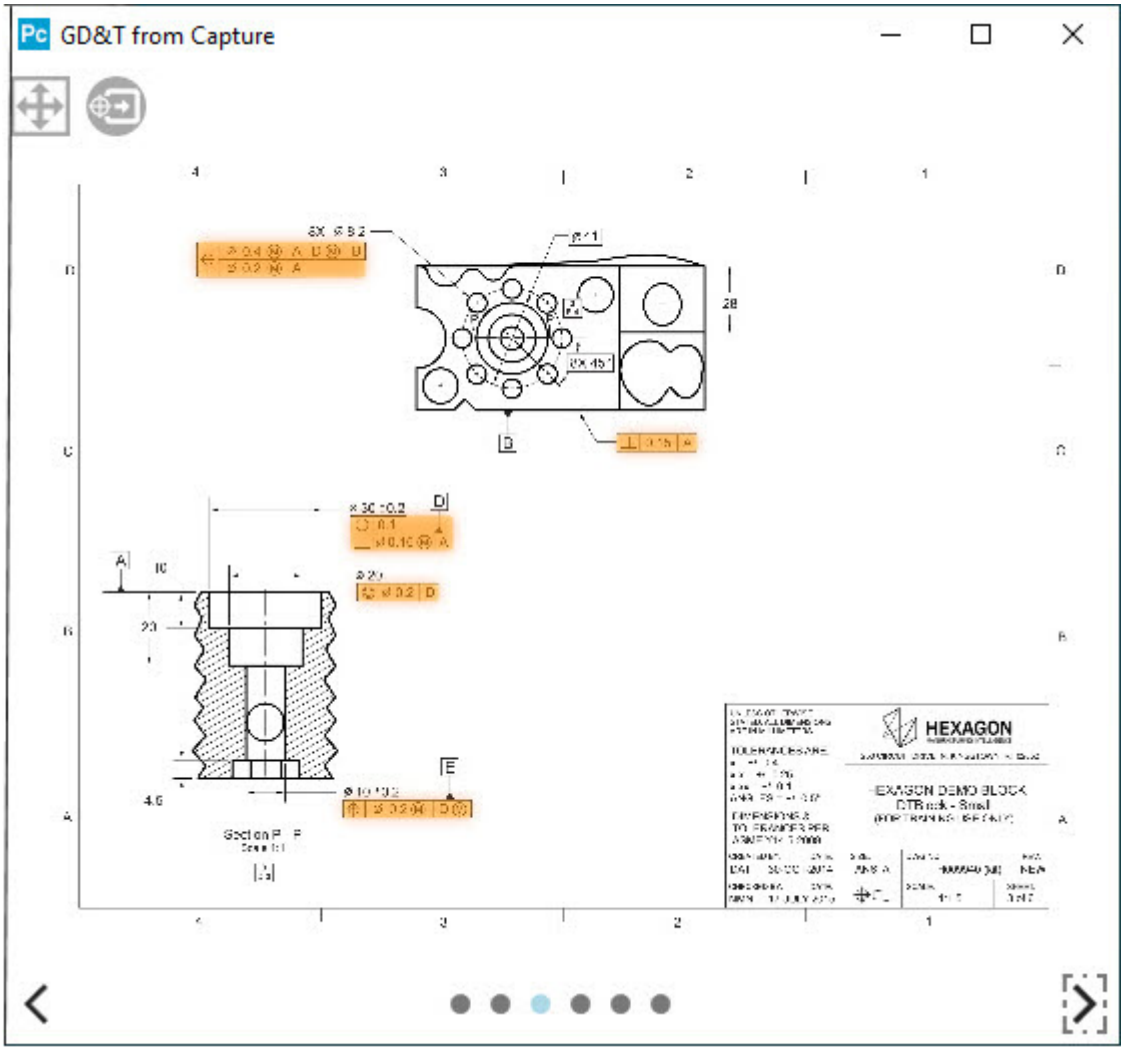
Question: What happens to multi-line non-composite GD&T tolerances?

> *Answer: PC-DMIS imports these as two separate Geometric Tolerance commands.*

GD&T from Capture Window

When you import an image or .pdf file that contains GD&T tolerance information with the **GD&T Selection Mode (from File)** ( ) option, PC-DMIS uses Optical Character Recognition (OCR) to process the file.

PC-DMIS then displays the **GD&T from Capture** window and the detected tolerances:



GD&T from Capture window with detected GD&T tolerances in orange

This is a re-sizeable and movable window. You can double-click the title bar to maximize the window or to restore it to its previous size. The image on each page of the file scale to fit the window.

Screen Elements

Fit to page - This element sizes the contents of the current page to the dimensions of the window.

Process whole page - This element processes all highlighted orange GD&T tolerances on all pages.

Orange highlight - A GD&T tolerance with this color means it has been identified by OCR and can be imported into the routine.

Yellow highlight - A GD&T tolerance with this color means it is the active tolerance and that the OCR widget is waiting for you to take action to proceed. The software creates a temporary GD&T callout in the Graphic Display window, and the OCR widget provides some brief instructions on how to proceed.

Green highlight - A GD&T tolerance with this color has been processed, and an appropriate Geometric Tolerance or other similar command exists for it the routine.

- The gray dots at the bottom of the window show the total pages. The blue dot shows which page is the current page.

- The buttons at the bottom of the window let you go to next and previous pages.

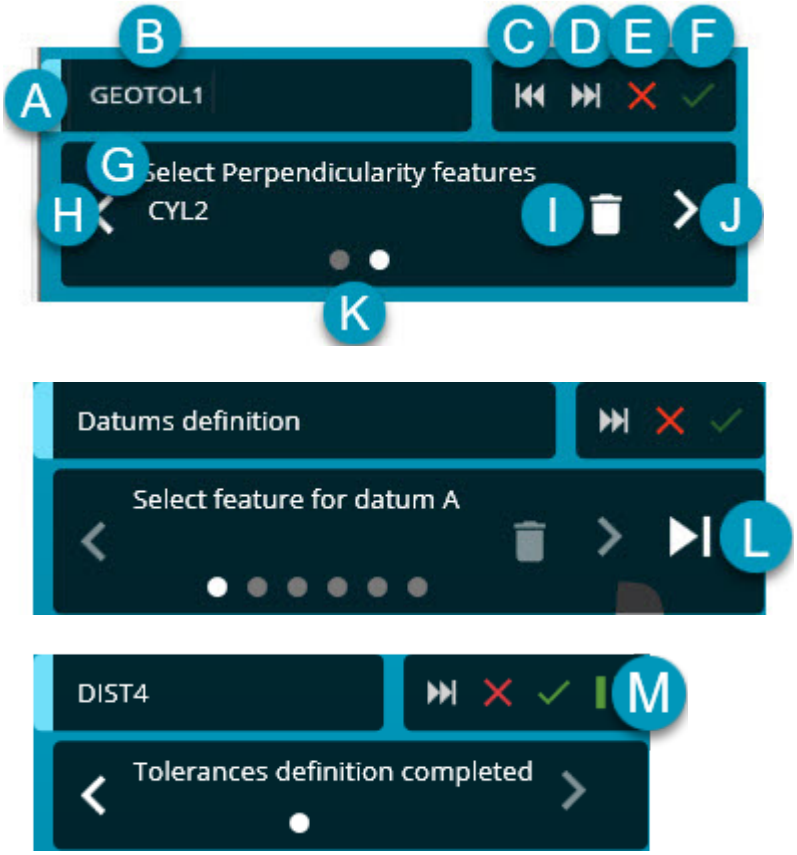
Panning and Zooming

Just like in the Graphic Display window, you can use the mouse wheel to zoom in and out on the drawing. You can right-mouse drag to pan the drawing.

OCR Widget

PC-DMIS uses this widget to import GD&T tolerances from a drawing with Optical Character Recognition (OCR). The widget appears if you select **GD&T Selection Mode (from File)** ( ), and you then select one or more GD&T tolerances to import from the GD&T from Capture window.

There are often multiple steps with instructions on the OCR widget for a given GD&T tolerance definition. For example, you often need to first select a datum feature (or features) from the CAD model and later select the considered feature (or features). These instructions and your selections occur across multiple steps.



Example of the OCR Widget for the highlighted GD&T tolerance.

A. This handle lets you drag and reposition the widget.

B. **Feature** - This box defines the name of the GD&T tolerance or step.

C. **Back** - This button only appears if there are multiple GD&T tolerances on a .pdf page or a capture of multiple tolerances, and you have skipped one or more of them with the **Skip** button. If you then click **Back**, the software returns to the skipped tolerance and highlights it in the **Selection Preview** window.

D. **Skip** - This button appears with a .pdf import or with a capture of more than one GD&T tolerance. By default, for each tolerance, you define the datums first (or datum targets). In this case, this button skips the current datum definition (or datums target definition). Once you move onto defining the rest of the GD&T tolerance, this button skips the highlighted GD&T tolerance. It then highlights the next available GD&T tolerance on a .pdf page or capture. For a file import, if there's only one GD&T tolerance on a page, the software asks if you want to proceed to the next page. If there are no more .pdf pages with GD&T tolerances, the software asks if you want to exit the GD&T import process. For an imported file, if you need to go back to a skipped item on a previous page, you must start the file import again.

E. **Cancel** - This button cancels the OCR process and closes the OCR widget and the **Selection Preview** window.

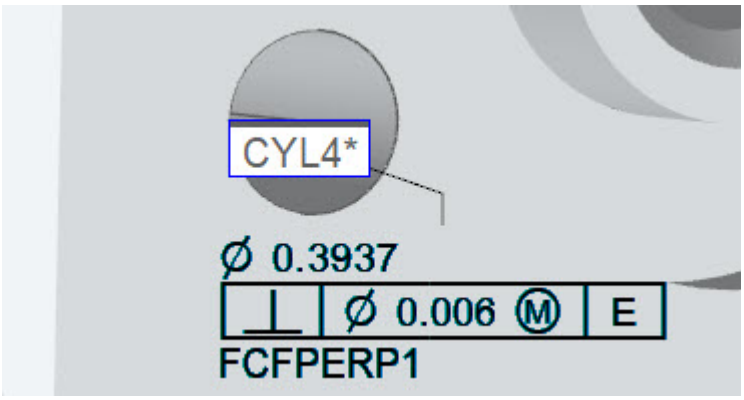
F. **Apply** - This button accepts the selected datum targets or features for the GD&T tolerance and moves onto the next part of the import or onto the next tolerance.

G. This field shows the instructions for the current step. You need to use QuickFeatures to select the indicated feature in the Graphic Display window.

H. **Previous** - This button goes back one step.

I. **Remove** - This button removes the selected feature from the current step.

J. **Next** - This button accepts the selection for the step and goes to the next step in the definition. The software enables this button once you define the minimum number of features. The temporary callout in the Graphic Display window updates as you progress through the definition:



Example of a temporary callout.

K. These dots show the number of steps to define one or more datums or to define a single GD&T tolerance. The white dot indicates the current step.

L. **Skip current feature definition** - This skips over the current datum definition.

M. **Pause** / **Resume** - The **Pause** button ( ) only appears if you are processing these types of callouts:

- Datum targets
- Linear distance dimensions
- Angle distance dimensions

To define these items can be a complex process. You may need to work with alignments, constructed features, or do other work in PC-DMIS. The **Pause** button is useful because it pauses the import process so that you can have nearly full access to PC-DMIS to finalize the callout's definition.

For Datum targets, the software enables this button once you have defined all the various datum target points, and the widget shows "Datums Target Definition Completed".

For the distance dimensions, it appears once you have defined both features, and the widget shows "Tolerances Definition completed".

Once you fulfill the callout's definition, you can click **Resume** ( ) to continue the import process.

Troubleshooting Error Messages and Warnings

PC-DMIS helps you to properly create your geometric tolerance command by providing many error messages and warnings. These messages may help you understand problems with your measurement routine. This topic provides additional details on many of these messages.

Message	Description	Solution
Warning: 2D primary datums do not constrain orientation so the datum feature's view will be used as an implied primary datum.	This is a warning message and not an error. Circles, lines, and 2D widths are 2D features, and are not able to constrain the orientation sufficiently. They are not recommended as primary datums. When you use a 2D feature as a primary datum, PC-DMIS levels to the view of the primary datum. In other words, the view becomes an implicit primary datum, and the specified primary datum becomes a secondary datum. For more information, see "How PC-DMIS Solves and Uses Datums".	You can continue to use geometric tolerances normally with this warning message. However, we recommend that you use a 3D primary datum instead, such as a plane, cylinder, 3D width, or sphere.

Warning: this type of constructed point does not have surface information. Therefore, it is treated similarly to the center of a sphere. Please use caution to ensure the results represent the specification.	This is a warning message and not an error. This warning is visible during these conditions: • When the constructed point is treated as a surfaceless 3D point. • When the point is used as a datum or as a considered feature. As discussed in "Structuring your Measurement Routine for Geometric Tolerances", in most cases we do not recommend using surfaceless 3D points, because you are taking over phases 2 and 3 of the conceptual evaluation process. If you do so, it is your responsibility to construct the feature according to appropriate standards. Because the point is treated like a sphere center, it is easy to get undesired behavior. (More Info) For more information about datum handling with surfaceless 3D points, see How PC-DMIS Solves Datums.	You can continue to use geometric tolerances normally with this warning message. However, in most cases we recommend that you use a feature that preserves the surface information. This way the geometric tolerance command can guarantee compliance to the applicable standard.

	For more information about considered feature handling with surfaceless 3D points, see Deriving the Toleranced Feature. For more information about the conceptual evaluation process, see Introduction to Geometric Tolerances and Feature Control Frames.	
Warning: simultaneous profile of a line tolerances are treated the same as profile of a surface.	This is a warning message and not an error. Profile of a line tolerances have a different meaning than profile of a surface tolerances, and it doesn't make sense (strictly speaking) to consider profile of a line tolerances simultaneously. For more information, see "Profile of a Line". However, PC-DMIS permits profile of a line tolerances to be included in simultaneous tolerances. It does this by treating them the same as profile of a surface.	You can continue to use geometric tolerances normally with this warning message. However, in most cases we recommend the following: • When cross sections are considered individually, use profile of a line specifications. • When several profile tolerances need to be considered simultaneously, use profile of a surface.

Warning: the [DF] modifier does not exist in ISO 5459:2011. The [DF] modifier (distance fixed) adds a location constraint to the datum. No [DF] modifier removes the location constraint.	This is a warning message and not an error. The [DF] modifier is not standardized as described in "Modifiers_for_Datums". However, it is functionally necessary in certain kinds of datum reference frames, and so PC-DMIS permits using this non-standardized modifier. For more details about how [DF] behaves, please refer to "Modifiers_for_Datums".	You can continue to use geometric tolerances normally with this warning message. However, in most cases we recommend that you do the following: • Contact your country's representatives to the ISO TC/213 family of standards, letting them know you need the [DF] modifier to be standardized in ISO 5459. • Verify that the functionality achieved with the [DF] modifier satisfies your functional needs.

Composite position specifications require more than one feature.	Composite position specifications are intended to control the location of a pattern to itself. It doesn't make sense to specify composite position of a single feature.	We suggest that you either: • Ensure your composite position specification includes at least two features. • Change your composite position specification to be two separate position specifications. • Or replace the lower segment of the composite position specification with an orientation specification instead, because the lower segments of composite position specifications do not have location constraints to the datum reference frame.

Simultaneous profile of a line tolerances without any datums are not supported.	As discussed in "Profile of a Line", it doesn't make sense (strictly speaking) to include profile of a line tolerances in simultaneous tolerance commands. If there are no datums referenced, then it makes even less sense because there are no datums or workplanes that you can select to control the orientation of the cross sections. Therefore, profile of a line specifications, without any datums inside simultaneous tolerance commands, are not supported.	We suggest that you either: • Change your profile of a line specification to be profile of a surface. • Or ensure that your profile of a line specifications are not considered simultaneously.

Datum feature <feature name> is 2D. It needs a higher-precedence datum to constrain its workplane.	**Case 1:** As discussed in "How PC-DMIS Solves and Uses Datums", some feature types are 2D, and their workplane needs to be constrained by higher-precedence datums. **Case 2:** Sometimes this error occurs because a constructed 3D BFRE line was used as a secondary datum. It is very common for the THEO line vector of these lines to be non-parallel to the primary datum plane. This means that the nominal workplane of the line is not parallel to the primary datum plane, and so the primary datum plane does not constrain the workplane of the secondary datum line.	For **Case 1**, the two most common solutions to this problem are: (1) measure the datum feature as a 3D feature, and (2) use one or more higher-precedence datums to constrain the datum feature's workplane. For **Case 2**, change the constructed 3D BFRE line to be a constructed 2D BFRE line, so that the nominal workplane of the line is parallel to the primary datum plane.

		For Best Fit (BF) or Best Fit Recompensate (BFRE) constructions, while you can use any feature type for your input features, BF and BFRE fit types are typically used with point features or point sets (a scan of points, a feature set with points, or an expression that resolves to an array of points). For details on using the Best Fit and Best Fit Recompensate methods to construct features, see the "Understanding Best Fit (BF) and Best Fit Recompensate (BFRE) Constructions" topic in the PC-DMIS Core documentation.

Feature <feature name> has too few points to fit uniquely.	This error indicates that the considered feature doesn't have enough points for a unique fitted shape. For example, PC-DMIS cannot uniquely fit a cylinder with only four surface points. Features with less than the absolute minimum number of points produce this error. (More Info) Generally, we recommend that you measure features as densely as practical. However, the absolute minimum number of points for each kind of feature are listed here: • Plane: 3 points • Surface line: 2 points • Surface circle: 3 points • Cylinder: 5 points • Cone: 6 points • Sphere: 4 points • 3D width: 4 points • 2D width: 3 points	Increase the number of points measured.

	Features with the absolute minimum number of points have all deviations equal to zero (with some exceptions too rare and complex to document here). Therefore, such features have zero measured form error.	

Datum <datum reference> has too few points to fit uniquely.	The most common way to get this error is when the surface points of the feature are not placed in a way that constrain any degrees of freedom. (More Info)	Measure the datum feature as a full 3D feature (plane, cylinder, cone, sphere, 3D width, and so on) instead of as a 2D or 1D feature (surface line, surface circle, 2D width, surface point, 1D width). If that is not possible, ensure that the datum feature and its surface points actually do constrain the necessary degrees of freedom.

		Suppose a datum reference frame has a primary datum plane, with surface normal Z-plus. The secondary datum is a cylinder with axis vector Z-plus, and the tertiary datum is a surface point. The orientation of the tertiary surface point determines whether this error occurs or not. If the surface normal of the point is parallel to the vector between the cylinder and the surface point, you will get this error because the point will not constrain rotation about the cylinder. However, if the surface normal of the point is any other direction, you will not get this error.

	You can also get this error if your datum feature has less than the absolute minimum number of points, but that is not a common way to get this error.	

Freeform feature(s) need points in more places to fit uniquely	You get this error when the geometric tolerance command cannot determine the degrees of freedom that are optimizable for the freeform-considered features, subject to the datum reference frame. To know those feature command types that are considered freeform, see the "Feature Types With and Without Surface Data" topic of the PC-DMIS Core documentation. One of the ways you can get this error is if you don't measure enough of the full surface to help the geometric tolerance command understand the surface. Perhaps you only measured a single point on the surface, or only one cross section.	You can fix the error in these ways: • Sample more of the surface. For example, if you measured only in one cross section, measure in more than one cross section. • Make sure all of the nominal vectors of your measured points are exactly correct. • If the nominal surface is almost symmetric, such that the degrees of freedom are unclear, constrain the uncertain degrees of freedom with additional datums in the datum reference frame. • If you don't have any datums referenced, ensure that the chosen workplane (under the **Reporting** tab of the **Geometric Tolerance** dialog box) matches the 2D considered feature's workplane.

	Another way you can get this error is when the nominal vectors of your measured points are not theoretically correct. For example, if you measure a plane, but the nominal vectors are not exactly planar. In this case, the geometric tolerance command determines that the surface isn't quite planar, but it is not able to determine whether the surface is cylindrical, spherical, conical, or complex. A third way you can get this error is when the nominal surface is almost symmetric in some way, but not quite. For example, perhaps it is almost planar, or almost cylindrical. In these cases, the geometric tolerance command cannot determine the optimal degrees of freedom. Finally, this error can also occur for profile of a line to no datums when you select an incorrect workplane.	

Freeform feature(s) need(s) points in more places to fit uniquely.	You get this error when the geometric tolerance command cannot determine the degrees of freedom that are optimizable for the freeform considered features, subject to the datum reference frame. To know those feature command types that are considered freeform, see the "Feature Types With and Without Surface Data" topic. One of the ways you can get this error is if you don't measure enough of the full surface to help the geometric tolerance command understand the surface. Perhaps you only measured a single point on the surface, or only one cross section. Another way you can get this error is when the nominal vectors of your measured points are not theoretically correct. For example, if you measure a plane, but the nominal vectors are not exactly planar. In this case, the geometric tolerance command thinks the surface isn't quite planar, but it won't be able to tell whether the surface is cylindrical, spherical, conical, or complex.	You can fix the error in these ways: • Sample more of the surface. For example, if you measured only in one cross section, measure in more than one cross section. • Make sure all of the nominal vectors of your measured points are exactly correct. • If the nominal surface is almost symmetric, such that the degrees of freedom are unclear, constrain the uncertain degrees of freedom with additional datums in the datum reference frame.

	A third way you can get this error is when the nominal surface is almost symmetric in some way, but not quite. For example, perhaps it is almost planar, or almost cylindrical. In these cases, the geometric tolerance command cannot determine the optimal degrees of freedom.	
Profile of a line tolerances need their workplane defined by the datum reference frame.	Profile of a line tolerances have 2D considered features. Their workplane needs to be constrained by the datum reference frame.	*If you have one or more datums referenced*, ensure that the datum reference frame constrains the workplane of the 2D considered features. *If you don't have any datums referenced*, ensure that the chosen workplane (under the Reporting tab in the dialog box) matches the 2D considered features' workplane.
This tolerance requires the data to be measured in circular cross sections.	Some tolerances, such as circularity of a cylinder, or the CIRCULAR_ELEMENTS local size interpretation, need their data to be measured in circular cross sections.	Re-measure the considered feature so that the data is arranged in circles. You may find a measurement strategy helpful, but you do not have to use one.

This local size tolerance requires the data to be measured in circular cross sections. To Fix this either measure the feature using circular cross sections or turn off local size in the Report tab	When reporting position, the orientation and runout of some local size tolerances (such as ASME CIRCULAR_ELEMENTS) require that you measure the data in circular cross sections.	Turn off local size (if not required) or re-measure the considered feature so the data is arranged in circular cross sections.
The tolerance needs at least one datum.	Several tolerances, such as perpendicularity, require at least one datum.	Add a primary datum to the tolerance.
A multi-feature datum cannot mix features with surface data and features without surface data.	Multi-feature datums include datum patterns and common datums. They must all either have surface data or all lack surface data. For information on feature command types that have and do not have surface data, see "Feature Types With and Without Surface Data".	Choose datums that all have surface data or choose datums that do not have any surface data.
Features' orientation must be compatible with their polar tolerance zones.	Polar tolerances zones include radial-arc tolerance zones and right-angle-to-radial tolerance zones. The considered features must be nominally parallel to the polar axis defined by the datum reference frame.	Ensure that all of your considered features are nominally parallel to the polar axis, or stop using polar tolerance zones.

Features with polar tolerance zones may not center on the polar origin.	Polar tolerances zones include radial-arc tolerance zones and right-angle-to-radial tolerance zones.	The considered features must not be coaxial with the polar axis. If you have a considered feature that is coaxial with the datum axis, you typically need to use a diametric tolerance zone instead of a polar tolerance zone.
The datum reference frame must define a clear polar origin.	Polar tolerances zones include radial-arc tolerance zones and right-angle-to-radial tolerance zones. They only make sense when the datum reference frame defines a clear polar axis.	Ensure the datum reference frame defines a clear polar axis.
Multi-feature datums at RMB must have surface data.	Multi-feature datums include datum patterns and common datums. If the multi-feature datum does not have a material modifier, then the datum features must have surface data.	Re-measure the datum features so they have surface data.
For perpendicularity tolerances, the nominal considered features must be perpendicular to the primary nominal datum.	The most common cause of this error is incorrect THEO values in the considered features and/or datum features.	Ensure that the considered features are nominally perpendicular to the primary datum.

For parallelism tolerances, the nominal considered features must be parallel to the primary nominal datum.	The most common cause of this error is incorrect THEO values in the considered features and/or datum features.	Ensure that the considered features are nominally parallel to the primary datum.
The orientation of a planar tolerance zone must be fully defined by the datum reference frame.	You get this error with planar tolerance zones on axial features such as cylinders, cones, and circles. Specifically, when the datum reference frame doesn't constrain the orientation of the tolerance zone, the actual value is not well defined.	You can fix the error in these ways: • Ensure that the datum reference frame fully constrains the orientation of the tolerance zone. • Use a diametric tolerance zone.
These simultaneous tolerances must use the DEFAULT tolerance zone math type.	You get this error when all these conditions are met: • You have multiple profile tolerances. • No datums belong to a simultaneous tolerance command. • The profile tolerances have different tolerance zone math types.	Set all the profile tolerance zone math types to **DEFAULT**.

Datums at RMB without surface data that follow datums at MMB or LMB are not supported.	The geometric tolerance command does allow datums without a material modifier to follow datums that have a material modifier. However, the no-material-modifier datum must have surface data.	Re-measure the lower-precedence datum so it has surface data.
When a tolerance specifies more than one considered feature, all the features must be pattern compatible. This means they must have the same type of shape, the same nominal size, and the same inner/outer.	When there are multiple considered features, they must be identical, except for having different locations and orientations. So, for example, cylinders must be all inner or all outer, and they must all have the same nominal size.	Use separate geometric tolerance commands for features that are not identical. If necessary, use a simultaneous tolerance command to consider all the features simultaneously.

Feature is used twice in fundamentally different ways, where the nominal shape (or lack thereof) must be considered differently in the two contexts.	This is a very unusual error. The most common way to get this error is with a simultaneous position and profile of a slot, notch, or ellipse: • Position treats the feature as a circle without surface data. • Profile treats the feature as a freeform feature with surface data. The error occurs because the simultaneous tolerance needs to treat the same feature two different ways at the same time.	You can fix the error in these ways: • Use only profile and not position to control the position of the slot. • Create a cast circle or generic circle from your slot, notch, or ellipse, and do simultaneous position of the cast circle with the profile of the slot.
Simultaneous tolerances must have identical datum reference frames.	This error occurs if geometric tolerances in your simultaneous tolerance have different reference frames; or the datums in those tolerances are not identical, are out of order, or use different modifiers.	Ensure that all geometric tolerances in your simultaneous tolerance command have identical datum reference frames. The datums must be the same, in the same order, with the same modifiers.
Simultaneous tolerances must be position or profile tolerances.	You get this error if you aren't using the correct geometric tolerances for the simultaneous tolerance.	Ensure all geometric tolerances in your simultaneous tolerance command are either position or profile tolerances.

Multi-feature datum error. This error may occur from incorrect nominals (X, Y, Z or I, J, K vectors) or an unsupported combination of features.	You get this error when you try to reference an unsupported combination of features as a common datum.	Review the table of supported feature combinations and general guidelines for common datums. Also, check the feature nominals for the multi-feature datum in question and make any corrections needed.
Specification requires a fully constrained tolerance zone.	Some tolerances, such as symmetry and concentricity, require that the tolerance zone is fully constrained by the datum reference frame.	Ensure that the datum reference frame fully constrains the tolerance zone.
Translation modifier is invalid because the datum does not have any translation degrees of freedom that could be unlocked.	There are many circumstances where the geometric tolerance command allows you to put a translation modifier on a datum where it does not make sense.	Remove the translation modifier from the datum.
Datum is invalid because it constrains no degrees of freedom.	If your secondary or tertiary datum constrains no degrees of freedom, this error occurs. Most likely, this either means (a) your print is wrong, or (b) there is a mistake in your measurement routine.	If this error happens with a new geometric tolerance, double-check your print and your feature types. Pay special attention to best fit lines, as discussed in Feature Types With and Without Surface Data.
Runout tolerances require features that are concentric with the datum reference frame.		Ensure that all considered features are nominally concentric with the datum reference frame.

Too many points for this type of calculation.	This error occurs when using a **DEFAULT** math option with too many points. It can happen due to the feature math option, the datum math option, or the tolerance zone math option. The cutoff for how many points is "too many" is several tens of thousands of points.	You can fix the error in these ways: • Use only a few thousand points. • Use the **LSQ** math option.
Concentricity tolerances require input features that are concentric with the datum reference frame.		Ensure all considered features are nominally concentric with the datum reference frame.
Symmetry tolerances require input features that are symmetric with the datum reference frame.		Ensure all considered features are nominally symmetric with the datum reference frame.
Invalid per-unit extent.		Ensure that the per-unit length and/or per-unit width is correct.
There is insufficient point density for the per-unit tolerance.		Re-measure the considered feature with increased point density.

The datum customization is invalid.	The geometric tolerance command allows customized ASME datum reference frames. This error occurs when the customization does not make sense mathematically. It is very common to make mistakes with customized DRFs, and that can result in this error.	You can fix the error in these ways: • Stop using datum customization. • For every datum in the datum reference frame, ensure that the customization results in a unique and fully-defined invariant.
Circles used to calculate the extracted median line must include at least 90 degrees of arc.	As discussed in "Deriving the Toleranced Feature", several ISO geometric tolerances use the extracted median line as the toleranced feature. All circular cross sections must have at least 90 degrees of arc. This error can also happen with straightness of an axis (either ASME or ISO). As discussed in the "Straightness" topic, straightness of an axis requires that you measure the surface data in circular cross sections. If any of the cross sections have less than 90 degrees of arc, PC-DMIS shows this error message.	Ensure that every circular cross section in your considered feature contains at least 90 degrees of arc.

When using a sample plane, it must be nominally orthogonal to the considered feature.		Ensure that the feature's sample plane is nominally perpendicular to the considered feature's axis. For information about how the sample plane is defined, see "Deriving the Toleranced Feature".
Feature <feature name> and its child features are out of synchronization. Please re-execute to re-synchronize them.	If you change a feature's measurement strategy, or if you change the number of rows in the measurement strategy, the feature can get out of synchronization with its child features, until the feature has been executed.	Execute the feature.
Segment <segment number> contains an invalid datum reference frame for the lower segment of a composite tolerance.	As discussed in "Position", "Profile of a Line", and "Profile of a Surface", lower segments of composite tolerances have strict rules to govern their datum reference frame.	Ensure that all lower segments' datum reference frames comply with the rules.

Datums referenced at MMB/LMB must have been previously toleranced at MMC/LMC to their higher precedence datums. Where no such tolerance is found, zero at MMC/LMC will be applied.	This is a warning to alert you that you should have already created the applicable Geometric Tolerance command(s) for any datum feature(s) with a material condition modifier. If you have not created the applicable Geometric Tolerances for the referenced datum with a material condition modifier, PC-DMIS uses a Geometric Tolerance of 0.0 MMC to determine the MMB/LMB (Maximum/Least Material Boundary) value.	You can continue to use geometric tolerances normally with this warning message. You should, however, check the drawing and ensure your routine already includes all Geometric Tolerances relating to the datum features. See the "Datum Reference Messages" section of the "How PC-DMIS Solves and Uses Datums" topic for more details.
Geometric tolerance calculation failed.	This indicates some internal problem in the calculation. Please file a request to open a support ticket with Hexagon Technical Support (support.hexagonmi.com).	With your ticket request, provide the following information: • Steps to duplicate the error message • Your measurement routine (.prg file) • Your CAD model (.cad file) • Supply a copy of the drawing and call-out you're trying to verify • Any probe files used (.prb files) • The debug file

The projected tolerance zone must have a positive projected distance.	The number that follows the P modifier defines the distance to project the zone beyond the feature, such as when evaluating a cylinder. The number must be a positive value.	Make sure that the projection zone's number is a positive value, not negative.

Scanning Your Part

Scanning Your Part: Introduction

PC-DMIS allows you to define a point measurement by scanning the surface of the part at specified increments. This provides you with a way to scan and digitize your part's surfaces.

PC-DMIS supports scanning in these products:

- PC-DMIS CMM - Using a touch trigger or analog probe on a CMM
- PC-DMIS Laser - Using a laser probe
- PC-DMIS Portable - Using a hard probe on a portable arm

For information on the above approaches to scanning, consult the appropriate documentation. The documentation for each product discusses the available scans and procedures to follow within those environments to create those scans.

The main topics in this chapter discuss information common to scanning in any of the supported applications as well as common functions of the scanning dialog boxes (**Insert | Scan**). They do not cover the specifics on how to create a scan, since the methods for doing so depend on your specific application.

The main topics discussed here include:

- Components of a Scan
- Working with CAD Surfaces
- Common Functions of the Scan Dialog Box

- Common Functions of the BASICSCAN Dialog Box
- Additional Manual Scan Options

Changing Animation Speeds: If you want to modify your offline animation speeds, see the **Execution** area on the **General** tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**). In addition, see "Executing and Debugging Measurement Routines Offline" in the "Working in Offline Mode" chapter.

Components of a Scan

Advanced scans in PC-DMIS are composed of "basic scans". For example, a Patch scan is actually made up of rows of data, where each row is a basic scan. The basic scans act as building blocks for the higher-level scans, such as Patch scans. The PC-DMIS CMM documentation discusses advanced scans and basic scans.

Working with CAD Surfaces

When you create scans, you often need to select one or more surfaces that you want PC-DMIS to scan. PC-DMIS shows selected surfaces in the defined highlight color:

Example showing a surface highlighted when selected.

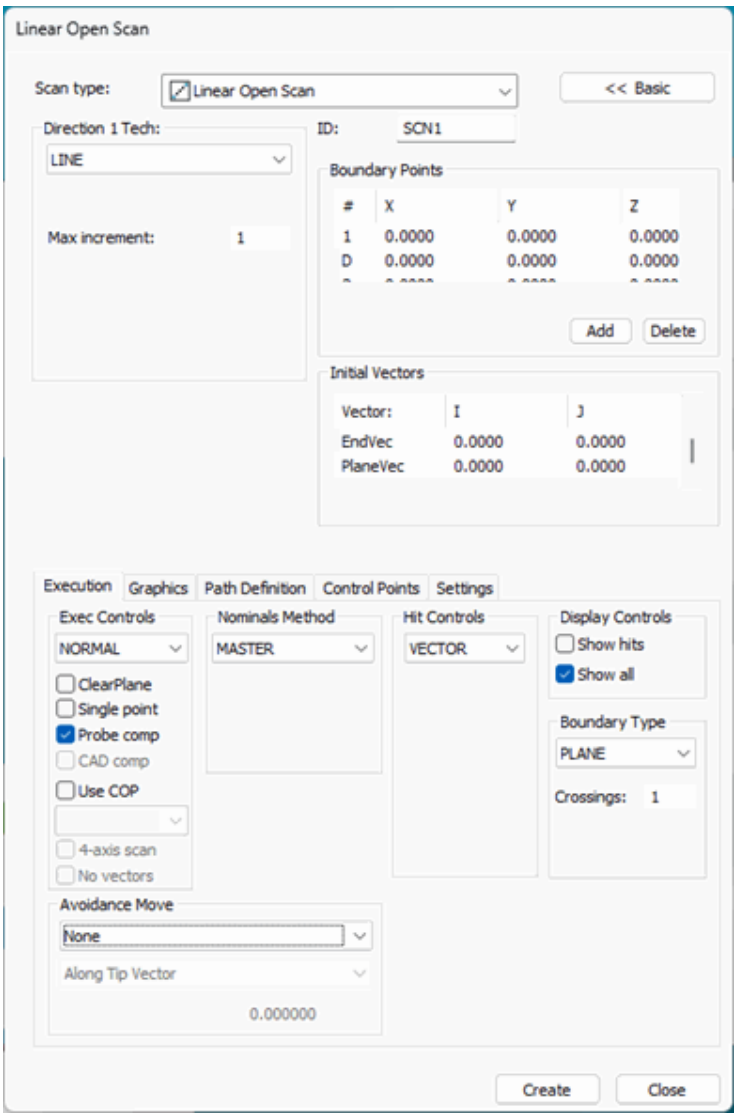
For more information on the highlight color, see the "Colors Tab" topic in the "Editing the CAD Display" chapter.

To deselect (or select) a desired surface:

1. Ensure that your part displays surface data.
    - Enable Surface Mode. To do this, from the **Graphic Modes** toolbar (**View | Toolbars | Graphic Modes**), select the **Surface Mode** icon ( ).
    - Show the part in solid view. To do this, from the **Graphic View** toolbar (**View | Toolbars | Graphic View**), select the **Show Graphic Window as Solid** icon ( ).
2. Access the appropriate scan dialog box (**Insert | Scan**), and start to define the scan.
3. As needed, click on a surface or surfaces to select them. If you make a mistake and need to deselect a surface, press Ctrl and click on the surface.

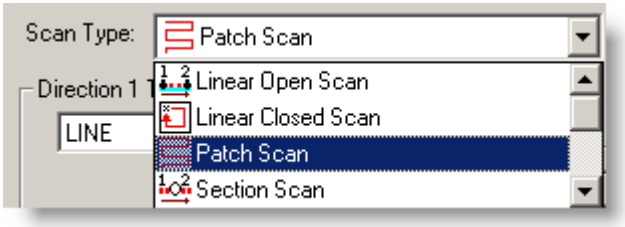
Common Functions of the Scan Dialog Box

Many of the functions described below are common to many of the scan dialog boxes (**Insert | Scan**) used in the supported applications. Options that relate specifically to one scan mode are appropriately indicated.



Scan Dialog Box

Scan Type

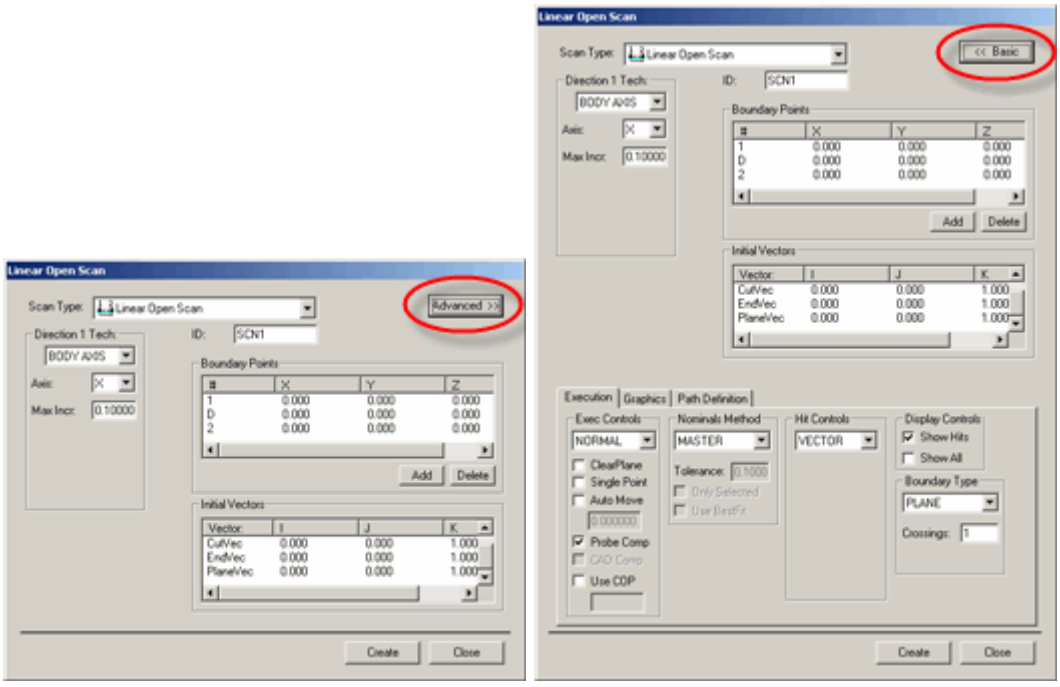


The **Scan Type** list in the scan dialog box (**Insert | Scan**) lets you switch between available scans. If you select a new scan, the dialog box changes to the selected scan type.

Basic and Advanced Buttons

The **<<Basic** and **Advanced>>** buttons in the scan dialog box (**Insert | Scan**) switch between displaying basic scanning options on the scan dialog box and more in-depth, advanced options.

- Click **Advanced>>** to expand the dialog box to include the **Execution**, **Graphics**, and **Path Definition** tabs in the lower section. Each tab contains additional options that you can use to define your scan.
- Click **<<Basic** to hide the more advanced items and display the basic information you need to create the scan.



Example showing basic options (left) and advanced options (right).

ID

The **ID** box in the scan dialog box (**Insert | Scan**) displays the ID of the scan to create.

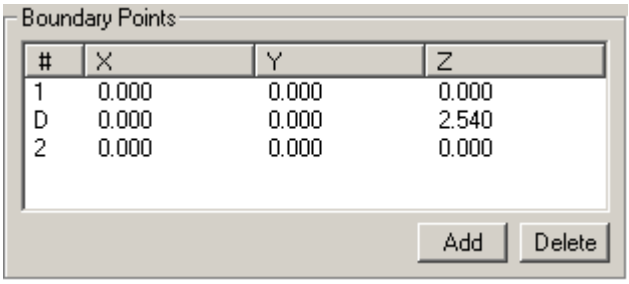
Measure

If you select the **Measure** check box in the scan dialog box (**Insert | Scan**) and click the **Create** button, PC-DMIS starts to measure the scan immediately. If you do not select the **Measure** check box when you click **Create**, PC-DMIS inserts a scan object into the Edit window that you can measure later. This enables you to set up a series of scans that you can insert into the Edit window and measure at a later time.

This check box is available *only* when PC-DMIS is Online.

Boundary Points Area

To define the boundary of a scan in the scan dialog box (**Insert | Scan**), PC-DMIS allows you to key in or measure points, or use CAD data.



Boundary Points Area

This function is only available for DCC scans.

LINEAROPEN - These scans can also be measured without an end point. Delete the end point, and PC-DMIS keeps measuring the scan until you manually stop it. You cannot delete the starting point and direction point.

LINEARCLOSE - These scans need to have the start and direction points. You cannot delete or add boundary points.

PATCH - These scans need to have at least three boundary points to create a triangular patch to work with. You can use the **Add** and **Delete** buttons in the **Boundary Points** area to add or delete extra points. It adds a **Closed Scan** check box to this area.

Closed Patch Scan Use the **Closed Patch Scan** check box to indicate that you would like to scan a closed feature like a cylinder, cone, slot, etc. If you select this check box, PC-DMIS reduces the number of boundary points needed to define the scan boundary. You would need to enter only the start and direction points and an end point. The end point indicates how far down and up the feature the scan needs to execute. The start and direction points together with the Initial Vector define the Cut Plane vector. Usually, the Cut Plane vector is parallel to the axis of the feature that you are measuring.

SECTION - Section scans use this area to set the boundary points for the SECTION scan, find holes defined in the CAD data, and toggle between displaying data for holes or for boundary points. Section scans add the **Cut CAD** and **Show Cut** buttons to this area for this purpose.

Cut CAD After you define a boundary and click **Cut CAD**, PC-DMIS automatically searches through the CAD data for any hole features along the scan's path. Any hole edges along the scans path are indicated with a integer for the point followed by a

"H" (i.e. 2H, 3H, etc.). The hole edge points are set at a default distance of 0.0787 inches from the theoretical hole edge.

You can cut CAD with specific, user-selected surfaces. To do this, select the boundary points, select the **Select** check box, select the desired surfaces, and then click **Cut CAD**. PC-DMIS then cuts only the selected surfaces to find the hole or holes.

You do not need to click Cut CAD if your CAD does not contain hole features. If you do not use this button, PC-DMIS scans the part using the given start and end boundary points.

When cutting surfaces, PC-DMIS uses only the surfaces that appear in the first View (the Blue View).

See "Setting up the Screen View" in the "Editing the CAD Display" chapter. When you have a complex CAD drawing with multiple surfaces, you can arrange groups of surfaces into CAD levels. (See the "Working with CAD Levels" topic in the "Editing the CAD Display" chapter.) Doing this helps you restrict Section CAD Cut operations to specific portions of the CAD model.

Use the **Show Cut** button to switch between displaying boundary or hole data. After you define a boundary and select the **Cut CAD** button, click **Show Cut** to switch to the appropriate display.

PERIMETER - These scans works the same as the LINEAROPEN scan.

ROTARY - These scans require you to have at least a start point and a direction point (shown as **1** and **D** respectively in the **Boundary Points** list and on the CAD display).

- If you don't have an end point (shown as **2**), PC-DMIS continues to measure the scan along the specified direction until it returns to the start point.
- If you have a start point and an end point, PC-DMIS scans along the specified direction until it reaches the end point.

  PC-DMIS defaults to providing you with a start, direction, and end point in the **Boundary Points** area. You can delete the end point, but you cannot delete the start or direction point.

  As you define each boundary point (by either clicking on the CAD or typing in the values), PC-DMIS automatically snaps each point to the radius distance from the center point unless you didn't define a radius. In this case, the first boundary point you define also defines the radius.

The **Boundary Type** area is only available in DCC Mode for Linear Open, Linear Close, Patch, Section, and Rotary scans.

Setting Boundary Points Using the Keyin Method

To use the keyin method to set the boundary of a scan:

1. Double-click the desired boundary point in the # column in the scan dialog box (**Insert | Scan**). This displays the **Edit Scan Item** dialog box.

Edit Scan Item Dialog Box

2. Manually edit the X, Y, or Z value.

3. Click the **OK** button to apply the changes.

The **Cancel** button disregards any changes that have been made and closes the dialog box.

The **Next** button accepts the changes and then brings up the next boundary point for you to edit.

Setting Boundary Points Using the Measured Point Method

To set the boundary of the scan using measured points, touch the probe on the part. This automatically updates the value of the boundary point that is currently selected in the **Boundary** list. The focus then moves to the next boundary point (if there are any in the list).

In the case of a PATCH scan, an extra boundary point is added automatically if the current point is the last point in the list. The PATCH scan displays the last point (this is the same as the previous point). PC-DMIS deletes this last point when you select the **OK** button in the scan dialog box (**Insert | Scan**).

Setting Boundary Points Using the CAD Data Method

PC-DMIS allows the selection of boundary points using both wireframe and surface data.

When you use CAD surface data:

1. Make sure that you have imported solid CAD data.

2. Make sure that the **Draw Surfaces** icon is selected from the **Graphic Modes** toolbar (**View | Toolbars | Graphic Modes**).

3. Access the scan dialog box that requires boundary points. Then, to select a boundary point, click on the desired location in the Graphic Display window.

The selected surface is highlighted. PC-DMIS automatically updates the value of the boundary point that is currently selected in the boundary list. The focus then moves to the next boundary point (if any are available). In the case of a PATCH scan, an extra boundary point is added automatically if the current point is the last point in the list.

When you use CAD wireframe data, there are two ways to select curve elements:

Mode 1 - Depth Curve

PC-DMIS uses a Depth curve during FindNoms operations to form a plane using two curves. Ideally, the Depth curve is normal to the other curves selected so that PC-DMIS can cross the two vectors (the vector of the Depth curve and the vector of any other selected curve) and form a plane from which it can find the nominals.

To indicate a Depth curve, select the **Depth** check box and then select a curve. Only one Depth curve is to be selected and this should be done after other curves have been selected.

1. Make sure that the **Curve Mode** icon is selected from the **Graphic Modes** toolbar.
2. Select the **Select** check box.
3. Select the **Depth** check box.
4. Select a curve.
5. Indicate the two CAD edges that are normal to each other.
6. Clear the check box.
7. Click on the part.

If a Depth curve is provided, PC-DMIS forms a plane by crossing the vector of each edge with the vector of the depth curve and piercing that plane to create a point.

Mode 2 - No Depth Curve

1. Select the **Select** check box.
2. Indicate the two CAD edges that are normal to each other.
3. Deselect the check box.
4. Click on the part.

If a depth curve is not selected, PC-DMIS simply drops the selected point onto the curve.

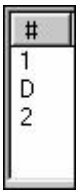
Only LINEAROPEN, LINEARCLOSE, and PATCH scans can use wire frame data.

Adding and Deleting Boundary Points

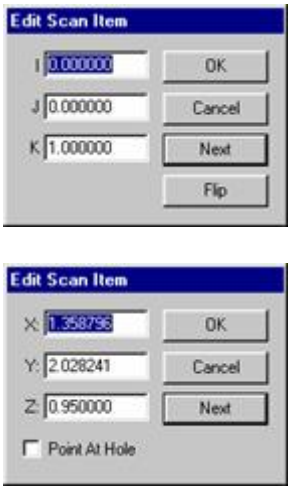
The **Add** and **Delete** buttons in the scan dialog box (**Insert | Scan**) enable you to add boundary points to the list of boundary points, or delete them. There are some restrictions about each type of scan. For example, a LINEARCLOSE scan will take only a Start and Direction point. It will not allow you to add more points or delete these two points. Please refer to each scan for specific restrictions.

Editing Boundary Points

You can edit boundary points by double-clicking the number of the desired point in the '#' column in the scan dialog box (**Insert | Scan**).



This displays the **Edit Scan Item** dialog box, which enables you to edit the X, Y, and Z values.



Example of the Edit Scan Item dialog boxes with the Flip button and the Point at Hole check box.

You can vary the column widths of the **Boundary Point** list by changing the width of the list display column header. To do this, select the right or left edge of a column header with the left mouse button and pull the edge to the desired size. You individually set and

determine the width of each list display. This information is saved in the INI file to be used each time you change the fields.

Flip:

The **Flip** button is only available when you edit a vector. Click this button to flip the selected vector.

Point At Hole:

The **Point At Hole** check box only becomes available when you work with Section scans. It allows you to change a non-hole point to a hole point.

A hole point defines where a linear section scan jumps over a hole that's found in its path. After you click the **Cut CAD** button, PC-DMIS places hole points on either side of any hole that interrupts the section scan.

Hole points are defined with the letter "H" after the point number (for example, 1H, 2H, 3H, etc.). These points, like any boundary point, are added to both the **Boundary Points** list and on the part model in the Graphic Display window.

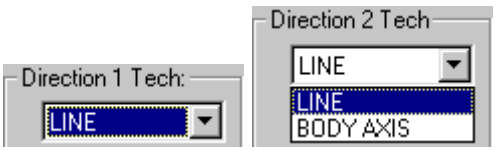
The **Point At Hole** check box is only available for non-hole points that you need to change to hole points. If you have a hole point that needs to be changed to a non-hole point, delete the hole point and create a new non-hole point.

Clearing Boundary Points

You can clear the **Boundary Points** list in the scan dialog box (**Insert | Scan**) of any of the scan types by right-clicking while the cursor is inside the **Boundary Points** list. A **Reset Boundary Points** button appears. Clicking this button resets all the boundary points to zero and the number of boundary points is set to the minimum for each scan type.

PC-DMIS doesn't allow you to clear the boundary points while you are using the **Cut CAD** button available on Section scans. In this case, you need to click the **Show Bnd** button to show the boundary points again before clearing the boundary points.

Direction Technique Areas



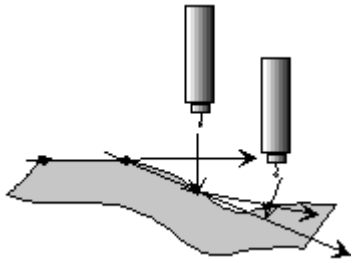
The **Direction 1 Tech** (left) and **Direction 2 Tech** (right) areas in the scan dialog box (**Insert | Scan**) determine how the scan takes hits. Most scans only scan in one row or line, so, they only have one set of direction techniques in the **Direction 1 Tech** list.

Patch scans are unique in that they scan over an area and so have additional rows of points and use a second set of direction techniques in the **Direction 2 Tech** list. In the **Direction 2 Tech** list, the selected technique determines the incremental technique that will be applied between rows.

Select the desired technique. PC-DMIS will automatically display the **Max / Min** or **Increment** boxes.

Line Technique

For Linear Open, Section and Patch scans - PC-DMIS determines each hit based on the set increment and the last two measured hits. The approach of the probe is perpendicular to the line between the last two measured hits. The probe will stay on the cut plane. PC-DMIS will start at the first boundary point and continue taking hits at the set increment, stopping when it reaches the end boundary point.



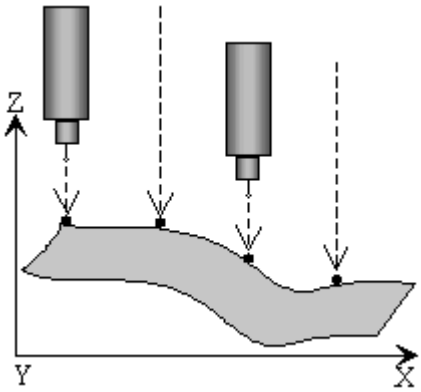
For Linear Closed scans - PC-DMIS determines each hit by the last two hits measured. The approach of the probe is perpendicular to the line between the last two measured hits. The probe will stay on the cut plane. PC-DMIS will not ask for the ending point when using this scanning technique. The scanning process terminates when the probe returns to the starting point.

For Rotary scans - PC-DMIS determines each hit based on the set increment and the last two measured hits. The approach of the probe is perpendicular to the line between the last two measured hits. The probe will always maintain the defined radial distance from the center point, perpendicular to the center point vector. PC-DMIS will start at the first boundary point and continue taking hits at the set increment, stopping when it reaches the end boundary point.

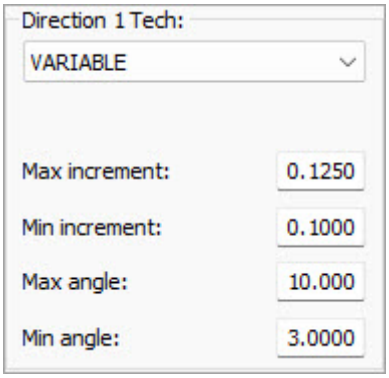
Body Axis Technique

The **BODY AXIS** technique in the scan dialog box (**Insert | Scan**) is only available for Patch and Linear Open scans when using a touch trigger probe.

PC-DMIS will take hits at the set increment along the current part's coordinate system. The approach of the probe is perpendicular to the indicated axis. The probe will stay on the cut plane. The approach vector will be normal to the selected axis and on the cut plane. The **BODY AXIS** technique uses the same approach for taking each hit (unlike the **LINE** technique which adjusts the approach to be perpendicular to the line between the previous two hits).



Variable Technique

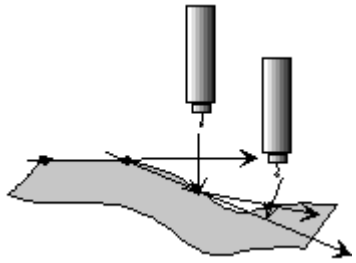


Available for Linear Open, Linear Closed, Patch, Section, and Rotary scans

The **VARIABLE** technique in the scan dialog box (**Insert | Scan**) enables you to set specific maximum and minimum angle and increment values that you can use to

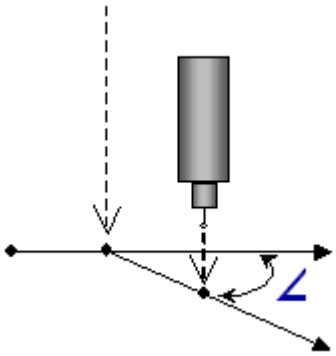
determine where PC-DMIS takes a hit. The probe's approach is perpendicular to the line between the last two measured hits.

To determine the increments between each hit, type the maximum and minimum values you want to use. You must also type the desired values for the **Max angle** and **Min angle** boxes. PC-DMIS takes three hits using the minimum increment. It then measures the angle between the first and second, and then the second and third hits.



- If the measured angle is between the **Max increment** and **Min increment** values, PC-DMIS continues to take hits at the current increment.
- If the angle is greater than the **Max angle** value, PC-DMIS erases the last hit and measures it again using one quarter of the current increment value.
- If the angle is less than the **Min angle** value, PC-DMIS takes the hit at the minimum increment value.

PC-DMIS again measures the angle between the newest hit and the two previous hits. It continues to erase the last hit and drop the increment value to one quarter of the increment until the measured angle is within the range defined, or the minimum value of the increment is reached.



- If the measured angle is less than the minimum angle, PC-DMIS doubles the increment for the next hit.
- If the measured angle is greater than the maximum increment value, PC-DMIS takes the hit at the maximum increment.

PC-DMIS again measures the angle between the newest hit and the two previous hits. It continues to double the increment value until the measured angle is within the range defined or the maximum increment is reached as shown below.

If ANGLE > MAX ANG then INC = INC / 4 until MIN INC

If ANGLE < MIN ANG then INC = INC * 2 until MAX INC

By default, Patch scans always start each new scan line with the minimum increment. If you would prefer that each new line starts with the increment from the previously scanned line, you can select the **Patch Scans Maintain Last Increment** check box on the **General** tab in the **Setup Options** dialog box (**Edit | Preferences | Setup**). For information, see "Patch Scans Maintain Last Increment" in the "Setting Your Preferences" chapter.

Nullfilter Technique

Available to Linear Open, Linear Close, Patch, Section, and Rotary scans**.**

The **NULLFILTER** technique in the scan dialog box (**Insert | Scan**) does not filter data at all. Whatever data PC-DMIS receives from the machine controller is the data given you. Although Probe Compensation and FindNoms are still applied there is no data reduction. This technique lets you control the increment of the hits by using the `OPTIONPROBE` command which sets the point increment during a scan. See the "Parameter Settings: Optional Probe tab" topic of the "Setting Your Preferences" chapter for more information.

PC-DMIS will start at the first boundary point and continue taking hits at the set increment, stopping when it reaches the end boundary point.

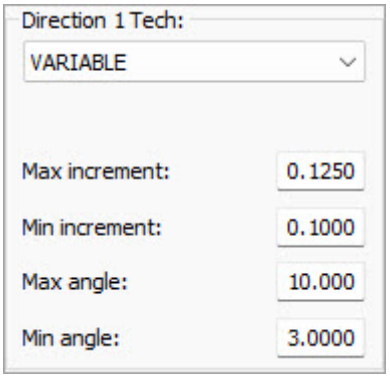
The **NULLFILTER** technique only appears in the **Direction 1 Tech.** list if you're using an analog probe head, such as the SP600.

For Rotary scans, the probe always maintains the defined radial distance from the center point, perpendicular to the center point vector.

Max and Min Boxes

These boxes are available for Linear Open, Linear Close, Patch, and Section scans if you select the **VARIABLE** scanning technique.

The **Max increment**, **Min increment**, **Max angle**, and **Min angle** boxes in the scan dialog box (**Insert | Scan**) are available when you use the **VARIABLE** scanning technique described in the "Variable Technique" topic. Only the **Max increment** box is available for *all* of the scanning techniques.



Example of the Direction 1 Tech area with options for the VARIABLE scanning technique.

Max increment

The **Max increment** box enables to set the maximum increment distance. Even though increments may increase while using the Variable option, the increments will never be greater than this distance.

Min increment

The **Min increment** box enables you to set the minimum increment. Even though increments may decrease using the Variable option, the increments will never be smaller than this distance.

Max angle

The **Max angle** box enables you to set the maximum angle. Even though angles measured may increase while using the Variable option, the angles will never be greater than this value.

Min angle

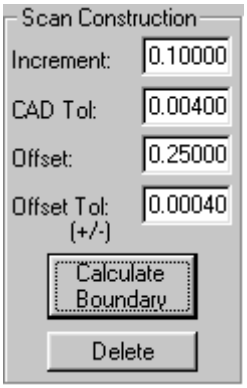
The **Min angle** box enables you to set the minimum angle. Even though angles measured may decrease while using the Variable option, the angles will never be less than this value.

Increment box

Available only for Patch scans.

Used with **Patch** scans, the **Increment** box in the scan dialog box (**Insert | Scan**) enables you to set the incremental distance between rows on the patch scan. For example, if you enter 0.5, then the scan sets the rows at increments of 0.5.

Scan Construction Area (for Perimeter Scan)



Used with the Perimeter Scan.

The **Scan Construction** area in the scan dialog box (**Insert | Scan**) has various options for constructing a Perimeter Scan. These include:

- Increment
- CAD Tol
- Offset
- Offset Tol (+/-)
- Calculate Boundary
- Delete

Increment Box for a Perimeter Scan

The **Increment** box in the scan dialog box (**Insert | Scan**) indicates the distance between each of the hit points on the scan.

CAD Tol

The **CAD Tol** box in the scan dialog box (**Insert | Scan**) is useful to detect neighboring surfaces. The larger the tolerance, the farther apart the CAD surfaces can be and still be recognized as a neighboring surface.

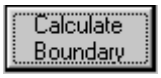
Offset

The **Offset** box in the scan dialog box (**Insert | Scan**) indicates the distance in from the perimeter where the scan will be created and executed.

Offset + / -

The **Offset Tol (+/-)** box in the scan dialog box (**Insert | Scan**) indicates the amount of allowable deviation from the offset value. It is a user supplied value.

Calculate Boundary

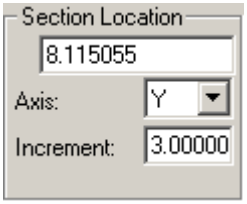


The **Calculate Boundary** button in the scan dialog box (**Insert | Scan**) determines the composite boundary of the input surfaces. The calculated boundary appears as red dots in the Graphic Display window.

Delete

The **Delete** button in the scan dialog box (**Insert | Scan**) deletes the previously created boundary.

Section Location area (for Section Scan)



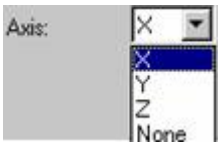
The box in the **Section Location** area in the scan dialog box (**Insert | Scan**) specifies the initial section at which you would want the scan to start.

If you want multiple sections at X = 5, X=5.5, X = 6, etc., you must first specify 5.0 as the initial section. After each scan, PC-DMIS will automatically jump to the next section at 5.5 and so on.

This value can be edited directly, or it can be set using the first boundary point. The first boundary point's coordinate value corresponding to the cut axis is the section location. When the first boundary point is defined by either taking a hit, selecting from CAD data, or keying in a value, the coordinate value for the cut axis is used.

If the first boundary point is set to 45, 37, 100 and the cut axis is Y, the section location is at 37. If the cut axis is X, the section location is 45.

Axis List



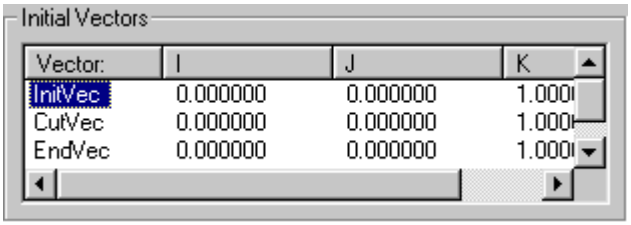
The **Axis** list in the scan dialog box (**Insert | Scan**) enables you to select the axis (**X**, **Y**, or **Z**) where you want multiple sections. The **None** option is also available. It allows you to select a "section line" on screen.

Scans do not usually allow you to work with curve data. However, if you select **None**, a section scan lets you select a graphically-displayed section line that is then used to define the cut plane and scanning path.

Increment

The **Increment** box in the scan dialog box (**Insert | Scan**) specifies the jump distance along the section axis after each scan is done.

Initial Vectors Area



The **Initial Vectors** area in the scan dialog box (**Insert | Scan**) displays a list of vectors that are used to start and stop a scan. Some scans do not use any initial vectors. These are UV, Grid, Perimeter, and FreeForm scans. The following lists the available initial vectors, when they are used, and their descriptions:

InitVec (Initial Touch Vector)

Used in Linear Open, Linear Closed, Section, Patch, Rotary, and Basic scan types.

The values that are displayed in the **Initial Touch Vector** row indicate the surface vector of the first point in the scanning process.

CutVec (Cut Plane Vector)

Used in Linear Open, Linear Closed, Patch, Section, and several Basic scan types.

A cut plane is used internally for DCC scanning calculations. This cut plane is derived differently for each supported scan type.

- *For Linear Open*, the Cut Plane vector (CutVec) is the cross product of the Initial Touch vector (InitVec) and the line between the start and end point. If there is no end point, the line between the start point and direction point is used.
- *For Linear Closed*, the Cut Plane vector (CutVec) is the cross product of the Initial Touch vector (InitVec) and the line between the start and end point.
- *For Patch Scan*, the cut plane vector (CutVec) is derived by crossing the Initial Touch vector (InitVect) and the line between the first and second point. The cut plane vector is then set to the correct direction by using the line between the second and third points. The End Touch vector (EndVec) is the vector used to take the second boundary points and is used to jump to the second row after completing the first row.
- *For Section Scan*, the Cut Plane and Initial Touch vectors are used to measure the scan. The Cut Plane vector is the cross product of the Initial Touch vector and the line between the start and end points. If there is no end point, then PC-DMIS uses the line between the start and direction points.

EndVec (End Touch Vector)

Used in Linear Open, Patch, Section, Rotary, and Line Basic scan types.

The End Touch vector is the approach vector of the scan at the end of the row. This is used only to stop the scan or to move to the next row (in the case of a Patch scan).

PlaneVec (Boundary Plane Vector)

Used in Linear Open, Linear Closed, Patch, Section, and Rotary scan types.

The Boundary Plane vector and the End Touch vector are used with the given Boundary Condition to stop the scan. The Boundary Plane Vector has different uses when applied to different Boundary Conditions:

- *For a Plane*, when used with a Plane Boundary Condition, it represents the normal vector of the Plane.
- *For a Sphere*, it is not used with the Sphere Boundary Condition.
- *For a Cylinder*, when used with a Cylinder Boundary Condition, it represents the Axis of the Cylinder.
- *For a Cone*, when used with a Cone Boundary Condition, it represents the Axis of the Cone.

DirVec (Initial Direction Vector)

Used in Rotary, Manual, and Line Basic scan types.

It represents the direction in which the scan will begin and is used with the Initial Touch vector to derive the Cut Plane vector.

SurfVec (Top Surface Vector)

Used in Linear Open and Linear Closed scan types.

This appears when you use the **Edge** hit type. It is the vector of the initial top surface of the edge and is used to start the scan.

vector1

Used in Linear Open and Linear Closed scan types.

This row is the surface normal vector of the first surface selected for angle hits. It appears when you use the **Angle** hit type. This corresponds to the **Surf 1 Vec** values in the **Angle Points** tab when creating Auto features. See "Creating an Auto Angle Point" in the "Measuring Features" chapter of the PC-DMIS CMM documentation.

vector2

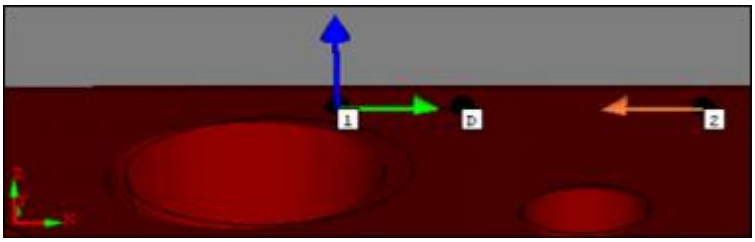
Used in Linear Open and Linear Closed scan types.

This row is the surface normal vector of the second surface selected for angle hits. It appears when you use the **Angle** hit type. This corresponds to the **Surf 2 Vec** values in the **Angle Points** tab when creating Auto features. See "Creating an Auto Angle Point" in the "Measuring Features" chapter of the PC-DMIS CMM documentation.

Graphical Representation of Scan Vectors

When setting up the start, direction, and end points of the scan, PC-DMIS allows you to see a graphical representation of the initial touch vector, the direction vector, and the vector that is normal to the boundary plane where the scan will stop.

These vectors are shown as blue, green, and orange colored arrows in the Graphic Display area of your part.



Example showing vectors with colored arrows.

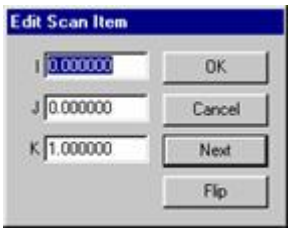
Vectors and their graphical representations are:

- Initial Touch: Blue arrow
- Direction: Green arrow
- Boundary Plane: Orange arrow

Editing Vectors

To edit each vector, double-click on the vector to edit in the vector column in the scan dialog box (**Insert | Scan**).

This displays the **Edit Scan Item** dialog box:



Edit Scan Item Dialog Box

Use the different fields to edit the **I**, **J**, and **K** values.

- Click the **OK** button in the **Edit Scan Item** dialog box to apply any changes that you made.

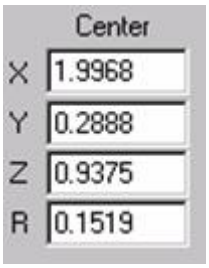
- Click the **Cancel** button to close the **Edit Scan Item** dialog box without applying any changes.
- Click the **Next** button to cycle through the available vectors in the **Initial Vectors** list. Some of the initial vectors can be flipped. If so, the **Flip** button becomes available in the **Edit Scan Item** dialog box.
- Click the **Flip** button to reverse the direction of the selected vector.

Select Center (for Rotary Scan)

Choosing the **Select Center** check box in the scan dialog box (**Insert | Scan**) enables you to click on the CAD to indicate the center point. You can select a surface point or wireframe point. PC-DMIS fills in the Center Point boxes with the XYZ information for the selected point.

When you select this check box, be aware that the boundary points of the scan will not be updated. PC-DMIS will only update the boundary points when you clear this check box.

Center Point and Radius (for Rotary Scan)

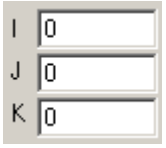


The X, Y, and Z values of Center in the scan dialog box (**Insert | Scan**) define the center point of the ROTARY scan.

You can directly type the center point **X**, **Y**, and **Z** values, or you can choose the **Select Center** check box and click on the CAD drawing to take the center point directly from the CAD model.

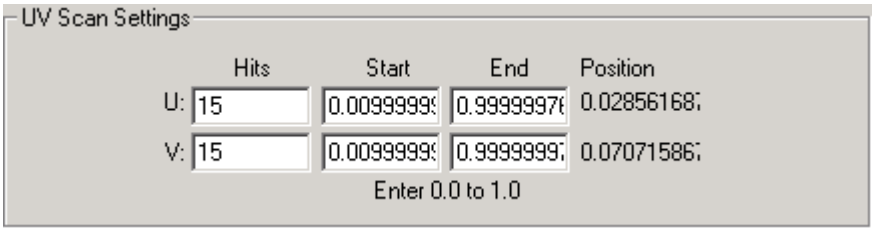
R defines the radius. When PC-DMIS executes the scan it will rotate around the center point maintaining this distance as the scan moves from the Start to the End point.

IJK (for Rotary Scan)



The **I**, **J**, and **K** values in the scan dialog box (**Insert | Scan**) make up a vector normal to the plane in which the **Radius** is maintained from the center point. PC-DMIS will follow this vector when performing the scan.

UV Scan Settings Area



UV Scan Settings Area

The **UV Scan Settings** area in the scan dialog box (**Insert | Scan**) enables you to define your UV scan. It contains the U and V rows and allows you to define the following controls.

- The **Hits** values allow you to specify how many hits the scan will take on the surface in the U or V direction.
- The **Start** and **End** values allow positioning of the hit matrix on the surface that is being scanned. These values can be set for both the **U** and **V** rows and apply to the scan along the U and V axes. Note that UV space uses numbers between 0.0 and 1.0 to represent the entire surface. So 0.0, 0.0 will be on the opposite diagonal corner from 1.0, 1.0.
- The non-editable **Position** fields indicate the probe 's current position along the U and V axes.

Grid Scan Settings Area

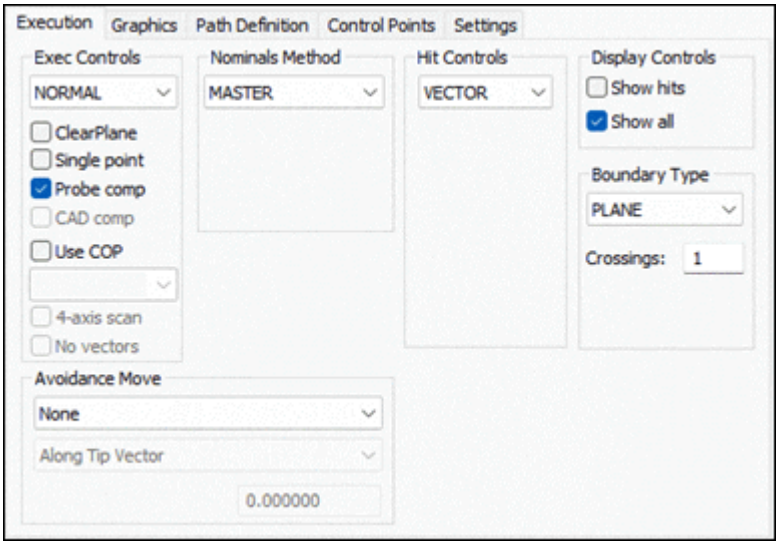
The **Grid Scan Settings** area in the scan dialog box (**Insert | Scan**) lets you define the number of hits to equally space in the A and B directions of a Grid scan. The A direction is horizontal, B is vertical.

If you typed 20 in the A direction and 20 in the B direction, PC-DMIS would attempt to space 20 rows and 20 columns of points on the combined selected surfaces within the rectangular area.

In the image below, only the top surface on the Hexagon block is selected. PC-DMIS only drops points onto that surface, not the others.

Example of a grid scan with 20 points in the A and B directions.

Execution Tab

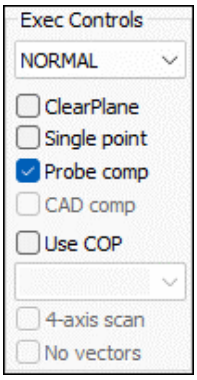


Scan Dialog Box - Execution Tab

The options on the **Execution** tab in the scan dialog box (**Insert | Scan**) let you determine what happens when you execute the scan being created. It contains these areas:

- Exec Controls Area
- Avoidance Move Area
- Nominals Method Area
- Hit Controls Area
- Display Controls Area
- Boundary Type Area

Exec Controls Area



The options in this area on the **Execution** tab in the scan dialog box (**Insert | Scan**) aren't used for all scan types. For example, manual scans only use a few of these options.

Manual scans use the following Exec Controls options:

- 3D check box
- CAD Comp check box (if FindNoms is selected)
- Use COP check box when there is a laser probe
  Execute list - This list lets you determine how PC-DMIS executes a scan after the scan has been learned.

  Normal - PC-DMIS executes the scan in its 'normal' manner; it triggers a hit when the probe touches the part.

  If a DCC scan is executed, PC-DMIS takes hits at each of the learned locations in stitch scanning mode, storing the newly measured data. The displayed nominals are the same as when the scan was learned and *cannot* be re-calculated using a different Nominals mode.

  Re-learn - PC-DMIS executes the scan as though it is learning it. All learned measured data replaces the new measured data. The nominal is re-calculated depending on the Nominals Mode (see "Nominals Mode"). Re-learn completely ignores the settings in the **Path Definition** tab and relearns the path as it goes.

  If a DCC scan is being re-learned, PC-DMIS relearns the scan from the beginning, instead of taking hits at the learned locations (as it would do in the case of the NORMAL mode).

  Defined - PC-DMIS allows the controller to ‘define’ a scan. PC-DMIS gathers all hit locations from the editor and passes them onto the controller for scanning. The controller will then adjust the path allowing the probe to pass through all the points. The data is then reduced according to the increment provided and the new data will replace any old measured data.

When this option is used after Generating the scan Offline, the nominal locations obtained from CAD are used every time to drive the CMM.

This mode is available only when you use analog probe heads that can do continuous contact scanning.

> The **Defined** mode with Perimeter scans does not support hole avoidance. Ensure that there aren't any holes in your scan's pathway with this execution mode; if there are, either adjust your Perimeter scan's path or switch to the **Normal** execution mode.

ClearPlane check box - The **ClearPlane** check box inserts a CLEARP MOVE a predetermined distance relative to the current coordinate system and part origin before taking the first hit.

After the last point in the scan is measured, the probe stays at probe depth until called to the next feature. Using clearance planes reduces programming time because the need to define intermediate moves is reduced. (See "Parameter Settings: Clearplane Tab" in the "Setting Your Preferences" chapter for additional information on clearance planes.) This option is only available for DCC scans.

Single Point check box - The **Single Point** check box considers each hit as a single measured point.

If this option is check marked, PC-DMIS will make each hit a measured point and insert it into the measurement routine. This sequence will happen after the manual scan has been reduced. If the scan is in DCC Mode, it takes place after the scan has been learned.

Probe Comp check box - The **Probe Comp** check box allows you to determine whether or not PC-DMIS turns on probe compensation for this specific scan.

In most cases you probably don't need to perform this compensation since a scan's FINDNOMS operation automatically does it. However, if you don't have CAD and want to reverse-engineer a part, you should select this check box.

CAD Comp check box - This check box determines whether or not PC-DMIS compensates for each point using the 3D surface vector from the CAD file. If not selected, PC-DMIS uses a 2D cut plane as usual.

This check box becomes available for selection if you select FINDNOMS from the list in the **Nominals Method** area or if you click on the CAD model in the Graphic Display window.

Inner Bound check box (not shown in image) - This check box allows you to determine whether PC-DMIS will perform an interior or an exterior perimeter scan.

- If selected, PC-DMIS will perform an interior perimeter scan.

- If deselected, PC-DMIS performs an exterior perimeter scan.

For a description of interior or exterior scans see the "Performing a Perimeter Advanced Scan" topic in the PC-DMIS Laser documentation.

Use COP check box - This check box determines whether or not the scanned points also get added to an existing Pointcloud (COP) command. If you select this check box, you can type the ID for the COP command into which you want to add the newly scanned points. If the COP command doesn't yet exist, PC-DMIS prompts if it should generate it for you.

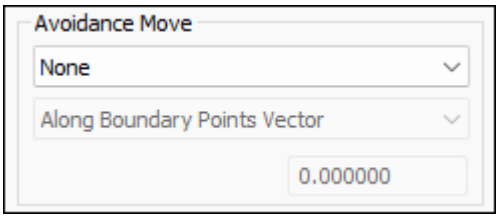
For information on COP commands, access the PC-DMIS Laser documentation where this command is discussed.

4-axis scan check box - Select this check box to allow scanning on a rotary table while the table is moving.

No vectors check box - This option is a special function of the Leitz B5 controller used for Technology Server 1.5 with PC-DMIS I++ DME machine interface. The purpose of this function is to find the highest point in the measured scanning trajectory.

For example, let us say you select this option and then run a rotary table scan around the edge of a blade. PC-DMIS will perform the scan without collision when only the points of the trajectory are sent to the controller, and not the surface point vectors of the defined scan.

Avoidance Move Area



Avoidance moves are special moves that you add to your scans to help PC-DMIS avoid driving the probe through the part during surface scans.

You can define the type of avoidance move, the approach path for the probe tip, and the distance to move before and/or after PC-DMIS creates the scan.

Type list - You can use this list to define the type of avoidance move:

None - If you select this option, PC-DMIS does not perform an avoidance move.

Before - If you select this option, PC-DMIS only performs the avoidance move before the scan.

After - If you select this option, PC-DMIS only performs the avoidance move after the scan.

Both - If you select this option, PC-DMIS performs the avoidance move before and after the scan.

Approach Path list - You can use this list to select the direction along which PC-DMIS performs the avoidance move:

Along Boundary Points Vector - If you select this option, PC-DMIS applies the avoidance move along the vector of the first scan path point and/or along the vector of the last scan point.

Along Tip Vector - If you select this option, PC-DMIS applies the avoidance move along the probe tip's vector.

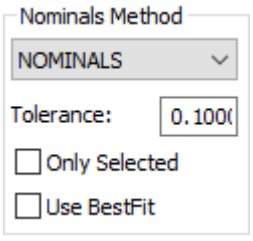
Along Cut Vector - If you select this option, PC-DMIS applies the avoidance move along the cut vector of the scan.

The **Along Cut Vector** option is available only if the selected scan has a defined cut vector.

Distance box - You can use this box to specify the distance that the probe moves during the avoidance move.

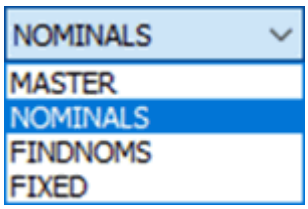
PC-DMIS applies the avoidance move to the entire scan, not to each basic scan defined within the scan.

Nominals Method Area



This area on the **Execution** tab of the **Scan** dialog box (**Insert | Scan**) contains these items:

- **Nominals** list



The **Nominals** list lets you determine how PC-DMIS gathers nominals for the measured data.

- **MASTER** - When you select this option, PC-DMIS treats the measured data from the first scan as nominal data. Subsequent scans are then compared to this data. When you select **MASTER** with a DCC scan and **Normal** from the **Execute** list, PC-DMIS executes a Stitch-type scan using the measured data.
- **FINDNOMS** - When you select this option, PC-DMIS pierces the CAD model to locate the closest location on a CAD surface to the measured point. It then sets the nominals to the location found on the CAD surface.

  With the Circle, Cylinder, and Axis types of Basic Scans, there is no need to have CAD data to find the nominals. To execute the Basic Scan, PC-DMIS obtains the nominals from the nominal data you supply. For more information, see "Nominals Mode Tab" in PC-DMIS Core documentation.

  If proper nominals are not found, PC-DMIS prompts you to provide a new Find Nominal tolerance.

  
  You can enter a new value in the **Tolerance** box and apply it to either the current scan or to the entire measurement routine.

  - If you select **Yes**, PC-DMIS uses the new tolerance to find nominals.
  - If you select **No,** PC-DMIS proceeds as follows:

  If proper nominals still cannot be found for any hit after you provide the new tolerance, PC-DMIS prompts you to confirm whether the hits can be deleted.

  - If you select **Yes**, PC-DMIS deletes the hits.
  - If you select **No**, the hits remain in the scan.
- **NOMINALS** - When you use this option, PC-DMIS uses any measured data from the first scan as nominal data. This option allows you to relearn the scan without relearning the nominals. The main difference between **NOMINALS** and **MASTER** is that the **NOMINALS** option constructs a nominal curve from the

nominal data. PC-DMIS then compares subsequent scan executions to this nominal curve, using the value specified in the **Find Noms Tol** box.

You can use the Nominals mode with the **RELEARN** option from the **Execute** list in the **Exec Controls** area. For more information, see "Exec Controls area" in the PC-DMIS Core documentation.

If you toggle to `NOMINALS` in the Edit window from a different mode, PC-DMIS automatically creates the nominal curve from the current theoretical data. This may take some time, depending on the amount of data used. Also, if the Edit window is set to `NOMINALS` and you toggle to a different mode, PC-DMIS deletes the nominal curve.

For descriptions of **LEAST_SQR**, **VECTOR_LST_SQR**, **MIN_MAX**, and **VECTOR_MIN_MAX**, see "The Best Fit Alignment Methods" in the "Creating and Using Alignments" chapter.

- **FIXED** - When you select this option, PC-DMIS keeps nominals the same in every execution of the measurement routine.

  The FIXED nominal method is available only when you select **DEFINED** from the **Execute** list in the **Exec Controls** area.

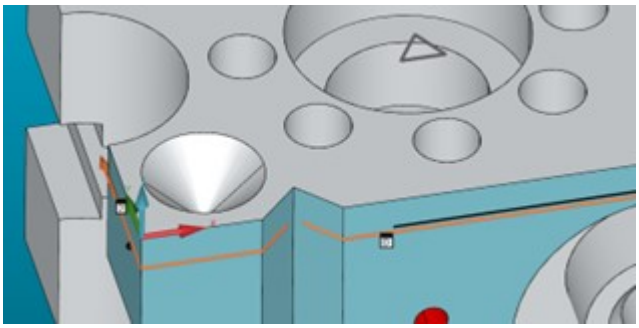
  Important Points:

  - You must use the **FIXED** nominals method only for 2D curves. PC-DMIS disables the **CAD Comp** check box in the **Exec Controls area** for this method.
  - This method only supports the Vector type of Hit Controls.
  - When you use this method, PC-DMIS selects and greys out the **Probe comp** check box in the **Exec Controls** area of the **Execution** tab.
  - The **Direction 1 Tech** list only offers the **NULLFILTER** technique. In this technique:
    - The **Point density** setting under the **Settings** tab controls the number of points that PC-DMIS generates per mm.
    - It also controls the points sent back by the controller.
  - You can adjust the point density to control the spacing between points in the **Path Definition** tab. To do this:
    - Define the point density in the **Settings** tab.
    - Generate the path in the **Path Definition** tab.

- It is important to have dense points (a high number of points) returned by the controller for this method to ensure accurate measurements. During execution, if the point density is set to less than 10 points/mm, PC-DMIS requests the controller to send back points at a minimum density of 10 points/mm. If the point density is set higher than 10 points/mm, PC-DMIS sends the point density request to the controller based on your specified value.

- This method removes any unreachable points from the scan path. Unreachable points are locations where the probe tip cannot physically reach due to the shape of the part.

  For example, as shown in this image, PC-DMIS removes points from the scan path where the probe tip cannot reach the surface due to the part's V shape:

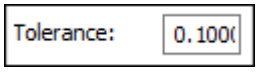


- This method considers the current probe tip radius. If the probe tip is replaced with one that has a different radius, regenerate the path to ensure that PC-DMIS removes the correct number of points from internal sharp corners.

- This method also removes nominal points at external corners of parts. At these points, the controller changes force from one direction to another. PC-DMIS controls the radius within which the points are removed by the **RemoveExternalCornerRadiusForFixed** settings entry, with a default value of 0.2 mm. You can increase this value or set it to 0 to remove points at external corners.

- You must generate the path only after you select the **FIXED** option from the **Nominals** list. This ensures that PC-DMIS removes points near corners and unreachable areas of the scan path while it generates the path.

- **Tolerance** box



The **Tolerance** box allows you to set a new nominal tolerance if proper nominals are not found when you use the **FINDNOMS** option from the **Nominals** list.

Ensure that the tolerance value is sufficient to compensate for the probe's radius. If the value is too low, PC-DMIS may display an error message stating that it cannot find the part when it attempts to generate the scan.

- **Use BestFit** check box

When you select the **Use BestFit** check box, PC-DMIS performs a temporary BestFit alignment on the scan to find better nominals for the measured data. For more information, see the **FINDNOMS** option in the **Nominals** list.

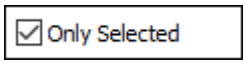
PC-DMIS follows this sequence for your scan:

- Performs a FindNoms operation.
- Uses the found nominal points and the measured data of the scan to create an internal Best Fit alignment. If it is a Patch scan, the Best Fit is 3D.
- Performs a FindNoms operation.
- Uses the found nominal points and the measured data of the scan to create another internal Best Fit alignment. If it is a Patch scan, the Best Fit is 3D.
- Performs a FindNoms operation.
- Restores the original alignment.

This check box is useful for parts with large deviations from nominal data, as it helps PC-DMIS find nominal data that more accurately represents the part.

For more information on Best Fit alignments, see "Creating a Best Fit Alignment" in the "Creating and Using Alignments" chapter of the PC-DMIS Core documentation.

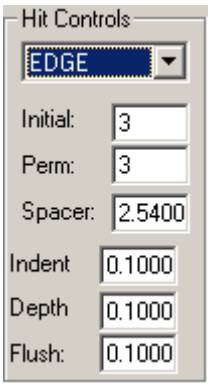
- **Only Selected** check box



When you execute a scan in your measurement routine and search for nominal values for the scan's measured points, you can use the **Only Selected** check box to have PC-DMIS only look for the nominals on the currently selected set of surfaces.

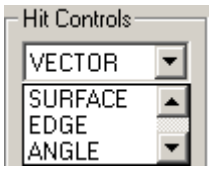
If any of your selected surfaces are already defined as priority surfaces in the **Edit CAD Elements** dialog box, PC-DMIS maintains their priority over other selected surfaces in the set. For more information, see "Editing CAD" in the "Editing the CAD Display" chapter of the PC-DMIS Core documentation.

Hit Controls Area



The **Hit Controls** area on the **Execution** tab in the scan dialog box (**Insert | Scan**) contains a list that controls where hits are taken. Other boxes in this area get hidden or displayed depending on the type of hit selected from the hit type list. This area contains these items:

Hit Type list



The **Hit Type** list contains these hit types:

- VECTOR - The scan uses vector hits.
- SURFACE - The scan is taken along a surface and uses surface hit data.
- EDGE - The scan is taken along an edge. When **Edge** hits are used and CAD data is available, PC-DMIS will allow you to enter a flush thickness for the nominals. This thickness is applied normal to the edge approach vector when finding the nominals for the scan. (This is contrary to the regular thickness that is applied along the surface normal.)
- ANGLE - This scan uses ANGLE hit data.

The scan will always do a stitch scan regardless of the probe head type.

Initial box

The **Initial** box allows you to set how many sample hits are taken before each actual point is measured. These sample hits are taken only the *first* time a scan is run.

Perm box

The **Perm** box allows you to set how many sample hits are permanently taken before each actual point is measured. These sample hits are taken *each* time the scan is run.

Spacer box

The **Spacer** box allows you to set the distance between sample hits.

Depth box

The **Depth** box allows you to set the depth from the edge where the sample hits will be taken. This option is only available if **EDGE** is selected from the **Hit Type** list.

Indent box

The **Indent** box allows you to set the indent on the top surface from the edge where the sample hits will be taken. This option is only available if **EDGE** is selected from the **Hit Type** list.

Indent 1 box

The **Indent 1** box allows you to set the indent on the top surface from the edge where the sample hits will be taken. This option is only available if **ANGLE** is selected from the **Hit Type** list.

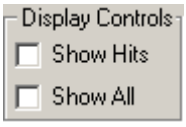
Indent 2 box

The **Indent 2** box allows you to set the indent on the top surface from the edge where the sample hits will be taken. This option is only available if **ANGLE** is selected from the **Hit Type** list.

Flush box

The **Flush** box allows you to enter a flush thickness for the nominals if an **Edge** or **Angle** hit type is used and CAD data is available. This thickness is applied normal to the edge approach vector when finding the nominals for the scan. (This differs from the regular thickness which is applied along the surface normal.)

Display Controls Area



The **Display Controls** area on the **Execution** tab in the scan dialog box (**Insert | Scan**) lets you determine what kind of information the scan displays in the Edit window. It contains these items:

Show Hits check box

If you select this check box, PC-DMIS displays each scan in the Edit window as a set of the measured hits surrounded by a scan object and an end measured object. If this option is chosen, all of the hits will be displayed in the Edit window. If you don't select it, the hits will not be shown.

Show All check box

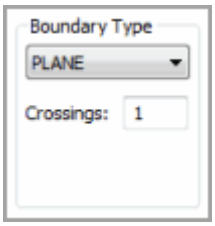
If you select this check box, PC-DMIS will display in the Edit window all of the scan parameters, such as:

- Cut planes
- Boundary points
- Direction vector
- Initial approach vector

If you don't select it, PC-DMIS only displays these data types in the Edit window:

- Increments
- Techniques
- Hit Types

Boundary Type Area

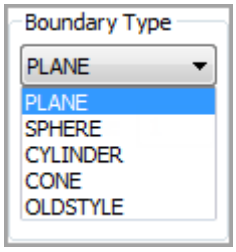


The **Boundary Type** area on the **Execution** tab in the scan dialog box (**Insert | Scan**) creates an imaginary feature that acts as a boundary around a scan's end point. By default, this feature is a plane at the end point that when crossed one time stops the scan. However, you can define the end boundary type to be a different type of feature.

Boundary types are available only for **Linear Open**, **Linear Close**, **Patch**, **Section**, and **Rotary** scans in DCC Mode.

The area contains these items:

Boundary Type list



The boundary type list lets you choose how a scan ends. Each boundary type uses a value from the **Crossings** box.

Plane - The scan stops after the probe crosses the plane at the end point the given number of times.

Sphere - The scan stops after the probe crosses (breaks) the sphere at the end point the given number of times.

Cylinder - The scan stops after the probe crosses (breaks) the cylinder at the end point the given number of times. The cylinder is unbounded (i.e. is considered infinite in length).

Cone - The scan stops after the probe crosses (breaks) the cone at the end point the given number of times. The cone is unbounded (i.e. is considered infinite in length).

OldStyle - (Retained for backwards compatibility)

Previous versions of PC-DMIS used a combination of boundary crossings and scan increments to stop the scan. OldStyle is not actually an option

that you choose, rather it is an internal setting for scans that were created in earlier versions of PC-DMIS.

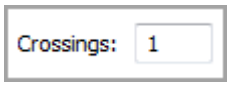
When scans from PC-DMIS version 2.3 are read into version 3.0 and higher, they are converted and their respective boundary conditions are tagged as OldType.

The Edit Window command line for the OldStyle boundary type reads:

```
BOUNDARY/OLDSTYLE, x,y,z,PlaneVec=i,j,k,
EndVec=i,j,k
```

- **PlaneVec**: This vector defines the plane normal vector at the end point.
- **EndVec**: The approach vector at the end point.

Crossings box



The **Crossings** box determines how many times a scan crosses the selected boundary type before stopping the scan. For example, if you specify that the number of crossings is two, the scan will stop once the probe's ball center crosses the given condition’s surface (planar, spherical, cylindrical, conical etc.) two times.

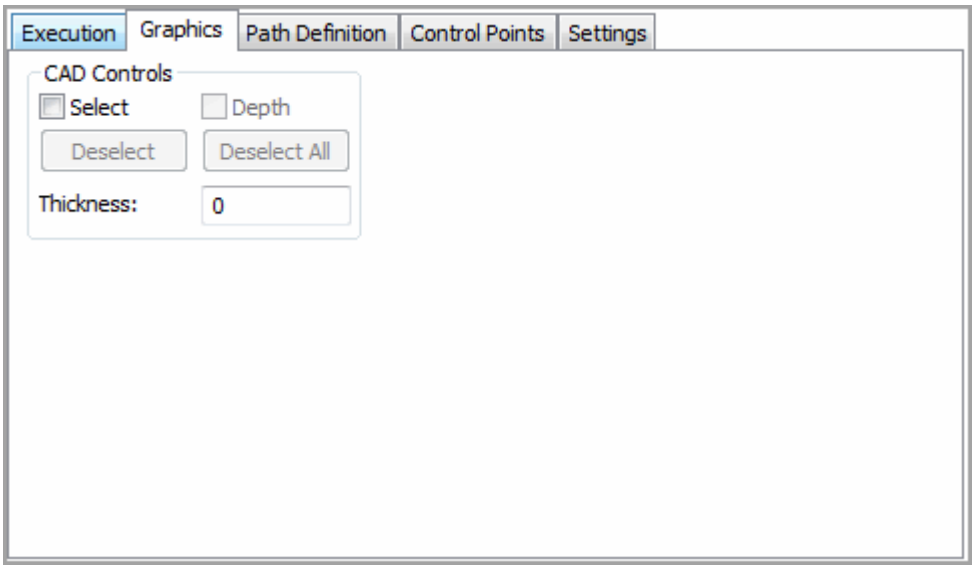
Linear Closed scans always require at least two boundary crossings even if the **Crossings** box specifies a lower number.

Radius box
The **Radius** box appears when you select either **Sphere** or **Cylinder** as your boundary type. It lets you define the radius of that boundary type feature.

Angle box
The **Angle** box appears when you select **Cone** as your boundary type. It lets you define the cone's total 'included' angle.

You can change the boundary condition at any time for a scan. If you choose a new condition for a DCC scan, PC-DMIS applies it to all basic scans making up the DCC scan. If, however, you chose to change a specific value in a condition, for example, maybe the radius of the sphere boundary type, PC-DMIS does not propagate that change to the basic scans. You would have to change that value in each basic scan yourself.

Graphics Tab



Scan Dialog Box - Graphics Tab

The **Graphics** tab in the scan dialog box (**Insert | Scan**) lets you use the on-screen CAD model to aid in creating a scan. This tab contains the **CAD Controls** area. This area lets you specify the CAD surface/wireframe elements that will be used to find nominals as well as the part's thickness.

In some cases, a scan might start over a certain surface and travel over many other surfaces before completion. In such cases, PC-DMIS does not know which CAD elements are to be used to find nominals. It must therefore search through every surface in the CAD model. If the CAD model has many surfaces, it might take a long time before the FINDNOMS operation is successful.

The **Graphics** tab has these options:

Select check box

Selecting this check box and clicking on surfaces lets you define the exact surfaces to scan. Manually determining the surfaces to scan helps speed up the FINDNOMS process. Once a CAD surface is selected, it is highlighted in the Graphic Display window. The Status bar displays the number of surfaces that have been selected. If the **Select** check box isn't selected, PC-DMIS assumes any clicks on the surface to be Boundary Points.

Two edges that are normal to each other must be selected for every surface the scan is going to travel over. If the scan is going over three surfaces, six edges (representing the three surfaces) must be selected in the proper order. The first two edges indicate surface one. The third and fourth edges indicates surface two. Edges' five and six make up the third surface, and so on.

Deselect button

If you select an incorrect surface, click on that surface a second time. This will deselect the surface. Clicking the **Deselect** button will deselect one surface at a time with each click of the button from a group of highlighted surfaces until all are deselected. Clicking the **Deselect All** button will deselect all highlighted surfaces at once.

The **Deselect** button removes one highlighted CAD element at a time from a group of CAD elements that are created using the **Select** check box.

Deselect All button

The **Deselect All** button removes *all* the selected CAD elements that are created using the **Select** check box.

Depth check box

This check box is used only when selecting Curve elements. You can indicate a particular CAD curve element as a Depth element.

To use the **Depth** check box:

1. Select all other CAD elements first.
2. Select the **Depth** check box.
3. Select a CAD element.

The Depth curve is used during FINDNOMS operations. Whenever PC-DMIS has to find nominals from curve elements, it will take the vector of the Depth CAD element, cross it with the vector from the other selected CAD elements to get a plane. It will then pierce the plane to get the proper nominal. If many CAD elements are selected, the closest pierce point is used as the nominal point. When CAD wireframe data is being used, PC-DMIS will look for the wireframe data in pairs.

vector1 check box

The **vector1** check box only appears if you select **Angle** from the **Hit Type** list and you are using surface data. It allows you to select CAD surfaces that PC-DMIS will use to find the nominal. You can indicate the group of surfaces that PC-DMIS uses to find the angle hit Surf 1 Vec by selecting this check box and then selecting CAD surfaces from the Graphic Display window.

vector2 check box

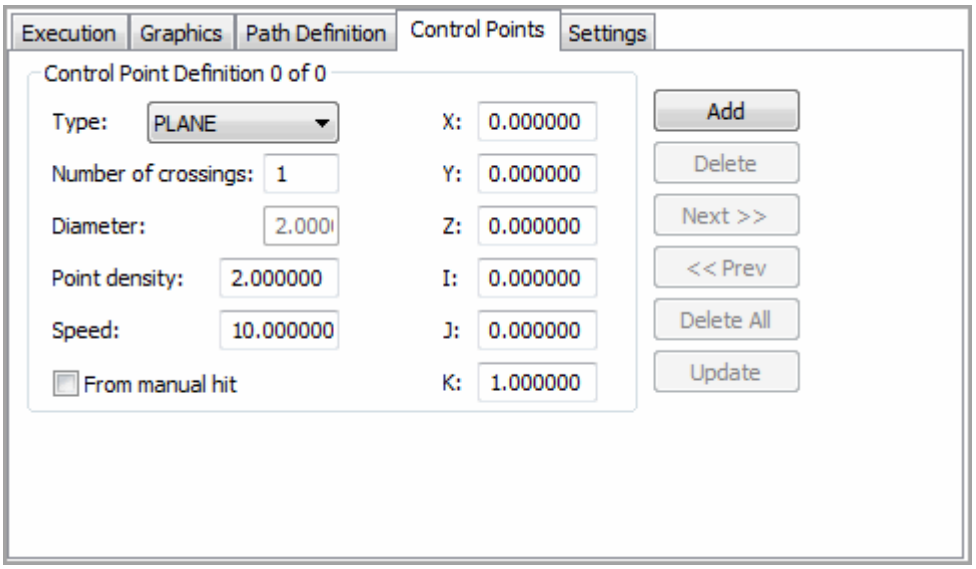
The **vector2** check box only appears if you select **Angle** from the **Hit Type** list and you are using surface data. It allows you to select CAD surfaces that PC-DMIS will use to find the nominal. You can indicate the group of surfaces that PC-DMIS uses to find the angle hit Surf 2 Vec by selecting this check box and then selecting CAD surfaces from the Graphic Display window.

Thickness box

The **Thickness** box allows you to input the part thickness. Positive or negative values can be used. This amount is primarily used for thin parts (plastic or sheet metal) where the CAD data only describes one side. Often with thin parts, the CAD engineer will only draw one side of the part, and then specify the material thickness. PC-DMIS will apply this material thickness automatically when using the CAD surface data.

This thickness is applied along the surface normal vector when FINDNOMS mode is selected and PC-DMIS pierces the CAD surfaces to get the nominals, even when using Edge hits.

Control Points Tab



Scan Dialog Box - Control Points Tab

> The **Control Points** tab only appears if you use an analog probe head that allows continuous contact scanning.

The **Control Points** tab in the scan dialog box (**Insert | Scan**) enables you to add control points to your scan. Control points interrupt the normal scan functions and allow you to define specific locations on the scan which alter the scan speed, point density, or both. Good continuous scans often require different scan speeds and/or point densities for different parts of the scan.

The ability to add control points has been added to these types of scans:

- Linear Open
- Linear Closed
- Patch
- Section
- Line (Basic Scan)

The **Control Points** tab contains the **Control Points Definition** area. This area lets you define each control point. It contains the following items.

Type list
This list defines the type of control point. The available types include:

1. Plane
   `PLANE, X, Y, Z, I, J, K, Num Crossings, Scan Speed, Point Density`
2. Sphere
   `SPHERE, X, Y, Z, I, J, K, Num Crossings, Scan Speed, Point Density, Diameter`
3. Cone
   `CONE, X, Y, Z, I, J, K, Num Crossings, Scan Speed, Point Density, Angle`
4. Cylinder
   `CYLINDER, X, Y, Z, I, J, K, Num Crossings, Scan Speed, Point Density, Diameter`

These types are similar to the boundary points.

The **Control Points** tab has these options:

Number of crossings box
This box defines the number of times the probe must cross the interrupt boundary before adjusting the specified parameters.

Diameter box
This box defines the diameter of the **Cylinder** or **Sphere** control point.

Angle box
This box defines the half angle of the **Cone** control point.

Point density box
This box defines the density of the points that are read into the scan data during a continuous contact scan. This is listed as the number of points per mm.

Speed box
This box defines the speed of the machine while it traverses the part surface performing scans.

From manual hit check box
If you select this check box, you can define the control point's XYZ and IJK location by manually taking a hit with the probe or by clicking on the part model.

XYZ boxes
These boxes define the XYZ location of the control point.

IJK boxes
These boxes define the IJK vector of the control point.

Add button
Adds a new, undefined control point.

Delete button
Deletes the current control point.

Next button
Goes to the next control point. The boxes in the area change to show the new point's data.

Prev button
Goes to the previous control point. The boxes in the area change to show the new point's data.

Delete All button
Deletes all the control points in the scan.

Update button
Updates all the control points in the scan with the setting for the current control point.

Adding and Using Control Points

1. Select the menu option **Insert | Scan** to open the **Scan** dialog box.
2. Define your scan. Based on your type of scan, PC-DMIS automatically defines the minimum number of boundary points for these scan types:
    - Plane
    - Sphere
    - Cone
    - Cylinder
3. Click the **Control Points** tab.
4. Add interrupt point locations by one of these three available methods:
    - **Method 1** - Key-in point locations. Click the **Add** button and then type the required values for each point.
    - **Method 2** - Select the **From manual hit** check box and then use the machine to touch the locations on the part where you want to have the control points. PC-DMIS adds the information to the **Control Points** dialog box.
    - **Method 3** - Select the **From manual hit** check box and then in the Graphic Display window, click on the CAD model where you want to have the control points. PC-DMIS adds the information to the **Control Points** dialog box.

    For the last two methods, PC-DMIS automatically snaps the chosen points to the cut plane of the scan for all scan types except Patch scans.

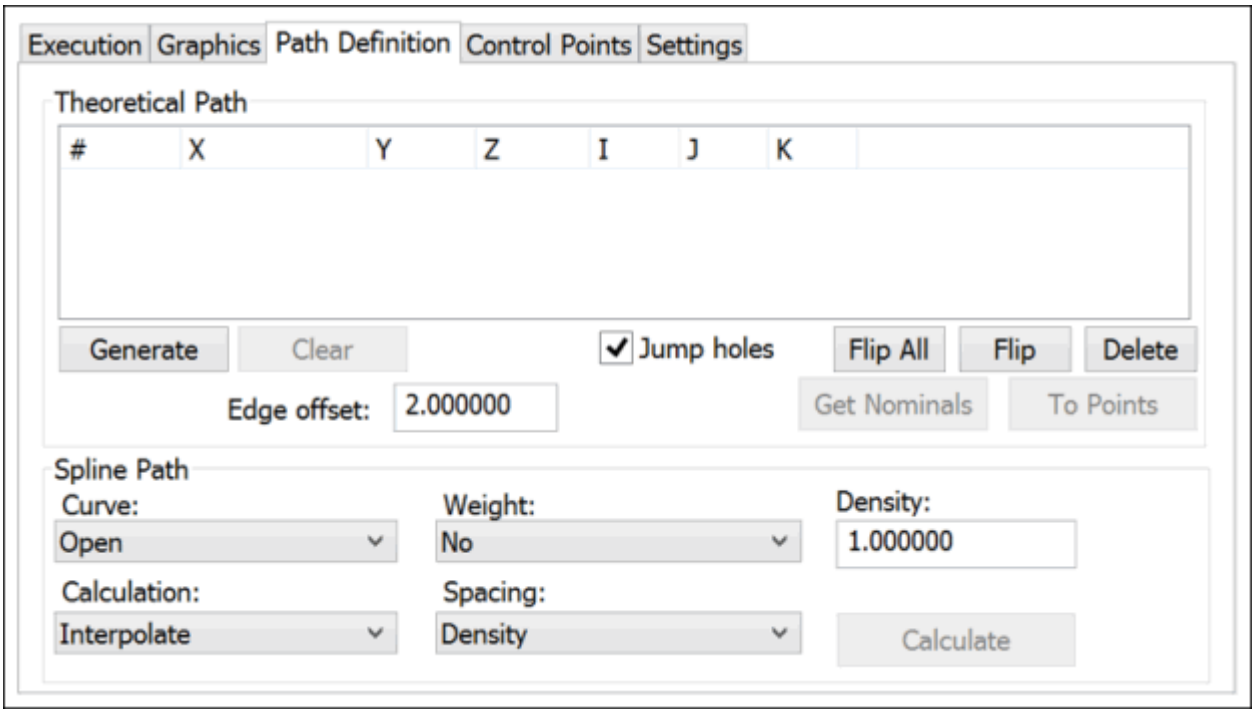
5. Continue to use the methods in step 4 to define all the desired control points.
6. Once you define all your control points, click the **Create** button. The **Scan** dialog box closes and creates your scan.
7. If you want to edit, delete, or add additional control points, click the **Control Points** tab at any time and make the modifications as needed.

Scanning after Adding Control Points

Once you've defined all the control points and created your scan, during execution, PC-DMIS does the following.

1. The scan will initially use the globally set **Scan Speed** and **Point Density** values.
2. As it scans along the path and passes within the parameters defined by the control points, the scan behavior changes as directed by the control points.
3. Once the scan is completed, the **Scan Speed** and **Point Density** will return to the globally set values.

Path Definition Tab



Path Definition Tab - Spline Path Area

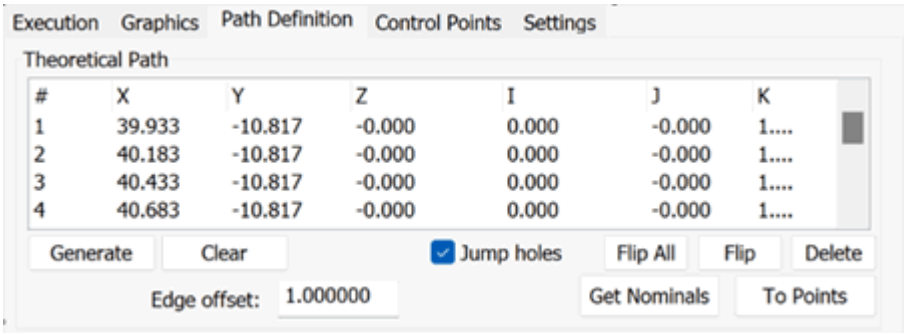
Only some scans support the **Spline Path** area. These include: Linear Open, Linear Closed, Patch, Section, and Freeform. On other scans, the **Spline Path** area does not appear.

The **Path Definition** tab in the scan dialog box (**Insert | Scan**) has, at most, two areas:

Theoretical Path and **Spline Path**

You can use these areas to generate a theoretical pathway for your scan and, on supported scans, you can fit the theoretical data points to a secondary path called a spline path. This essentially filters the number of theoretical points.

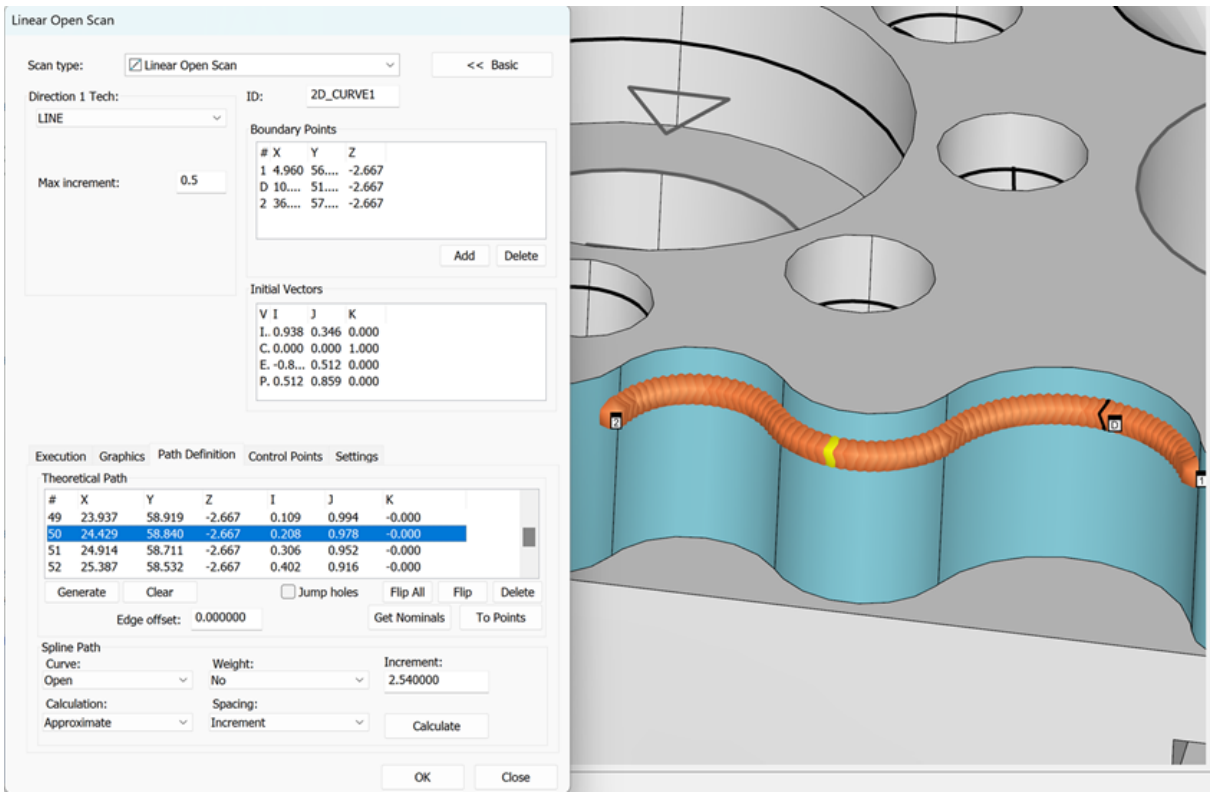
Theoretical Path Area



The **Theoretical Path** area on the **Path Definition** tab in the scan dialog box (**Insert | Scan**) contains some or all of these items depending on the type of scan selected:

- **Theoretical Path** list

  This list displays the theoretical pathway that your scan will take when executed. It displays the XYZ and IJK data for each point. To import points from a text file, click the **Read File** button (if using a Freeform scan). You can also click the **Generate** button to have PC-DMIS automatically generate the theoretical points. When you click on a point in the # column, PC-DMIS highlights the point in yellow in the Graphic Display window. In the case of a Freeform scan, you can click the points on the CAD model to create them.



Example showing the selected point in yellow.

To edit the value of any theoretical point:

1. Double-click the appropriate point number in the # column. The **Edit Theo Data** dialog box appears.
2. Change the values in the desired **X**, **Y**, **Z** and **I**, **J**, **K** boxes.
3. Click **OK**. The change appears in the **Theoretical Path** list.

To cycle through the point in the **Theoretical Path** list, click the **Next** button in the **Edit Theo Data** dialog box. This enables you to edit them one by one.

- To delete all of the points in the list, right-click on the list and select **Delete All Theoretical Points**.
- To delete a single point, select the point and then click **Delete**.

- **Generate** button

  First, select the required boundary point. The **Generate** button takes information from the CAD model and automatically generates the theoretical pathway within the scan's boundary for these supported scans: Linear Open, Linear Closed, Patch, and Section.

  PC-DMIS always uses the **Find Nominal Tolerance** value on the **Execution** tab when it generates nominal data for the scans and finds the nominals for the learned scan.

- **Clear** button

  Use this button to remove all of the points in the **Theoretical Path** list.

- **Read File** button

  This button appears when you use a Freeform scan. It lets you import points from a text file with a .txt filename extension. The text file should be in a comma-delimited format with one point on each line, like this: X,Y,Z,I,J,K

- **Jump holes** check box

  The **Jump holes** check box determines whether or not the theoretical path should jump over holes and other hole-like features in the surface.

  - If you select the check box, point data that does not lie within the selected surface (such as hole features) does not appear in the **Theoretical Path** list and will be skipped during scan execution.
  - If you clear the check box, the routine scans into hole-like features.

  When you work with Surface Mode and a tactile probe, the **Jump holes** check box is always selected when the scan spans through multiple surfaces. When you work with Curve Mode and a tactile probe, the **Jump holes** check box is not available for selection. The scan will always jump when multiple curves are selected.

  When you work with a spot laser probe in Surface Mode or Curve Mode, PC-DMIS records the last setting of the **Jump holes** check box and sets it accordingly.

  This appears on all scans but Perimeter and Freeform. It is not supported in these scans.

- **Edge offset** box

  The **Edge offset** option defines the minimum distance away from a boundary/edge where scan points are considered valid. Scan points that are closer to the boundary that the specified offset distance are not allowed. For example, if you set your offset distance to .5 mm, any scan point located within .5 mm of the boundary/edge is not allowed. This is used with the **Jump holes** option.

  PC-DMIS records the value that you enter for the **Edge offset** option and converts it into the appropriate unit of the next measurement routine.

- **Get Nominals** button

  This button lets you find the nominal after a scan has been learned or executed. PC-DMIS finds the nominals for the scan from the CAD data that is available.

- **To Points** button

This button runs a process where the individual points that make up an existing scan can be converted into single points after execution. PC-DMIS creates single points and places them in a group. The Group ID is the same as the scan ID.

For example:

1. Place your cursor on a scan using hit data in the Edit window.
2. Press the F9 key to display the **Scan** dialog box.
3. Select the **To Points** button.

PC-DMIS converts all hit data into single points and creates a group in the Edit window.

- **Flip** button

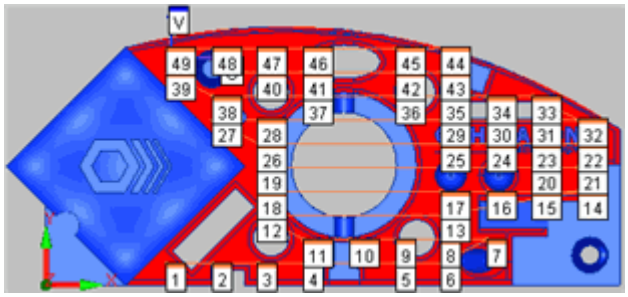
  This button flips the approach vectors of the theoretical scan point that is selected in the **Theoretical Path** list.

- **Flip All**

  This button reverses all of the vectors for all points in the **Theoretical Path** list.

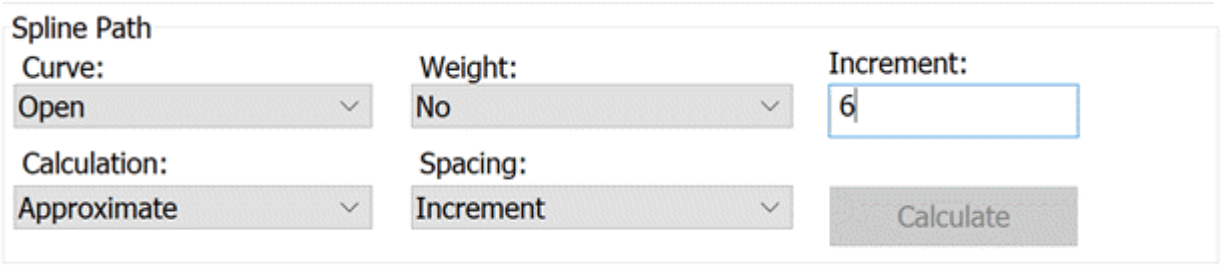
- **Label Hits** check box

  This check box determines whether or not PC-DMIS should label each hit in the scan. Labeled hits look something like this:



Example of a UV scan with labeled hits.

Spline Path Area



Spline Path Area

The **Spline Path** area on the **Path Definition** tab in the scan dialog box (**Insert | Scan**) contains several options that you can use to create a spline path to which your scan's theoretical path will be fitted.

This option is not available for Perimeter, Rotary, UV, and Grid scans.

To create a theoretical path and fit it to a spline path, do the following:

1. Select a scan type that supports a spline path (Linear Open, Linear Closed, Patch, Section, or Freeform).
2. Select the **Path Definition** tab.
3. Define the theoretical path. In the case of the Freeform scan, you can use the **Read File** button to import a pre-existing set of theoretical data points, or click **Generate**. The **Generate** button automatically generates a set of theoretical data points between your starting point and ending point from the existing CAD data.

   In the case of the Freeform scan, the **Generate** button does not exist. Instead, click on the CAD itself to select the theoretical points.

4. The points appear in the **Theoretical Path** list and show their XYZ and IJK data. As long as you have more than five points in the **Theoretical Path** list, you can fit it to a spline path by using the **Calculate** button in the **Spline Path** area. You don't have to fit the theoretical path to a spline path, but if the theoretical path list contains too many points, then you want to use the spline function to reduce or spread the points equally.
5. Define the parameters as described below for the spline path to which you will fit the theoretical path.
6. When the **Theoretical Path** and **Spline Path** areas are filled out, click **Calculate** in the **Spline Path** area. PC-DMIS changes the theoretical data to fit the parameters that you specified in the **Spline Path** area.
7. When you have the points as you like them, click **Create** to generate the scan.

The **Spline Path** area offers the following choices:

Curve list
This list contains two options: **Open** and **Closed**. An open curve passes through the start, control, and end points and then stops. A closed curve does the same, but when the curve passes through the end point, it also returns to the start point.

Calculation list
This list contains two options: **Approximate** and **Interpolated**. It determines whether the spline path passes through points in the spline (interpolated) or simply approaches the points (approximate). **Interpolated** results in sharper curves. **Approximate** results in smoother curves.

Weight list
This list contains two options: **Yes** and **No**. What you select determines whether or not PC-DMIS should give the points a weight when it constructs the spline path. If you select **Yes**, PC-DMIS gives them a weight according to how close they are to other points on the curve. The further they are from other points, the greater weight they have in the fitting process.

Spacing list
This list contains two options: **Increment** and **Number of Hits**.

- If you select **Increment**, PC-DMIS creates the spline path points at a given increment defined by the value in the **Increment** box.
- If you select **Number of Hits**, PC-DMIS creates the spline path points using and spacing the number of hits you specify in the **Number of Hits** box.

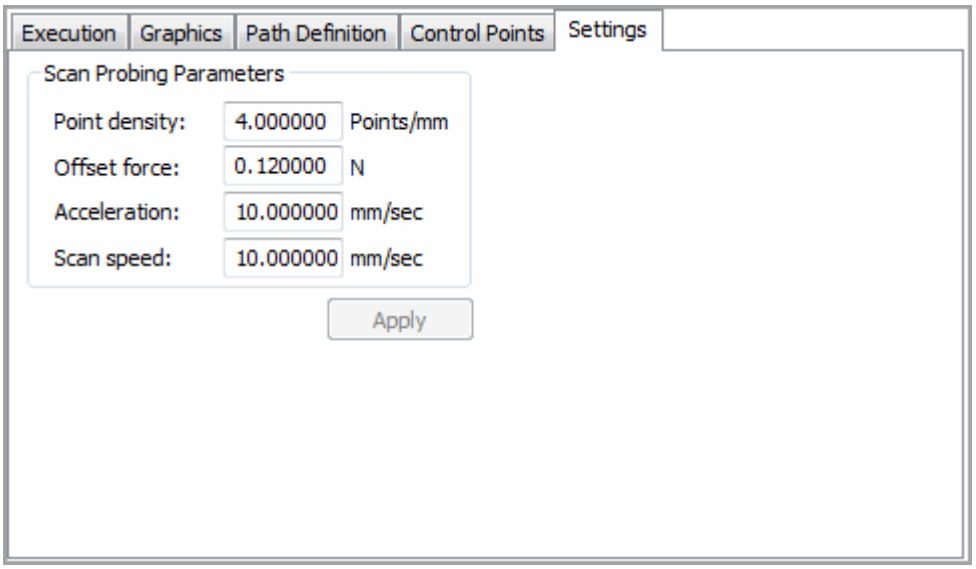
Increment or Number of Hits box
This box controls the number of hits along the scan's path.

- If you selected **Increment** in the **Spacing** list, this box holds the increment value. The distance between two path points is equal to this increment. The smaller the increment, the greater the number of path points.
- If you selected **Number of Hits** in the **Spacing** list, this box holds the number of hits to space along the theoretical pathway.

If you typed **50**, PC-DMIS would attempt to generate fifty points along the scan path.

Calculate button
This button calculates the spline and fits the theoretical data points to the spline, usually filtering out several hits. This button only becomes enabled if you have at least five hits in the **Theoretical Path** list.

Settings Tab



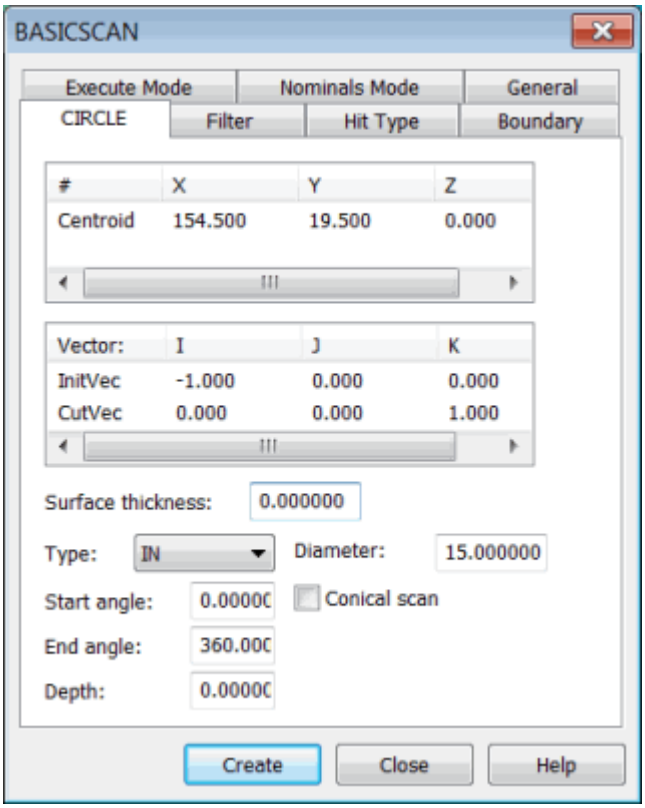
Scan Dialog Box - Settings Tab

The **Settings** tab only appears if you use an analog probe head that allows continuous contact scanning.

This tab in the scan dialog box (**Insert | Scan**) contains the **Scan Probing Parameters** area. Using the items in this area, you can modify these frequently used scan parameters, without having to leave the scan dialog.

These options are also included on the **Motion** tab or the **Opt. Probe** tab in the **Parameter Settings** dialog box (Edit | Preferences | Parameters). See the "Parameter Settings: Optional Probe tab" and "Parameter Settings: Motion tab" topics in the "Setting Your Preferences" topic for information.

Common Functions of the BASICSCAN Dialog Box



BASICSCAN Dialog Box

Many of the functions in the **BASICSCAN** dialog box (**Insert | Scan | Circle**, **Cylinder**, **Axis**, **Center**, or **Line**) are common to basic scans. Some of these options are the same as the options in the advanced scans and have already been discussed. (For additional information, see "Common Functions of the Scan Dialog Box" in this chapter.)

The tabs in the dialog box help you define the scan.

[Basic Scan] Tab

The [Basic Scan] tab in the **BASICSCAN** dialog box (**Insert | Scan | Circle**, **Cylinder**, **Axis**, **Center**, or **Line**) is the main tab for each basic scan feature. It is one of these tabs:

- **CIRCLE**
- **CYLINDER**
- **AXIS**
- **CENTER**
- **LINE**

The options on this tab include the following.

#, X, Y, and Z Columns

- Displays the points used to generate the scan. These include the following:

- **Start Point**: Used with axis, center, and line scans. This point is the start point from which the execution starts.
- **End Point**: Used with axis, center, and line scans. This point is the end point at which the execution ends.
- **D**: Used with a line scan. The Direction Point starts the scan and calculates the cut plane. The probe always remains within the cut plane while doing the scan.
- **Centroid**: Used with circle and cylinder scans. This point (found in the first list in the # column) is the center of the circle or cylinder. You can type the center directly or get it from the machine or CAD. For a cylinder, this is the center from which the execution starts.

X, **Y**, and **Z** - These columns display the coordinates for the item in the # column.

Vector, I, J, and K Columns

Vector - Displays the type of vector. These include the following:

- **InitVec**: Used with all of the basic scans. The **InitVec** is the surface normal vector of the point the scan defines as 0 degrees for the circle and cylinder scan types. It is the surface vector of the starting point for the other scan types.
- **CutVec**: Used with circle, cylinder, center, and line scans. The **CutVec** defines the plane in which the feature lies.
- **EndVec**: Used with the line scan. The end vector is the approach vector at the end point of the scan.
- **DirVec**: Used with the line scan. The direction vector is the vector from the start point to the direction point.

I, **J**, and **K** - These columns display the IJK vector information for the vector.

Surface Thickness Box

This is used with all basic scans. Use the **Surface thickness** box to enter the part thickness. PC-DMIS applies this material thickness automatically when it uses CAD surface data. This thickness is applied along the surface normal vector when **FINDNOMS** mode is selected. PC-DMIS pierces the CAD surfaces to get the nominals.

Control Points Button

This is used with the line scan. This button displays the **Control Points** dialog box. This dialog box contains controls that are similar to the **Control Points** tab in the scan dialog box. For more information, see "Control Points Tab".

This button appears only if you are using a continuous contact probe (analog probe), such as the SP600. You can select it once you define the Start, Direction, and End Points of the line scan.

Type List

The **Type** list defines the type of circle, cylinder, or center scan to perform. When you use it with circle and cylinder scans, this switches between:

- **IN**: Defines the scan as a hole.
- **OUT**: Defines the scan as a stud.
- **PLANE**: A plane circle is executed on the plane the circle is lying on.

When you use this option with center scans, it switches between the available centering methods:

- **Axis:** The Start Point **(S)** is projected on the defined Axis **(A)**. The resulting point is **(SP)**. The **InitVec** is projected in the plane defined by the Projected point **(SP)** and the axial direction **(A)**. The direction **(N)** thus defined is vertical to the axial direction. Thereafter, as centering is performed, the probe's center point remains in the plane defined by the axial direction and **(SP)**. Centering takes with/against the direction **(N)** as an input, and the probe tip is free in the direction defined by the axial direction **(A)** crossing the direction (**N**).
  - **S** = Start Point
  - **A** = Defined Axis / Axial direction
  - **SP** = Projected Start Point
  - **N** = Direction vertical to the axial direction
- **Plane:** After probing the point defined by the *Start Point*, the CMM centers with/against the probe direction while remaining free in the plane defined by the *CutVec*.

Diameter Box

This is the diameter value for Circle and Cylinder feature scans.

Conical Check Box

This check box enables you to perform circle scans more quickly when not perpendicular to the part surface. PC-DMIS continues to monitor the probe force as needed.

Start Angle Box

This box defines the start angle (in degrees to scan) from the start point for circle scans. You can use both positive and negative angles.

- PC-DMIS considers positive angles as counterclockwise.

- PC-DMIS considers negative angles as clockwise.
- PC-DMIS considers the **CutVec** as the axis about which the angle rotates.

End Angle Box

This value is the same as the **Start angle** box except that it defines the end angle for circle scans. With start and end angles, you can define a specific portion of a hole or stud to scan.

Angle Box

When you perform cylinder scans, this value defines how far around the cylinder to scan. For example, if you type 360, it scans one complete revolution. If you type 720, it scans two revolutions, and so forth.

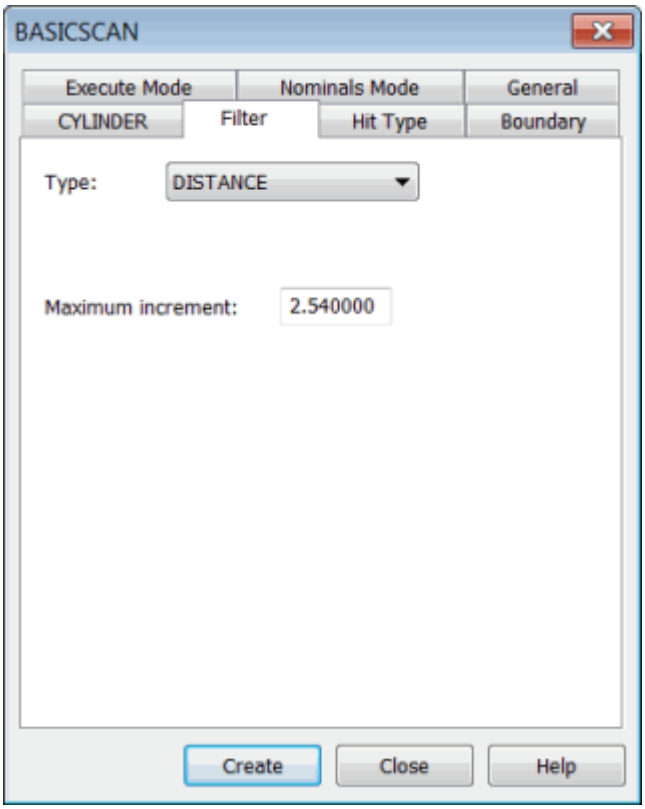
Depth Box

This value is the depth applied against the **CutVec** direction for circle and cylinder scans. You can use both positive and negative values.

Pitch Box

This box defines the distance between threads along the axis of the feature when you perform cylinder scans. This enables your scan to move in a spiral-like fashion along the cylinder.

Filter Tab

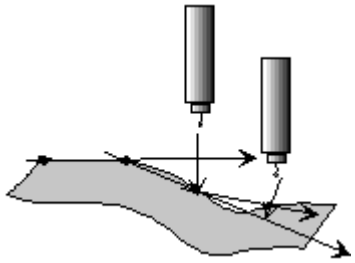


BASICSCAN Dialog Box - Filter Tab

The following options are available on the **Filter** tab in the **BASICSCAN** dialog box (**Insert | Scan | Circle**, **Cylinder**, **Axis**, **Center**, or **Line**). For more information about the **BASICSCAN** dialog box, see "Common Functions of the BASICSCAN Dialog Box".

Distance Type

For Line Basic and Axis Basic scans - PC-DMIS determines each hit based on the set increment and the last two measured hits. The approach of the probe is perpendicular to the line between the last two measured hits. The probe will stay on the cut plane. PC-DMIS will start at the first boundary point and continue taking hits at the set increment, and stop when it reaches the end boundary point.



For Circle Basic and Cylinder Basic scans - PC-DMIS determines each hit based on the set increment and the last two measured hits. The approach of the probe is perpendicular to the line between the last two measured hits. The probe will always maintain the defined radial distance from the center point, perpendicular to the center point vector. PC-DMIS will start at the first boundary point and continue taking hits at the set increment, and stop when it reaches the end boundary point.

Variable Type

For details, see "Variable Technique".

NULLFILTER Type

The **NULLFILTER** type is available for these scans: Line Basic, Circle Basic, Cylinder Basic, Axis Basic, and Center Basic.

The **NULLFILTER** technique does not filter data at all. Whatever data PC-DMIS receives from the machine controller is the data given you. Except for the center basic scan, probe compensation and the finding of nominals are still performed.

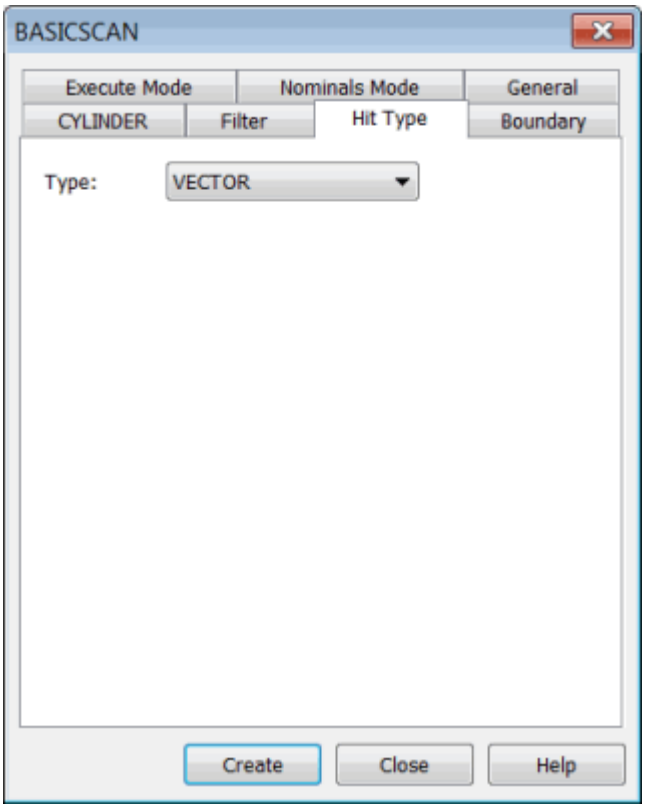
You control the increment of the hits by using the OPTIONPROBE command, which sets the point increment sent to the controller during a scan. For more information, see "Parameter Settings: Optional Probe tab" in the "Setting Your Preferences" chapter.

PC-DMIS will start at the first boundary point and not filter any data points, and stop when it reaches the end boundary point.

Maximum Increment

Use the **Maximum increment** box to set the incremental distance between hits on a scan. For example, if you enter .5, then the scan touches the part at increments of .5.

Hit Type Tab



BASICSCAN Dialog Box - Hit Type Tab

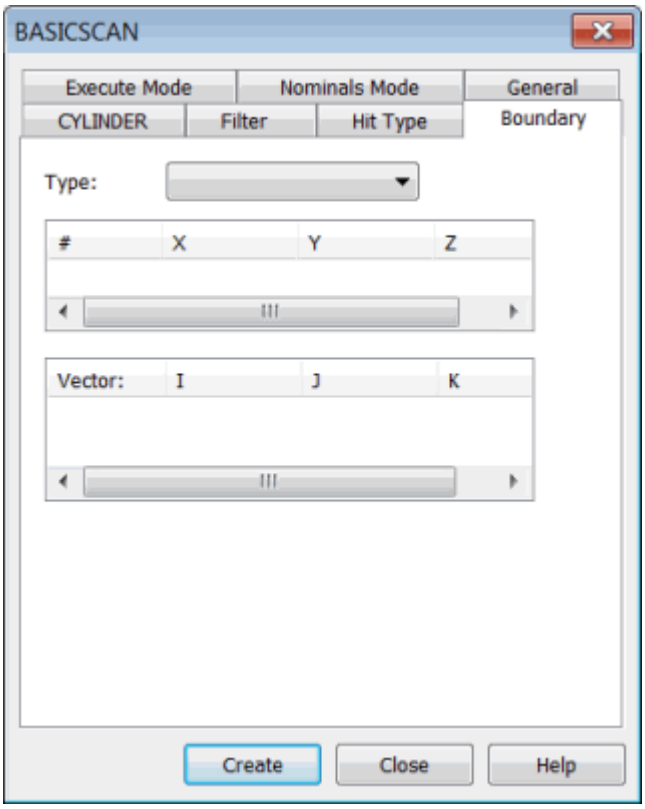
The options in the **Type** list on the **Hit Type** tab in the **BASICSCAN** dialog box (**Insert | Scan | Circle**, **Cylinder**, **Axis**, **Center**, or **Line**) determine the type of hits used for the scan. The options are:

- **VECTOR**
- **SURFACE** (available only for line scans)

The type of hit corresponds to the type of hit in scans previously defined. For more information, see **Hit Type** in "Hit Controls Area" in "Common Functions of the Scan Dialog Box".

For more information about the **BASICSCAN** dialog box, see "Common Functions of the BASICSCAN Dialog Box".

Boundary Tab



BASICSCAN Dialog Box - Boundary Tab

The options in the **Type** list on the **Boundary** tab in the **BASICSCAN** dialog box (**Insert | Scan | Circle**, **Cylinder**, **Axis**, **Center**, or **Line**) are:

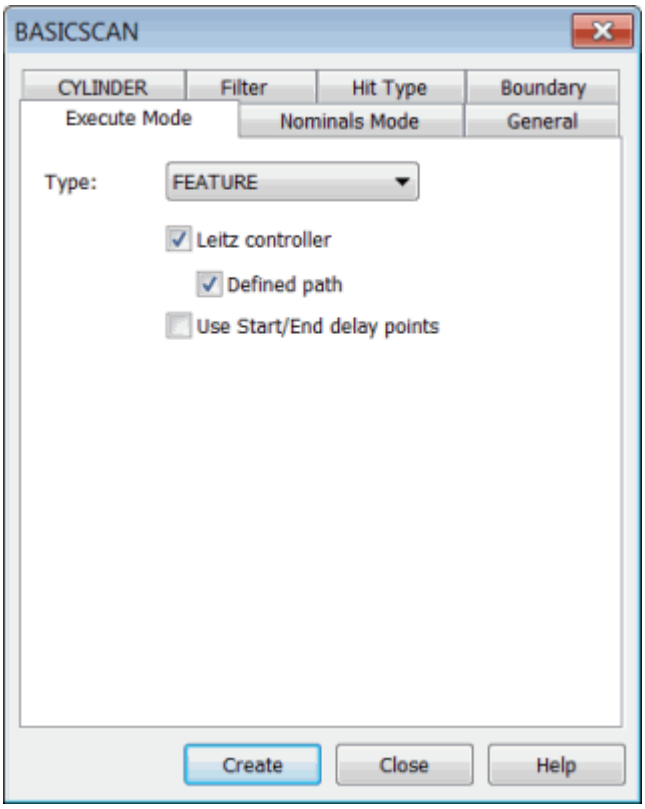
- Plane
- Sphere
- Cylinder
- Cone
- Oldstyle

Some basic scans, such as circle, cylinder, axis, and center, do not need a boundary condition since they are executed by the controller.

For descriptions, see "Boundary Type Area".

For more information about the **BASICSCAN** dialog box, see "Common Functions of the BASICSCAN Dialog Box".

Execute Mode Tab



BASICSCAN Dialog Box - Execute Mode Tab

The modes in the **Type** list on the **Execute Mode** tab in the **BASICSCAN** dialog box (**Insert | Scan | Circle**, **Cylinder**, **Axis**, **Center**, or **Line**) are:

- Normal
- Re-learn
- Defined

> For more information on the Normal, Re-learn, and Defined modes, see "Exec Controls Area".

- **FEATURE** - This mode is available only for analog probe heads. If you select this mode, PC-DMIS uses the built-in high speed scanning capability of the controller to execute a scan.

> If you selected a circle scan, PC-DMIS uses a corresponding circle scanning command in the controller and pass on the parameters to the controller to execute. In this case, PC-DMIS does not control the execution of the scans.

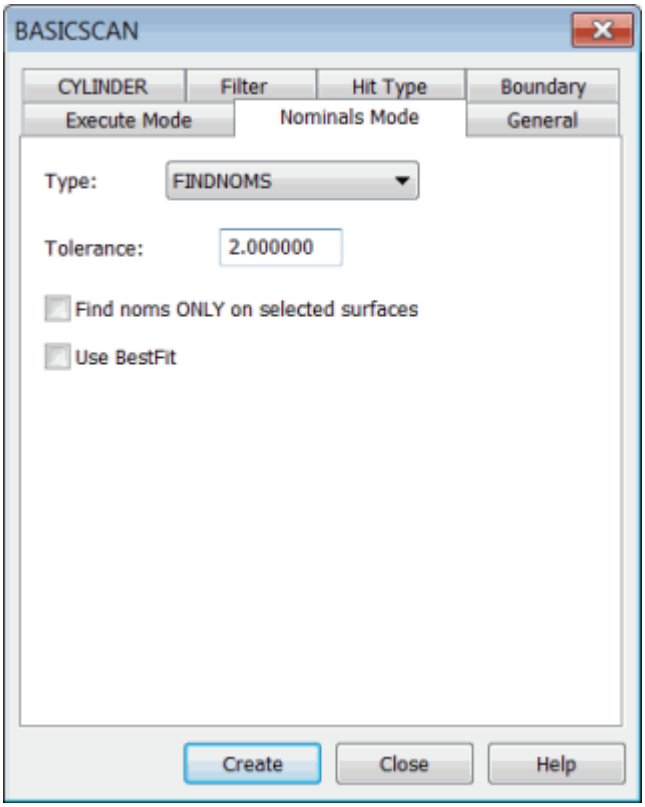
The **FEATURE** mode also enables you to use the following check boxes to further customize how PC-DMIS basic scans are done using this mode. Note that these check boxes only work with controllers that use Leitz interfaces.

- **Leitz controller** - Select this check box if running on a Leitz controller.
- **Defined path** - If you select this check box, PC-DMIS sends a distinct set of points defining the feature measurement path to the controller. If you clear this check box, PC-DMIS sends the feature-specific parameters to the controller.
- **Use Start/End delay points** - If you select this check box, PC-DMIS takes the points sent to the controller and discards those points taken during acceleration and deceleration of the probe during the scan, thereby filtering out fluctuation during these machine speed changes and improving the overall accuracy of the scan.

> ⚠ Be aware that when you use start/end delay points, the machine will over travel the defined start angle and end angle by the distance it takes to arrive at full speed when starting the scan. If you are not careful, this could cause a probe crash if there is an obstruction on the circle feature.

For more information about the **BASICSCAN** dialog box, see "Common Functions of the BASICSCAN Dialog Box".

Nominals Mode Tab



BASICSCAN Dialog Box - Nominals Mode Tab

The options in the **Type** list on the **Nominals Mode** tab in the **BASICSCAN** dialog box (**Insert | Scan | Circle**, **Cylinder**, **Axis**, **Center**, or **Line**) are:

- **MASTER** - Corresponds to Master mode, which is described in the "Nominals Mode" section.
- **FINDNOMS** - Corresponds to FindNoms mode, which is described in the "Nominals Mode" section. You can enter a FindNoms tolerance that can be applied when finding nominals for a basic scan. For more information, see **Nominals** list in "Nominals Method Area".

Find noms ONLY on selected surfaces - This check box causes PC-DMIS to look for nominal values for a scan's measured points on only the selected set of surfaces.

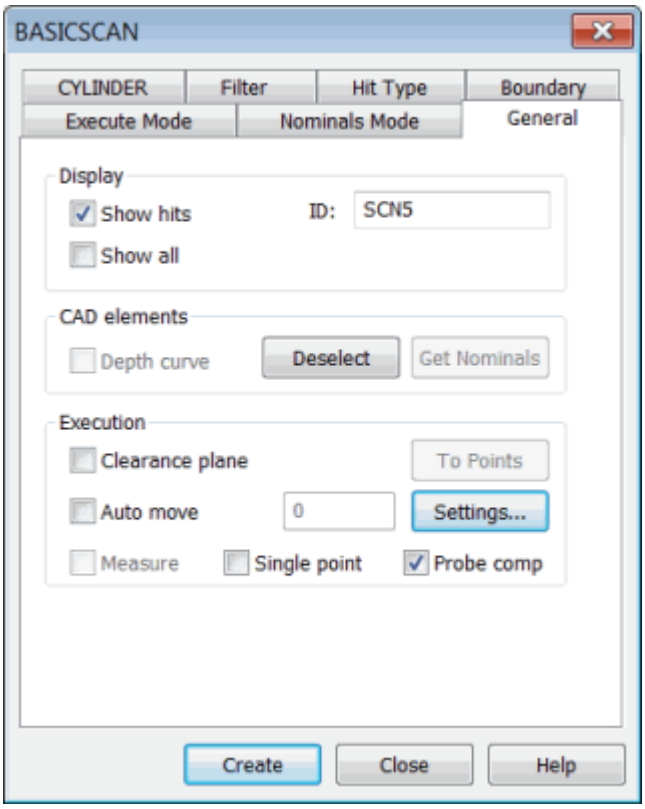
For the circle, cylinder, and axis basic scans, there is no need to have CAD data to find the nominals. To execute the basic scan, PC-DMIS obtains the nominals from the nominal data that you supply.

For example, if you entered nominal data such as center and diameter, to execute the circle, that data is used to find the nominals for the circle scan.

Use BestFit - This check box causes PC-DMIS to use best fit algorithms on the data found from the original FINDNOMS operation and then repeat the FINDNOMS operation. This finds the nominal data with greater accuracy when the actual part has a lot of error with respect to the CAD data.

For more information about the **BASICSCAN** dialog box, see "Common Functions of the BASICSCAN Dialog Box".

General Tab



BASICSCAN Dialog Box - General Tab

The following options are available on the **General** tab in the **BASICSCAN** dialog box (**Insert | Scan | Circle**, **Cylinder**, **Axis**, **Center**, or **Line**). For more information about the **BASICSCAN** dialog box, see "Common Functions of the BASICSCAN Dialog Box".

Display Area

- **Show hits** check box: If you select this check box, PC-DMIS displays each scan in the Edit window as a set of the measured hits surrounded by a scan object and an end measured object.
    - If you choose this option, all of the hits appear in the Edit window.
    - If you don't select it, the hits are not shown.
- **ID** box: Displays the current ID for the scan being created. You can change the ID.
- **Show all** check box: If you select this check box, PC-DMIS displays all of the scan parameters in the Edit window, such as:
    - Cut planes
    - Boundary points
    - Direction vector (**DirVec**)
    - Initial approach vector (**InitVec**)

If you don't select the check box, PC-DMIS displays only these data types in the Edit window:

- Increments
- Techniques
- Hit Types

CAD Elements Area

- **Depth curve** check box: The depth curve is used during FINDNOMS operations. Whenever PC-DMIS has to find nominals from curve elements, it takes the vector of the Depth CAD element and crosses it with the vector from the other selected CAD elements to get a plane. It then pierces the plane to get the proper nominal. If many CAD elements are selected, the closest pierce point is used as the nominal point. When CAD wireframe data is being used, PC-DMIS looks for the wire frame data in pairs.
- **Deselect** button: If you select an incorrect surface, you can click **Deselect** to deselect the selected surface (or you can press Ctrl and click on the surface to clear it). You can also click **Deselect** multiple times to deselect one surface at a time from a group of highlighted surfaces until all are deselected.
- **Get Nominals** button: Use this button to find the nominal after a scan has been learned or executed. PC-DMIS finds the nominals for the scan from the CAD data that is available.

Execution Area

- **Clearance plane** check box: To insert a CLEARP MOVE a predetermined distance relative to the current coordinate system and part origin, before taking the first hit, select this check box.

  After the last point in the scan is measured, the probe stays at probe depth until called to the next feature. The use of clearance planes reduces programming time because the need to define intermediate moves is reduced. (For additional information on clearance planes, see "Parameter Settings: Clearplane Tab" in the "Setting Your Preferences" chapter.) This option is only available for DCC scans.
- **Auto move** check box: To turn on Auto Moves for each scan, select this check box. Once it is selected, you can type the distance for the move in the box.
- **Measure** check box: If you select this check box, the measurement process for this auto feature begins immediately after you click the **Create** button.
- **Single point** check box: To consider each hit as a single measured point, select this check box. If you select this check box, PC-DMIS makes each hit a measured point and inserts it into the measurement routine. This sequence will happen after the manual scan has been reduced. If the scan is in DCC Mode, it takes place after the scan has been learned.

- **Probe comp** check box: Use this check box to specify whether or not PC-DMIS turns on probe compensation for this specific scan. In most cases, you probably don't need to perform this compensation, since a scan's FINDNOMS operation automatically does it. However, if you don't have CAD and want to reverse-engineer a part, you should select this check box.
- **To Points** button: To run a process where the individual points that make up an existing scan can be converted into single points after execution, select this button. The scanned set is then deleted.

  For example:

  1. Place your cursor on a scan using hit data in the Edit window.
  2. Press the F9 key to display the **BASICSCAN** dialog box.
  3. Select the **To Points** button. PC-DMIS converts all hit data into single points and deletes the scan from the Edit window.

- **Settings** button: Enables you to change the probe setting that is relevant to scanning: scan speed and scan point density.

Additional Manual Scan Options

In addition to the scanning options detailed in "Common Functions of the Scan Dialog Box", when executing or learning a manual scan, the **Execution** dialog box (**File | Execute** or **File | Partial Execution**) shows the **New Row** and **Scan Done** buttons. For more information on these buttons, see the "Using the Execution Dialog Box" topic in the "Using Advanced File Options: Introduction" chapter.

Inserting Move Commands

Inserting Move Commands: Introduction

This chapter discusses the various move commands that you can place in your measurement routine. Move commands provide you with the ability to alter the movement of the probe between hits.

The main topics covered in this chapter reflect the move commands that you can insert from the **Insert | Move** submenu and any other move commands. These topics include:

- Inserting a Move Point Command
- Using a Moveset Command
- Inserting a Move Increment Command
- Inserting a Move Circular Command
- Inserting Clearance Moves with Collision Detection
- Inserting a Move Sync Command
- Inserting a Move Sweep Command
- Inserting a Move All Command
- Inserting a Move Exclusion Zone Command
- Inserting a Move Rotary Table Command
- Inserting a Clear Point Move
- Inserting a Clearance Plane
- Inserting a Move Clear Plane Command
- Using the ClearanceCube
- Inserting Clearance Moves Automatically

Inserting a Move Point Command

The difference between the Move Point and Move Increment commands is that the Move Point command moves the probe to a specific location in your volume. The Move Increment command moves your probe from its current position to a specified amount in the X, Y, and Z directions. You must be very careful with the Move Increment command since it could cause a crash if you do not account for obstacles when you define this command.

For example, suppose there's a feature on your part that you need to avoid crashing into and you perform two incremental moves of X=0, Y=0, Z=50 and X=100, Y=0, Z=0. This defines probe movements of 50 units in the Z direction and 100 units in the X direction. If you get a false trigger halfway through the second move increment command and you click **Continue**, your probe, which has already moved 50 units, will proceed to make the same 100 unit move from where the false trigger occurred. The net result is that your probe will move a total of 150 units and may end up crashing into another feature.

You can use the **Move Point** command to insert a move point into your measurement routine. When PC-DMIS encounters this command, the probe moves to that XYZ location.

To use this option, select **Insert | Move | Move Point** or **Operation | Move To**.

- On the **Insert | Move** menu, there are two **Move Point** commands. The first **Move Point** automatically inserts a move point command at the current probe location. You need to modify the XYZ values in the Edit window.
- If you selected **Operation | Move To**, or if you selected the second **Insert | Move | Move Point** menu, PC-DMIS displays the **Move Point** dialog box. With this dialog box, you can fill out the information before PC-DMIS inserts the command.

If you attempt to insert the move point in a location that PC-DMIS does not allow, the software asks you if you want to insert the move point at the next valid location.

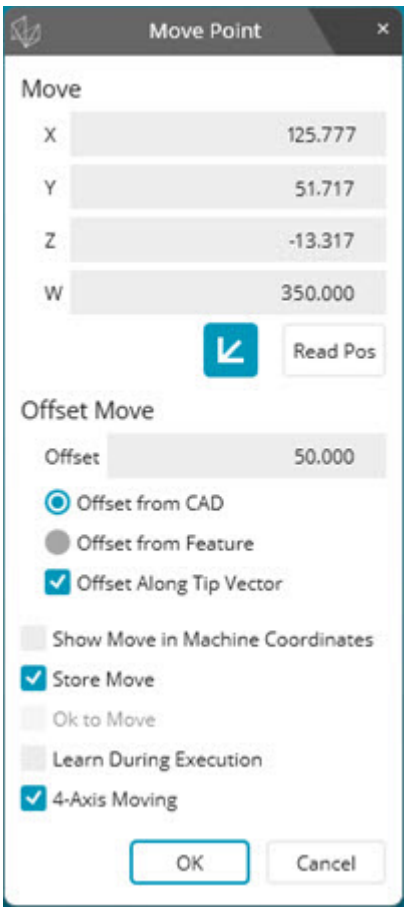
The Edit window command line for a sample Move Point reads:

```
MOVE/POINT tog1,<x,y,z>
```

tog1 - This field displays either NORMAL or RELEARN.

x,y,z,w - These fields display the X, Y, Z, and if a rotary table is defined in your measurement routine, the W component which determines the rotary table's rotational angle move point location. The location is always displayed using the current part alignment's coordinates.

To change the values that appear in the Edit window, select the desired value and type a new value, or press F9 on the command to open the **Move Point** dialog box.



Move Point Dialog Box

This dialog box provides you with a more user-friendly way of creating or editing the `MOVE/POINT` command as well as additional options for the move point. The options in the **Move Point** dialog box are discussed in the topics listed below.

If you want to access the dialog box before inserting a MOVE/POINT command, select **Operation | Move To**.

When you insert a `MOVE/POINT` command, PC-DMIS automatically marks it for execution.

Using Move Points While Animating

If you select this menu option during probe path animation with the CMM, PC-DMIS always asks whether to insert the move before or after the current position. The current position appears in the status bar.

Inserting Move Points from the Status Bar

You can also insert a move point while the system is in Program mode. To insert it, place the cursor on the Status bar over the readouts and click the left mouse button.

Inserting Move Points from the Jog Box

You can press the **PRINT** button on the jog box (on Sharpe32 systems) while in Learn mode to automatically insert a move into the measurement routine. The `PrintButton` entry must be set to **True** for this to work.

If the **4-Axis Moving** option is selected when you press the **PRINT** button on the jog box, PC-DMIS adds the W angle after the X, Y, and Z position in the Edit window's command line. Using the **Move Point** dialog box example image above, you can see that the W angle is set to 350 which creates this command line in the Edit window:

```
MOVE/POINT,NORMAL,<125.777,51.717,-13.317>,350
```

When you execute the above command, the X, Y, and Z movement and the rotary table rotation movement are performed in a synchronized motion.

Moving In Only 1 or 2 Axes

In the Edit window in Command mode, you can set one of the axis values to blank (which means that you completely delete the value) to give the axis a relative move of zero during measurement routine execution. This essentially lets you have a hybrid relative and absolute move point behavior using the `MOVE/POINT` command.

This feature only works fully in Command mode. If you use Summary mode to do this, the field disappears from the Edit window. If you want to then set it back to a number value, you need to set it in Command mode.

For example, suppose that you want to move in only two axes. Create an Edge Point feature followed by a `MOVE/POINT` command. Execute the measurement routine. Now, delete the X value of the command and execute the measurement routine again. There won't be any X component in the move point motion, regardless of where you take the edge point.

Move

Move Area

The **Move** area contains **XYZ** boxes that display the X, Y, and Z nominal for the position of the `MOVE/POINT` or the increment distance of the `MOVE/INCREMENT` command.

To change the X, Y, or Z value, follow these steps:

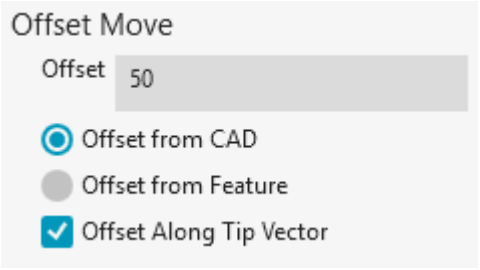
1. Select the value that you want to change.
2. Type a new value.

After you enter a new value, PC-DMIS draws the animated probe at the new location. This location indicates the location of the stored move. When you click the **Create** button, PC-DMIS inserts the Move command and positions the CMM to the location that you specified. If you created an offset move, PC-DMIS updates the values in the **XYZ** boxes to match the computed offset location.

- The **Cartesian/Polar** icon switches the display of the X, Y, and Z values between the Cartesian and Polar coordinate systems. The **XYZ** labels display **RAH** when you switch to Polar.

The **Read Pos** button reads the current position of the probe and places those values in the **X**, **Y**, and **Z** boxes. This is helpful if you have manually moved your probe to a new location and you want to use its current position as your move point.

Offset Move



Offset Move Area

The **Offset Move** area lets you create move points offset from a selected CAD point or from a selected feature's centroid.

Offset - This box determines the offset distance from the CAD point or feature centroid. The unit of measurement is the same as your measurement routine. The default is 50 mm or 1.96 inches.

Offset from CAD - If you select this option and click on the CAD, PC-DMIS computes the move point at the selected point on the surface and offsets the move point by the specified distance.

- If you clear the **Offset Along Tip Vector** check box, PC-DMIS creates the move point offset away from the surface along the surface's normal vector.
- If you select the **Offset Along Tip Vector** check box, PC-DMIS creates the move point in the direction of the probe tip's vector.

Offset from Feature - If you select this option and click on a feature, PC-DMIS computes the move point by the offset distance at the feature's centroid.

- If you clear the **Offset Along Tip Vector** check box, PC-DMIS creates the move point offset in the direction of the feature's vector.

- If you select the **Offset Along Tip Vector** check box, PC-DMIS creates the move point in the direction of the probe tip's vector.

Offset Along Tip Vector - You can select this check box to offset the move point along the active tip's vector. If you clear the check box, PC-DMIS offsets the move point along either the CAD's surface vector or along the feature's vector.

Different feature types have different vectors. When the software offsets along a vector of the feature, PC-DMIS uses the vector that gives the best representation of being "outward" from the surface of the part.

Show Move in Machine Coordinates

- If you mark the **Show Move In Machine Coordinates** check box, PC-DMIS displays the move point's location in the dialog box in machine coordinates.
- If you clear the **Show Move In Machine Coordinates** check box, PC-DMIS displays the move point's location in the dialog box in the current part alignment's coordinates.

This does not affect how the command appears; the command always appears with the current part alignment's coordinates.

Store Move

If you mark the **Store Move** check box, PC-DMIS inserts the appropriate move command (`MOVE/POINT` or `MOVE/INCREMENT`) for the given X, Y, Z values into the measurement routine.

OK to Move

If you select the **OK to Move** check box, PC-DMIS immediately moves the probe to the X, Y, Z position (or by the X,Y,Z increment amount) when you click **OK** or **Create**. This allows you to position the CMM without storing the move.

This option fills in the X, Y, Z values with the current position of the probe.

Learn During Execution

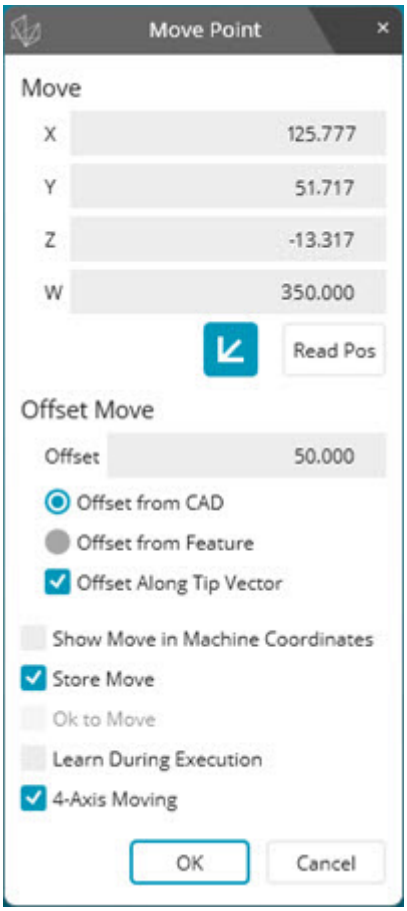
If you mark the **Learn During Execution** check box, PC-DMIS moves to and relearns the XYZ point location that appears in the **Move Point** dialog box during execution. You must also mark the **Store Move** check box for this command to work. For information, see "Store Move".

The Edit window command line for a move point that PC-DMIS relearns during measurement routine execution would read:

```
MOVE/POINT, RELEARN
```

4-Axis Moving

The 4-Axis Moving option provides you with the option to move the rotary table to a specific location and then align the probe to that location.



Move Point Dialog Box

An example for a typical command line in the Edit window for the above settings in the **Move Point** dialog box would look like this:

```
MOVE/POINT,NORMAL,<125.777,51.717,-13.317>,350
```

When this command is executed, the `MOVE/POINT` command moves the rotary table to the W angle position defined in the command as 350 degrees.

Using a Moveset Command

About the Moveset Command

A Moveset command is a set of move points that you can store in a moveset. You can use the moveset to use with a ClearanceCube.

- A Moveset command has a feature ID and a ClearanceCube face that you can use to set for that feature ID.
- A Moveset command provides you with the ability to use ClearanceCube on parts with complex geometries.

Creating a Moveset Command

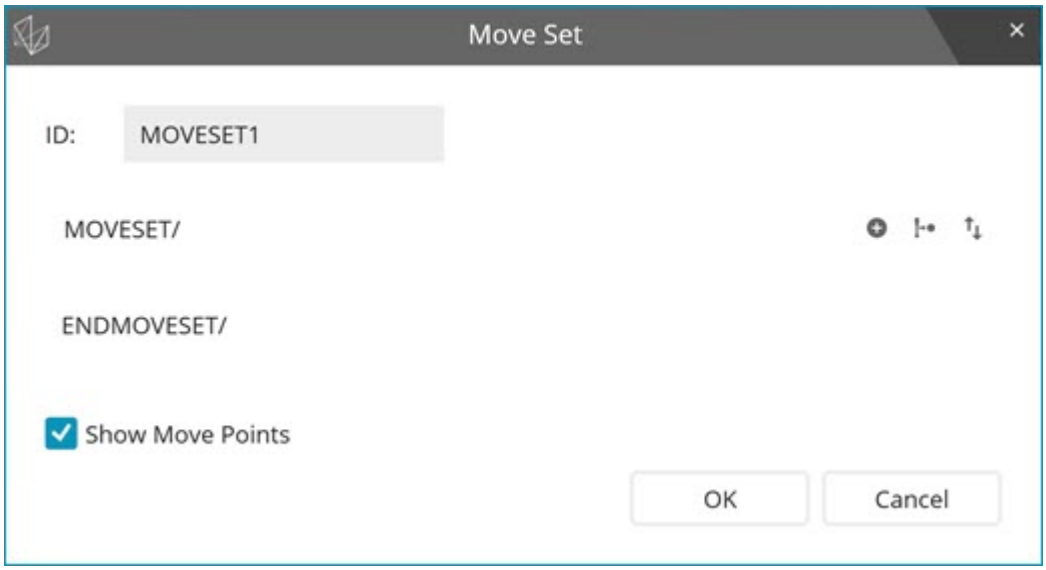
Use one of these methods to create a `MOVESET` command in the Edit window:

Method 1

1. Insert Move Points in the Edit window. To insert a Move Point, see "Inserting a Move Point Command".
2. Select the Move Points that you want to add to the `MOVESET` command.
3. Right-click the selected Move Points and click the **Convert to MoveSet** option.

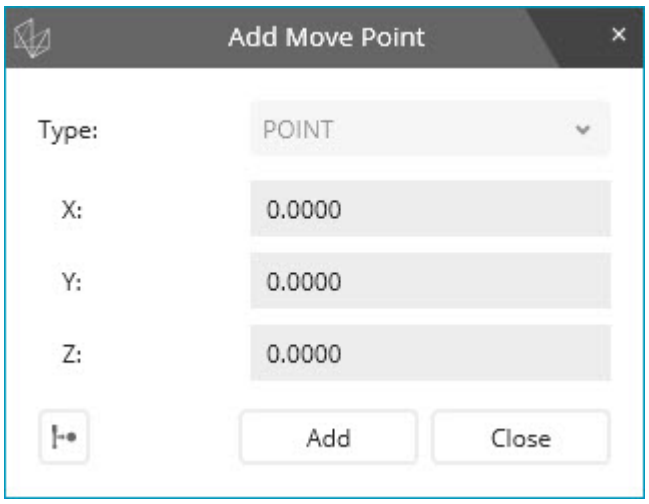
Method 2

1. Open the **Move Set** dialog box (**Insert | Move | Moveset**).



Move Set Dialog Box

2. From the **Move Set** dialog box, click the **Add** button to open the **Add Move Point** dialog box.



Add Move Point Dialog Box

3. From the **Add Move Point** dialog box, type the X, Y, and Z values in the **X**, **Y**, and **Z** boxes and then click **Add**. You can also click the **Read Machine Position** button or press the **Print** button on the jog box to add Move Points at the current tip position.

4. You can add multiple Move Points and then click **Close** to return to the **Move Set** dialog box.

5. From the **Move Set** dialog box, click the **Read Machine Position** button to add a Move Point at the current machine position.

6. To arrange Move Points in a specific order, click and drag a Move Point to a desired location. To reverse the order of an entire set of Move Points, click the **Reverse** button.

7. From the **Move Set** dialog box, click **OK**.

> Click the **Cancel** button before you click the **OK** button to close the dialog box without inserting a `MOVESET` command.

Editing a Moveset Command

To edit a `MOVESET` command, follow these steps:

1. Place your cursor on the command, right-click on it, and select **Edit** to open the **Move Set** dialog box.

2. Select a `MOVESET` command from the **MOVESET/ ENDMOVESET/** area.

3. To open the **Edit Move Point** dialog box, click **Edit** or double-click on the `MOVESET` command.

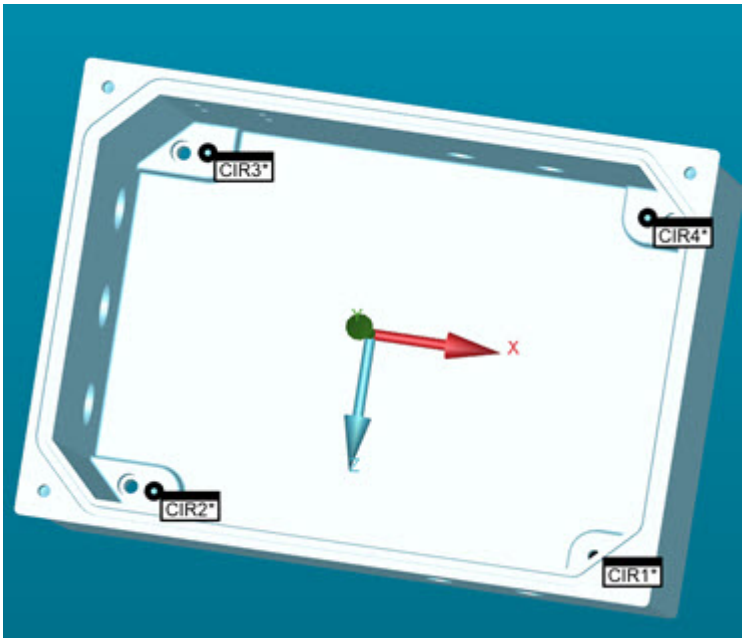
4. To remove a MOVESET command, click .

Using a Moveset Command with ClearanceCube

You can use a MOVESET command to implement ClearanceCube for complex geometric parts.

A MOVESET command enables you to measure selected dimensions using mini-routines with a ClearanceCube.

Suppose you want to measure the four circles shown in the image.



Example of using Moveset with a NIST part.

Since the holes are too deep inside the part, if you define a ClearanceCube for each circle, the probe tip moves too far before and after measuring the circles.

You may also want to use a mini-routine and perform a measure dimension that is associated with just one circle.

To do this, you can use the MOVESET command.

```
GRP1          =GROUP/SHOWALLPARAMS=YES

MOVESET2      =MOVESET/
ENDGROUP/ID=GRP1
```

This example shows you how to create a group to measure circles deep within a part. You must insert the `MOVESET` commands before the first measured circle and after the last measured circle.

You must set the ClearanceCube to active for MOVESET commands and then set it to inactive for the circles in a group.

- The first MOVESET command has ClearanceCube at the start.
- The last MOVESET command has ClearanceCube at the end.
- The ClearanceCube for all circles between the two MOVESET commands is set as off.
- The avoidance moves define the motion of the probe between the measurements of the circles.

Important Notes

This important information may help you to work on a MOVESET command:

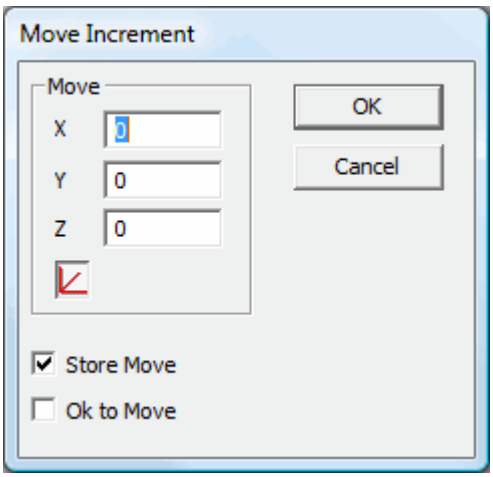
- The MOVESET command supports move points only of the Point type. You cannot use a MOVESET command for incremental moves or any other type of moves.
- You can use the MOVESET command for measurement routines that do not use ClearanceCube. This helps to place multiple move points in a single MOVESET command.

Inserting a Move Increment Command

The difference between the Move Point and Move Increment commands is that the Move Point command moves the probe to a specific location in your volume. The Move Increment command moves your probe from its current position to a specified amount in the X, Y, and Z directions. You must be very careful with the Move Increment command since it could cause a crash if you do not account for obstacles when you define this command.

For example, suppose there's a feature on your part that you need to avoid crashing into and you perform two incremental moves of X=0, Y=0, Z=50 and X=100, Y=0, Z=0. This defines probe movements of 50 units in the Z direction and 100 units in the X direction. If you get a false trigger halfway through the second move increment command and you click **Continue**, your probe, which has already moved 50 units, will proceed to make the same 100 unit move from where the false trigger occurred. The net result is that your probe will move a total of 150 units and may end up crashing into another feature.

The **Insert | Move | Move Increment** menu option displays the **Move Increment** dialog box. You can use this dialog box to define the move increment command before you insert the command into your measurement routine.



Move Increment Dialog Box

When you click **OK**, PC-DMIS inserts the Move Increment command.

The Edit window command line for a Move Increment would read: `MOVE/INCREMENT, x, y, z`

When PC-DMIS encounters this command, it moves the probe the indicated XYZ *distance* (not an XYZ *location* as in a `MOVE/POINT` command). You must select the **Store Move** check box for this command to appear in the Edit window.

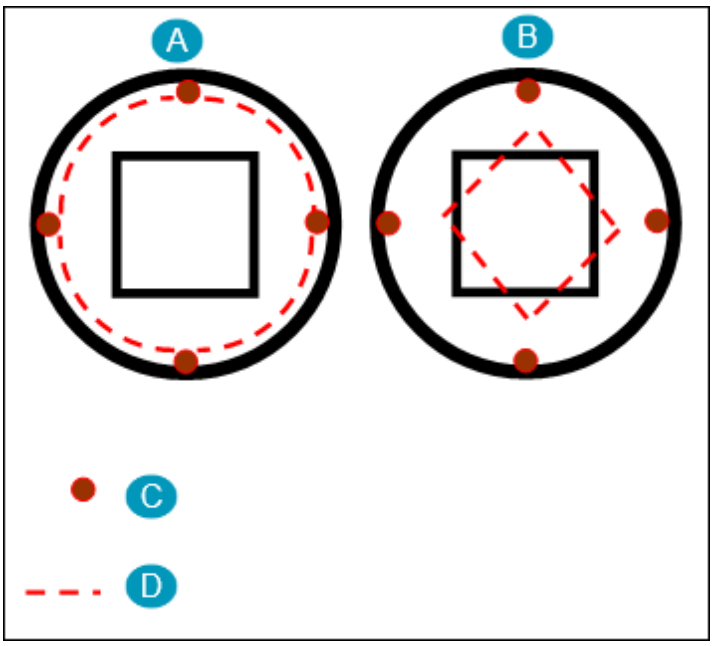
For descriptions of the **Move** area and the **Store Move** and **Ok to Move** check boxes, see the same topics under the **Move Point** dialog box above.

Inserting a Move Circular Command

The **Insert | Move | Move Circular** option allows you to insert a `MOVE/CIRCULAR` command at the cursor's location in the Edit window.

When PC-DMIS encounters this command, the probe follows a circular path when it takes the next hit. It moves from one point to another in a circular fashion based on the radius of the feature you are measuring.

By taking a circular path, the probe may avoid colliding with certain features that would otherwise be in the way of the standard straight line path. For example, if you are measuring a hole that has a square pin inside, that pin may block your probe path unless you use Move Circular.



A. *Circular path avoids inside feature*

B. *Normal path collides with inside feature*

C. *Probe Hits*

D. *Probe Path*

Overall, this command has very specific uses, although using it to measure a pin speeds up measurement somewhat since PC-DMIS doesn't have to move as far away from its last hit.

Inserting Clearance Moves with Collision Detection

When marked, the **Operations | Graphic Display window | Clearance Moves | With Collision Detection** menu item adjusts the Auto feature path line preview from the previous feature to the current feature to avoid possible collisions between the two features. When you create the Auto feature, PC-DMIS automatically inserts one or more `MOVE/POINT` commands into your measurement routine to avoid the collision. See "Show Hit Targets Toggle" in the "Creating Auto Features" chapter where the Auto feature path line previews are discussed.

Inserting a Move Sync Command

Multiple arm measurement routines have commands that control multiple arms. Each machine executes these commands separately, keeping both arms moving.

The **Insert | Move | Move Sync** menu option allows you to insert a `MOVE/SYNC` command into the Edit window.

Using this command on dual-arm machines allows you to synchronize the motion of the arms. Whichever arm reaches the `MOVE/SYNC` command in the measurement routine first will stop and wait until the other arm also arrives before they proceed together with the rest of the measurement routine.

Inserting a Move Sweep Command

The `Move/All` command replaces the `Move/Sweep` command. Please use the `Move/All` command instead of the `Move/Sweep` command. For details on the `Move/All` command, see the "Inserting a Move All Command" topic in the PC-DMIS Core documentation.

The **Insert | Move | Move Sweep** menu item inserts the following sweep block into the Edit window.

```
SWEEPSTART/

MOVE/SWEEP

SWEEPEND/
```

Movement commands that are inside of `SWEEPSTART` and `SWEEPEND` command blocks cause the probe to move in all five axes simultaneously. This occurs when you use certain controllers, such as the PHS wrist with a Sharpe32Z controller.

Three of these axes are the X, Y, and Z axes. These are used when moving the machine itself. The other two axes refer to the probe's AB angle movement.

This command only functions with a continuous type wrist (CW43, CW43Light, or PHS) and a Renishaw SP600 analog probe.

Movement in these five axes takes place simultaneously. This differs from a PH9 wrist, which must first move the machine in the X, Y, and Z axes. Then, when the machine stops, the probe orientation (AB angles) moves.

Suppose your current CMM position is 10, 10, 10 (in X, Y, and Z), and your wrist orientation (AB position) is 0, 0. You want to move the CMM to 20, 20, 20 and the probe orientation to 0, 180. A PHS wrist using the `Move/Sweep` commands can perform both movements simultaneously. A PH9 wrist first moves the CMM and then moves the wrist orientation.

For comparison:

- A PH9 wrist can move between 0º and 110º in the A axis and between +180º to -180º in the B axis.
- A PHS wrist can move between -180º and +180º in both the A and B axes at 0.1º increments.

Advantages of using `MOVE/SWEEP` commands include:

- A much more fluid movement. This makes it easier to measure hard to reach features.
- Saved time. You don't need to wait for the CMM's ram and arm to move to the X, Y, and Z location before changing the probe's orientation.
- A slight improvement in accuracy from reduced vibration.

PC-DMIS requires at least three `MOVE/SWEEP` commands between the `SWEEPSTART/` and `SWEEPEND/` command block. These move commands are essential to generate the elliptical movement path.

Inserting a Move All Command

The `MOVE/ALL` command will function with any motorized probe head - continuous or indexing - and any probe combination.

The **Insert | Move | Move All** menu option inserts a `MOVE/ALL` command into the Edit window.

A `MOVE/ALL` command is the same as a `MOVE/POINT` command combined with a TIP / command. This command has the benefit of rotating the probe head together with machine movement.

When using a wrist device (PHS, CW43L, or CW43) this movement is synchronized such that the wrist's AB movement will start and end its motion at the same time that the machine starts and ends the X,Y, and Z movement.

When using this command with an indexable wrist such as a PH10M, this movement cannot be synchronized and will occur at an unspecified time during the machine movement (depending on time delays in the signal processing of the electronic hardware). Because of this, the AB wrist movement may not always complete by the time the machine performs the X, Y, and Z move.

The Edit window command looks like this:

```
MOVE/ALL,X,Y,Z,TIP=T1A0B0, SHANKIJK=0, 0, 1, ANGLE=0
```

- `X,Y,Z` allow you to specify the X, Y, and Z coordinates to which to move the probe.
- `TIP= T1A0B0` shows the AB wrist movement to perform.
- `SHANKIJK = IJK` allows you to specify the shank's vector.
- `ANGLE=0` specifies the theoretical angle.

Note that the probe head angle is usually be a predefined TIP position.

Maestro Users

For Maestro CMM users, PC-DMIS provides a `DIRECTION` option that you can use with the `MOVE/ALL` command:

- `DIRECTION=CCW` - This option allows you to define the swivel direction of the wrist as either `CW` , `CCW` , or `LEGACY` . The settings for this option are:

  `CW` - This setting rotates the wrist in the clockwise direction.

  `CCW` - This setting rotates the wrist in the counter-clockwise direction.

  `LEGACY` - This setting allows for the Maestro system to determine the direction of the wrist rotation.

  The command in the Edit window for each of these settings might look something like:

```
MOVE/
ALL,<10,10,0>,TIP=T1A45B45,SHANKIJK=-0.5,0.707,0.5,ANGLE
=180,DIRECTION=CW

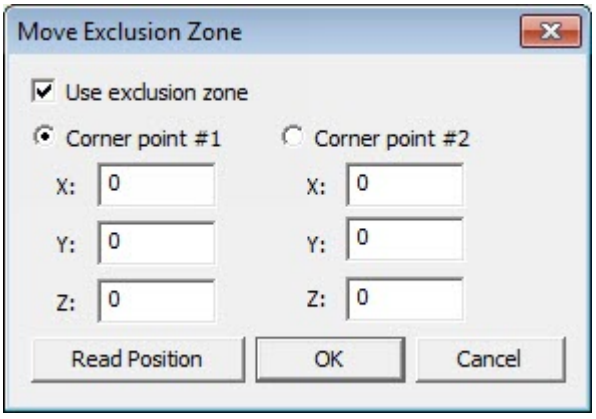
MOVE/
ALL,<20,200,0>,TIP=T1A45B45,SHANKIJK=-0.5,0.707,0.5,ANGL
E=180,DIRECTION=CCW

MOVE/
ALL,<0,0,0>,TIP=T1A0B0,SHANKIJK=0,1,0,ANGLE=-90,DIRECTIO
N=LEGACY
```

Inserting a Move Exclusion Zone Command

The **Insert | Move | Exclusion Zone** menu option allows you to insert a move exclusion zone so that the two arms on a dual arm system don't collide with each other.

Selecting this option opens the **Move Exclusion Zone** dialog box.



Move Exclusion Zone Dialog Box

You can use this dialog box to insert a `MOVE/EXCLUSIVE_ZONE` command into the Edit window.

The `MOVE/EXCLUSIVE_ZONE` command applies to either the Arm1 or the Arm2.

Before PC-DMIS executes this command, it makes sure that the arm assigned to the command has not already requested an exclusive move zone that overlaps with the new request.

If there is a conflict of movement, the `MOVE/EXCLUSIVE_ZONE` command waits until the arm assigned to the command has released the commanded volume, and then it proceeds to execute the motion commands listed below the `MOVE/EXCLUSIVE_ZONE` command.

Defining a Move Exclusion Zone

There are some things to keep in mind when you define an exclusion zone (**Insert | Move | Exclusion Zone** menu option):

- In the measurement routine, you need to have a `MOVE/EXCLUSIVE_ZONE` command before each section of commands that move either arm into the overlapping region of the dual arm volume. The `MOVE/EXCLUSIVE_ZONE` command should define a 3D box around all the motion that is about to be commanded in the overlapped area of the dual-arm CMM.
- There must be a `MOVE/EXCLUSIVE_ZONE=OFF` command after the probe has been withdrawn from the overlapped part of the dual-arm CMM.

For example, if you want each arm to check a common sphere using automatic sphere commands, you should set up the measurement routine like this:

`MOVE/EXCLUSIVE_ZONE=ON` (for Arm 1)
`AUTO/SPHERE` (for Arm 1)
`MOVE/EXCLUSIVE_ZONE=OFF` (for Arm 1)
`MOVE/EXCLUSIVE_ZONE=ON` (for Arm 2)
`AUTO/SPHERE` (for Arm 2)
`MOVE/EXCLUSIVE_ZONE=OFF` (for Arm 2)

The following steps describe how to define the exclusion zone.

Step 1 Enable the Exclusion Zone

Select the **Use exclusion zone** check box. This allows you to edit the X, Y, and Z values under the **Corner point #1** and **Corner point #2** options.

Alternately, if you click on an already inserted `MOVE/EXCLUSIVE_ZONE` command in the Edit window and press the F9 key, the **Move Exclusion Zone** dialog box opens, and you are able to select or deselect this check box.

- If this box *is selected* when you click the **OK** button, PC-DMIS will display the following command in the Edit window:
  `MOVE/EXCLUSIVE_ZONE=ON, CORNER1=x,y,z,CORNER2=x,y,z`
- If this box is *not selected* when you click the **OK** button, PC-DMIS will display the following command in the Edit window:
  `MOVE/EXCLUSIVE_ZONE=OFF`

Step 2 Enter Corner Point Values

Type the X, Y, and Z values for **Corner point #1** and **Corner point #2**. You can read in the probe's current into the selected corner point by clicking the **Read Position** button.

Defining two corners sets up the exclusion zone; be sure to select the corner points that will correctly define the exclusion zone. The two points (corner 1 and corner 2) represent two corners that are *diagonal* from each other.

A rectangular zone can be created in 3D space from two points if you use the current coordinate system to create the sides. A combination of different parts of the two points can construct the eight points needed to form the rectangular area.

This is shown below:

First corner = X1, Y1, Z1

Second corner = X2, Y2, Z2

Third corner = X1, Y1, Z2

Forth corner = X1, Y2, Z1

Fifth corner = X1, Y2, Z2

Sixth corner = X2, Y1, Z1

Seventh corner = X2, Y1, Z2

Eight corner = X2, Y2, Z1

Step 3 Click OK

Finish defining the Exclusion Zone by clicking the **OK** button. PC-DMIS then places the defined information into the Edit window, which reads:

```
MOVE/EXCLUSIVE_ZONE=TOG1,CORNER1=X,Y,Z,CORNER2=X,Y,Z
```

TOG1
This defines whether the exclusion zone is in effect or not. This toggle field switches between ON and OFF.

X, Y, Z
These coordinates define the corner points used to form the exclusion zone.

To close the dialog box without making any changes to your measurement routine, click the **Cancel** button.

Move Exclusion Zones with Iterative Alignments

If you use exclusion zones (**Insert | Move | Exclusion Zone**) with iterative alignments, PC-DMIS automatically computes the starting and ending lines of the measurement routine that are to be re-executed. This means that PC-DMIS ends execution at the last feature used as part of the iterative alignment. This could prevent an arm from releasing the exclusion zone to the other arm, which thereby stops the measurement routine.

To resolve this, insert a start label for the iterative alignment. PC-DMIS executes from the label to the command just in front of the iterative alignment, which causes the arms to release the exclusion zone.

For information on how to use a start label with iterative alignments, see "Start Label" under "Description of the Iterative Alignment Dialog Box".

Inserting a Move Rotary Table Command

The **Insert | Move | Move Rotary Table** menu item allows you insert a `MOVE/ROTAB` command at the cursor's current location.

Command line in the Edit window:

```
MOVE/ROTAB,angle,DIRECTION,feature
```

Command line with a stacked configuration:

```
MOVE/ROTAB, angle, DIRECTION, angle2, DIRECTION2,feature
```

`Direction` = determines the direction of the table rotation. The available options are:

Clockwise
Rotates the table in a clockwise direction until it reaches the angle entered in the **Rotate Table Angle** box.

Counterclockwise
Rotates the table in a counterclockwise direction until it reaches the angle entered in the **Rotate Table Angle** box.

Shortest
Rotates taking the shortest route (either clockwise or counterclockwise) until it reaches the angle entered in the **Rotate Table Angle** box.

`angle` and `angle2` = the relative offset angle used to rotate the table.

`feature` = the feature or alignment to which that the table will rotate to.

When PC-DMIS encounters this command, it rotates the table to a position determined by whichever `MOVE/ROTAB` command is active. If both an angle and a feature are defined, PC-DMIS rotates to an angle which is the sum of the angle to rotate the defined feature to +Z and the offset angle.

Consider a measurement routine that has multiple different `MOVE/ROTAB` commands. If you click on a particular portion of the measurement routine and select the **Move Rotary Table** menu option, PC-DMIS rotates the table to the position determined by whichever `MOVE/ROTAB` command is active at that point in the measurement routine.

This menu option is only available if your PC-DMIS license is configured for rotary tables.

Inserting a Clear Point Move

The **Insert | Move | Clear Point** menu option inserts a `MOVE/CLEARPOINT` command into the Edit window. This command, when executed, moves to the clear point position that is defined in the **Clear Point** tab of the **Parameter Settings** dialog box. In addition, it uses the move sequence defined in the **Clear Point** tab to control the form of the move. See the "Parameter Settings: Clear Point tab" topic in the "Setting Your Preferences" chapter.

Inserting a Clearance Plane

The `CLEARP` command (**Insert | Parameter Change | Clearance Planes**) allows you to define a clearance plane value for the current workplane. Clearance planes, in essence, create an envelope around a part where the probe will always travel to when it moves from one feature to another.

The **Clearance Plane** tab of the **Parameters** dialog box allows you to turn clearance planes on globally. The `CLEARP` command only defines the clearance plane for the first hit of a feature. To use the defined clearance plane, open a new line, at any place beneath the `CLEARP` command location in the Edit window, and type the command: `MOVE/CLEARPLANE` , or select **Insert | Move | Move Clearplane** from the menu.

To define a new clearance plane, select **Edit | Preferences | Parameters**, and then use the **Clearance Plane** tab to define the new plane's values.

For an in-depth discussion on how to define and work with clearance planes, see "Parameter Settings: Clearance Plane tab" in the "Setting Your Preferences" chapter.

Inserting a Move Clear Plane Command

The **Insert | Move | Move Clearplane** command allows you to insert the `MOVE/CLEARPLANE` command between blocks and within features.

A `MOVE/CLEARPLANE` command works in conjunction with a preceding `CLEARP/` command and a following motion command to move to a clearance plane. The `MOVE/`

`CLEARPLANE` command gives permission for the next move, measure, tip selection, or Auto feature command to move to the predefined clearance plane prior to execution.

The probe remains at the clearance plane until a command is encountered that moves the probe away from the clearance plane, such as a `MEAS HIT` , or `MOVE/POINT` command. If you want the probe to move to the clearance plane before each hit of a measured feature, then a `MOVE/CLEARPLANE` command must be inserted directly before each `HIT/` command.

PC-DMIS searches for the clearance plane definition. For this command to work, the parameters must have already been set.

To set the parameters for a Clearplane command:

1. Access the **Parameter Settings** dialog box (**Edit | Preferences | Parameters**).
2. Select the **Clearance Plane** tab.
3. Type the distance for the **Value** box in the **Active Plane** area.
4. Type the distance for the clearance plane in the **Value** box of the **Pass Through** area.
5. Select the **Clearance Planes Active** check box.
6. Click the **OK** button.

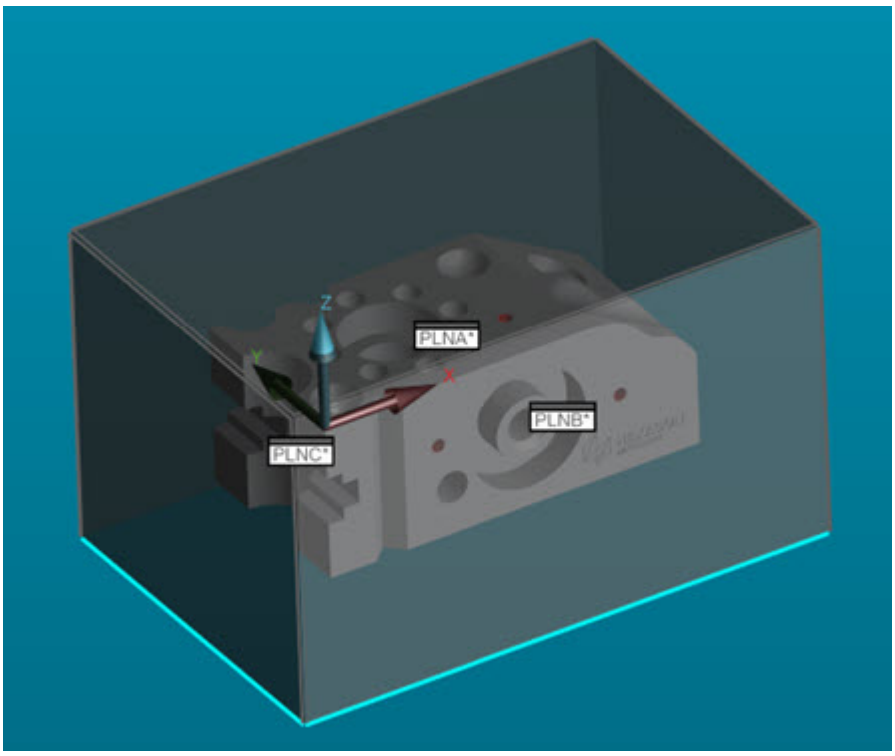
If the parameters have not been set, PC-DMIS displays an error message.

The Edit window command line for a sample Move Clearplane would read:
`MOVE/CLEARPLANE`

For an in-depth discussion on how to define and work with clearance planes, see "Parameter Settings: Clearance Plane tab" in the "Setting Your Preferences" chapter.

Using the ClearanceCube

A ClearanceCube is a three-dimensional virtual box that you define in PC-DMIS. It's purpose is to act as an invisible protective envelope that surrounds your part and its fixture. During measurement routine execution, PC-DMIS uses the faces of the ClearanceCube as safe pathways for your probe to travel to avoid collisions with your part.



A sample ClearanceCube surrounding the CAD model.

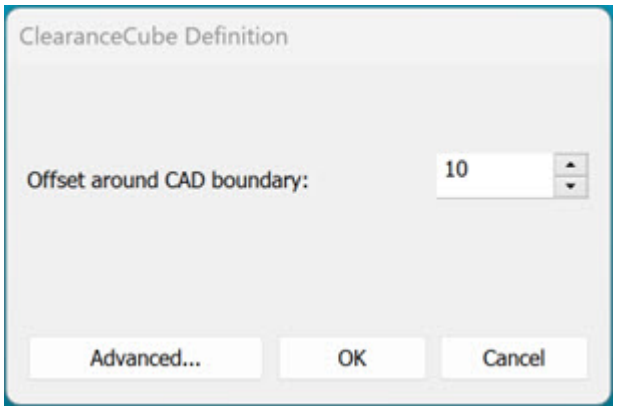
Defining The ClearanceCube

You can define the ClearanceCube in a measurement routine with or without a CAD model.

Measurement Routine with CAD

To define a ClearanceCube in a measurement routine with a CAD model, follow these steps:

1. Select **Operation | Graphic Display Window | ClearanceCube**, or from the **ClearanceCube** toolbar, click the **Clearance Cube Definition** icon . This opens the **ClearanceCube Definition** dialog box.



ClearanceCube Definition Dialog Box

Offset around CAD boundary - Type an offset value in this box or use the up and down arrows to increase or decrease the current value by one. Based on this value, PC-DMIS draws the ClearanceCube around the CAD model the current distance away from the part on all six sides. PC-DMIS uses the same units of measurement as the measurement routine.

Advanced - This button expands the dialog box from a single-tab to a multi-tabbed dialog box. The tabs on the advanced dialog box include: **Size** and **Constraints**. This button then changes to read **Simple**. Click the button again to display the simple dialog box.

You can use the advanced area to:

- Customize the ClearanceCube offset along each axis.
- Define a ClearanceCube for a measurement routine that does not use a CAD model.
- Set the constraints for the ClearanceCube.

If you use the **Advanced** tab to customize the size, the offset box in the simple definition dialog box displays "N/A".

OK - This button defines and activates the ClearanceCube.

Cancel - This closes the dialog box without saving the changes.

2. Type an offset value in the **Offset around CAD boundary** box.
3. Click the **Advanced** button to customize the size and constraints for the ClearanceCube.
4. Click **OK** to close the dialog box.

Measurement Routine without CAD

To define a ClearanceCube in a measurement routine without a CAD model, follow these steps:

Prerequisites

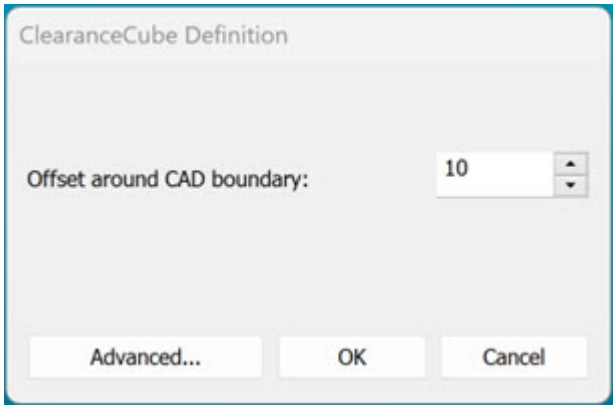
1. Create an alignment that controls all six degrees of freedom of the part.
2. Set **CAD = Part** (**Operation | Graphic Display Window | CAD Equals Part**).

You must create an alignment and then set CAD Equals Part even though you do not have a CAD model in your measurement routine.

If you don't complete the prerequisite steps before you define the ClearanceCube, PC-DMIS displays an error that informs you to complete the required steps.

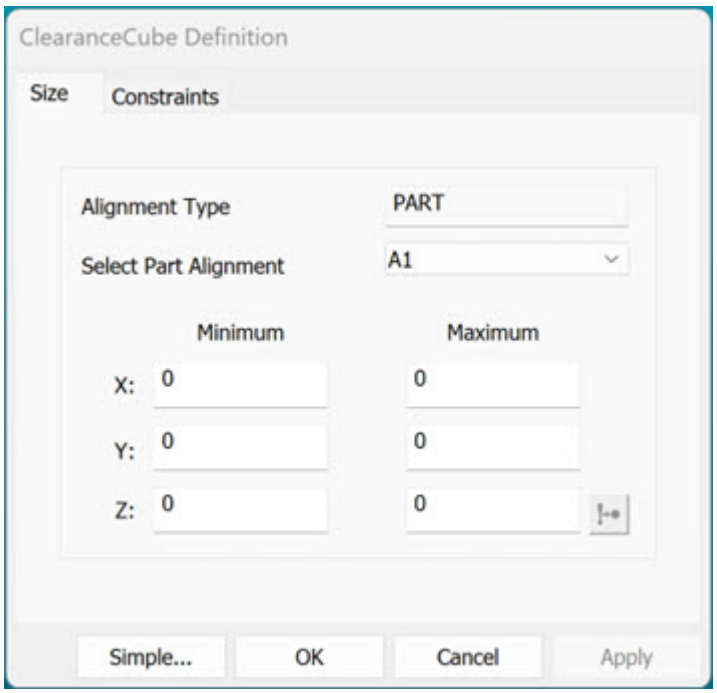
Define ClearanceCube

1. Select **Operation | Graphic Display Window | ClearanceCube**, or from the **ClearanceCube** toolbar, click the **Clearance Cube Definition** icon . This opens the **ClearanceCube Definition** dialog box.



ClearanceCube Definition Dialog Box

2. Click **Advanced** to open the **Size** and **Constraints** tabs on the **ClearanceCube Definition** dialog box.



ClearanceCube Definition Dialog Box - Advanced Option

3. In the **Size** tab, from the **Select Part Alignment** list, select the part alignment in which you want to define ClearanceCube.

4. In the **Minimum** and **Maximum** area, type the location values for the ClearanceCube in the **Minimum XYZ** and **Maximum XYZ** boxes relative to the selected alignment.

You must make sure that the minimum value of each axis is smaller than the maximum value of the corresponding axis.

5. Click **OK** to close the dialog box. If you want to define a ClearanceCube and continue to modify its definition, click **Apply**.

You cannot define a ClearanceCube from the STARTUP alignment. PC-DMIS does not display this alignment in the STARTUP alignment list.

Re-import a CAD in a Measurement Routine with ClearanceCube

When you re-import a CAD model into a measurement routine with a pre-defined ClearanceCube, you must consider these factors:

- **ClearanceCube is defined using CAD**

  When you re-import a CAD model into a measurement routine, PC-DMIS redefines the ClearanceCube automatically. PC-DMIS uses the same offset boundary for each side as defined in the original CAD model.

- **ClearanceCube is defined using Part Alignment**

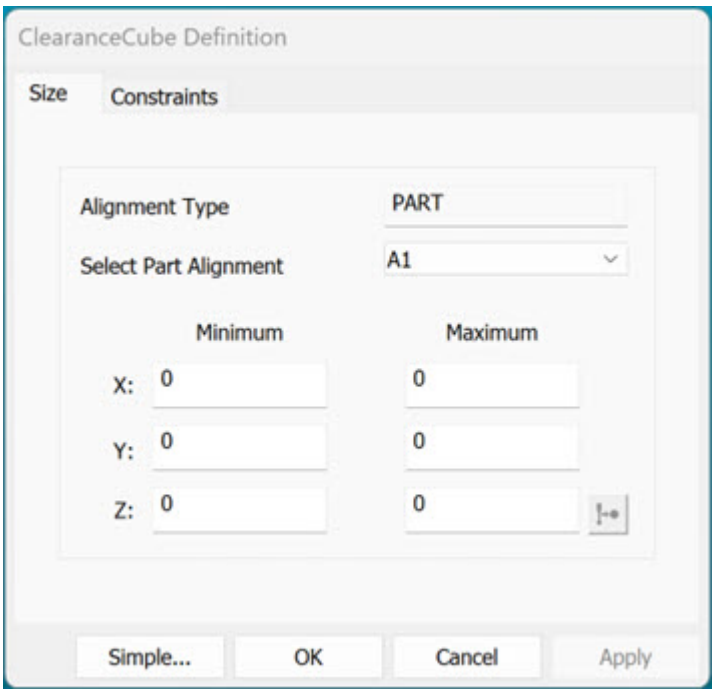
  PC-DMIS redefines the ClearanceCube by default with a 10 mm offset to the CAD model's boundary.

- **ClearanceCube was created using Part Alignment in previous versions**

  PC-DMIS 2023.2 and later versions do not allow you to define a ClearanceCube with part alignment if a CAD model is available. PC-DMIS redefines the ClearanceCube and displays a message to inform you of the new ClearanceCube settings.

ClearanceCube Definition - Size tab

To open the **Size** tab in the **ClearanceCube Definition** dialog box, click the **Advanced** button.



ClearanceCube Definition Dialog Box - Size Tab

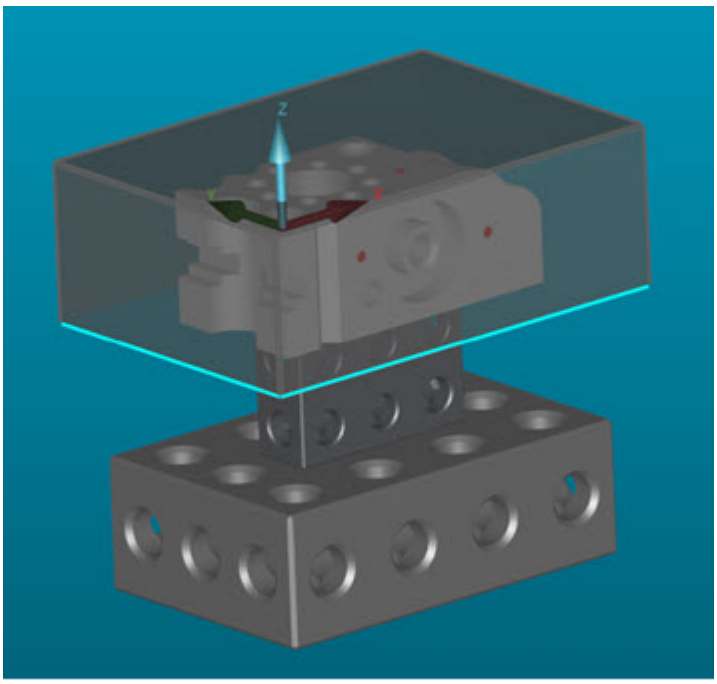
For a measurement routine with a CAD model, PC-DMIS defines the minimum and maximum boundary of the ClearanceCube in the CAD alignment.

For a measurement routine without a CAD model, PC-DMIS defines the minimum and maximum boundary of the ClearanceCube in one of the alignments created in the measurement routine.

You can modify the boundary in each axis as desired.

Defining the ClearanceCube to be Smaller than the CAD Boundary

You can define the ClearanceCube to be smaller than the CAD boundary when you have a CAD model that includes a large fixture.



Example showig a ClearanceCube smaller than the CAD boundary with a large fixture.

PC-DMIS displays a warning message when the ClearanceCube is smaller than the CAD boundary to confirm or cancel the ClearanceCube definition process.

Resize ClearanceCube using CAD

When you are in the **ClearanceCube Definition** dialog box:

- To resize ClearanceCube, drag any side of the ClearanceCube box.
- To rotate the CAD model, press Ctrl and right-click.

Teach Size of ClearanceCube

You can teach to define the size of the ClearanceCube:

Ensure that the probe tip you want to use is the active tip. If required, position your mouse pointer in the Edit window at the desired tip command.

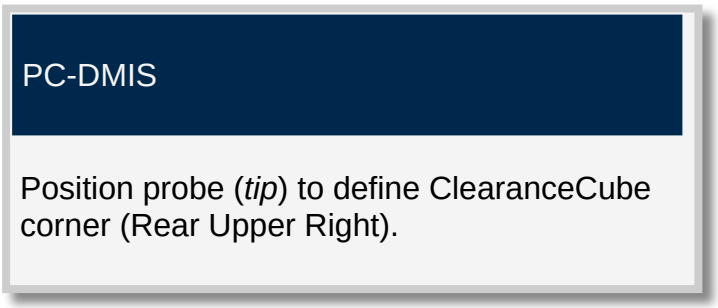
1. In the **ClearanceCube Definition** dialog box, from the **Maximum** area of the **Size** tab, click the **Teach** button. PC-DMIS displays this message:

   PC-DMIS

   Position probe (*tip*) to define ClearanceCube corner (Front Lower Left).

   where *tip* is the active probe tip at the cursor's current location in the Edit window.

2. Position the probe tip at the front lower left corner of the ClearanceCube and then click **OK** (or press the **Done** button on the jogbox). This message appears:

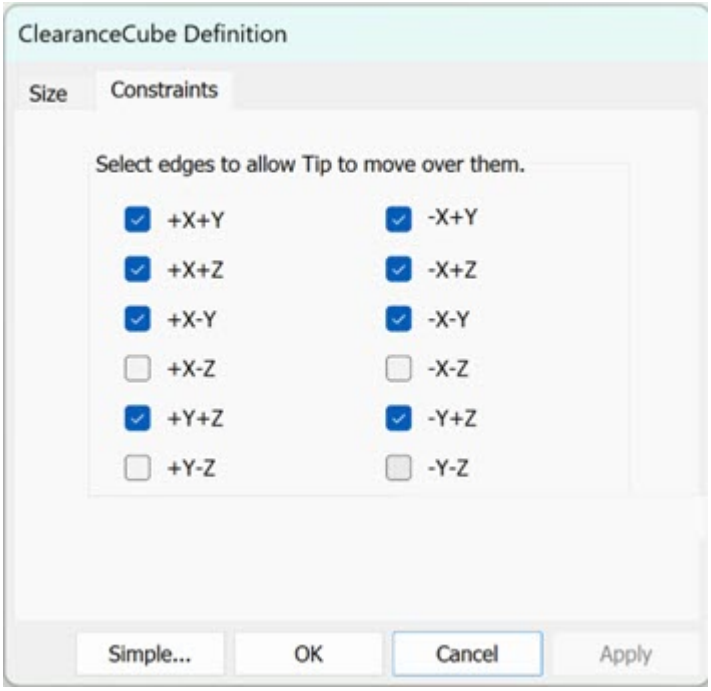


3. Position the probe tip at the rear upper right corner of the ClearanceCube and then click **OK** or press the **Done** button on the jogbox.

4. PC-DMIS automatically fills in the values in the **Minimum XYZ** and **Maximum XYZ** boxes and draws the ClearanceCube.

ClearanceCube Definition - Constraints tab

Use the **Constraints** tab to specify which of the 12 edges you want to allow the tip to move over. If you do not select an edge, PC-DMIS does not move the tip.



ClearanceCube Definition Dialog Box - Constraints Tab

If an edge is cleared, PC-DMIS does not move the tip over that edge. You can use constraints to restrict tip movement to avoid collision with the clamps.

The Graphic Display window displays those edges in blue on the ClearanceCube. If none of the four edges of a face are selected, PC-DMIS displays that face in bright yellow.

Clear Edges Using the CAD Model

You can select or deselect an edge that you want or not want to pass over using the CAD in the Graphic Display window. To do this, with the **ClearanceCube Definition** dialog box displayed, click an edge on the CAD in the Graphic Display window. You can see as you select or deselect the edge on the CAD model, PC-DMIS selects or deselects that same edge.

You can also rotate the CAD model with this dialog box open. To do this, press the Ctrl button and right-click and then move your mouse cursor to the desired rotation position.

ClearanceCube Settings for Feature or Moveset Command

You must set ClearanceCube motion for every feature in a measurement routine.

- PC-DMIS moves the tip to the starting face set for a feature before the measurement of the feature.
- PC-DMIS moves the tip to the ending face set for a feature after the measurement of the feature.

PC-DMIS does not execute ClearanceCube moves if it is set off for a feature.

ClearanceCube Settings for Tip Command

You can activate ClearanceCube motion for tip commands.

- If the tip change completes safely in front of the part face, set the ClearanceCube motion for the TIP command to the Off condition. You must ensure that the last position of the tip is safe for rotation or change.

If ClearanceCube motion is activated for the TIP command, PC-DMIS needs to move the tip to a safe location. The tip must be located on the face of or outside of the ClearanceCube.

This can be accomplished by either:

- Setting ClearanceCube motion to the ending face of the last feature

  Or,

- Adding a Moveset command and setting the ClearanceCube motion to the ending face

PC-DMIS displays the message during execution of a measurement routine if the ClearanceCube is activated for the TIP command and located inside the ClearanceCube.

ClearanceCube Settings for Scan Command

The Advance Scans are containers for BASICSCAN commands. You can set ClearanceCube motion for a scan and each BASICSCAN in a scan.

```
SCN1        =FEAT/SCAN,LINEAROPEN,NUMBER OF HITS=185,SHOW HITS=NO,SHOWALLPARAMS=NO
             MEAS/SCAN
               BASICSCAN/LINE,NUMBER OF HITS=50,SHOW HITS=NO,SHOWALLPARAMS=NO
               ENDSCAN
               BASICSCAN/LINE,NUMBER OF HITS=22,SHOW HITS=NO,SHOWALLPARAMS=NO
               ENDSCAN
               BASICSCAN/LINE,NUMBER OF HITS=23,SHOW HITS=NO,SHOWALLPARAMS=NO
               ENDSCAN
               BASICSCAN/LINE,NUMBER OF HITS=90,SHOW HITS=NO,SHOWALLPARAMS=NO
               ENDSCAN
             ENDMEAS/
```

Example of a BASICSCAN command in a scan.

PC-DMIS executes the scan and the Basic scan in this way:

PC-DMIS moves the ClearanceCube based on the starting face of the scan (SCN1).
PC-DMIS executes the Auto Move before scanning as defined in the scan command.

> PC-DMIS moves the ClearanceCube based on the starting face of the Basic scan (SCN1.1).
> PC-DMIS scans the Basic scan (SCN1.1).
> PC-DMIS moves the ClearanceCube based on the ending face of the Basic scan (SCN1.1).
>
> PC-DMIS repeats these Basic scan SCN1.1 steps for SCN1.2 through SCN1.n.

PC-DMIS executes the Auto Move after scanning as defined in the scan command (SCN1).
PC-DMIS moves the ClearanceCube based on the ending face of the scan (SCN1).

Tip Moves Using Constrained Edges

Tip has activated ClearanceCube Moves set to ON

When you define constraints for some feature edges, PC-DMIS does not allow the tip to cross those edges. PC-DMIS does allow the tip to move freely at the T1A0B0 rotation height. Because of this, you must use a shorter fixture and clamp configuration for your part than this height. In some cases, you may have to use a `MOVESET` command to move the tip to the desired location.

If all four edges of a ClearanceCube face are constrained, PC-DMIS shows the edges in a light blue color in the Graphic Display window. PC-DMIS does not allow you to use this face for ClearanceCube motion.

Tip has activated ClearanceCube Moves set to OFF

When the TIP command becomes active with ClearanceCube move set to OFF, you must ensure that the tip crosses the correct edges and only edges that are not constrained. You may have to use `MOVESET` commands to achieve the correct path for the tip's motion.

ClearanceCube Settings

You can use the ClearanceCube Settings window to define the ClearanceCube motion for each feature and tip in the measurement routine.

ClearanceCube Settings Window

PC-DMIS displays the **ClearanceCube Settings** window automatically when you activate ClearanceCube for the measurement routine.

From the **ClearanceCube** toolbar, you can use the **ClearanceCube Settings Window** icon to show or hide this window. You can also open this window from the **View | Other Windows | ClearanceCube Settings** menu option.

You can dock the ClearanceCube Settings window at the top or bottom of the Graphic Display window. To float the ClearanceCube Settings window, press the Ctrl button and then click and drag the window to the desired location.

- **ID(s)** - This list displays one or more feature IDs based on your selection of features in the Edit window. To do this, follow these steps:

  1. Place your cursor on a feature in Command Mode or select a feature in Summary Mode to display or edit the settings for the ClearanceCube.
  2. To edit the ClearanceCube settings for more than one feature at the same time, select them in the Edit window and then make the necessary changes.
  3. From the **ID(s)** list, select Features or Tips. This box appears when you select multiple features and tips in the Edit window.
  4. Based on your selection from the **ID(s)** list, the list shows the features or tips. Select the item in the list for configuration.

If you position your mouse cursor over a command in Command Mode or select a command in Summary Mode that does not require ClearanceCube settings, PC-DMIS displays the message “ClearanceCube is not required for the selected commands”.

- **Activate ClearanceCube Moves** - This switch determines whether you want to use ClearanceCube motion for the features you selected in the **ID(s)** list.

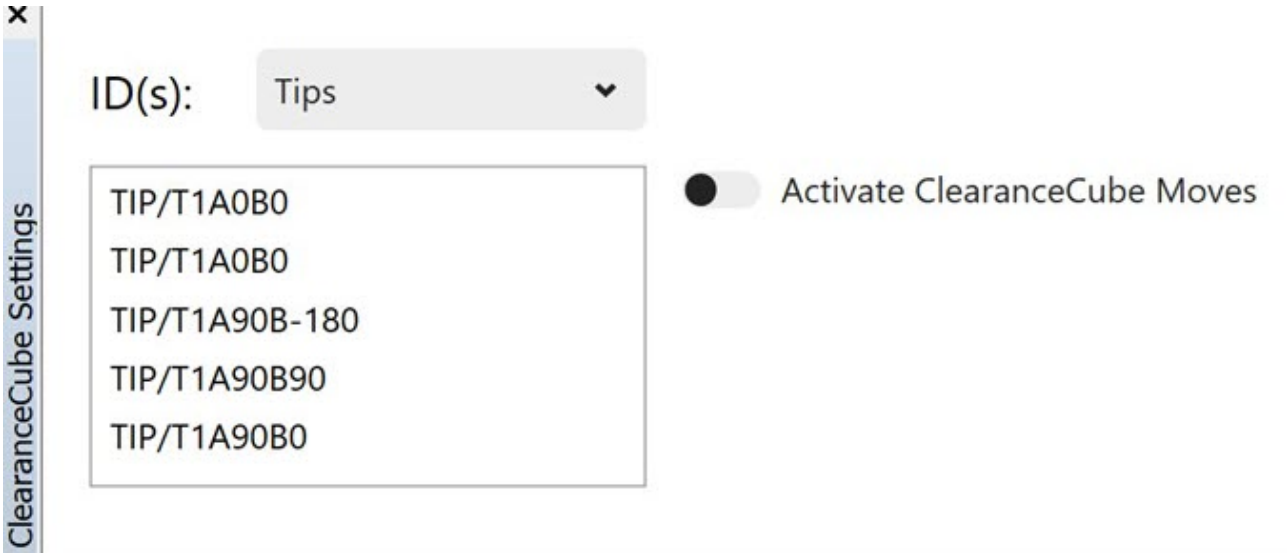
- **Starting Face** - This determines the ClearanceCube face that PC-DMIS moves to before it measures the feature. You have these options:
  - Select a face
  - Use Tip Vector
  - Set the Starting Face to OFF if you only want the ending motion to occur for the feature.
- **Ending Face** - This determines the ClearanceCube face that PC-DMIS moves to after it measures the feature. You have these options:
  - Select a face
  - Use Tip Vector
  - Set the Ending Face to OFF if you only want the starting motion to occur for the feature.

The feature vector determines the default setting for the ClearanceCube **Starting Face** and **Ending Face** options. PC-DMIS marks the **ClearanceCube uses Tip Vector for Start/End Face** check box in the **General** tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**) by default. It is recommended to use the tip vector.

Based on constraints set in the **Constraints** tab, the selection of some axes for the starting and ending faces may not be available.

For Tip Commands

From the **ID(s)** list, select the features or tips. This box appears only when you select multiple features and tips in the Edit window.



ClearanceCube Settings Window - Tips Option

When you select the **Tips** option from the **ID(s)** list, the **ClearanceCube Setting** window only shows the **Activate ClearanceCube Moves** setting.

The ClearanceCube Shortcut Menu

In addition to the ClearanceCube Settings dialog box, PC-DMIS provides a right-click menu. To access this menu, follow these steps:

1. If you are in Command Mode, place your cursor on a feature. If you are in Summary Mode, click a feature to select it.
2. Right-click the feature and select the **Path | ClearanceCube** option.
3. From the **Starting Face** and **Ending Face** list, select the face to align the ClearanceCube to. The available options are -X, +X, -Y, +Y, -Z, +Z, Use Tip Vector, and Off.

ClearanceCube Toolbar

ClearanceCube Toolbar

Use the **ClearanceCube** toolbar (**View | Toolbars | ClearanceCube**) to enable or disable options related to ClearanceCube functionality. See "Using the ClearanceCube" in the "Editing the CAD Display" chapter.

The following icons are available:

ClearanceCube Definition - This icon displays the **ClearanceCube Definition** dialog box. For more details on the dialog box, see the "(Simple) ClearanceCube Definition" topic. You can also press Alt + C to open the dialog box.

Activate ClearanceCube Motion - This icon enables or disables ClearanceCube motion.

- If enabled, your measurement routine uses the ClearanceCube to control its motion and *disables clearance planes*.
- If disabled, your measurement routine uses existing clearance plane commands to control its motion.

You cannot deactivate ClearanceCube if any feature in a measurement routine uses ClearanceCube motion.

Show ClearanceCube - This icon shows or hides ClearanceCube in the Graphic Display window.

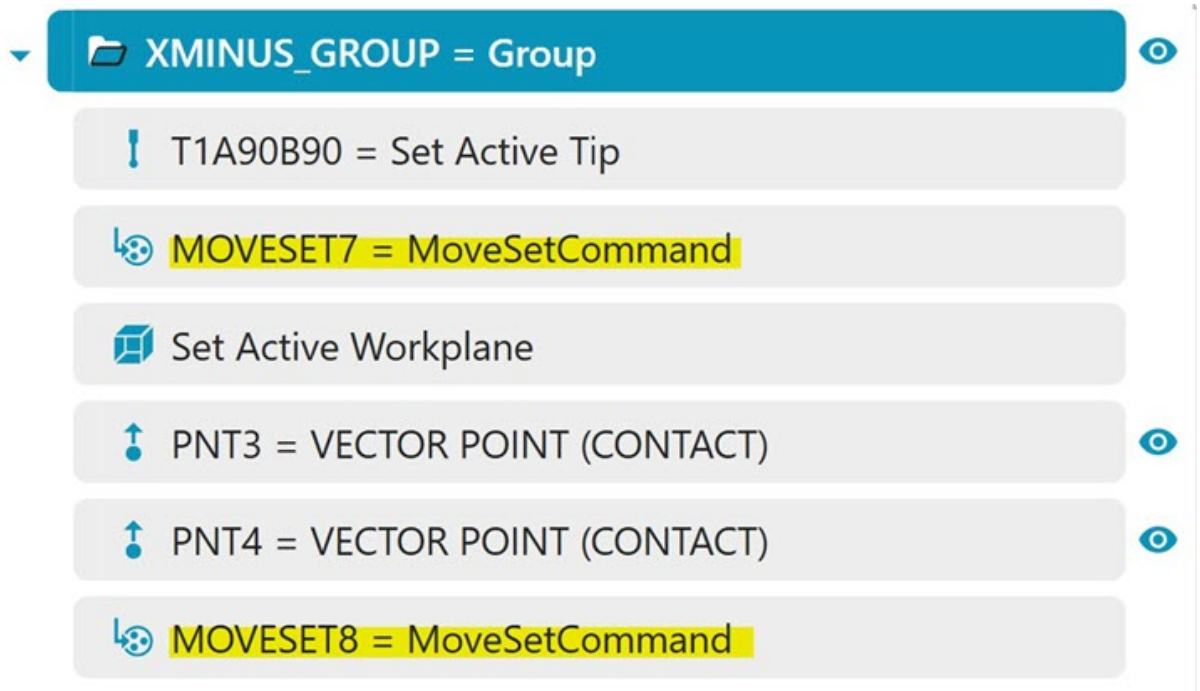
To increase transparency through ClearanceCube in the Graphic Display window, select the **High quality transparency** check box in the **OpenGL** tab of the **CAD and Graphic Setup** (**Edit | Graphic Display Window | OpenGL**) dialog box.

ClearanceCube Settings window - This icon shows or hides ClearanceCube Settings window.

Important Notes

PC-DMIS provides the ClearanceCube moves along with these additional commands to help you safely navigate around your part during execution:

- Avoidance Move - Use Avoidance Move commands with Auto features to safely move to the next feature in your measurement routine. You can select the Avoidance Move command along the feature or tip vector direction.
- Moveset command - The Moveset command is a set of move points. You must select the ClearanceCube for the Moveset command. Use this command to move the tip so that it is in front of the surface that is inside a complex geometry. You can also use this command at the beginning of a group and at the end of a group to bring the tip to the front of a part face where features are located.



Important Information When Using ClearanceCube

- PC-DMIS supports using ClearanceCube only on single arm systems. It *does not* support ClearanceCube on Dual Arm systems.
- When you activate ClearanceCube, PC-DMIS disables any Clearance Plane commands in the current measurement routine. You can only use Clearance Plane or ClearanceCube in a measurement routine.
- Be sure to check for collisions before you execute your measurement routine. For more information, see "Detecting Collisions".
- Make sure you place the probe tip outside the ClearanceCube before you start the execution of your measurement routine.
- You can start execution or partial execution or block execution with the tip located inside the ClearanceCube if required. This can happen when execution stops due to a chip in a bore. You can clear the error and then continue execution of the measurement routine from where it stopped.
- The width of ClearanceCube in any direction cannot be smaller than 1 mm. This helps you to ensure the correct definition of the ClearanceCube.
- You must ensure the safe execution of a measurement routine, desired ClearanceCube motion settings, and scan command when you open a measurement routine created in a version before PC-DMIS 2023.2.

Inserting Clearance Moves Automatically

Once you import or create features and perform a path optimization, you need to ensure that your probe won't collide with your part during measurement. PC-DMIS contains menu options in the **Operation | Graphic Display Window | Clearance Moves** submenu that insert clearance moves automatically as `MOVE/POINT` commands to help avoid unintentional collisions with the part. These menu items under the **Clearance Moves** submenu are discussed below.

For more information on how to detect collisions, see "Detecting Collisions" in the "Editing the CAD Display" chapter.

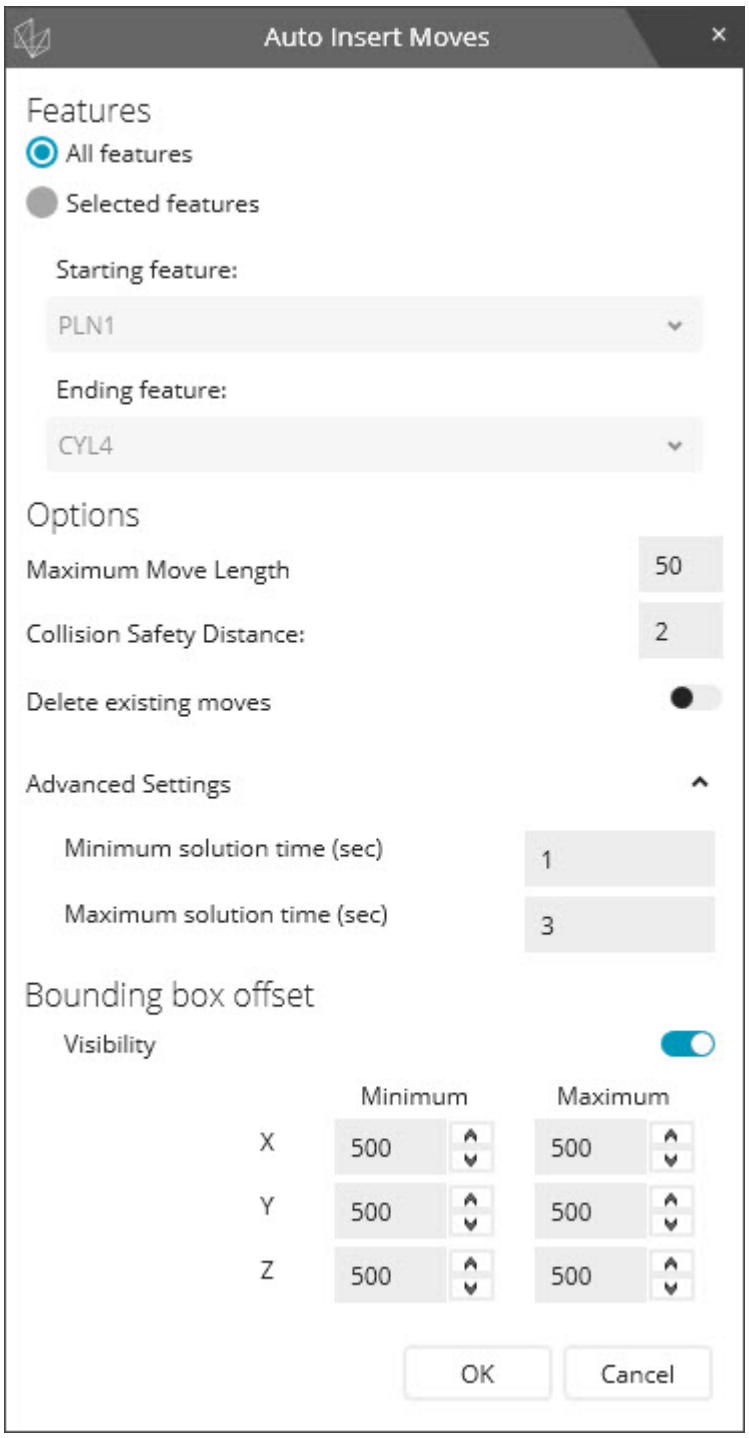
Detecting Collisions

Clearance Moves Menu Items

These are the menu items under the **Operation | Graphic Display Window | Clearance Moves** submenu:

Auto Insert Moves

The **Auto Insert Moves** menu option (**Operation | Graphic Display Window | Clearance Moves | Auto Insert Moves**) opens the **Auto Insert Moves** dialog box. You can use this dialog box to add clearance moves (`MOVE/POINT` commands) between all features or between selected features. For information on how to do this, see the "Using Auto Insert Moves" topic below.



Auto Insert Moves Dialog Box

When you click **OK**, PC-DMIS inserts the `MOVE/POINT` commands.

PC-DMIS does not place move commands prior to the first feature; make sure there is a clear path between the probe's start position and the first feature.

All features - PC-DMIS places the move commands between all features.

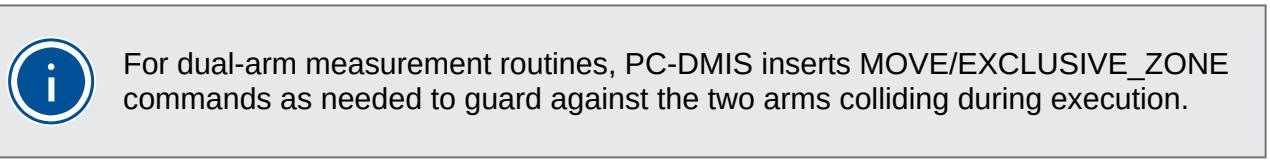
Selected features - PC-DMIS places the move commands between a range of two features that you can select from this area. The **Starting feature** and **Ending feature** lists beneath this option show the features. (You can also select the two features from the Edit window before you open this dialog box.)

Maximum Move Length - This value defines the maximum length of a move. This value is in mm or inches, based on the measurement routine's units. This means any `MOVE/POINT` commands that the algorithm calculates to move the probe from one location to another cannot exceed this value.

PC-DMIS attempts to go directly to the next feature, but compensates for collisions by inserting clearance move commands. It continues this process until it defines a collision free path to the next feature. More than one move command may be inserted between features. The higher the value, the lower the amount of time PC-DMIS spends calculating these moves. The recommended value is 100 mm (3.93 inches).

Collision Safety Distance - This value defines a safety distance around the part. A move is considered a safe move if it moves the probe this distance away from the part. To prevent the creation of too many moves, the value of **Maximum Move Length** should be greater than the collision safety distance value.

Delete existing moves - This switch determines whether to delete any pre-existing move commands in the measurement routine.



Advanced Settings

Minimum Solution time (sec) - This value is the minimum number of seconds that the algorithm uses to plan a move between two feature commands. A higher value increases the accuracy of the move, but it also increases the computation time. The recommended value is 1 second.

Maximum solution time (sec) - This value is the maximum number of seconds that the algorithm uses to plan a move between two feature commands. A higher value increases the accuracy of the move, but it also increases the computation time. The recommended value is 3 seconds.

Bounding box offset - This area lets you define a cubic region or cubic-like rectangular region that PC-DMIS uses to calculate the automatic insert moves. *This region is not a clearance cube.* You may find this functionality useful if you have a fixture or some other obstruction around certain regions of your part and you don't want PC-DMIS to calculate moves near those areas. In that case, you can define a region, and PC-DMIS calculates the moves only within this region.

The maximum and minimum ranges for each axis let you define a more precise space for PC-DMIS to calculate the moves.

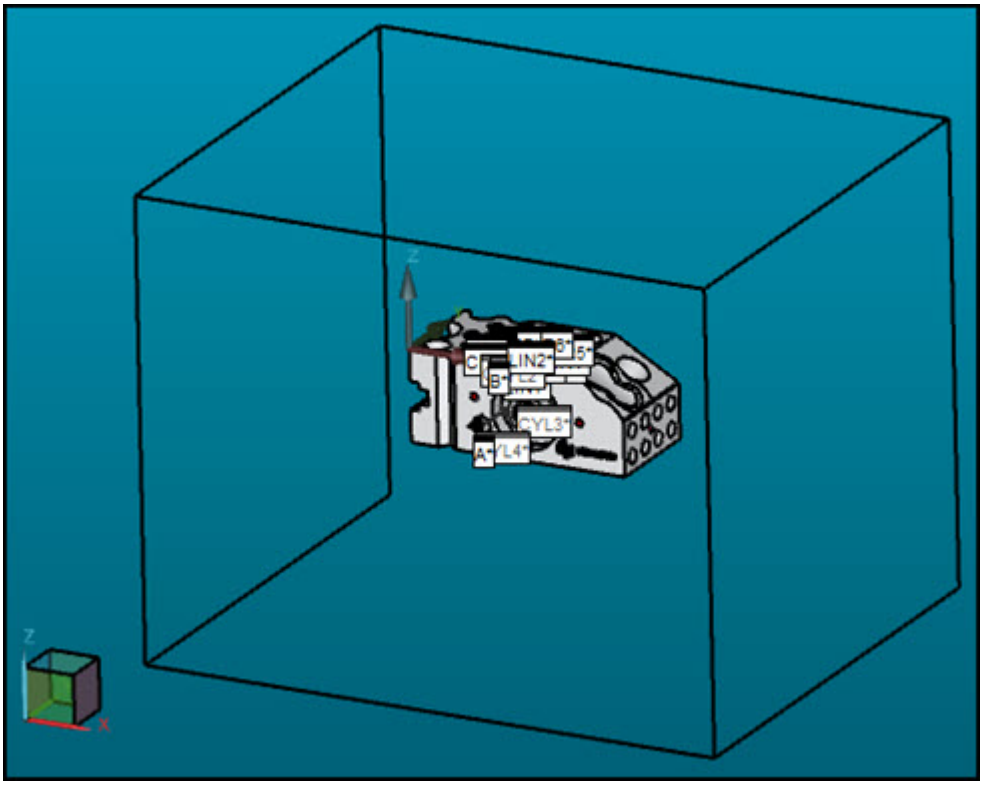
The offset values are based from on the surface sides, not from the alignment origin. This value is in mm or inches, based on the measurement routine's units.

The software adds this value to the CAD model's existing bounding box offsets. The recommended value is 1000 mm (39.3 inches).

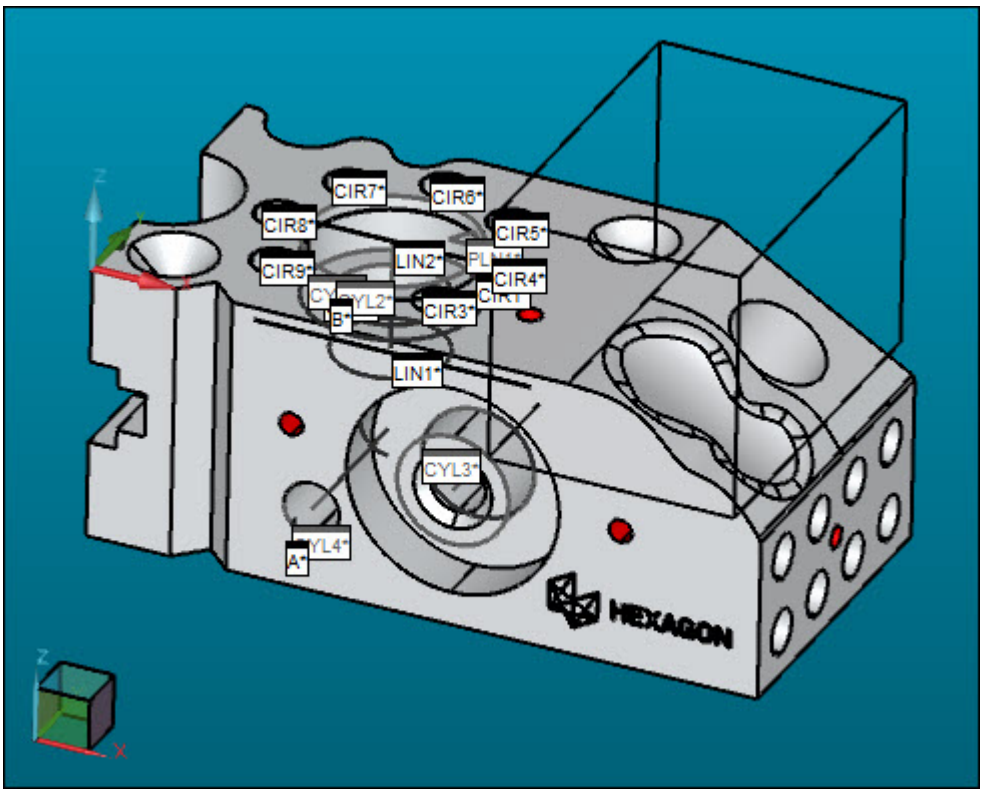
The small up and down arrows in each box adjust the value by 10 percent of the maximum size of the bounding box with each click.

Visibility - This switch lets you show or hide the bounding box region in the Graphic Display window while the dialog box remains open.

The image below shows the bounding box at 100 mm in all axes:



The image below shows the bounding box with minimum X, Y, and Z values of -80, 20, and -45 and maximum X, Y, and Z values of 4.0, -20, and 40:



Within Feature

This menu item (**Operation | Graphic Display Window | Clearance Moves | Within Feature**) only works in QuickFeatures mode. If you select this menu item from the check box and you create a QuickFeature, PC-DMIS checks the probe path inside the feature and adds clearance moves as needed *within* the feature. This is different from the **With Feature Creation** menu item below, which adds clearance moves *between* features.

With Feature Creation

You can choose **With Feature Creation** menu item (**Operation | Graphic Display Window | Clearance Moves | With Feature Creation**) to enable it or disable it. The menu item shows a check mark when enabled.

With this menu item enabled, PC-DMIS uses a simple algorithm to automatically insert `MOVE/POINT` commands as you add features to the measurement routine. The angle between the features must be within a range of 30 to 150 degrees. The algorithm cannot solve anything outside this range. For example, two circle features at different depths but on the same face, results in a 0 degree angle between them and can't be solved. When you insert move commands, this menu item behaves similarly to the **Auto Insert Moves** dialog box and uses one feature above and below the newly inserted feature as the start and end features. This menu item also uses the distance defined in the `CollisionMoveClearanceInMM` entry.

The QuickFeatures menu item activates a new algorithm to generate safe clearance moves as you add QuickFeatures. Automatic safe moves between features that use different probe tip angles are not yet supported. You must manually define those moves.

This functions only in Offline mode.

With Collision Detection

The **With Collision Detection** menu item is not supported for QuickFeatures.

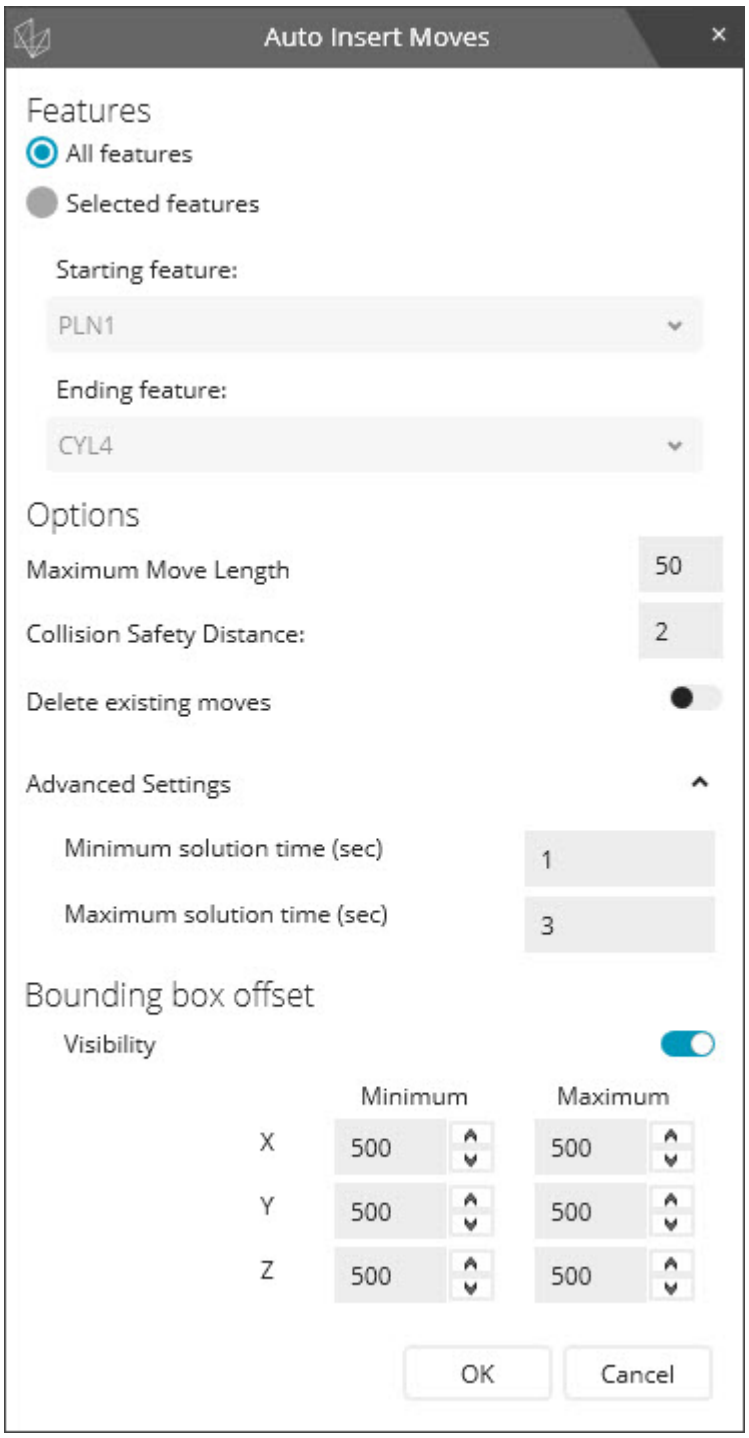
You must select the **With Feature Creation** menu item (**Operation | Graphic Display Window | Clearance Moves | With Feature Creation**) to enable the **With Collision Detection** option. When enabled, this option shows a check mark.

If you enable the **With Collision Detection** menu item, the software extends the functionality of **With Feature Creation** so that you aren't limited by the angle restrictions between features. PC-DMIS uses the collision detection algorithm to detect collisions instead of the simple algorithm. It provides clearance moves between the range of features. For each collision found, it then inserts the appropriate clearance moves.

Using Auto Insert Moves

This procedure helps you insert safe clearance moves for your probe between all features or some features in your measurement routine. This procedure uses information discussed in the "Auto Insert Moves" subtopic in the "Clearance Moves Menu Items" topic above. Refer to that subtopic if you need more information on anything in this procedure.

1. Choose **Operation | Graphic Display Window | Clearance Moves | Auto Insert Moves**. The software opens the **Auto Insert Moves** dialog box.



Auto Insert Moves Dialog Box

2. From the **Auto Insert Moves** dialog box, define whether to insert moves between **All features** or between a range of **Selected features**.

3. If you choose **Selected features**, define a range between two features. Use the **Starting feature** and **Ending feature** lists to choose the two features.

4. If you want a different maximum distance value for your moves, you can modify the default **Maximum Move Length** value. The higher the value, the lower the amount of time PC-DMIS spends calculating these moves. To prevent the creation of too many moves, this value should be greater than the **Collision Safety Distance** value.

5. If you want a different safety distance, you can modify the default **Collision Safety Distance** value.

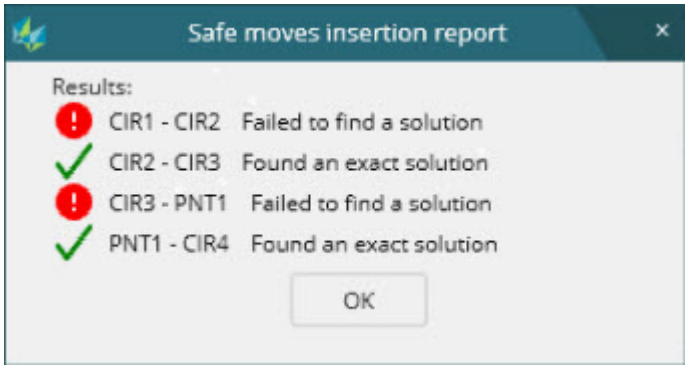
6. If you want to delete all existing moves in your measurement routine before this routine inserts new move commands, move the **Delete existing moves** switch to on.

7. If you need to make changes to the **Advanced Settings**, expand **Advanced Settings**, and make your changes.

8. Click **OK** to start the move insertion process. The software's algorithm calculates and generates safe moves between the features. Once it finishes, it shows a **Safe Moves Insertion Report** dialog box.

   You can press ESC at any time during the generation process to cancel the process and remove any moves the software inserted.

9. From the **Safe Moves Insertion Report** dialog box, hover your pointer over the items to review the results. Then click **OK** to close the dialog box.



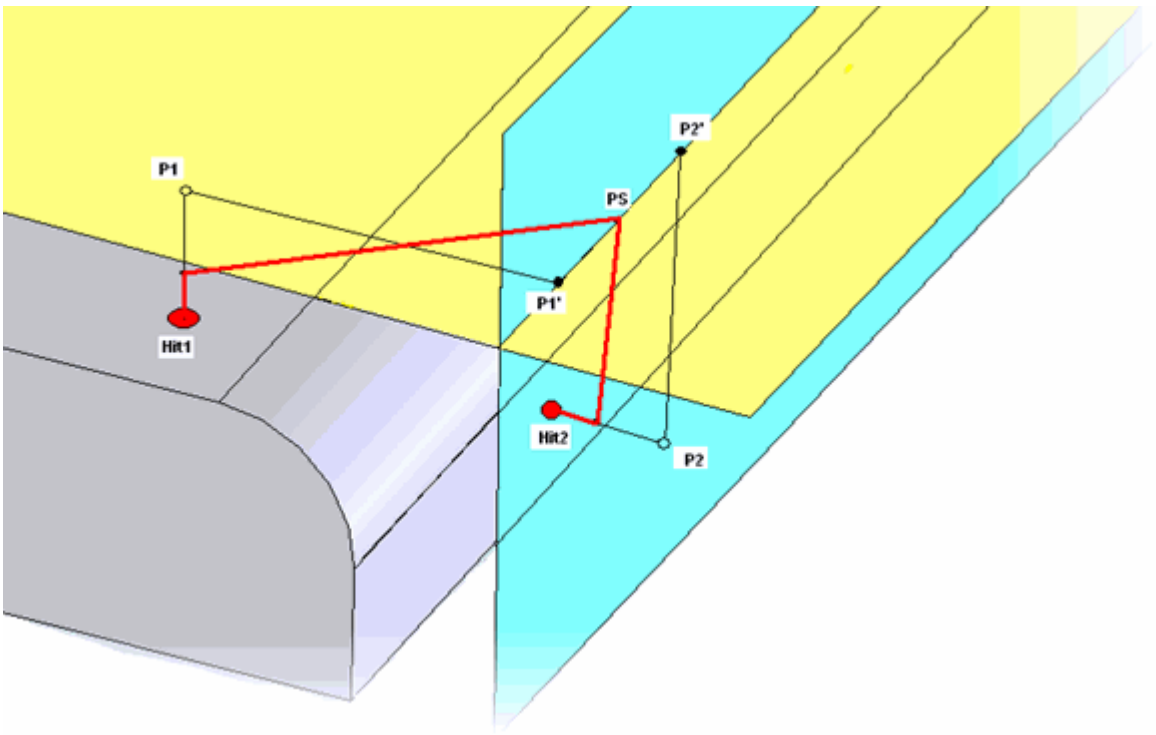
Safe moves insertion report Dialog Box

If the **Safe Moves Insertion Report** failed to find a solution between features, you may need to increase the **Bounding box offset size** under **Advanced Settings**. You may also need to increase the solution times. You can do that by increasing the **Minimum solution time (sec)** and **Maximum solution time (sec)** values.

If the results say you have an invalid start or target command position, this may be due to an incorrect probe tip assigned to measure those commands.

Diagram of MOVE/POINT Calculations

This diagram shows where PC-DMIS calculates a `MOVE/POINT` command between two hits:



- **Hit1** - The last hit
- **P1** - Offset point from Hit1 in vector direction
- **Hit2** - The new hit
- **P2** - Offset point from Hit2 in vector direction. This is the created MOVE/POINT.
- **Yellow Plane** - The plane through P1
- **Blue Plane** - The plane through P2
- **P1'** - Projected P1 in the vector direction of P2
- **P2'** - Projected P2 in the vector direction of P1
- **PS** - Symmetry Point between P1' and P2': This is the new move point.

If the angle between the vector of Hit1 and the vector of Hit2 is bigger than 150°, no move point is needed.

Branching by Using Flow Control

Branching by Using Flow Control: Introduction

Suppose you have a part with many features, but you just want to measure a few features over and over to get a comprehensive statistical set of data for those features. Suppose you want to jump to a particular part in your measurement routine dependent on a response from the user. You can accomplish tasks such as these, and many others, by using flow control commands. By setting up conditions for certain commands, you can control the flow of your measurement routine.

This chapter provides you with the information you need to accomplish such tasks. It explains the syntax for conditional statements, loops, and subroutines. It also provides many code samples.

The main topics covered in this chapter include the following:

- Using Control Pairs
- Using Generic Loops
- Using Labels
- Branching on an Error
- Branching with Subroutines
- Ending a Measurement Routine

Command Mode Commands after Comments

Because many of the code samples in this chapter use typed `COMMENT` commands, consider the following:

After you insert a PC-DMIS comment, to type additional PC-DMIS commands in Command Mode, you must first press Enter *twice* after the `COMMENT` command. This tells PC-DMIS that you no longer want to add text to the comment but are ready to add a new command.

Using Control Pairs

The **Insert | Flow Control Command | Control Pairs** submenu offers various paired commands that work within the Edit window to govern or "control" the proper flow of the measurement routine. To insert a control pair type command into the Edit window, simply type the command, or choose a command from this submenu.

When you use a conditional branching statement to test for a the value of a YES / NO comment, be aware that your test should look for an uppercase "YES" or "NO" value. A lowercase "Yes" or "No" will not work. For information on comments, see the "Inserting Programmer Comments" topic in the "Inserting Report Commands" chapter.

If / End If

The **Insert | Flow Control Command | Control Pairs | If / End If** menu option allows you to add a conditional block to the measurement routine. The items between the IF and the END IF commands will only execute if the expression for the IF command evaluates to true (nonzero). Otherwise, flow of execution will jump to the first command after the `END/IF` command.

The Edit window command line for an IF / END IF statement reads:

```
IF/expression

END_IF/
```

To insert the If / End If commands, follow these steps:

1. Place the cursor in the desired location of the Edit window.
2. Select **If / End If** from the menu bar. The IF / END IF statement will appear in the Edit window.

Code Sample of If / End If

Consider the following example that asks the user if he or she would like to measure a point feature.

```
C1= COMMENT/YESNO,Would you like to measure the point
feature, PNT1?
IF/C1.INPUT=="YES"
   PNT1=FEAT/POINT,RECT
   …
   …
   ENDMEAS/
END_IF/
```

Explanation of Sample Code

C1=COMMENT/YESNO

This line takes and stores the YES or NO response from the user.

IF/C1.INPUT=="YES"

This line is the expression. It tests to see if the input of comment 1 is a YES. If it's a YES then the IF statement is TRUE and continues executing the statements after the IF statement, in this case it measures the `PNT1` feature. If NO it moves to the END_IF statement.

END_IF

This line ends the execution of commands inside the IF / END IF block of code. Any command following this line is where PC-DMIS will go to if the user clicks **No** at the comment.

Else If / End Else If

The **Insert | Flow Control Command | Control Pairs | Else If / End Else If** menu option allows you to add a conditional block to the measurement routine. The items between the ELSE IF and the END ELSE IF commands will only execute if the expression for the ELSE IF command evaluates to true (nonzero). The ELSE IF / END ELSE IF block must be positioned directly *after* an IF / END IF block or another ELSE IF / END ELSE IF block. If all IF / ELSE IF expressions above the current block have evaluated to false, then the expression will be evaluated. If the expression evaluates to false (zero), then execution will jump to the next command following the END ELSE IF command. If any of the IF / ELSE if expressions above the current block evaluate to true, all subsequent ELSE IF / END ELSE IF blocks in this sequence will be skipped.

The Edit window command line for a ELSE IF / END ELSE IF statement reads:

```
ELSE_IF/expression

END_ELSE_IF/
```

To insert the ELSE IF / END ELSE IF commands:

1. Place the cursor in the desired location of the Edit window, after an existing IF/END IF statement or ELSE IF/END ELSE IF statement.
2. Select **Else If / End Else If** from the menu bar. The ELSE IF / END ELSE IF statement will appear in the Edit window.

This type of block is only valid when positioned *after* an IF / END IF or ELSE IF / END ELSE IF block. Invalidly positioned control pairs are shown in red text in the Edit window.

Code Sample of Else If / End Else If

Consider the following example that displays a message notifying the user when any one of the X, Y, or Z values for a measured point exceeds defined tolerances:

```
PNT2=FEAT/POINT,RECT
…
…
ENDMEAS/
IF/PNT2.X<6.9 OR PNT2.X>7.1
   COMMENT/OPER,"The measured X value of PNT2: " + PNT2.X +
" is out of tolerance."
END_IF/
ELSE_IF/PNT2.Y<3.3 OR PNT2.Y>3.5
   COMMENT/OPER,"The measured Y value for PNT2: " + PNT2.Y +
" is out of tolerance."
END_ELSEIF/
ELSE_IF/PNT2.Z<.9 OR PNT2.Z>1.1
   COMMENT/OPER,"The measured Z value for PNT2: " + PNT2.Z +
" is out of tolerance."
END_ELSEIF/
```

Explanation of Sample Code

This code first tests the X value of the point. If the condition evaluates to false, then the code tests for the Y value. If the condition for the Y value evaluates to false, then it tests for the Z value.

If any of these conditions evaluates to true, PC-DMIS displays the comment associated with it and skips the remaining conditional statements.

```
IF/PNT2.X<6.9 or="" pnt2.x="">7.1
```

This line is the expression. It tests to see if the measured X value is less than 6.9 or greater than 7.1. If it exceeds either of these boundaries it executes the first comment.

```
END_IF
```

This line ends the execution of commands inside the IF / END IF block of code. Any command following this line is where PC-DMIS will go to if the IF THEN condition evaluates to false.

```
ELSE_IF/PNT2.Y<3.3 or="" pnt="" 2.y="">3.5
```

This line is the expression for the first ELSE_IF command. It only gets executed if the IF / END IF block above it returns false. It tests to see if the measured Y value is less than 3.3 or greater than 3.5. If it exceeds either of these boundaries it executes the second comment.

```
END_ELSEIF/
```

This line ends the execution of commands inside the first ELSE IF / END ELSE IF block of code.

```
ELSE_IF/PNT2.Z<.9 or="" pnt2.z="">1.1
```

This line is the expression for the second ELSE IF command. It only gets executed if the ELSE IF / END ELSE IF block above it returns false. It tests to see if the measured Z value is less than .9 or greater than 1.1. If it exceeds either of these boundaries it executes the third comment.

```
END_ELSEIF/
```

This line ends the execution of commands inside the second ELSE IF / END ELSE IF block of code.

Else / End Else

The **Insert | Flow Control Command | Control Pairs | Else / End Else** menu option allows you to add a conditional block to the measurement routine. The items between the ELSE and the END ELSE commands will execute only if all other if / end if and else if / end else if blocks above the else block have failed (All evaluated to zero). ELSE / END ELSE blocks must be located at the end of a set of IF / END IF or ELSE IF / END ELSE IF blocks in order to be valid.

The Edit window command line for a ELSE / END ELSE statement reads:

```
ELSE/

END_ELSE/
```

To insert Else / End Else commands:

1. Place the cursor in the desired location of the *Edit window*. Note that Else / END ELSE blocks must be positioned after an IF / END IF or ELSE IF / END ELSE IF blocks.
2. Select **Else / End Else** from the menu bar. The ELSE / END ELSE statement will appear in the Edit window.

Code Sample of Else / End Else

Consider the following example that asks the user if he or she would like to measure a point feature.

```
C1= COMMENT/YESNO,Would you like to measure the point
feature, PNT1? Clicking No measures the next feature.
IF/C1.INPUT=="YES"
   PNT1=FEAT/POINT,RECT
   …
   …
   ENDMEAS/
END_IF/
ELSE
   PNT2=FEAT/POINT,RECT
   …
   …
   ENDMEAS/
END_ELSE
```

Explanation of Sample Code

C1=COMMENT/YESNO

This line takes and stores the YES or NO response from the user.

IF/C1.INPUT=="YES"

This line is the expression. It tests to see if the input of comment 1 is a YES. If it's a YES then the IF statement is TRUE and continues executing the statements after the IF statement, in this case it measures the `PNT1` feature. If NO it moves to the END_IF statement.

END_IF

This line ends the execution of commands inside the IF / END IF block of code. Any command following this line is where PC-DMIS will go to if the user clicks **No** at the comment.

ELSE

If the above IF / END IF block evaluates to false then command lines falling after this line and before the END_ELSE line will be executed. In this case, PNT2 gets executed.

END_ELSE

This line ends the execution of commands inside the ELSE / END_ELSE block of code.

While / End While

The **Insert | Flow Control Command | Control Pairs | While / End While** menu option allows you to add a conditional loop to the measurement routine. The items between the WHILE and the END WHILE command will continue to execute in a loop until the condition (or expression) keeping the loop activated is no longer met, meaning the expression for the while loop evaluates to FALSE (i.e. zero). The WHILE command can be added anywhere in the measurement routine. The expression is tested at the start of each loop.

The Edit window command line for a WHILE / END WHILE statement reads:

```
WHILE/expression

END_WHILE/
```

To insert a While / End While option, follow these steps:

1. Place the cursor in the desired location of the Edit window.
2. Select **While / End While** from the menu bar. The WHILE / END WHILE statement appears in the Edit window.

Code Sample of While / End While

Consider the following example that measures a feature an amount specified by the measurement routine user.

```
C1=COMMENT/INPUT,How many times would you like to measure
PNT1? Please type an integer only.
ASSIGN/COUNT=0
WHILE/COUNT<C1.INPUT
   PNT2=FEAT/POINT,RECT
   …
   …
   …
   ENDMEAS/
   ASSIGN/COUNT=COUNT+1
   COMMENT/OPER,"Measured "+COUNT+" out of "+C1.INPUT+"
times."
END_WHILE/
```

Explanation of Sample Code

C1=COMMENT/INPUT

This line takes and stores the integer input from the user into the variable `C1.INPUT` .

`ASSIGN/COUNT=0`
This line initializes `COUNT` , a user-defined variable, and gives it an initial value of 0. The code uses this variable to count the number of times PC-DMIS measures the feature inside the loop.

`WHILE/COUNT<C1.INPUT`
This line is the expression. It tests to if the value of `COUNT` (initially set to 0) is less than the integer selected by the user. If this tests true, then the statements in following `WHILE/` and before `END_WHILE/` are executed

`ASSIGN/COUNT=COUNT+1`
This line increments the `COUNT` variable by one so that it eventually exits the loop when it fails the condition test.

`COMMENT/OPER,"Measured "+COUNT+" out of "+C1.INPUT+" times."`
This line displays a message showing the number of times, out of the total, that the loop is running.

`END_WHILE`
This line ends the execution of commands inside the `WHILE / END WHILE` block as long as the condition is false. Otherwise, when PC-DMIS encounters this command it loops back to the `WHILE` statement.

Do / Until

The **Insert | Flow Control Command | Control Pairs | Do / Until** menu option allows you to add a conditional loop to the measurement routine. The items between the DO and the UNTIL commands will continue to execute in a loop until the expression of the UNTIL command evaluates to TRUE (nonzero). The DO/ UNTIL commands can be added anywhere in the measurement routine. The expression is tested at the end of each loop.

The Edit window command line for a DO / UNTIL statement reads:

```
DO/

UNTIL/ expression
```

To insert DO / UNTIL commands:

1. Place the cursor in the desired location of the Edit window.
2. Select **Do / Until** from the menu bar. The DO / UNTIL statements will appear in the Edit window.

Code Sample of Do / Until

Consider the following example that measures a feature an amount specified by the measurement routine user. This is similar to the example given under the While / End While topic, except that PC-DMIS tests for the condition at the end of the loop instead of at the beginning.

```
C1=    COMMENT/INPUT,Type the number of times PC-DMIS should
measure the PNT1 feature:(type an integer only)
ASSIGN/COUNT=0 DO/
   PNT1=FEAT/POINT,RECT
   …
   …
   ENDMEAS/
   ASSIGN/COUNT=COUNT+1
   COMMENT/OPER,"Measured "+COUNT+" out of "+C1.INPUT+"
times."
UNTIL/COUNT==C1.INPUT
```

Explanation of Sample Code

C1=COMMENT/INPUT

This line takes and stores the integer input from the user into the variable `C1.INPUT` .

ASSIGN/COUNT=0

This line initializes `COUNT` , a user-defined variable, and gives it an initial value of 0. The code uses this variable to count the number of times PC-DMIS measures the feature inside the loop.

DO/

Begins the `DO / UNTIL` loop. All statements are executed at least once and measurement routine flow exits out of the loop once the expression evaluates to false.

ASSIGN/COUNT=COUNT + 1

This line increments the `COUNT` variable by one so that it eventually exits the loop when it fails the condition test.

COMMENT/OPER,"Measured " + COUNT + " out of " + C1.INPUT + " times."

This line displays a message showing the number of times, out of the total, that the loop is running.

UNTIL/COUNT == C1.INPUT

This line ends the execution of commands inside the `DO / UNTIL` loop as long as the condition evaluates to false. Otherwise, when PC-DMIS encounters this command it loops back to the `DO` statement.

Select / End Select

The **Insert | Flow Control Command | Control Pairs | Select / End Select** menu option allow for the addition of a conditional block that is used in conjunction with the CASE / END CASE and Default Case / End Default Case pairs. The expression for the Select command provides data that is compared against the expression in the Case statements. If the two expressions evaluate to the same thing, then the statements within the Case / End Case Block will execute. The SELECT / END SELECT block surrounds the sets of CASE / END CASE and DEFAULT CASE / END DEFAULT CASE blocks.

The Edit window command line for a SELECT / END SELECT statement reads:

```
SELECT/expression

END_SELECT/
```

To insert the Select / End Select commands:

1. Place the cursor in the desired location of the Edit window.
2. Choose **Select / End Select** from the menu bar. The SELECT / END SELECT statements will appear in the Edit window.

Code Sample of Select / End Select

The pairs, `SELECT / END_SELECT`, `CASE / END_CASE`, `DEFAULT CASE / END_DEFAULT CASE`, all work together to evaluate multiple conditions providing a wide range of alternatives.

Suppose you have five circles, labeled CIR1 through CIR5, and you want the operator to be able to measure a circle by simply pressing a key on the keyboard. You could use code similar to the following:

Entire Code

```
DO/
   C1=COMMENT/INPUT,Type a number to measure that circle:
   ,FOR CIR1 - Type 1
   ,FOR CIR2 - Type 2
   ,FOR CIR3 - Type 3
   ,FOR CIR4 - Type 4
   ,FOR CIR5 - Type 5
   ,Any other character exits the loop
   SELECT/C1.INPUT
      CASE/1
         CIR1=FEAT/CIRCLE
         …
         …
         ENDMEAS/
      END_CASE
      CASE/2
         CIR2=FEAT/CIRCLE
         …
         …
         ENDMEAS/
      END_CASE
      CASE/3
         CIR3=FEAT/CIRCLE
         …
         …
         ENDMEAS/
      END_CASE
      CASE/4
         CIR4=FEAT/CIRCLE
         …
         …
         ENDMEAS/
      END_CASE
      CASE/5
         CIR5=FEAT/CIRCLE
         …
         …
         ENDMEAS/
      END_CASE
      DEFAULT CASE
         COMMENT/OPER,Now exiting loop.
      END_DEFAULT CASE
   END_SELECT
UNTIL C1.INPUT < 1 OR C1.INPUT > 5
```

Explanation of Sample Code

SELECT/C1.INPUT

This line of code takes a number or string value (in this case a number) typed by the user and determines which `CASE/END_CASE` block will execute from the input. Notice that `SELECT/END_SELECT` pair surrounds the entire list of code. All `CASE/END_CASE` and `DEFAULT CASE/END_DEFAULT CASE` pairs must reside within these two lines.

`END_SELECT`

This marks the end of the code held inside the `SELECT/END SELECT` pair.

`CASE/1 through CASE/5`

Depending on the value of `C1.INPUT`, one of the CASE code blocks executes. For example, if `C1.INPUT` evaluates to 1, the CASE 1 block of code executes, measuring CIR1. If it evaluates to 2, then the CASE 2 block of code executes, measuring CIR2, and so forth.

`END_CASE`

These lines end the specific case blocks of code.

`DEFAULT CASE`

If the value of the `C1.INPUT` doesn't match any of the defined CASE statements (if the value isn't a number one through five) then the `DEFAULT CASE` code block executes. In this case it displays a message letting you know that you are exiting the loop.

Notice how the `DO / UNTIL` loop surrounds the entire code sample. This allows the user to continue to choose from the menu created from the `COMMENT/INPUT` line until the user selects a character not recognized by the CASE statements.

Case / End Case

The **Insert | Flow Control Command | Control Pairs | Case / End Case** menu option allows you to add a conditional block to the measurement routine. The items between the CASE and the END CASE commands will execute if the expression for the case statement evaluates to a value equal to the expression of the corresponding SELECT command. Otherwise, the block of statements will be skipped. The CASE / END CASE statement block must be located directly after a SELECT command or an END CASE command of a previous CASE / END CASE block. Also, PC-DMIS cannot compare multiple expressions on a single case statement.

The Edit window command line for a CASE / END CASE statement reads:

```
CASE/expression

END_CASE/
```

To insert the Case / End Case option:

1. Place the cursor in the desired location of the Edit window. Note the positional requirements stated above.

2. Select **Case / End Case** from the menu bar. The CASE / End CASE statements will appear in the Edit window.

Default Case / End Default Case

The Insert | Flow Control Command | Control Pairs | Default Case / End Default Case menu option allows you to add a conditional block to the measurement routine. The items between the DEFAULT CASE and the END DEFAULT CASE commands will execute if all other expressions in previous CASE / END CASE blocks within the corresponding SELECT / END SELECT block evaluated to false. Only one DEFAULT CASE / END DEFAULT CASE block is allowed within a SELECT/ END SELECT block. The DEFAULT CASE / END DEFAULT CASE block must be located after all CASE / END CASE blocks within the SELECT / END SELECT block.

The Edit window command line for a DEFAULT CASE / END DEFAULT CASE statement reads:

```
DEFAULT CASE/

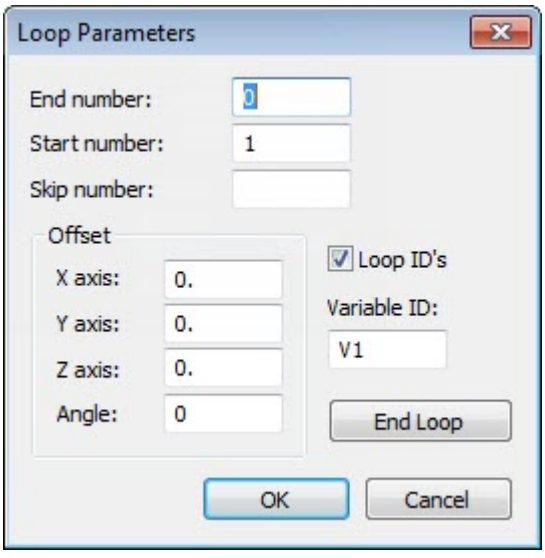
END_DEFAULT_CASE/
```

To insert DEFAULT CASE/ END DEFAULT CASE commands:

1. Place the cursor in the desired location of the Edit window noting positional limitations as stated above.

2. Select **Default Case / End Default Case** from the menu bar. The DEFAULT CASE / END DEFAULT CASE statements will appear in the Edit window.

Using Generic Loops



Loop Parameters Dialog Box

The **Insert | Flow Control Command | Looping** menu option displays the **Loop Parameters** dialog box. You can use this dialog box to create a `LOOP` command that repeats the measurement routine (or portions of the measurement routine) with or without any of the offsets. The `LOOP` command can be added anywhere in the measurement routine, although this function is most useful at the beginning and end of the measurement routine.

Start Number - This box tells PC-DMIS the starting position number in a series of parts.

Suppose you have 10 parts, and you want to start with position number 5. You would enter 10 for the total number of parts and 5 for the starting position.

End Number - This box tells PC-DMIS how many times to loop through the measurement routine. This number is usually the same as the number of parts that the fixture holds (or patterns on the part) in the X, Y, or Z direction. PC-DMIS also asks for the starting part (pattern) number.

Suppose you have 10 parts in the X direction, and you want to start with position number 5. For the **End Number** box, type 10. For the **Start Number** box, type 5.

Skip Number - In a loop, PC-DMIS repeats a measurement routine the indicated number of times. The **Skip Number** box allows you to skip a specified increment. Note that you cannot *skip* the *first* increment using this box, but you can change the **Start Number** to 2 and effectively skip over it that way.

Suppose you want to set the parameter to skip every third increment of the loop. If the number three is indicated, PC-DMIS measures the first and second part and then skips to the fourth part.

Offset - The offset area contains these boxes:

X Axis, Y Axis, Z Axis - These boxes define the X, Y, and Z offset distances between parts, or patterns on the same part. These values offset the part by the defined offset distances once the loop executes.

Angle - This box sets up the angular offset between parts, or patterns on the same part. The first offset is based on the part's origin. PC-DMIS offsets the part by the angle value once the execution loops.

The software bases the offset distances on the part's origin. The first time through the loop, PC-DMIS uses the part's origin. The second time through the loop, it moves

by the offset distances. The third time through the loop, it moves by the offset distances multiplied by two, and so on.

If you have an alignment command inside a loop, and the loop uses offsets, you *must* define all axes for that alignment. Additionally, the alignment inside the loop must use features measured inside the loop.

Loop IDs - This check box determines whether PC-DMIS displays the current loop value in square brackets in the feature ID.

Suppose you have a circle feature of CIR1. It becomes CIR1[1] on the first time through the loop, CIR1[2] on the second time through the loop, and so on.

Feature IDs in Statistical Databases

If you select the **Loop IDs** check box and send statistical data to a database, in some cases, PC-DMIS may not display these loop IDs in the database.

Consider the following:

If you have a `STATS/ON` command and a `STATS/UPDATE` command *inside a loop block*, then loop IDs are not displayed inside the database.

If you have a `STATS/ON` command *outside a loop block* and a `STATS/UPDATE` command *inside a loop block*, then loop IDs are not displayed inside the database.

If you have a `STATS/ON` command *outside a loop block* and a `STATS/UPDATE` command *outside a loop block*, then loop IDs are displayed inside the database.

If you have a `STATS/ON` command *inside a loop block* and a `STATS/UPDATE` command *outside a loop block*, then loop IDs are displayed inside the database.

Variable ID - This box allows you to define the variable name used to track the loop's current iteration (or current loop within the number of specified loops). During the measurement routine's execution, this variable is equal to the current iteration number of the loop.

End Loop - This button completes the looping process. You must follow the command `LOOP/START` with the command `LOOP/END` in the Edit window.

Uses for Looping

There are three main uses for the looping functionality:

- You have a multiple part fixture that holds a grid of parts. The fixture should use consistent spacing between the rows. The translation / rotation offsets allow you to index from one part to the next in the grid of parts.
- You have a fixture that holds one part and you want to swap in a new part before each loop of the measurement routine. A `COMMENT` command is helpful to stop the CMM when the part is being replaced with a new one. The command can be at the beginning or end of the loop.
- You want to use the loop functionality to rotate the measurement routine to measure a different portion of the same part. For example, you could create a measurement routine to measure a complicated hole pattern that was duplicated ten times on the part. Your measurement routine would only need to measure one of the hole patterns. You could then use the loop functionality to offset the measurement routine to measure the other nine occurrences of the pattern.

If you're using an alignment inside of a loop, PC-DMIS allows you to use the active alignment in the `ALIGNMENT/START` command line instead of always recalling a previously stored alignment. See the "Using an Alignment Inside Loops" topic in the "Creating and Using Alignments" chapter.

Creating a Loop

1. Select **Insert | Flow Control Command | Looping** from the menu bar to display the **Looping Parameters** dialog box.
2. Define the values in the dialog box.
3. Select parameters as needed (such as **Number of Parts**, **Start Number**, **Skip Number**, **Offsets Angle**).
4. Place the cursor in a location in the Edit window where you want to begin the loop.
5. Click the **OK** button to insert the `LOOP/START` command block.

   The Edit window command line for looping reads:

```
VARNAME = LOOP/START, ID = Y/N, NUMBER = 0, START
          = 1, SKIP = , OFFSET: XAXIS = 0, YAXIS = 0,
ZAXIS = 0, ANGLE = 0
```

To complete the looping procedure, you must finish the loop with a `LOOP/END` command. PC-DMIS loops any Edit window commands encompassed by the `LOOP/START` and `LOOP/END` commands.

You can insert the `LOOP/END` command in one of these ways:

- In the Edit window, type `LOOP/END.`
- Select the **Insert | Flow Control Command | End Loop** menu item.
- From the **Looping Parameters** dialog box, click the **End Loop** button.

Using the Print Command in a Loop

To use the `PRINT` command in a loop in PC-DMIS, do this:

1. Insert the `LOOP/START` and `LOOP/END` commands in your measurement routine.
2. Insert the `PRINT` command between the loop commands where you want it.
3. In the Edit window, click on the `PRINT` command. Then press the F9 key to show the **Output Configuration** dialog box for that `PRINT` command. For details on how to set the output and printer options for the Report window, see "Setting Output and Printer Options for the Report Window" topic in the "Using Basic File Options" chapter.
4. Select one of the output format tabs (**Report**, **DMIS**, or **Excel**) to define the format for your `PRINT` command.
5. Select the check box in the upper left of the tab page to enable the options for the output.
6. Define where to send the generated report:
    a. Click the browse (...) button to the right of the path and file name box to display the **Save As** dialog box.
    b. On the **Save As** dialog box, define the file name and click **Save**.
7. Make any other changes that you need. For example, if you want to view each report after PC-DMIS generates them, select the **Show Report** check box.
8. If you want to generate outputs in multiple formats, press the next tab and repeat steps 4 through 7.
9. Click the **OK** button to save your changes to the `PRINT` command.

The `PRINT` command works almost the same inside of loops as it does outside of loops. The difference is that internally, PC-DMIS keeps track of what was output, and only outputs data that was executed after executing the last `PRINT` command.

For example, consider the code snippet below. When PC-DMIS executes the `PRINT` command for the first time, the software creates the first output file with *all* the collected data up to that point. This means the first output file includes data collected before the `LOOP/START` command as well. The next time the `PRINT` command executes, PC-DMIS only executes the contents within the loop. This means the second data file only contains the data from within the loop. This repeats until the measurement routine ends.

```
.
.
.
 Loop Start
      CIR1 = CIRCLE (CONTACT)
      CIR2 = CIRCLE (CONTACT)
      Move Point
      Move Point
      Move Point
      Move Point
      CIR3 = CIRCLE (CONTACT)
      Move Point
      Move Point
      Move Point
      CIR4 = CIRCLE (CONTACT)
      CIR5 = CIRCLE (CONTACT)
      CIR6 = CIRCLE (CONTACT)
      CIR7 = CIRCLE (CONTACT)
      CIR8 = CIRCLE (CONTACT)
      LOC1 Passed: CIR1
      Print Report
 Loop End
.
```

```
.
.
```

Using Labels

You can use a `LABEL` command with a `GOTO` or an `IF GOTO` command to control where the execution flow gets sent based on certain conditions. The label name cannot have spaces and must not exceed 230 characters. PC-DMIS displays the label name using all capital letters.

To create a `LABEL` command, do one of the following:

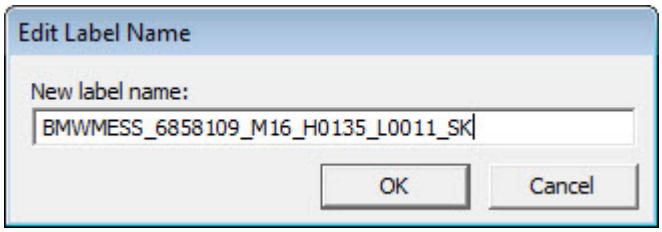
Type the Command

1. Position the cursor on a blank line in the Edit window.
2. Type LABEL and then press the Tab key.
3. In the highlighted field, type a new label name.

or

Choose the Command

1. Position the cursor in the Edit window.
2. From the menu bar, select **Insert | Flow Control Command | Label** to access the **Edit Label Name** dialog box.
3. In the **New label name** box, type the name for the label.



Edit Label Name Dialog Box

4. Click **OK** to insert the label name in the next possible location in the Edit window.

The LABEL command in the Edit window's Command Mode reads:
`ID = LABEL/`

Where ID represents the specified label name.

For information on using the `GOTO` command with labels, see the "Jumping to a Label Using GOTO" topic.

For information on using the `IF_GOTO` command with labels, see the "Jumping to a Label Based on Conditions" topic.

Jumping to a Label Using GOTO

You can tell your measurement routine to jump to a specific label by creating a GOTO command.

To create a GOTO command, do one of the following:

Type the Command

1. Position the cursor on a blank line in the Edit window.
2. Type GOTO and then press the Tab key.
3. Type the label name to jump to.

or

Choose the Command

1. Position the cursor in the Edit window.
2. Select the menu option **Insert | Flow Control Command | Goto** to open the **GoTo** dialog box.

GoTo Dialog Box

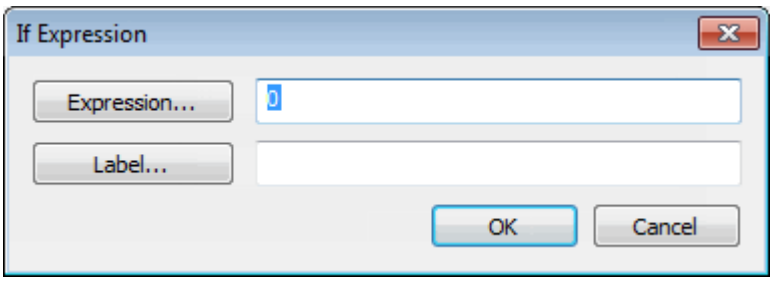
3. If labels already exist in the measurement routine, they appear in the **Current labels** box.
4. From the **Current labels** box, select the desired label, or in the **GoTo Label** box, type a label name.
5. Click **OK** to insert the GOTO command in the next possible location in the Edit window.

The GOTO command in the Edit window's Command Mode reads:
```
GOTO/label_ID
```

Where label_ID represents the name of the specified label. The label name cannot have spaces and must not exceed 230 characters.

If the label has not yet been created, the label name appears highlighted in red in the Edit window's Command Mode and that GOTO command is ignored during execution.

Jumping to a Label Based on Conditions



If Expression Dialog Box

With the **Insert | Flow Control Command | If Goto** option, you can use the **If Expression** dialog box to create IF GOTO statements within your measurement routine. When the measurement routine is executed and PC-DMIS encounters an IF GOTO statement, the routine flow moves to the label identification if the specified expression evaluates to a non-zero value.

The Edit window command line for an IF_GOTO statement reads:

```
IF_GOTO/expression, GOTO=Label
```

Expression - If you click **Expression**, the expression builder opens. With the expression builder, you can create a variety of different expressions that you may need within your measurement routine. Once you create the expression it appears in the **Expression** box. For information on creating expressions, see the "Using Expressions and Variables" chapter.

Label - If you click **Label**, the **Goto** dialog box opens. From the **Goto** dialog box, you can choose what label you want the routine flow to move to when the defined expression is met. The chosen label appears in the **Label** box. Or if you know the label name, you can type it in the box. For more information on labels, see "Jumping to a Label".

Reset Loop

The Reset Loop command resets the execution tree in a loop. You can add the Reset Loop command to support multiple part measurements using these command pairs:

- While/End While
- Do/Until
- Loop/End Loop

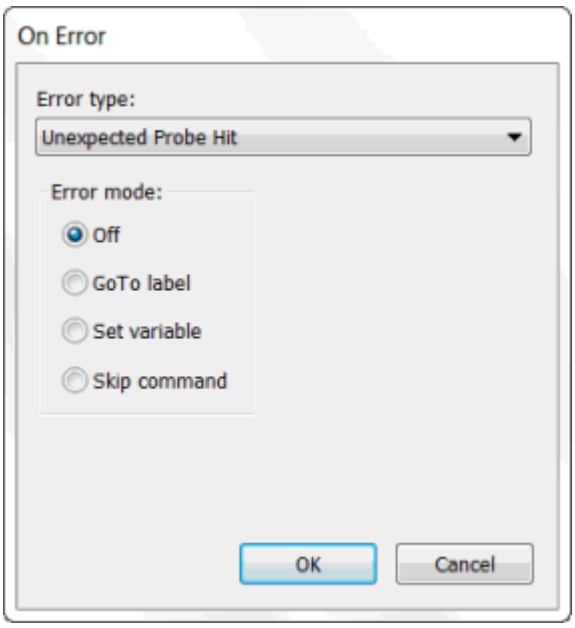
You must use the Reset Loop command within one of these loops. The command has no effect if you place it outside a loop. To insert a Reset Loop command, select **Insert | Flow Control Command | Reset Loop** menu option. The Edit window command line for a Reset Loop command would read: `RESET LOOP/`

For multiple part measurements, you can get a report of the last part measured in the loop. To do this, insert the Reset Loop command at the start of the loop as shown in this image:

The reset loop removes all the objects from the execution tree.

Branching on an Error

The **Insert | Flow Control Command | On Error** option opens the **On Error** dialog box:



On Error Dialog Box

You can use this dialog box to tell PC-DMIS the action to take when a machine error occurs.

Error type - PC-DMIS tracks these error conditions:

- Unexpected probe hit
- Missed probe hit
- Reflector not found - This is used with the Tracker in PC-DMIS Portable.
- Laser error - If you are using a laser configuration, see the "Handling Laser Sensor Errors with On Error Command" topic in the PC-DMIS Laser documentation.
- Temperature Outside Limits - The Temperature Compensation command in the measurement routine raises this error if one or more of the temperatures for the X axis, Y axis, or Z axis scale or part are above the maximum limit or below the minimum limit that is defined for the Temperature Compensation command.

  The On Error command must be placed above the Temperature Compensation command in the measurement routine.

- Calibration Outside Limits - The Check Calibration Limits command in the measurement routine raises this error if one or more calibration error checks are outside the limits. For more information on the Check Calibration Limits command, see "About Check Calibration Limits" in the PC-DMIS Toolkit Modules documentation.

The On Error command must be placed above the Check Calibration Limits command in the measurement routine.

Error mode - PC-DMIS can take these possible actions depending on the error type:

- **Off** - PC-DMIS does nothing.
- **GoTo label** - The measurement routine flow moves to a defined label (see "Using Labels"). These options become available:
  - **Label ID** - Type a reference to a label that doesn't exist yet.
  - **Current labels** - Lists all the labels in the measurement routine.
- **Set variable** - Sets a variable's value to one.
- **Skip command** - The measurement routine flow skips over the current command and moves to the next marked command in the measurement routine.

For details on how PC-DMIS reports dimensions that use skipped features during execution, see the "Reporting a Dimension Using a Feature Skipped During Execution" topic in this documentation.

By default, all measurement routines start with the action for both types of errors set to **Off** (PC-DMIS does nothing). The action mode for each error type can be changed throughout the measurement routine.

During execution, if PC-DMIS encounters an `ONERROR/UNEXPECTED HIT/JUMPTOLABEL` command, any unexpected hits that occur after that point in the measurement routine cause the execution to jump to the specified label. The action to "set a variable's value to one" causes the variable to be set as soon as the specified error type occurs. This value of the variable can then be tested using an IF statement to cause execution to jump to a new point in the measurement routine.

Using the On Error Command

1. Select **Insert | Flow Control Command | On Error** to open the **On Error** dialog box.
2. In the **Error type** list, select the error type as the condition for branching.
3. In the **Error mode** area, select the option that defines the action to take place when that condition is met.
4. To add the On Error command, click **OK**. To close the dialog box without applying any changes, click **Cancel**.

On Error Supported Interfaces

Some interfaces support the On Error command. To see if your interface supports the command, refer to the following table.

- If your interface is in the table, a small black box indicates the error type that the interface supports.
- If your interface is not in the table, then it's not able to use the On Error command.

Supported Interfaces	Unexpected Probe Hit	Missed Probe Hit	Reflector Not Found

Branching with Subroutines

Subroutines are blocks of code in your measurement routine or in an external measurement routine that are usually referenced repeatedly, allowing for more concise programming. PC-DMIS allows you to pass information to "arguments" (or local variables) in the subroutine. The types of arguments that can be passed into a subroutine are numeric values, variables, text strings, and feature names.

Subroutine command blocks are enclosed within SUBROUTINE and ENDSUB commands.

Once you have created a subroutine in your measurement routine you can "call" it from your current measurement routine or from another measurement routine, causing the measurement routine execution flow to go into the specified subroutine, executing commands contained within the subroutine command block. Measurement routine flow will then return to the statement immediately following the calling statement.

Subroutines are called by using the CALLSUB command.

External Subroutines

External subroutines, or subroutines located in a measurement routine outside of the calling measurement routine, do not have access to features, variables, or alignments from the calling measurement routine. The subroutine would still have access to items within its own measurement routine. The external measurement routine and the calling measurement routine must use the same units of measurement.

Nesting Subroutines

You can nest subroutines within other subroutines. The only limitation to the number of arguments and nested subroutines is the amount of available memory.

Creating a New Subroutine

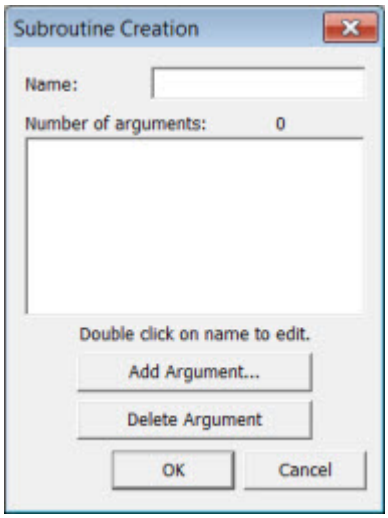
Creating a Subroutine by Typing SUBROUTINE

You can insert this command by typing SUBROUTINE in the Edit window's Command Mode, and then pressing TAB. Once the command is inserted, you will need to specify the subroutine's name and any arguments it has. See the subroutine syntax and example below for this information.

Type the ENDSUB command and press TAB to end the command block. Any Edit window commands placed within this command block will be considered part of the subroutine and will be executed when the subroutine is called.

Creating a Subroutine by Using the Subroutine Menu Item

1. Select **Insert | Flow Control Command | Subroutine** from the submenu. This displays the **Subroutine Creation** dialog box. For information on this dialog box, see the "Understanding the Subroutine Creation Dialog Box" topic.

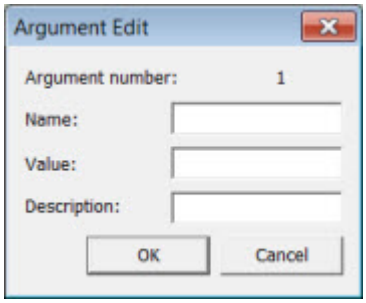


Subroutine Creation Dialog Box

2. Give the subroutine a name by typing it in the **Name** box. The name is limited to 180 or fewer characters. If you enter 181 or more characters a "Line too long" error message appears.

   When you click the **OK** button, the name is automatically shortened to the first 180 characters, and the **Subroutine Creation** dialog box closes.

3. If your subroutine uses arguments (place holders for information passed into the subroutine), add them one by one by clicking the **Add Argument** button. The **Argument Edit** dialog box appears. For information on this dialog box, see the "Understanding the Argument Edit Dialog Box" topic.



Argument Edit Dialog Box

4. Give your argument a name by typing it in the **Name** box.

5. Give your argument a default value by typing it in the **Value** box. The subroutine will use the default value if no values are passed into the subroutine from the `CALLSUB` statement. Valid argument values can be numeric values, variables, text strings, and feature names.

6. If you want to give the argument a description, type it in the **Description** box.

7. Click **OK** in the **Argument Edit** dialog box to create the argument.
8. Repeat steps 3 through 7 for each argument you want in your subroutine.
9. Click the **OK** button in the **Subroutine Creation** dialog box to finish creating your subroutine. This subroutine will appear inside the Edit window with any defined arguments.
10. End your subroutine by selecting the **Insert | Flow Control Command | End Sub** menu option. This places an `ENDSUB/` command in the Edit window, completing the subroutine's command block. Any other measurement routine commands you want in your subroutine must be added inside the subroutine's command block, before the `ENDSUB` command.

Syntax for a Subroutine Command Block

The Edit window command line syntax for a sample subroutine command block would read:

```
SUBROUTINE/<Name>,
<A1> = <Arg1> : <Description>,
<A2> = <Arg2> : <Description>,
=
<Commands>
ENDSUB/
```

SUBROUTINE/ is the command used to start the subroutine command block.

<Name>= The name of the subroutine. The name is limited to 256 or fewer characters. If you enter 257 or more characters, the name is automatically shortened to 256 characters.

<A1>= The first argument (or local variable) used in the subroutine. This variable generally cannot be accessed outside of the subroutine.

<A2>= Second argument used in the subroutine. This variable generally cannot be accessed outside of the subroutine. Additional arguments can be added as needed.

<Arg1> = The default value for the first argument.

<Arg2>= The default value for the second argument.

<Description> = The description for the argument.

<Commands> = Other Edit window commands can be inserted as needed after the arguments and before the ENDSUB command.

ENDSUB/ is the command used to end the subroutine command block.

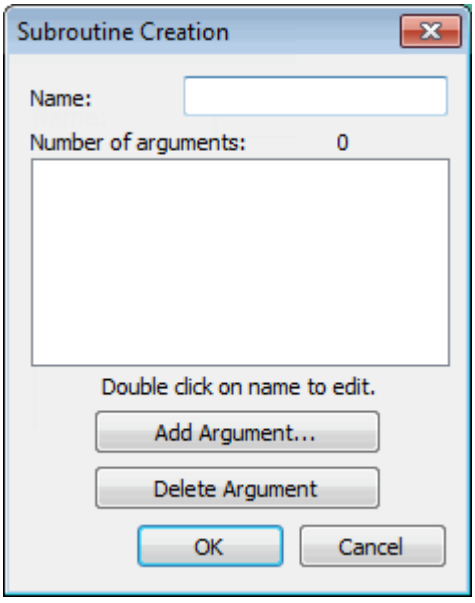
Example Subroutine Command Block

For example, a finished subroutine that takes operator data and displays it to the report might look like this:

```
SUBROUTINE/GET_OPERATOR_INFO,
    OPNAME = <Operator> : OPERATOR NAME,
    SHIFT = <Shift> : SHIFT TIME,
    =
   COMMENT/REPT,OPNAME
   COMMENT/REPT,SHIFT
ENDSUB/
```

Understanding the Subroutine Creation Dialog Box

To access the **Subroutine Creation** dialog box, select **Insert | Flow Control Command | Subroutine**.



Subroutine Creation Dialog Box

The following options are available in the **Subroutine Creation** dialog box:

Name - This box defines your subroutine. This is the name to use when you call the subroutine later. If you have multiple subroutines in a single measurement routine, each name must be unique.

> The name is limited to 180 or fewer characters. If you enter 181 or more characters in the **Name** box, a "Line too long error" message appears.
>
> When you click the **OK** button, the name is automatically shortened to the first 180 characters, and the **Subroutine Creation** dialog box closes.

Number of arguments - This list shows the arguments for the subroutine you are creating. Arguments appear in this area in this form:

```
<NAME> = <VALUE> : <DESCRIPTION>
```

For example, if one of your arguments is named "Diameter" with a default value of 3, your argument in this list may appear as:

```
DIAMETER = 3 : The hole's diameter
```

PC-DMIS uses the default value whenever another value is not passed from the `CALLSUB` command.

To edit an argument, double-click on the argument you want to change. The **Argument Edit** dialog box opens, allowing you to make the changes. See "Understanding the Argument Edit Dialog Box" for information on this dialog box.

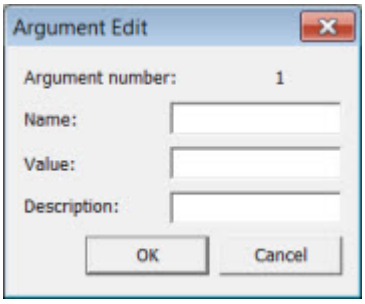
Add Argument - This button adds new arguments to your subroutine. Click on this button to open the **Argument Edit** dialog box appears. For information on this dialog box, see "Understanding the Argument Edit Dialog Box".

Delete Argument - This button allows you to delete arguments from your subroutine. Select the argument from the list and then click the **Delete Argument** button to remove it.

Editing an Existing Subroutine

To edit an existing subroutine you can always use the Edit window's Command Mode and edit the subroutine directly. Alternately, you can access the **Subroutine Creation** dialog box by placing your cursor on the subroutine in the Edit window and pressing F9. This brings up the **Subroutine Creation** dialog box. For information on this dialog box, see the "Understanding the Subroutine Creation Dialog Box" topic.

Understanding the Argument Edit Dialog Box



Argument Edit Dialog Box

The **Argument Edit** dialog box appears whenever you choose to create or edit an argument within either the **Subroutine Creation** dialog box (**Insert | Flow Control Command | Subroutine**) or the **Call Subroutine** (**Insert | Flow Control Command | Call Sub**) dialog box.

The **Argument Edit** dialog box can be used in these two contexts:

- To define a subroutine's arguments and their default values in a `SUBROUTINE` command block.
- To define the values that will be passed into the subroutine from a `CALLSUB` command.

The following options are available in the **Argument Edit** dialog box:

Name - This box defines the name for the argument you are creating or editing.

Value - This box defines the value of the argument.

If creating or editing the `SUBROUTINE` command, this is the default value used if no value is passed into the subroutine by the `CALLSUB` statement.

If creating or editing the `CALLSUB` command, this is the value passed into the subroutine.

Valid values can be:

- Numeric
- Variable
- Text String - Text strings must be enclosed in double quotation marks.
- Feature Name - The feature name must be bounded by curly brackets, for example {F1}.

Description - Defines the description of the argument for the subroutine. This description will appear next to the argument in the Edit window's `SUBROUTINE` command block.

Calling a Subroutine

To call a subroutine, you need to insert a `CALLSUB` command into your measurement routine to call an existing subroutine from the current measurement routine or a subroutine from an external measurement routine.

When a CALLSUB command executes, PC-DMIS executes all the commands in the subroutine. This includes even unmarked commands.

The called subroutine must have been created in a valid PC-DMIS version (versions 2021.1 through 2026.2).

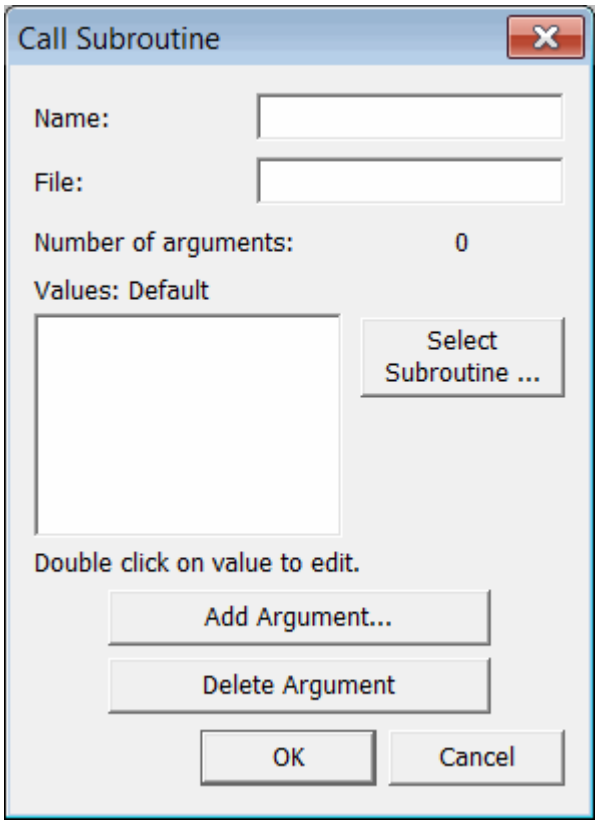
Calling a Subroutine by Typing CALLSUB

You can insert this command by typing CALLSUB in the Edit window and then pressing the Tab key on your keyboard where you want the command to appear in the Edit window.

Once the command is inserted, you will need to specify the subroutine's name, its location if it is in an external measurement routine, as well as any values to pass to available arguments. See "Passing Arguments into a Subroutine" for examples of passing arguments.

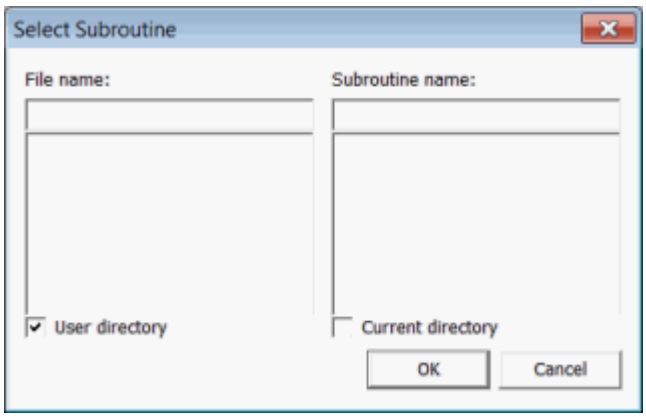
Calling a Subroutine Using the Call Sub Menu Item

1. Select the **Insert | Flow Control Command | Call Sub** option from the submenu. The Call Subroutine dialog box opens. See "Understanding the Call Subroutine Dialog Box" for information on this dialog box.



Call Subroutine Dialog Box

2. Click the **Select Subroutine** button. The Select Subroutine dialog box opens.



Select Subroutine Dialog Box

3. Select either the **User directory** check box or the **Current directory** check box, or both. If the measurement routine the subroutine is from resides in the directory specified to be searched for subroutines, select the **User directory** check box. If it is from the current directory, select the **Current directory** check box. PC-DMIS lists all the measurement routines available for selection.

4. Select the measurement routine that contains the subroutine you want. You will see all subroutines associated with the selected measurement routine appear in the **Subroutine name** box.

5. Select the subroutine you want to call.

6. Click the **OK** button. The subroutine information you are going to call will appear in the **Name** and **File** boxes of the **Call Subroutine** dialog box.

7. If you want to pass information into the subroutine, click the **Add Argument** button, and use the **Argument Edit** dialog box to define arguments and values to pass. See "Understanding the Argument Edit Dialog Box" for information on this dialog box. See "Passing Arguments into a Subroutine" for examples of passing arguments.

8. Click the **OK** button again. PC-DMIS adds the `CALLSUB` command in the selected location of the Edit window.

Syntax for the CALLSUB Command

The Edit window command line syntax for calling a subroutine is this:

```
CS1         =CALLSUB/<Name>, <File>:<Arg1>,<Arg2>,
```

CS1 = the label ID given to the `CALLSUB` command.

<Name> = the name of the subroutine to be called.

<File> = the full path way to the measurement routine that contains the subroutine to call. If this field is blank, PC-DMIS looks in the current measurement routine for the subroutine.

<Arg1> = the value to be passed to the first argument in the subroutine. If this field is blank, PC-DMIS uses the default value defined for the first argument in the subroutine instead.

<Arg2> = the value to be passed to the second argument in the subroutine. If this field is blank, PC-DMIS uses the default value defined for the second argument in the subroutine instead. This syntax sample shows only two arguments. You can pass other arguments to your subroutine if needed.

In your `CALLSUB` command, you should keep a set of pointers to all of the objects made for the subroutine so that you can easily refer to them afterwards, using the subroutine's ID. For more information on pointers, see "Pointers" in the "Using Expressions and Variables" chapter.

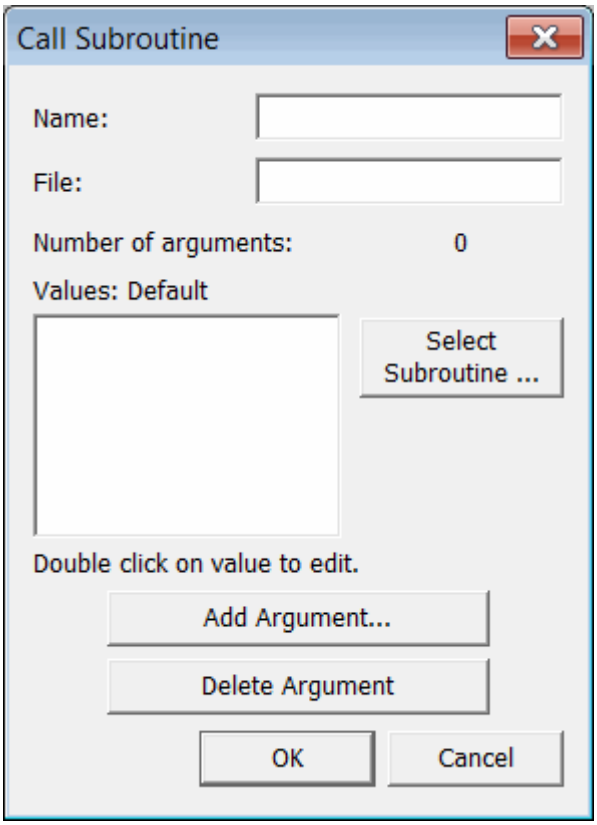
Example CALLSUB Command

```
CS1         =CALLSUB/GET_OPERATOR_INFO,D:
\MEASROUTINES\V42SUBROUTINETEST.PRG:V1,V2,,
```

This example `CALLSUB` command, CS1, calls a subroutine named GET_OPERATOR_INFO located within the measurement routine V42SUBROUTINETEXT.PRG located in the D:\MEASROUTINES\ directory.

It passes two values - in this case the variables V1 and V2 - into the subroutine.

Understanding the Call Subroutine Dialog Box



Call Subroutine Dialog Box

The following describes the options available in the **Call Subroutine** dialog box.

Name box

The **Name** box contains the name of the subroutine you have selected after using the **Select Subroutine...** button.

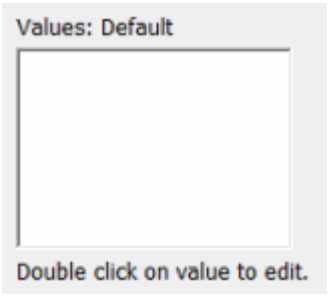
The name is limited to 180 or fewer characters. If you enter 181 or more characters in the **Name** box, a "Line too long error" message appears.

When you click the **OK** button, the name is automatically shortened to the first 180 characters, and the **Call Subroutine** dialog box closes.

File box

The **File** box contains the directory pathway to the subroutine file you have called.

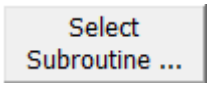
Values box



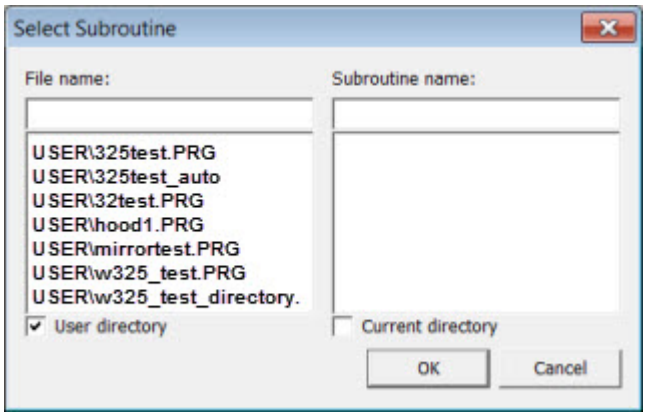
The **Values** box contains a list of the values of each argument associated with the subroutine. These values will get passed into the subroutine when the subroutine is executed.

To change these values, double-click on the value you want to change. The **Argument Edit** dialog box appears. See "Understanding the Argument Edit Dialog Box" for information on this dialog box.

Select Subroutine button



The **Select Subroutine** button displays the **Select Subroutine** dialog box



Select Subroutine Dialog Box

This dialog box allows you to call previously-created subroutines by searching in the user directory or the current directory. See "Calling a Subroutine" for information on the **Select Subroutine** dialog box.

Add Argument button

This button defines a value to pass to the arguments for the subroutine.

Delete Argument button

This button allows you to delete arguments from the **Values** box. Select the value displayed, and then click the **Delete Argument** button. The argument associated with that value is then deleted.

To add a new argument using the Call Subroutine Dialog box:

To add a new argument into your `CALLSUB` command to pass into the subroutine:

1. Inside the **Call Subroutine** dialog box, click the **Add Arg** button to open the **Argument Edit** dialog box.
2. Click in the **Value** box.
3. In the **Value** box, type the value for the argument.
4. Click **OK**.

To edit existing arguments using the Call Subroutine Dialog box:

To edit an existing argument inside your `CALLSUB` command:

1. In the **Call Subroutine** dialog box, double-click on the value of the argument you want to change. A value box appears and shows the default value for the called subroutine.
2. Type a new value.
3. Click the **OK** button.

For additional information on how to edit or create new arguments for a subroutine, see "Creating a New Subroutine" and "Editing an Existing Subroutine".

To delete arguments from a Call Subroutine command:

1. Place the cursor on the `CALLSUB` command.
2. Press F9 to access the **Call Subroutine** dialog box.
3. From the list of arguments, select one or more arguments.
4. Click the **Delete Arg** button.
5. Click **OK**.

You can also delete an argument in the Edit window text directly. To do this,

1. Place PC-DMIS in Command Mode.

2. Place the cursor on the `CALLSUB` command, and press TAB until you highlight the desired argument.
3. Type the letters "del" to delete the argument. Note that pressing Delete or Backspace doesn't truly delete the argument, they merely change the argument to an empty argument.

Using CALLSUB Statements in Multiple Arm Mode

If you assign a `CALLSUB` *statement to Arm1*; all of the commands in the subroutine are assigned to Arm1 when the subroutine is called.

If you assign a `CALLSUB` *statement to Arm2*; all of the commands in the subroutine are assigned to Arm2 when the subroutine is called.

If you mark a `CALLSUB` *statement for both arms*, PC-DMIS leaves the subroutine markings as they were originally set.

If a subroutine contains a `MOVE/SYNC` *command in it*, and you assign the `CALLSUB` statement to Arm1 or Arm2, at execution time PC-DMIS displays an error indicating that this is invalid and the subroutine is not called.

For information on assigning a command to execute for a specific arm, see the "Assigning a Command to an Arm" topic in the "Using Multiple Arm Mode" chapter.

Subroutine Examples

Consider the information in the following topics for some examples of passing arguments and subroutines in general.

- Passing Arguments into a Subroutine
- Code Sample of a Subroutine

Passing Arguments into a Subroutine

The types of arguments that you can pass into a subroutine are numeric values, variables, text strings, and feature names. To pass values into arguments, type the value within the **Value** box of the **Argument Edit** dialog box, or directly into an inserted `CALLSUB` command in Command Mode.

For details on how to do this, see "Creating a New Subroutine" and "Understanding the Argument Edit Dialog Box".

Passing Variables into a Subroutine

Arguments that can pass data back are variables. When you use a variable as an argument to a subroutine, any changes that occur to the corresponding variable in the subroutine are passed back and become the value of the variable that was passed in.

Example of Passing Variables:

This example shows how a variable's value, used as an argument to a subroutine, is modified and passed back from a subroutine:

```
            ASSIGN/V1=6
CS4        =CALLSUB/MYSUB,:V1,,
            SUBROUTINE/MYSUB,
                A1 = 0 : FIRST ARGUMENT,
                 =
            ASSIGN/A1=A1+1
            COMMENT/OPER,NO,FULL SCREEN=NO,AUTO-
CONTINUE=NO,OVC=NO,
            The value of A1 is:
            A1
            ENDSUB/
```

Code Explanation with Execution Flow

First, the V1 variable is assigned a value of 6.

The `CALLSUB` statement then calls the subroutine and passes the V1 variable as the first argument.

The `SUBROUTINE/MYSUB` statement defines MYSUB as a subroutine.

A1 is the name for the first argument; so when the call is made, A1 initially has the same value that V1 has at the time of the call, 6.

The subroutine then executes its two statements:

- The first statement is an `ASSIGN` command that increments the value of A1 to 7.
- The second statement is a `COMMENT/OPER` command that shows the updated A1 value.

The subroutine then ends with the `ENDSUB/` command.

The flow of execution then returns to the statement that directly follows the `CALLSUB` command. This is another `COMMENT/OPER` command that shows the final value of V1.

As execution jumps back, any variables that were used as arguments, V1 in this case, are updated to the value of the corresponding variables in the subroutine, A1 in this case. So, after returning from the subroutine, V1 now has a value of 7. That value was passed back from the subroutine.

Passing Number Values into a Subroutine

Arguments can also take numeric characters.

Example of Passing Number Values:

This example shows how to pass number values into a subroutine. It passes up to two numbers and then adds them together.

```
CS1         =CALLSUB/SUM_NUMBERS,:,
CS2         =CALLSUB/SUM_NUMBERS,:5,10,,
             SUBROUTINE/SUM_NUMBERS,
                 NUM1 = 1 : FIRST NUMBER,
                 NUM2 = 1 : SECOND NUMBER,
                  =
             ASSIGN/TOTAL=NUM1+NUM2
             COMMENT/OPER,NO,FULL SCREEN=NO,AUTO-
CONTINUE=NO,OVC=NO,
             NUM1 + "+" + NUM2 + "=" + TOTAL
             ENDSUB/
```

In the first `CALLSUB` command, (CS1), no number values are passed into the subroutine. The default numbers, 1 for NUM1 and 1 for NUM2 are used instead, and the sum total is 2.

In the second `CALLSUB` command, (CS2), two number values are passed, 5 and 10. So, NUM1 is 5 and NUM2 is 10, and the sum total is 15.

Passing Text Strings into a Subroutine

Arguments can also take a text string. To pass a text string, make sure the alphanumeric characters are placed within double quotation marks.

Example of Passing Text Strings:

This example shows how to pass string values into a subroutine. It passes two string values into the two parameters and then displays them in the report:

```
CS1         =CALLSUB/GET_OPERATOR_INFO,:"BOB
JONES","MORNING",,,
             SUBROUTINE/GET_OPERATOR_INFO,
                 OPNAME = "<NO PASSED OPERATOR>" :
OPERATOR NAME,
                 SHIFT = "<NO PASSED SHIFT>" : SHIFT
TIME,
                  =
             COMMENT/REPT,
             OPNAME
             COMMENT/REPT,
             SHIFT
             ENDSUB/
```

The first argument, `OPNAME` , receives the passed value of "BOB JONES" and the second argument, `SHIFT` , receives "MORNING". The two `COMMENT/REPT` commands then send the passed strings to the inspection report.

Passing Feature Names into a Subroutine

You can pass feature names within curly brackets. For example, in the `CALLSUB` command, if you use {PNT1} as a parameter, the software passes PNT1 into the subroutine. When you pass the feature name in this manner, the subroutine has full access to that feature.

Example of Passing Feature Names:

This example passes in the PNT1 feature name into the subroutine, giving your subroutine complete access to the feature. If no value is passed then the default feature name of F1 is used. This subroutine then queries you for a new value and changes the theoretical X value for the feature.

```
CS1         =CALLSUB/CHANGE_THEO_X,:{PNT1},,
C1          =COMMENT/INPUT,NO,FULL SCREEN=NO,
             Passed feature:
             FEAT1
             The current theo X is:
             FEAT1.TX
             Type a new theo X value:
             ASSIGN/FEAT1.TX=C1.INPUT
             COMMENT/OPER,NO,FULL SCREEN=NO,AUTO-
CONTINUE=NO,OVC=NO,
             "Feature updated to " + FEAT1.TX
```

Because the subroutine has access to the passed feature, the statement `ASSIGN/FEAT1.TX=C1.INPUT ?>` modifies the theoretical X value of the actual PNT1 feature. PNT1 will now permanently have its theoretical X value changed.

Code Sample of a Subroutine

The following code sample allows the operator to have a choice of changing the theoretical X, Y, and Z values of a feature after its measurement. Subsequent runs then use the updated theoretical values.

```
PNT1        =GENERIC/POINT,DEPENDENT,CARTESIAN,$
             NOM/XYZ,<5,10,15>,$
             MEAS/XYZ,<7,12,17>,$
             NOM/IJK,<0,0,1>,$
             MEAS/IJK,<0,0,1>
C1          =COMMENT/YESNO,NO,FULL SCREEN=NO,AUTO-
CONTINUE=NO,
             Do you want to change the theoretical values for
PNT1?
             IF/C1.INPUT=="YES"
CS1         =CALLSUB/CHANGETHEO,:,
             END_IF/
             COMMENT/OPER,NO,FULL SCREEN=NO,AUTO-CONTINUE=NO,
             The XYZ theoretical and actual values for PNT1
are:
             "Theo X= "+PNT1.TX
             "Theo Y= "+PNT1.TY
             "Theo Z= "+PNT1.TZ
             --------------------
             "Actl X= "+PNT1.X
             "Actl Y= "+PNT1.Y
             "Actl Z= "+PNT1.Z
             ROUTINE/END
             SUBROUTINE/CHANGETHEO,
                 POINT1={PNT1}:,
                  =
             DIMINFO/PNT1;ICON,DIMID,FEATID,VERT,HORIZ,,$
                    HEADINGS,;MEAS,,,,,,,,
C2          =COMMENT/INPUT,NO,FULL SCREEN=NO,
             Type the new X theo value for PNT1.
             "Its current value is "+PNT1.TX
             ASSIGN/PNT1.TX=C2.INPUT
C3          =COMMENT/INPUT,NO,FULL SCREEN=NO,
             Type the new Y theo value for PNT1.
             "Its current value is "+PNT1.TY
             ASSIGN/PNT1.TY=C3.INPUT
C4          =COMMENT/INPUT,NO,FULL SCREEN=NO,
             Type the new Z theo value for PNT1.
             "Its current value is "+PNT1.TZ
             ASSIGN/PNT1.TZ=C4.INPUT
             ENDSUB/
```

Explanation of Sample Code

C1=COMMENT/YESNO

This line takes and stores the YES or NO response from the user.

```
IF/C1.INPUT=="YES"
```

This line is the expression. It tests to see if the input of comment 1 is a YES. If it's a YES then the IF statement is TRUE and continues executing the statements after the IF statement, in this case it measures the `PNT1` feature. If NO it moves to the END_IF statement.

```
CS1=CALLSUB/CHANGETHEO,:,
```

This line calls the subroutine named CHANGETHEO. The flow of the measurement routine now jumps to the `SUBROUTINE/CHANGETHEO` line.

```
SUBROUTINE/CHANGETHEO
```

This line initializes the CHANGETHEO subroutine. Measurement routine flow continues with the execution of code between this line and the `ENDSUB/` line.

```
POINT1={PNT1}:,
```

This is the only argument of the subroutine. It allows the subroutine to access information from the PNT1 feature.

```
C2=COMMENT/INPUT,C3=COMMENT/INPUT,C4=COMMENT/INPUT
```

These input comments all take the new theoretical X, Y, and Z values from the user and store them in C2.INPUT, C3.INPUT, and C4.INPUT respectively.

```
ASSIGN/PNT1.TX=C2.INPUT
```

This line takes the theoretical X value from C2.INPUT and assigns it to the `PNT1.TX` variable. `PNT1.TX` is a PC-DMIS variable that holds the theoretical X value (denoted by TX) for the point with the ID label of PNT1.

```
ASSIGN/PNT1.TY=C3.INPUT
```

This line takes the theoretical Y value from C3.INPUT and assigns it to the `PNT1.TY` variable. `PNT1.TY` is a PC-DMIS variable that holds the theoretical Y value (denoted by TY) for the point with the ID label of PNT1.

```
ASSIGN/PNT1.TZ=C4.INPUT
```

This line takes the theoretical Z value from C4.INPUT and assigns it to the `PNT1.TZ` variable. `PNT1.TZ` is a PC-DMIS variable that holds the theoretical Z value (denoted by TZ) for the point with the ID label of PNT1.

```
ENDSUB/
```

This line ends the subroutine, and measurement routine flow returns to the line immediately following the subroutine call. In this case, the `END_IF/` statement. The measurement routine flow then continues with the next operator comment which displays the theoretical and actual X, Y, and Z values, and then the measurement routine ends with the `ROUTINE/END` command.

Command Mode Commands after Comments

After you insert a PC-DMIS comment, to type additional PC-DMIS commands in Command Mode, you must first press Enter *twice* after the `COMMENT` command. This tells PC-DMIS that you no longer want to add text to the comment but are ready to add a new command.

Ending a Measurement Routine

The **Insert | Flow Control Command | End Routine** menu item inserts a `ROUTINE/END` command into the Edit window. Whenever PC-DMIS encounters this command during routine execution, it immediately stops measurement routine execution.

This command is useful when you want to end a measurement routine earlier than usual, based on defined conditions.

Tracking Statistical Data

Tracking Statistical Data: Introduction

PC-DMIS allows you to track and manage statistical data for your measured parts. Information in any dimension or tracefield can be sent to a selected statistical software package by inserting a `STATS` command before the dimension or tracefield. Alternately, you can send statistics to a text-based XML file by using the `XMLSTATS` command.

The main topics in this chapter include the following:

- Using Tracefields
- Sending Current Stats to a File
- Using the Statistics Options Dialog Box
- Sending Data to a Local DataPage+ Database
- Sending Statistics to an XML file using DataPageStats.exe
- Sending Statistics to an XML File using XMLSTATS/ON
- Table of Supported Methods

Using Tracefields

PC-DMIS uses tracefields to send additional information into your statistical database along with your measurement results. A tracefield consists of a name, a message, and a value.

You can use the following items with tracefields:

Trace Field dialog box - You can use this dialog box to insert a `TRACEFIELD` command in the Edit window. For more information on this dialog box, see "Inserting Tracefields".

Read Trace Value in a Variable - You can use the `GETTRACEVALUE()` function to get trace values from a variable. For more information on how to read a trace value from a variable, see "GETTRACEVALUE()" under "String Functions" in the "Using Expressions and Variables" chapter.

Q-DAS Tracefields - You can insert Q-DAS tracefields and send K-Field information to your database. For more information on how to insert Q-DAS tracefields, see "Inserting Q-DAS Tracefields".

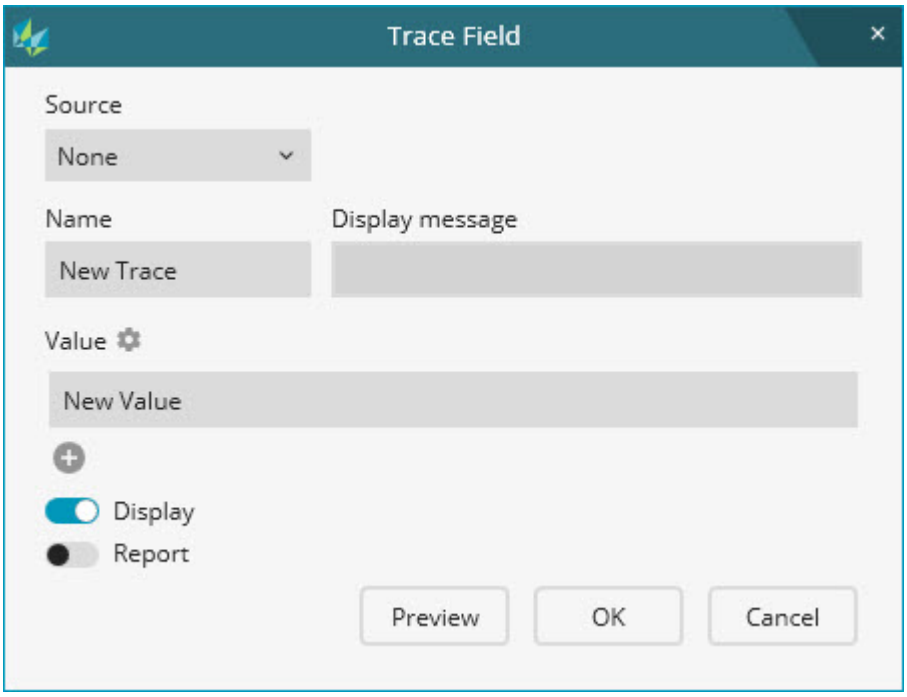
Trace used in Report Header - This item lets you display the values in the report header. For more information on how to use tracefields in the report header, see "Variables and Headers" under "Displaying a Variable's Value" in the "Reporting Measurement Results" chapter.

Inserting TRACEFIELD Commands

With the **Trace Field** dialog box, you can insert a `TRACEFIELD` command in the Edit window. (You can also manually type the command into the Edit window.)

Trace Field Dialog Box

Select **Insert | Statistics Command | Tracefield** to open the **Trace Field** dialog box.



Trace Field Dialog Box

Source - This list defines the location from where PC-DMIS gets the tracefield information.

None - This option lets you type the tracefield name, display message, and value in the dialog box.

Q-DAS - This option reads tracefield information from the Q-DAS configuration file. This option is only available if you insert the `TRACEFIELD` command after the `STATS/ON,Q-DAS` command in a measurement routine. For more information on how to create a Q-DAS configuration file, see the Q-DAS Configurator help file.

Name - This box defines the tracefield's name.

If you select **None** from the **Source** list, type the trace name in the box.

If you select **Q-DAS** from the **Source** list, the **Name** box becomes a drop-down list. From the list, select the trace name.

The drop-down list displays the trace names from the Q-DAS configuration file. (You can choose a different configuration file from the **Statistic/ON Q-DAS** dialog box.)

Each trace name displays a tooltip that provides information about the K-field description.

Display message - This message is the message that PC-DMIS shows for the trace during execution.

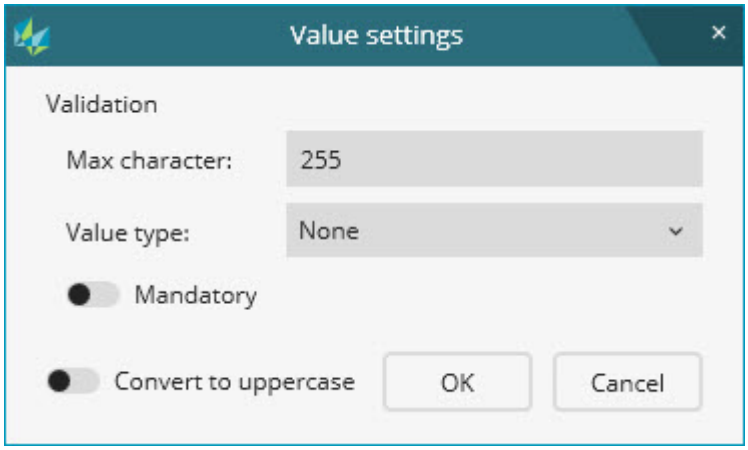
If you select **None** from the **Source** list, type the message in the box.

If you select **Q-DAS** from the **Source** list, the **Display message** box displays a trace name's description from the Q-DAS configuration file. You cannot edit this description.

Value - This box defines the tracefield's value. You can define the settings for the value.

Click the **Value settings** icon to open the **Value settings** dialog box. This dialog box lets you define settings for the value. When you type the value in the **Value** box, PC-DMIS validates the value with the settings.

If you select **Q-DAS** from the **Source** list, you cannot define the settings in the **Value settings** dialog box. PC-DMIS validates the value based on the selection of the configuration file.



Value settings Dialog Box

Max character - This option defines the maximum number of characters for the value. You can type any number between 1 and 255, inclusive. The default value is 255.

Value type - This option defines the type of value. From the list, you can select the type.

None - This type lets you enter any value with the limited number of characters set in the **Max character** box.

Integer - This type lets you enter the whole number.

Float - This type lets you enter the decimal value.

Date/Time (dd.MM.yyyy[/HH:mm:ss]) - This type lets you enter the date and time in the format:

dd.MM.yyyy/HH:mm:ss or dd.MM.yyyy

where

dd - Day of the month as digits. Use a leading zero for single-digit dates.

MM - Month as digits with a leading zero for single-digit months.

yyyy - Year represented by four digits.

HH - Hours with a leading zero for single-digit hours; 24-hour clock. For example, 9 A.M. appears as 09:00. 1 P.M. appears as 13:00.

mm - Minutes with leading zero for single-digit minutes.

ss - Seconds with leading zero for single-digit seconds.

Alphanumeric - This option lets you enter characters such as letters and decimal digits.

File name - This type lets you enter the file name based on your computer's operating system.

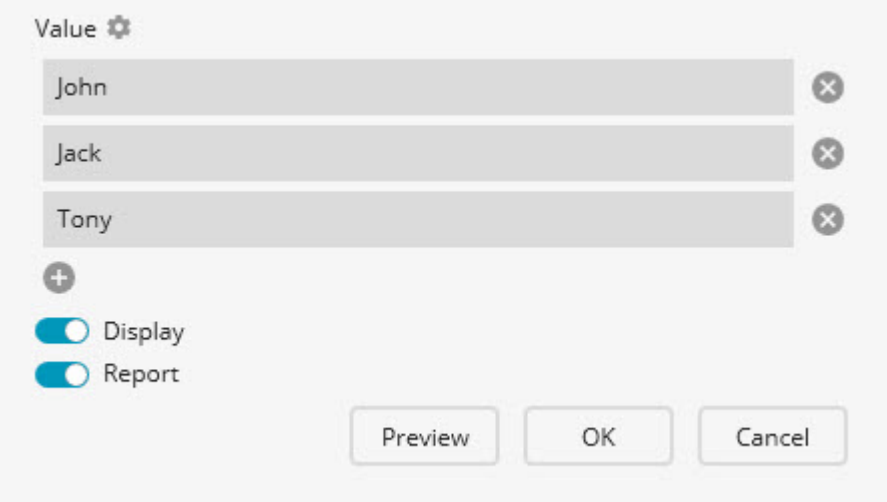
In the Windows 10 operating system, the file name does not allow characters such as \, /, :, *, ?, ", <, >, and |.

Mandatory - This switch determines whether the operator can skip the trace during execution. If you turn on the switch, the operator cannot skip the trace during execution and must type a value.

Convert to uppercase - This switch converts the value characters into uppercase.

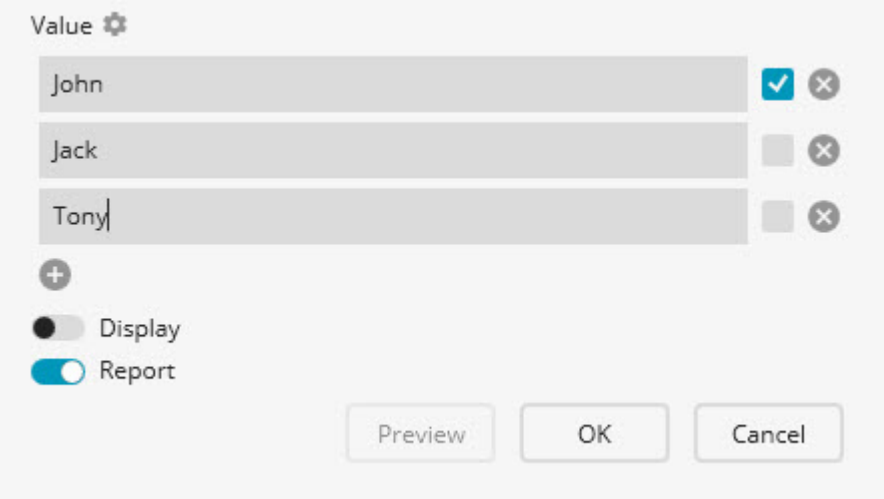
You can have a single value, or you can have multiple rows of values. To add a row for a value, click the **Add** button .

- If the **Display** switch is on, PC-DMIS adds a **Remove** button ( ) for each row.



During execution, the value in the first row becomes the selected value. You can change the value from the list when PC-DMIS displays the dialog box during execution. Otherwise, PC-DMIS sends the selected value to the statistical database.

- If the **Display** switch is off, PC-DMIS adds a check box and **Remove** button ( ) for each row.



To set a value as the selected value, mark the check box next to the value. During execution, PC-DMIS displays this value as the selected value.

To hide the dialog box during execution, and send the selected value to the statistical database, you can turn off the **Display** switch in the **Trace Field** dialog box.

To remove a row for a value, click the **Remove** button .

Display - This switch shows or hides the **Trace Field** dialog box during execution. If you hide the **Trace Field** dialog box, PC-DMIS doesn't display the dialog box for the operator to type or select the value. PC-DMIS sends the current value to the statistical software.

Report - This switch shows or hides the name of the trace and its value in the measurement report.

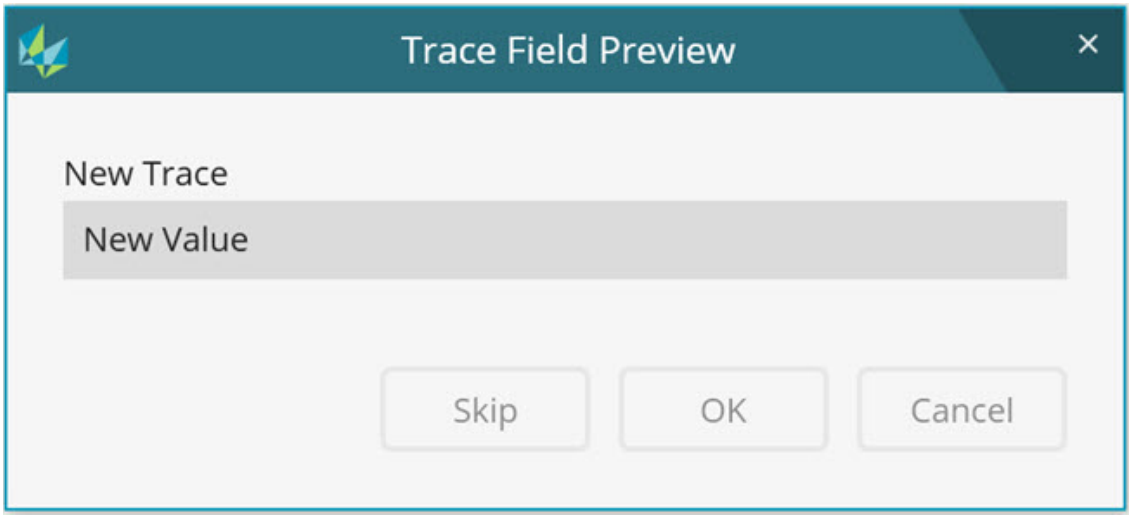
- If the tracefield name is Operator, the value is Sam, and the source is None, then the report shows:

```
TRACEFIELD Operator = Sam
```

- If the trace name is K0008, the value is Sam, and the source is Q-DAS, then the report shows:

```
TRACEFIELD Source = Q-DAS, K0008 = Sam
```

Preview - This button lets you preview the tracefield in a **Trace Field Preview** dialog box.



Trace Field Preview Dialog Box

The preview dialog box mimics the actual **Trace Field** dialog box that PC-DMIS shows during execution. Click × to close the preview.

You can see the `TRACEFIELD` command in these Edit window code snippets:

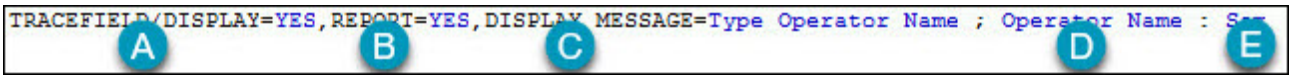
```
TRACEFIELD/DISPLAY=YES,REPORT=NO,DISPLAY
MESSAGE=Type Operator name ; Operator : Sam

TRACEFIELD/DISPLAY=YES,REPORT=NO,DISPLAY
MESSAGE=Batch number / Ident number ; K0006 : 4
```

TRACEFIELD Command in the Edit window

You can also use the Edit window to change the tracefield's name, display message, and current value.

The Edit window command line for a TRACEFIELD command looks like this:



Example showing a TRACEFIELD command.

A. **Display** - This toggle field controls whether to display the **Trace Field** dialog box during execution. This field switches between YES and NO.

B. **Report** - This toggle field controls whether to display the name of the trace and its value in the measurement report. This field switches between YES and NO.

C. **Display Message** - This field holds the message that appears for the tracefield during execution.

D. **Name -** This field holds the name of the tracefield.

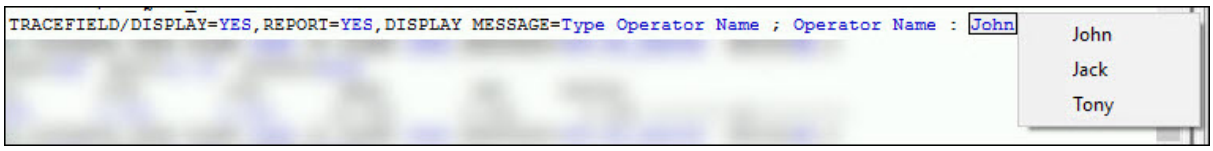
E. **Value -** This field holds the current value of the tracefield.

If you select **Source** as **None**, you can type or edit the trace name, display message, and value.

If you select **Source** as **Q-DAS**, the **Name** becomes a drop-down list. From the drop-down list, select the trace name.

If you have one row with a single value, you can type or edit the value.

If you have multiple rows each with its own value, you can select a value from a list of available values.



Using Variables

You can use variables in a `TRACEFIELD` command's fields under these conditions:

- You must define the variables that you want to use earlier in the routine above any `TRACEFIELD` commands.
- You must type the variable names into the corresponding fields in the `TRACEFIELD` command in the Edit window or in the dialog box.

You can type a variable into all the fields (name, message, or value) if **Source** is set to **None** in the dialog box. If **Source** is set to **Q-DAS**, you can type variables only in the value

field. Also, you can type a variable for a value only if the `TRACEFIELD` command contains a single value.

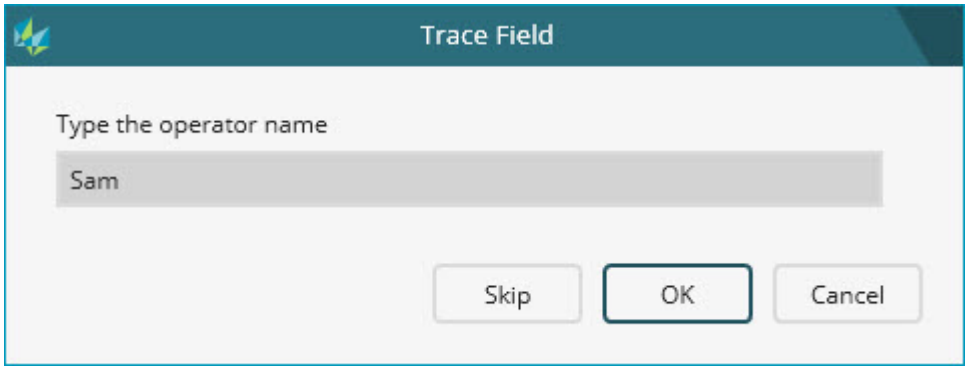
Use the GETTRACEVALUE() function to read a value from a `TRACEFIELD` command in the measurement routine. For information on this and all string functions, see "String Functions" in this documentation.

You can see the `TRACEFIELD` command after you set **Source** to **None** in the dialog box:

```
ASSIGN/V1="OPERATOR"
ASSIGN/V2="TYPE THE OPERATOR NAME"
ASSIGN/V3="Sam"
TRACEFIELD/DISPLAY=YES,REPORT=NO,DISPLAY MESSAGE=V2 ;
V1 : V3
```

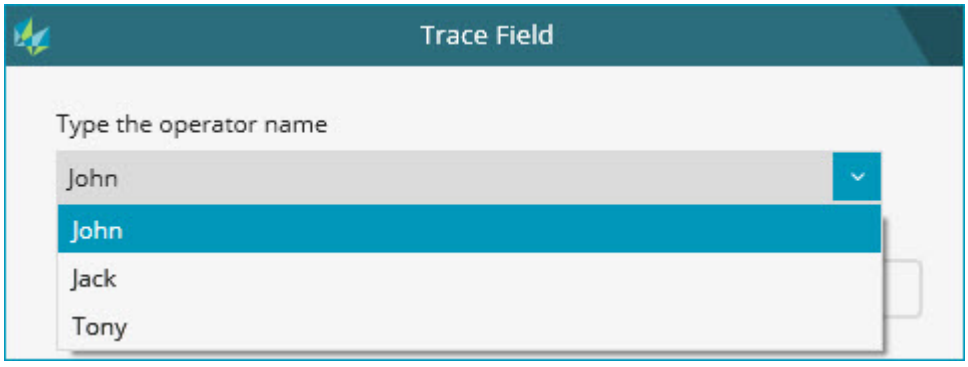
The Trace Field Dialog Box During Execution

For a single value, the **Trace Field** dialog box displays a box to type or edit a value:



Example of the Trace Field dialog box with a single tracefield value.

For multiple values, the **Trace Field** dialog box displays a list to select a value:



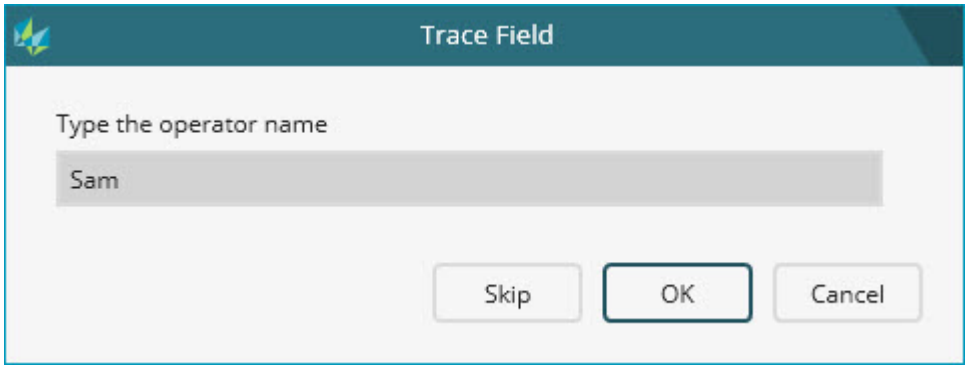
Example of the Trace Field dialog box with multiple tracefield values.

Execution Example - A Single TRACEFIELD Command

```
LIN1        =FEAT/LINE,CARTESIAN,UNBOUNDED
             THEO/<4.113,0,-6.449>,<1,0,0>
             ACTL/<4.113,0,-6.449>,<1,0,0>
             MEAS/LINE,2,ZPLUS
               HIT/BASIC,NORMAL,<4.113,0,-5.307>,<0,-1,0>,<4.113,0,-5.307>,USE THEO=YES
               HIT/BASIC,NORMAL,<87.972,0,-7.592>,<0,-1,0>,<87.972,0,-7.592>,USE THEO=YES
             ENDMEAS/
             TRACEFIELD/DISPLAY=YES,REPORT=NC,DISPLAY MESSAGE=Type the operator name ; Operator : Sam
LIN2        =FEAT/LINE,CARTESIAN,UNBOUNDED
             THEO/<0,4.366,-7.211>,<0,1,0>
             ACTL/<0,4.366,-7.211>,<0,1,0>
             MEAS/LINE,2,ZPLUS
               HIT/BASIC,NORMAL,<0,4.366,-7.302>,<-1,0,0>,<0,4.366,-7.302>,USE THEO=YES
               HIT/BASIC,NORMAL,<0,57.394,-7.12>,<-1,0,0>,<0,57.394,-7.12>,USE THEO=YES
             ENDMEAS/
```

Example showing a single tracefield command.

During execution, PC-DMIS displays a single `TRACEFIELD` command with the usual **Trace Field** dialog box:



Example of the Trace Field dialog box with a single tracefield value.

Skip - This button skips the tracefield and does not use the value. If the tracefield is mandatory, this button is not available.

OK - This button accepts the values for any executed tracefields.

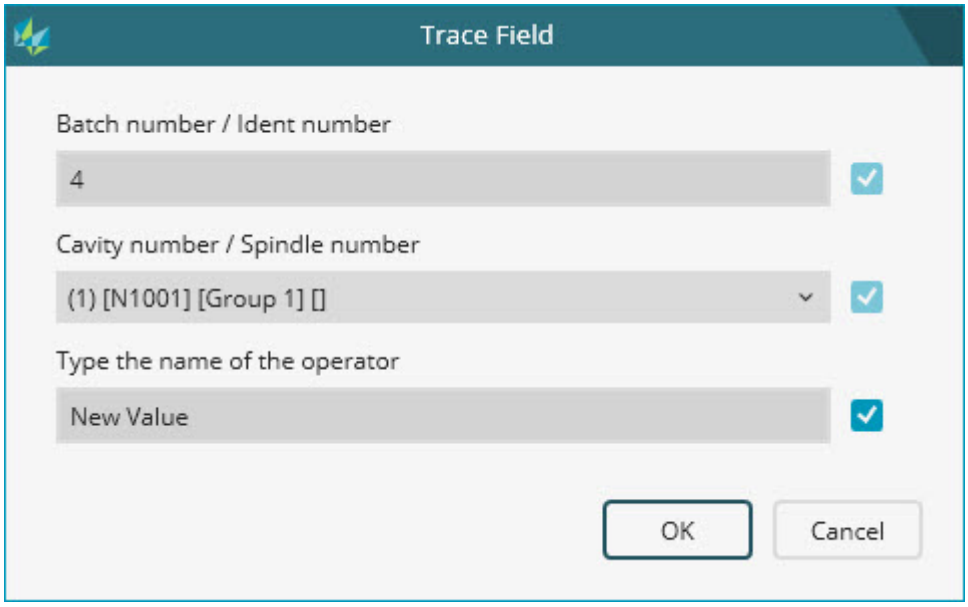
Cancel - This button cancels the execution of the PC-DMIS measurement routine.

Execution Example - Multiple Consecutive TRACEFIELD Commands

```
PLN1        =FEAT/PLANE,CARTESIAN,TRIANGLE
             THEO/<42.901,28.561,0>,<0,0,1>
             ACTL/<42.901,28.561,0>,<0,0,1>
             MEAS/PLANE,4
               HIT/BASIC,NORMAL,<77.785,5.533,0>,<0,0,1>,<77.785,5.533,0>,USE THEO=YES
               HIT/BASIC,NORMAL,<80.143,57.7,0>,<0,0,1>,<80.143,57.7,0>,USE THEO=YES
               HIT/BASIC,NORMAL,<9.926,48.571,0>,<0,0,1>,<9.926,48.571,0>,USE THEO=YES
               HIT/BASIC,NORMAL,<3.751,2.439,0>,<0,0,1>,<3.751,2.439,0>,USE THEO=YES
             ENDMEAS/
             TRACEFIELD/DISPLAY=YES,REPORT=NC,DISPLAY MESSAGE=Batch Number ; K0006 : 4
             TRACEFIELD/DISPLAY=YES,REPORT=NC,DISPLAY MESSAGE=Cavity Number ; K0007 : (1) [N1001] [Group 1]
             TRACEFIELD/DISPLAY=YES,REPORT=NC,DISPLAY MESSAGE=Type the name of the operator ; Operator : New Value
COP1        =COP/DATA,TOTAL SIZE=0,REDUCED SIZE=0,
             REF=,
COPFCOLORMAP1=COP/OPER,SURFACE COLORMAP,SHOW PARAMETERS=NO
             SIZE=0,REF=COP1,,
COPFCOLORMAP2=COP/OPER,SURFACE COLORMAP,SHOW PARAMETERS=NO
             SIZE=0,REF=COP1,,
```

Example showing three consecutive TRACEFIELD commands.

During execution, PC-DMIS combines multiple consecutive commands so that they appear in a single **Trace Field** dialog box. This combination of commands can save you time because PC-DMIS collects the information from a single dialog box instead of a dialog box for each command:



Example of the Trace Field dialog box with multiple values for consecutive tracefields.

Check Box - The blue check boxes allow you to include or skip a tracefield during execution.

- If you select any check boxes, PC-DMIS executes those tracefields.
- If you clear any check boxes, PC-DMIS skips those tracefields and does not use those values. If a tracefield is mandatory, the check box is not available for that tracefield.

OK - This accepts the values for any executed tracefields.

Inserting Q-DAS Tracefields

Select **Insert | Statistics Command | Q-DAS Tracefields** to insert the Q-DAS tracefields. This option inserts the tracefields for K-fields whose "**Value From**" properties are set to "**TRACE**" in the **Setup K-Field Configuration** window of the Q-DAS Configurator.

Q-DAS tracefields help you create measurement routines that support Q-DAS statistical software. For information on the Q-DAS Configurator, see the Q-DAS Configurator documentation.

Before you insert Q-DAS tracefields, you need to create a `STATS/ON,Q-DAS,DFQ` command. For information, see "Sending Statistics to a Q-DAS Database".

After you insert Q-DAS tracefields, if you update the Q-DAS configuration file (<name>.qdascfg.xml), you must re-insert the Q-DAS tracefields.

Here's an example of some Q-DAS tracefields in the Edit window:

```
QDAS_TRACEFIELDS=GROUP/SHOWALLPARAMS=No

EXECUTION CONTROL=AS MARKED

ENDGROUP/ID=QDAS_TRACEFIELDS
```

To expand the group, you can change `SHOWALLPARAMS` from No to Yes as shown in this code snippet:

```
QDAS_TRACEFIELDS=GROUP/SHOWALLPARAMS=YES

EXECUTION CONTROL=AS MARKED

    TRACEFIELD/DISPLAY=YES,REPORT=NO,DISPLAY
    MESSAGE=Batch Number ; K0006 :

    TRACEFIELD/DISPLAY=YES,REPORT=NO,DISPLAY
    MESSAGE=Cavity Number ; K0007 : (1) [N1001] [Group
    1]

    TRACEFIELD/DISPLAY=YES,REPORT=NO,DISPLAY
    MESSAGE=Operator Name ; K0008 : (1) [P001] [Operator
    1]

    TRACEFIELD/DISPLAY=YES,REPORT=NO,DISPLAY
    MESSAGE=Machine Number ; K0010 : (1) [M001] [Machine
    1]

    TRACEFIELD/DISPLAY=YES,REPORT=NO,DISPLAY
    MESSAGE=Gage Number ; K0012 : (1) [PM001] [CMM 1]
    [CMM Grp. 1]

    TRACEFIELD/DISPLAY=YES,REPORT=NO,DISPLAY
    MESSAGE=Part ID Number ; K0014 :

    TRACEFIELD/DISPLAY=YES,REPORT=NO,DISPLAY
    MESSAGE=Order ; K0053 :

    TRACEFIELD/DISPLAY=YES,REPORT=NO,DISPLAY
    MESSAGE=Part Number ; K1001 :

    TRACEFIELD/DISPLAY=YES,REPORT=NO,DISPLAY
    MESSAGE=Contract ; K1053 :

    TRACEFIELD/DISPLAY=YES,REPORT=NO,DISPLAY
    MESSAGE=Work Cycle / Operation Number ; K1086 :
```

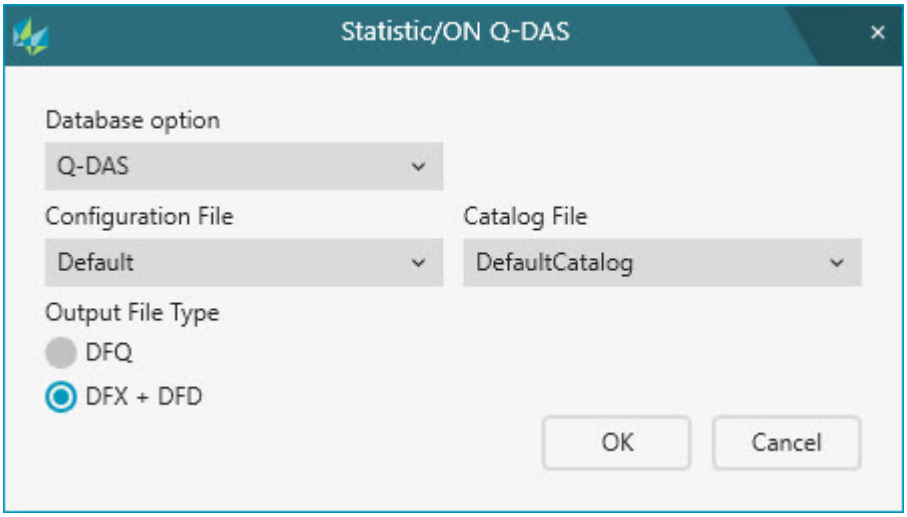
```
                TRACEFIELD/DISPLAY=YES,REPORT=NO,DISPLAY
               MESSAGE=Remark ; K1900 :

          ENDGROUP/ID=QDAS_TRACEFIELDS
```

Sending Statistics to a Q-DAS Database

The **Statistic/ON Q-DAS** dialog box lets you send the measurement data to the Q-DAS statistical software package.

The **Insert | Statistics Command | Statistics/ON, Q-DAS** menu option opens the **Statistic/ON Q-DAS** dialog box.



Statistic/ON Q-DAS Dialog Box

Database option - This option generates a file that the Q-DAS statistical software can read. The list only displays Q-DAS.

Configuration File - This file defines the type of measurement data and the additional information that PC-DMIS needs to collect during the execution of a measurement routine. From the list, select the configuration file. PC-DMIS provides a Default.Qdascfg.xml file.

You can use Q-DAS Configurator to create a configuration file. For more information on Q-DAS Configurator, see the Q-DAS Configurator help file.

You can find the configuration files in this folder:

C:\Users\Public\Documents\Hexagon\PC-DMIS\<version>\Q-DAS\Settings

Where <version> is the PC-DMIS version.

Catalog File - Q-DAS statistical software uses a catalog file to define information that is related to your manufacturing environment. This file is a text file that contains administrative and other data that K-fields can reference. Your organization creates this

catalog according to the requirements of the Q-DAS software and provides it for use. This file is location specific. For more information on the catalog file, see the Q-DAS Configurator help file. From the list, select the catalog file. PC-DMIS provides a DefaultCatalog.dfd file.

You can find the catalog files in this folder:

C:\Users\Public\Documents\Hexagon\PC-DMIS\<version>\Q-DAS\Catalogs

Where <version> is the PC-DMIS version.

Q-DAS Configurator creates a Q-DAS data file for each measurement routine. The Q-DAS data file contains information that Q-DAS statistical software needs to generate output files. Q-DAS Configurator saves the Q-DAS data file in the same folder as the measurement routine. The file name has the following format:

<name of measurement routine>.QdasData.xml

Where <name of measurement routine> is the name of the PC-DMIS measurement routine.

If a QdasData.xml file exists for the current measurement routine, then the **Configuration File** and **Catalog File** lists display the file names from the QdasData.xml file. You cannot change the file names from this dialog box.

To select the different configuration file or catalog file, or both, you need to use Q-DAS Configurator. For more information on Q-DAS Configurator, see the Q-DAS Configurator help file.

Output File Type - Q-DAS statistical software supports the Q-DAS ASCII Transfer Format. This option lists the formats that Q-DAS supports:

DFQ - This option sends the output to a .dfq file.

DFX + **DFD** - This option sends the output to .dfd and .dfx files.

Select the required output format.

OK - This button inserts the `STATS/ON,Q-DAS,DFX+DFD` or `STATS/ON,Q-DAS,DFQ` command into the Edit window.

Cancel - This button discards the changes and closes the dialog box. It does not insert the `STATS/ON,Q-DAS,DFX+DFD` or `STATS/ON,Q-DAS,DFQ` command into the Edit window.

Sending Current Stats to a File

The functionality of the **Operation | Send Current Stats To File** menu option depends on the statistical package you use, as described below.

If the `STATS/ON` command uses DataPage or DataPage+, PC-DMIS shows a **Save Statistics** dialog box asking if you want to save your statistical data.

- Click **No** to cancel the operation, no data is saved.
- If you click **Yes**, PC-DMIS shows an **Update** dialog box asking if you want to update the DataPage+ database.
- If you click **Yes** on this second dialog box, PC-DMIS updates the database.
- If you select **No**:
  - If the `STAT/ON` command uses DataPage, PC-DMIS creates an "XSTAT11.tmp" file.
  - If the `STAT/ON` command uses DataPage+, PC-DMIS creates an XML file.

If the `STATS/ON` command uses Q-DAS, PC-DMIS shows a **Save Statistics** dialog box to confirm that you want to save your statistical data or not.

If the current measurement routine was the last measurement routine you executed, then PC-DMIS creates the DFQ/DFX+DFD files. If not, you may not have the correct data set for this measurement routine. If the `STATS|ON` command is set to Q-DAS, to ensure your data set is correct before you save it, run the measurement routine and then select the **Operation | Send Current Stats to File** menu option. You can find the files in the "C:\Users\Public\Documents\Hexagon\PC-DMIS\Q-DAS\Results" folder. If you have not executed your measurement routine, PC-DMIS does not create DFQ/DFX+DFD files.

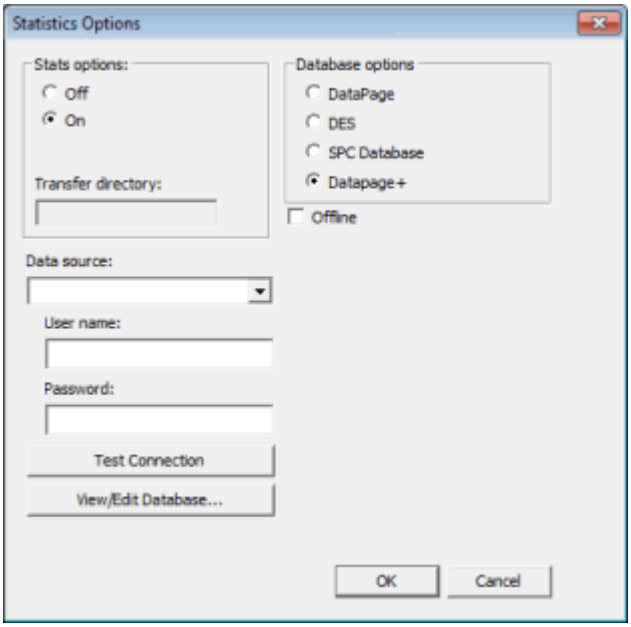
For details on sending statistical data to a Q-DAS database, see the "Sending Statistics to a Q-DAS Database" topic in the PC-DMIS Core documentation.

If you want to use your XSTATS11.tmp file with Q-DAS, be sure to execute the measurement routine first so that it sends the generated Q-DAS data to the .tmp file.

If you select **Send Current Stats To File**, PC-DMIS immediately sends all of the dimensions and tracefields that follow a `STATS/ON` command to the selected database. Statistics only get sent to a database if you have a database registered and have the `STATS/ON` command marked. With the `STATS/ON` command set to Datapage, PC-DMIS also sends statistical data to the XSTATS11.tmp file.

For details on the locations of PC-DMIS files, see "Understanding File Locations".

Using the Statistics Options Dialog Box



Statistics Options Dialog Box

The **Insert | Statistics Command | Statistics** menu option displays the **Statistics Options** dialog box. Use this dialog box to tell PC-DMIS what it should do with the results of a measurement. You can tell it to send that information to a specific statistical software package database.

Under **Stats options**, if you select **On** and click **OK**, it inserts a `STATS/ON` command into the measurement routine. If `STATS/ON` is inserted before any desired dimension or tracefield commands, then that dimension or tracefield information is sent to the selected statistical software package.

The dialog box changes depending on the database option selected from the **Database Options** area. For information on the changeable areas of the dialog box, see the items discussed in the **Database Options** sub-topics.

Stats Options

The **Stats Options** area is always available on the **Statistics Options** dialog box. The **Stats Options** area allows you to use the following commands.

- Off - Turning off statistical gathering
- On - Turning on statistical gathering
- Transfer - Transferring a stats file to a new directory

- Update - Updating the database
- Record - Recording specific data

Off - Turning Off Statistical Information (STATS/OFF)

Selecting the **Off** option stops statistical information from being sent from your measurement routine by inserting a `STATS/OFF` command. With stats off, Dimension or tracefield commands will *not* send statistical information to the database unless you select the Stats On option.

On - Turning on Statistical Gathering (STATS/ON)

Selecting the **On** option allows statistical information to go from your measurement routine to the database. With stats on, you can send data to the stats file, transfer the information to a different directory, or store the information in a database application.

Any dimensions that follow a `STATS/ON` command and precede the next `STATS/OFF` command are sent to the stats file or database upon execution of the next `STATS/TRANSFER`, `STATS/UPDATE`, or final command of the measurement routine. With the `STATS/ON` command, you can send the output information to multiple databases, even within the same measurement routine.

Upon each execution of a measurement routine that includes at least one `STATS/ON` command, PC-DMIS asks if it should send the output information to any statistical database directories. This prompt can be bypassed by selecting the **ALWAYS Update Database** check box accessible from the **Dimension** tab of the **Setup Options** dialog box (**Edit | Preferences | Setup**). For information on the **Dimension** tab, see the "Setup Options: Dimension tab" topic in the "Setting Your Preferences" chapter.

If you select **DataPage** from the **Database Options** area, PC-DMIS automatically calls the DPUPDATE.exe executable to insert the data in the XSTATS11.tmp file into any selected DataPage directories. You must run PC-DMIS with administrator privileges for DPUPDATE.exe to work.

Similarly, selecting the **DataPage+** option calls DPPLUSUPDATE.exe which in turn calls DataImporter to import the XML file into the DataPage+ database.

Turning stats on inside a loop can result in a slightly different output for the dimension and feature IDs in generated stats files such as the XSTATS11.tmp text file or the XML file.

For details on the locations of PC-DMIS files, see "Understanding File Locations".

The Edit window command line for a `STATS/ON` command block changes based on the specified database type. All `STATS/ON` commands start with this on the initial line: `STATS/ON,database option;`

database option = This toggle field indicates the database type to which the stats will be sent. This field can be DATAPAGE, DES, SPC_DATABASE, or DATAPAGE+. Depending on what you select here, the rest of the command can change.

With the DATAPAGE option, the command block looks like this:

```
STATS/ON,DATAPAGE,$

DIRECTORY=directory_name,$

READ=n1,WRITE=n2,MEMPAGES=n3,variable_name1,variable
_name2,$

STATS/END
```

With the SPC option, the command block looks like this:

```
STATS/ON,SPC_DATABASE,database_name
```

With the DES option, the command block looks like this:

```
STATS/ON,DES,DIRECTORY=directory
```

With the DATAPAGE+ option, the command block looks like this:

```
STATS/ON,DATAPAGE+,database_name,OFFLINE=y/n

RECORD=data_list
```

DIRECTORY=directory_name If the database option is DATAPAGE or DES, the value of **directory_name** should be a string that indicates the database directory to which the statistics will be sent. If you have more than one database directory, this DIRECTORY field repeats itself for each additional directory. Each one must be a valid database directory.

database_name = If the database option is SPC_DATABASE or DATAPAGE+, this string indicates the Data Source Name (DSN) of the database. For an SPC database, this name can be created in the ODBC options of the computer's control panel. For a DATAPAGE+ database, the DSN is usually created inside of the DATAPAGE+ tool. The DSN must be created to link to a valid database.

READ=n1 This is a read lock. **n1** indicates the maximum number of seconds PC-DMIS will wait for database access when reading. The default setting is 10 seconds. This field is only used for the DataPage database option.

WRITE=n2 This is a write lock. **n2** indicates the maximum number of seconds PC-DMIS will wait for database access when writing. The default setting is 20 seconds. This field is only used for the DataPage database option.

MEMPAGES=n3 This stands for memory pages. **n3** indicates the number of 4K memory pages to reserve for database tables when opening the database. This option will affect performance. The minimum number that can be entered is 4 (also default). This field is only used for the DataPage database option.

variable_name1 = This field indicates the variable name setting. If set to DIMENSION_NAME then dimension names will be displayed. If set to FEATURE-NAME then feature IDs will be displayed. This field is only used with the DataPage database option.

variable_name2 = This field determines whether or not control calculations should be used. If set to CONTROLCALC ON then control calculations are used. If set to CONTROLCALC OFF then they are not used.

OFFLINE = This YES/NO field determines if the offline options should be used. If set to YES, then the `RECORD=` field appears, specifying the info to write to the XML file. This field is only used with the DataPage+ database option.

RECORD=data_list This determines what data to record to the XML file. The value of **data_list** is either ALL, meaning all data is sent to the XML file, or a comma-separated listing of items. For example, if you wanted just dimension and hit information recorded, you would choose DIMENSION, HIT. This field is only used with the DataPage+ database option, and it is only available if `OFFLINE=YES` .

PC-DMIS and DataPage+ versions that support STATS/ON command

For information on supported methods and versions, see "Table of Supported Methods".

DataPage+ XML Handling

If you're using `STATS/ON` with a DataPage+ database name and `OFFLINE=YES` , a generated XML is created in the C:\Users\Public\Documents\Hexagon\PC-DMIS\ directory immediately after execution finishes. *Note that this directory is version independent.* It contains the transaction date and time, the DSN, as well as other information. You can limit this other information by using the **Record** option with the **Offline** check box.

Once generated, dpplusupdate.exe moves the file into the %AppData%/DataPage+/ForStatsFile directory for file handling. The DataImporter tool, if running, then looks in that directory and automatically imports the data into DataPage+. For information on using DataImporter, see the documentation that came with your installation of DataPage+.

The name of the XML is based on the current local time when it was generated. It uses this naming format:

<YYYY><MM><dd><hh><mm><ss>.xml

<YYYY> - The four digit year

<MM> - The two digit month

<dd> - The two digit day of the month

<hh> - The hour in 24-hour format

<mm> - The minutes

<ss> - The seconds

Transfer - Transferring a Stats File to a New Directory (STATS/TRANSFER)

The **Transfer** option allows statistical information from a measurement routine to be transferred to a specified directory upon execution of the `STATS/TRANSFER` command.

This option may be especially useful with the **Auto Update** option of DataPage or with an XML file generated from the **Record** option of the **DataPage+** database option. See "Record".

To transfer your stats to a different directory:

1. Click the **Transfer** option.
2. In the **Transfer Directory** box, enter the directory path of the directory to which you will transfer your stats file.

Update - Updating the Database (STATS/UPDATE)

The **Update** option creates a `STATS/UPDATE` command that tells PC-DMIS to update the statistical database every time the command is executed. The statistical software application must be installed and ON.

The **Always Update Database** check box from the **Dimension** tab of the **Setup Options** dialog box allows you to bypass the "Update Database Now?" message that PC-DMIS shows at the end of a measurement routine execution that contains a `STATS/ON` command. See the "Setup Options: Dimension tab" in the "Setting Your Preferences" chapter.

Record - Recording Specific Data (STATS/RECORD)

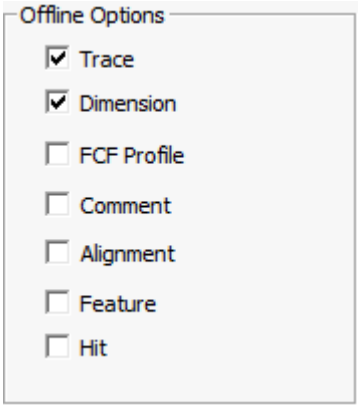
The original **DataPage+** output sends a lot of information to the database. This may bog down execution of some measurement routines. Some information may not even be desired.

The **Record** option in the **Stats options** area provides greater flexibility and speed for data output. It must follow a STATS/ON command to function. It does the following:

- It sends data by means of a dpplusupdate.exe utility that runs in the background. This means an active connection to a DataPage+ database is not used. In fact, you don't need to have a database defined at all.
- It writes data to an XML file.
- It lets you selectively target what data you want captured by editing the `STATS/ON` or `STATS/RECORD` commands to include the data you want the software to output to the XML file. You can do this using the **Offline** check box and the **Offline Options** area covered below.

How Record and the Offline Check Box Work

After the **Offline** check box is marked, the **Offline Options** area becomes available for edit to choose the specific items to record to the XML output.



Even if you don't have the **Record** option specifically selected, if **Offline** is marked and you click **OK**, the Edit window `STATS/ON` command is modified with a `RECORD` command to include the selected options.

For example, if you marked **Offline** and chose **Trace** and **Dimension**, your command would look something like this:

```
STATS/ON,DATAPAGE+,DATAPAGE_PLUS,OFFLINE=YES
RECORD=DIMENSION,TRACE,
```

This means during execution PC-DMIS would only send the **Dimension** and **Trace** information to the XML file until another `RECORD` command was encountered that told it to send something different or until it reached a `STATS/OFF` command.

Now, suppose later in the routine you chose the **Record** option and you wanted to include **Hit** information as well. The command would be this:

```
STATS/RECORD,DIMENSION,TRACE,HIT
```

This command, as long as it's following a `STATS/ON` command, would then limit the data sent to the XML file include trace, dimension, and hit information.

Database Options

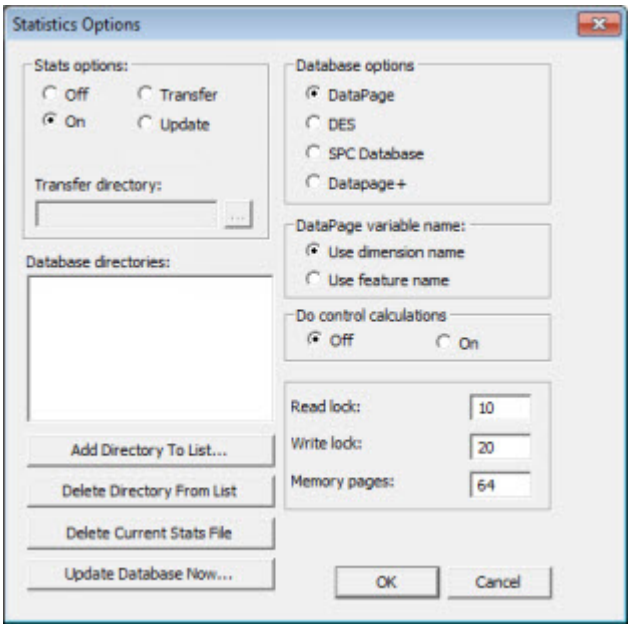
The options in the Database Options area determine which of these statistical software packages receives the measurement information:

- DataPage
- DES
- SPC Database
- DataPage+

Once you select an option, the **Statistics Options** dialog box changes to show specific information needed for that option.

The **DataPage+** option is the default option.

DataPage Option

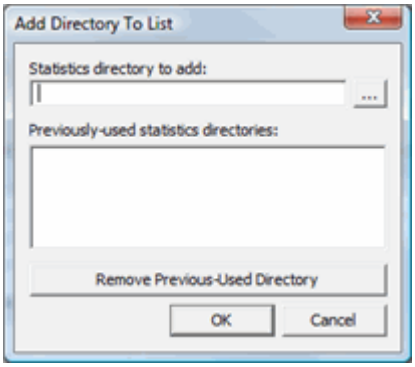


Statistics Options Dialog Box – DataPage Option

When you select the **Datapage** option, the **Statistics Options** dialog box changes to add the following items:

Database Directories - This list shows the different directories in which a database application could reside. You can add or delete directories from this list. A maximum of ten directories per `STATS/ON` command can be selected to which statistical information can be sent.

Add Directory to List - Displays the **Add Directory To List** dialog box that lets you specify a directory containing a database you want to use with DataPage:



Add Directory to List

When the dialog box appears, you can either type the pathway containing the database in the **Statistics directory to add** box, or click the ... button to browse to the directory. Then click **OK**. to add the specified directory into the **Database Directories** list.

Use the **Remove Previous-Used Directory** to remove previously defined directories.

Delete Directory from List - Deletes the selected database directory from the **Database Directories** list.

Delete Current Stats File - Deletes your xstats11.tmp file.

For details on the locations of PC-DMIS files, see "Understanding File Locations".

Update Database Now - Updates your database application with statistical data gained from your current measurement routine. Simply click this button and follow the instructions on screen. This uses DPUPDATE.exe to update the database.

Upon successful execution of a measurement routine, selected Dimension and tracefield information is stored within a file named XSTATS11.tmp. The information in this file can then be transferred to a different directory, printed out, or sent to a database application.

If a database application is unavailable, PC-DMIS displays a message informing you that it can't find the update executable (for the DataPage application, this is DPUPDATE.exe) to load XSTATS11.tmp into the database.

You must run PC-DMIS with administrator privileges for DPUPDATE.exe to work.

DataPage Variable Name - This area indicates whether the dimension name or feature name will be used to identify entries in DataPage. The maximum length of the name is 10 characters. To choose either the dimension name or the feature name, select the **Use Dimension Name** option or the **Use Feature Name** option.

Do Control Calculations - Contains options to indicate whether the control calculations that take place within Datapage should be used. Selecting the **On** option performs the out of tolerance control calculations. Additionally, it commands the DataPage statistics update program (DPUPDATE) to perform the control calculations and set the part/variable and in/out of tolerance/control indicators in the database. You can monitor this database using DataPage's Monitor mode by turning on the part/variables colors (red/yellow/green) based on those calculations. For additional information, see the help file that ships with DataPage's Monitor mode application.

To turn control calculations on or off simply select either the **On** or the **Off** option. The default setting is **Off**.

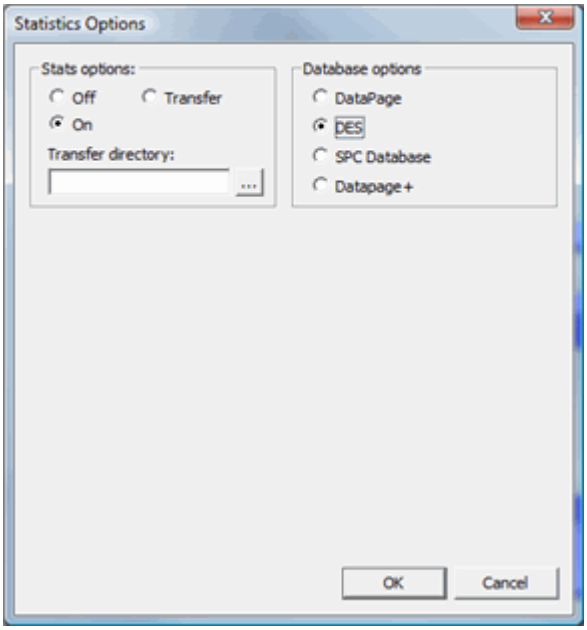
Read Lock - Determines the maximum number of seconds that PC-DMIS will wait for database access when reading. The default value is 10 seconds.

Write Lock - Determines the maximum number of seconds that PC-DMIS will wait for database access when writing. The default value is 20 seconds.

Memory Pages box - Determines the number of 4K pages to reserve for database tables when opening a database. The minimum (and default) number of pages that can be open is four.

DES Option

The DES option only functions with the statistical database program, DES. When you select DES, the **Statistics Options** dialog box changes so that it only includes the **Stats Options** area, the **Database Options** area, and the **OK** and **Cancel** command buttons.

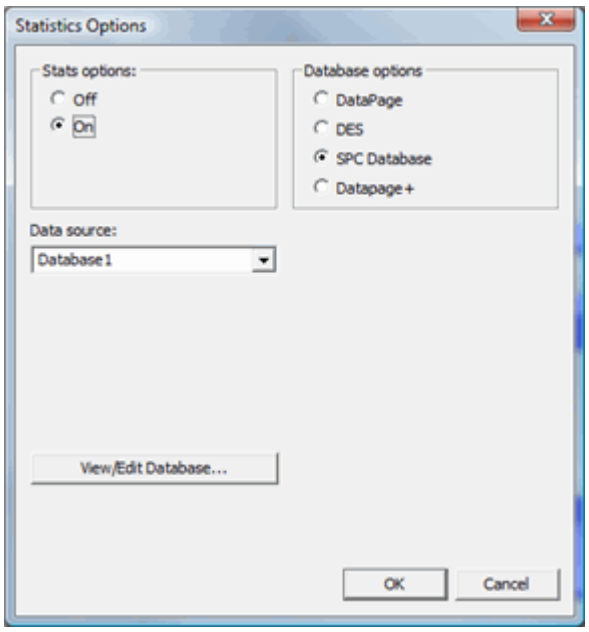


Statistics Options Dialog Box – DES Option

SPC Database Option

The **SPC Database** option only functions with PC-DMIS's own statistical database program, SPC. When you select the **SPC Database** option, the **Statistics Options** dialog changes to include the following:

- **Data source** list
- **View/Edit Database** button



Statistics Options Dialog Box - SPC Database Option

Data source list

This list contains predefined data sources. You can establish a connection between a selected data source and PC-DMIS in order to collect and store statistical data from PC-DMIS measurements results.

There are three ways you can establish a data source:

Use "ODBC Data Sources" from "Administrative Tools"

Use the **Data source** list to select a Data Source Name (DSN). A DSN is created initially by using the Open Database Connectivity (ODBC) options in the computer's Control Panel.

If you need to create a DSN:

1. Access the Windows **Control Panel**.
2. Select **Administrative Tools** (use the **Classic View** if using Vista).
3. Double-click on the **ODBC Data Sources** or **Data Sources (ODBC)** icon.
4. Follow the instructions in your operating system's Help file to create the DSN.

Use the Database Wizard

Click the **Database Wizard** icon from the **Wizards** toolbar inside of PC-DMIS to easily create a database. Simply follow the prompts to create the database. See "Wizards Toolbar" in the "Using Toolbars" chapter.

Use the Database Connection Properties dialog box within DataPage+

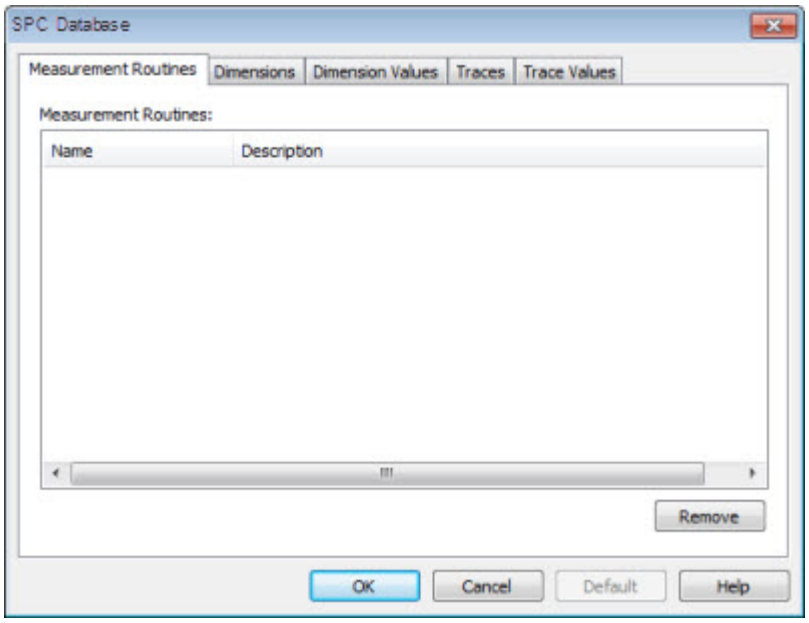
1. From within DataPage+, select **Tools | Database Connection**. The **Database Connection Properties** dialog box appears.

2. Following the documentation available within DataPage+, fill out the dialog box to create the DSN.

By using the ODBC, PC-DMIS can pass data directly to the SPC database, and the data can be viewed within a statistical package that supports the SPC database.

View/Edit Database button

The **View/Edit Database** button can only be used once a valid Data Source has been selected from the **Data Source** box. Clicking this button allows the data in the SPC database to be viewed and deleted from the **SPC Database** dialog box:



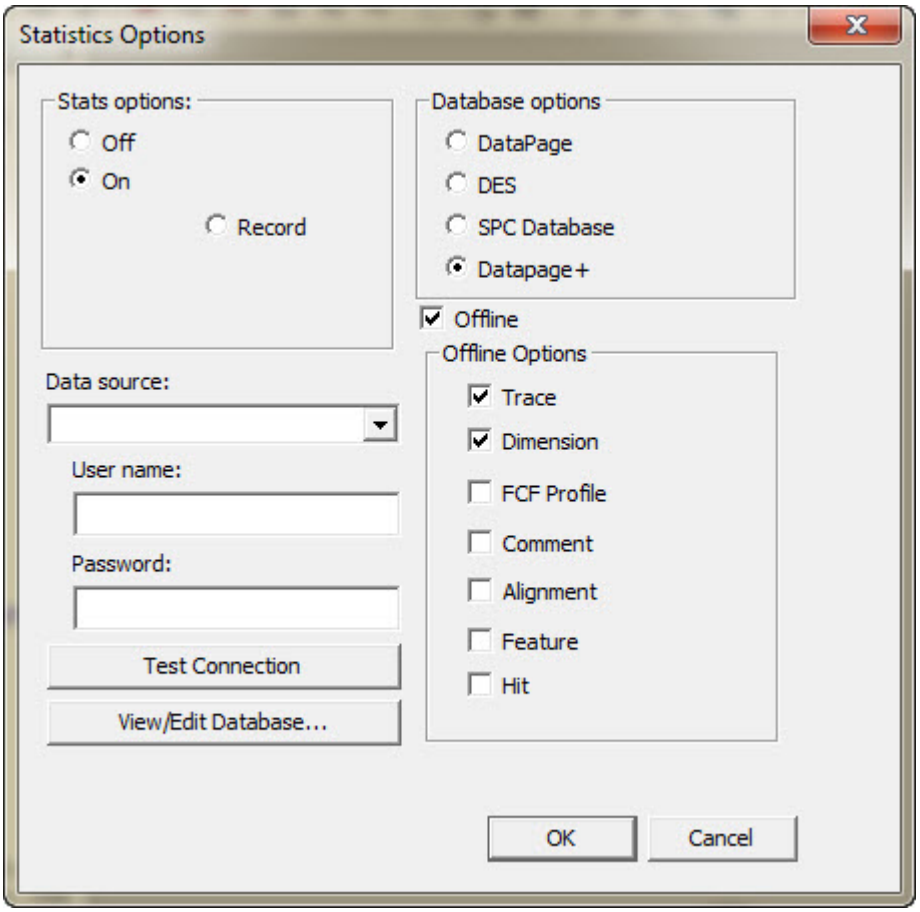
SPC Database Dialog Box

The SPC database can be viewed within PC-DMIS using the following tabs on the dialog box:

- Measurement Routines
- Dimensions
- Dimension Values
- Traces
- Trace Values

You can also view databases using the **SPC Database** menu option.

DataPage+ Option



Statistics Option - DataPage+ Option

If you select **DataPage+** from the **Database options** dialog box, the **Statistics Options** dialog box provides these options so that you can connect to a database used with DataPage+:

Stats options area
The off/on check box allows or stops statistical information to go from your measurement routine to the database. The **Record** option provides greater flexibility and speed for data output. See "Off", "On", and "Record" topics for more information.

Data source list
This list operates the same as the **Data Source** information discussed in the "SPC Database Option" topic.

User name box
In the **User name** box, type a user name for connecting to a password protecteddatabase.

Password box
In the **Password** box, type a password for connecting to a password protecteddatabase.

Test Connection button
This button attempts to establish a connection between PC-DMIS and the specified data source. It will display a success message if the connection successfully connects to the database.

View/Edit Database button
This button operates the same as the **View/Edit Database** information discussed in the table in "SPC Database Option" topic, except that the database is not an SPC database.

Database options area
This area determines which statistical software package receives the measurement information. See " Database Options" for more information.

Offline check box
Mark this check box if you want to send the data to a local DataPage+ database through Offline mode. See "Sending Data to a Local DataPage+ Database" and "Record".

See the "Sending Data to a Local DataPage+ Database" topic for more information.

Sending Data to a Local DataPage+ Database

To send statistical data from PC-DMIS to a local database used in DataPage+, you may need to create a new database.

> Legacy DataPage databases use a different database structure than DataPage+. Therefore, they cannot be used inside DataPage+. To continue building upon your existing data set, you need to perform a dump (or export) of your data and then import that data into a new DataPage+ database using the **Tools | Database Import** menu item in DataPage+. For more information, see the DataPage+ documentation on "Importing Data from an ASCII File".

After you have a database created, if you're using a supported version of PC-DMIS and DataPage+, you can then connect to that database from within your `STATS/ON` command by following the steps below. For information on supported methods and versions, see "Table of Supported Methods".

Step 1: Install .NET Framework v3.5

Before you can send data from PC-DMIS, your computer system must have the .NET Framework v3.5 installed. If needed, you can install it from this link:

http://msdn.microsoft.com/en-us/netframework/default.aspx

Step 2: Create a New DataPage+ Database

If you want to use a new database with DataPage+, you need to use the Database creation tools inside of DataPage+. To do this, start **DataPage+**, and select **Tools | Database connection**. See your DataPage+ documentation for information on creating the new database.

This automatically creates a database and data source for you to connect to from within PC-DMIS. After you have the database created, follow the instructions below to connect to an existing database.

Step 3: Connect to an Existing Data Source and DataPage+ Database

This step describes how to connect a `STATS/ON` command to an existing data source and database.

1. Select **Insert | Statistics Command | Statistics**. The **Statistics Options** dialog box appears.
2. From the **Database options** area, select **DataPage+**.
3. From the **Data source** list, select the name of your data source. If needed, specify a user name and password in the appropriate boxes. You can also send data offline by using the **Offline** check box. In that case, you don't need to establish a connection to the database. For more information, see "Sending DataPage+ Info without a Database Connection (Offline)" below.
4. Click **Test Connection**. If you have set things up correctly, a "Succeeded" message appears.

   The demo database that ships with DataPage+ is only for viewing purposes. You should not use it to send data from PC-DMIS.

5. Click **OK** to close the **Statistics Options** dialog box. Now, your `STATS/ON` command should send statistical data to the specified data source. Your final `STATS/ON` command might look something like this:

   ```
   STATS/ON,DataPage+,dpplus_database
   ```

   This connects to an existing database named dpplus_database.

Sending DataPage+ Info without a Database Connection (Offline)

See the "Record" topic.

Importing XML Data into your DataPage+ Database

You can also import statistical data from XML files into the DataPage+ database. You can send statistical data to XML files with these methods:

- Using DataPageStats.exe

- Using XMLSTATS/ON

You can then use a utility called DataImporter.exe (also in the DataPage+ installation directory). DataImporter.exe checks the directory that contains the generated XML files. It can then pull the data from the .xml files into the database.

For more information on DataImporter.exe, see "Using DataImporter.exe" in the DataPage+ documentation.

For more in-depth information, see the ReadMe.doc file that ships with DataPage+ and also the "XML Statistics Tools" section of the DataPage+ documentation.

Sending Statistics to an XML file using DataPageStats.exe

You can use the DataPageStats.exe utility in the DataPage+ installation directory to send statistics to an XML file. In your measurement routine, add an `External` command that points to this .exe file. Place the command either at the beginning or at the end of the measurement routine, depending on your requirements:

- If you want to receive all the data together, you should place the command at the end of your measurement routine.
- If you want to receive the data after the `External` command finishes execution, insert the command with a **-listening** parameter at the beginning of your measurement routine. For more information and examples, see "Using DataPageStats.exe" in the DataPage+ documentation.

The DataPageStats.exe utility creates an .xml file with the statistical data with each execution.

For information on supported methods and versions, see "Table of Supported Methods".

Sending Statistics to an XML File using XMLSTATS/ON

You can also send your statistical data to an XML file by using the `XMLSTATS/ON` command. This gives you access to the statistical data in a simple text format that you can then manually parse for use with third party tools. For information on supported methods and versions, see "Table of Supported Methods".

`XMLSTATS/ON` replaces the previous XML automation export utility named DataPageStats.exe that ships with DataPage+. You can then use the PcdmisXMLStatsToDatabase.exe utility in DataPage+ to monitor a directory and pull the data from the .xml files into the database. For information on how to do this, see

DataPage+ documentation. For information on how this differs from DataPageStats.exe, see "How XML STAT ON Differs from DataPageStats.Exe" below.

Using XMLSTATS/ON

To insert the `XMLSTATS/ON` command, type "XMLSTATS" and then press the Tab key on your keyboard in the Edit window's Command Mode; or select the **Insert | Statistics Command | XML Statistics** menu item. This command has the following syntax:

```
XMLSTATS/<TOG1>,<Directory>
```

<TOG1> - This field toggles between either ON or OFF, letting you choose whether or not to export statistical data for measurement commands that follow this command.

<Directory> - This field takes a string (without quotes) as the directory pathway in which the file will be created. The default pathway is the directory where you store your measurement routines.

`XMLSTATS/ON` only writes the XML during execution. It writes the file to the specified directory and automatically generates the .xml file's name using this format:

<Measurement Routine>_<Day>-<Month>-

-___
.XML

<Measurement Routine> - The measurement routine name without the PRG extension.

<Day> - The name of day the measurement routine was executed in local time.

<Month> - The name of the month the measurement routine was executed in local time.

<dd> - The day of the month in two digit number format in local time.

<YYYY> - The year the measurement routine was executed displayed in four digit format in local time.

<hh> - The hour the measurement routine was executed (in 24-hour local time).

<mm> - The minute the measurement routine was executed in local time.

<ss> - The second the measurement routine was executed in local time.

Thus, a measurement routine named "Test.prg" executed on August 12, 2010 at exactly 2:40:15 PM local time, would have this file name:
Test_Thursday_August-12-2010_14_40_15.XML

The XML file contains data for all commands that follow the `XMLSTATS/ON` until execution finishes or until execution encounters an `XMLSTATS/OFF` command. If execution encounters another `XMLSTATS/ON` command while writing to a file, it will write

a closing `</ExecutionTransaction>` tag in the XML file and then allow the next `XMLSTATS/ON` command to write another opening `<ExecutionTransaction>` tag.

For example, suppose you had this pseudo measurement routine:

```
XMLStats/ON
Dimension1
XMLStats/OFF
Dimension2
XMLStats/ON
Dimension3
```

Following execution, PC-DMIS would generate a single file with two `<ExecutionTransaction>` tags. The first tag would contain Dimension1:

```
<ExecutionTransaction DateTime=”Sometimestamp”>
   <XMLStats command data>
   <Dimension1 Data>
</ExecutionTransaction>
```

The second file generated would contain Dimension3:

```
<ExecutionTransaction DateTime=”Sometimestamp”>
   <XMLStats command data>
   <Dimension3 Data>
</ExecutionTransaction>
```

How XML STATS/ON Differs from DataPageStats.Exe:

- `XMLSTATS/ON` is faster than DataPageStats.exe.
- It outputs everything DataPageStats.exe did but includes more.
- You do not need to insert an external command at the end of your measurement routine as you did when using DataPageStats.exe.
- You can choose what data gets sent to the XML file by turning `XMLSTATS` commands on and off as needed.
- `XMLSTATS` adds a time stamp within each `<ExecutionTransaction>` tag pair. In addition, the filename itself, as discussed above, is comprised of the part name and the time of execution.

Table of Supported Methods

To import data from PC-DMIS, you can use DataPageStats.exe with any version of PC-DMIS and DataPage+. If you want to use `STATS/ON` command, consider the table below:

DataPage+	PC-DMIS	Supported Methods
Version 5.0 and earlier	Versions earlier than 2012 MR1	DataPageStats.exe
Version 2012 MR1 and later	DataPageStats.exe STATS/ON XMLSTATS/ON	
Version 5.1 and later	Versions earlier than 2012 MR1	DataPageStats.exe
	Version 2012 MR1 to 2015.0	DataPageStats.exe XMLSTATS/ON
	Version 2015.1 and later	DataPageStats.exe STATS/ON XMLSTATS/ON

Geometric Tolerance commands only support the STATS/ON method for statistical output to Datapage+ or Q-DAS.

Reporting Measurement Results

Reporting Measurement Results: Overview

For tutorials in your language, please contact your regional office or headquarters.

After you measure your part, it's important to be able to communicate your measurement results with others. PC-DMIS, by default, sends your measurement data to a standard textual report, called an inspection report. It includes comprehensive data about each feature measured by your measurement routine. You can send this report to the printer or to a file and later view stored reports by selecting **View | Inspection Report**. See "Viewing an Inspection Report" and "Printing the Report Window".

For many tasks, the standard inspection report may be exactly what you need. However, PC-DMIS also gives you some powerful tools to generate your own interactive reports. With these tools, you can use templates to determine exactly how your reports look and what information gets included in them. Also, with these templates, you can maintain a consistent look and feel across several reports.

In addition, you have the option to create reports for specific measurement routines called "Custom Reports". This is a useful solution when your reporting needs don't require the use of report templates.

You can only save report (.rpt) files in valid versions of PC-DMIS.

For this version of PC-DMIS, you can save your report file back to version 2021.1. That's the earliest valid version.

This chapter covers the following main topics:

- Reporting Tutorials
- Working with Legacy (HyperView) Reports
- Report Generation Sequence
- About the Report Window
- Using Standard Reports

- Viewing a Legacy Text Report
- Reported Tolerance Zones for Form Dimensions
- Rearranging Report Pages
- Modifying Standard Templates
- Using .DAT Files in Generated Reports
- Modifying the Report's Header
- Changing the Report's Text Colors
- Adding Notes to a Report
- About the Reporting and Form Editors
- Creating Templates
- Creating Forms
- Creating Custom Reports
- About Report Expressions
- Using PC-DMIS ActiveX Controls
- Tutorial - Using Scripting to Enhance your Report
- Working with PDF 3D Files
- QIF Report

Reporting Tutorials

This topic provides a list of available reporting tutorials. If you are new to the template-based reporting functionality that PC-DMIS uses, you should go through these tutorials in order to better understand how reporting is currently handled.

The tutorials below are displayed in the order that they appear in the overall documentation structure of the "Reporting Measurement Results" chapter. You may want to go through this chapter from the beginning to understand how the documentation topics are structured contextually.

- Tutorial - Creating a Report Template (Under the "Creating Templates" main topic)
- Tutorial - Creating Label Templates (Under the "Creating Templates" main topic)

- Tutorial - Customizing a Report Template (Under the "About Reports and Report Templates" main topic)
- Tutorial - Creating Forms (Under the "Creating Forms" main topic)
- Tutorial - Creating a Custom Report (Under the "Creating Custom Reports" main topic)

Additionally, you may find these other main reporting topics and procedures useful:

- Modifying Standard Templates
- Modifying the Report's Header
- Viewing a Legacy Text Only Report
- Changing the Report Window's Contents

Working with Legacy (HyperView) Reports

Legacy reporting (formerly known as HyperView reporting) existed in older 3.x versions of PC-DMIS. It provided the basis for the newer template and form and reporting environments used in 4.x and later versions.

By default, PC-DMIS uses the newer template approach to reporting. What does this mean for those of you with legacy Hyper Reports?

PC-DMIS provides the ability for you to:

- Migrate your HyperView reports into either a custom report or a form. See "Migrating Legacy (HyperView) Reports".
- Continue working directly with your HyperView Reports. You can create and edit reports. See "Using Legacy (HyperView) Reporting".

Migrating Legacy (HyperView) Reports

While you can now create and edit HyperView reports in version 4.3 MR1 and later, you may want to migrate your legacy HyperView reports into PC-DMIS's new reporting environment so that you can work with them there instead.

To convert an existing HyperView report:

1. Select **File | Reporting | Edit | Legacy Report** to open the HyperView report. The report will open in run mode.
2. Select **File | Convert To** and then select either **Report** or **Form**.

- If you select **Report**, PC-DMIS will convert your HyperView report to work with the **Custom Report Editor**. However, all objects may not be converted. Only objects supported by custom reporting will be converted. See "Creating Custom Reports".
- If you select **Form**, PC-DMIS will convert your HyperView report to work with the **Forms Editor**. However, all objects may not be converted. Only objects supported in Forms will be converted. See "Creating Forms".

You can then modify the report or form in the appropriate editor. The original HyperView report remains untouched.

Be aware that certain objects that used to appear in the HyperView Report Editor may not be supported by your selected migration route. For example, if your HyperView report contains button objects, and you migrate them into the Custom Report Editor, the buttons will appear in the editor, but they will not function in the Report window.

Using Legacy (HyperView) Reporting

PC-DMIS also supports the creation and editing of HyperView reports.

- To create a new legacy report, select **File | Reporting | New | Legacy Report**.
- To edit an existing legacy report, select **File | Reporting | Edit | Legacy Report**. The HyperView report will open in run mode. Press CTRL + E to toggle between editing the report in edit mode or testing it in run mode.

Since HyperView reporting is legacy functionality, the documentation doesn't actively exist as topics in this documentation. However, you can download a PDF file of the HyperView documentation by following the link below:

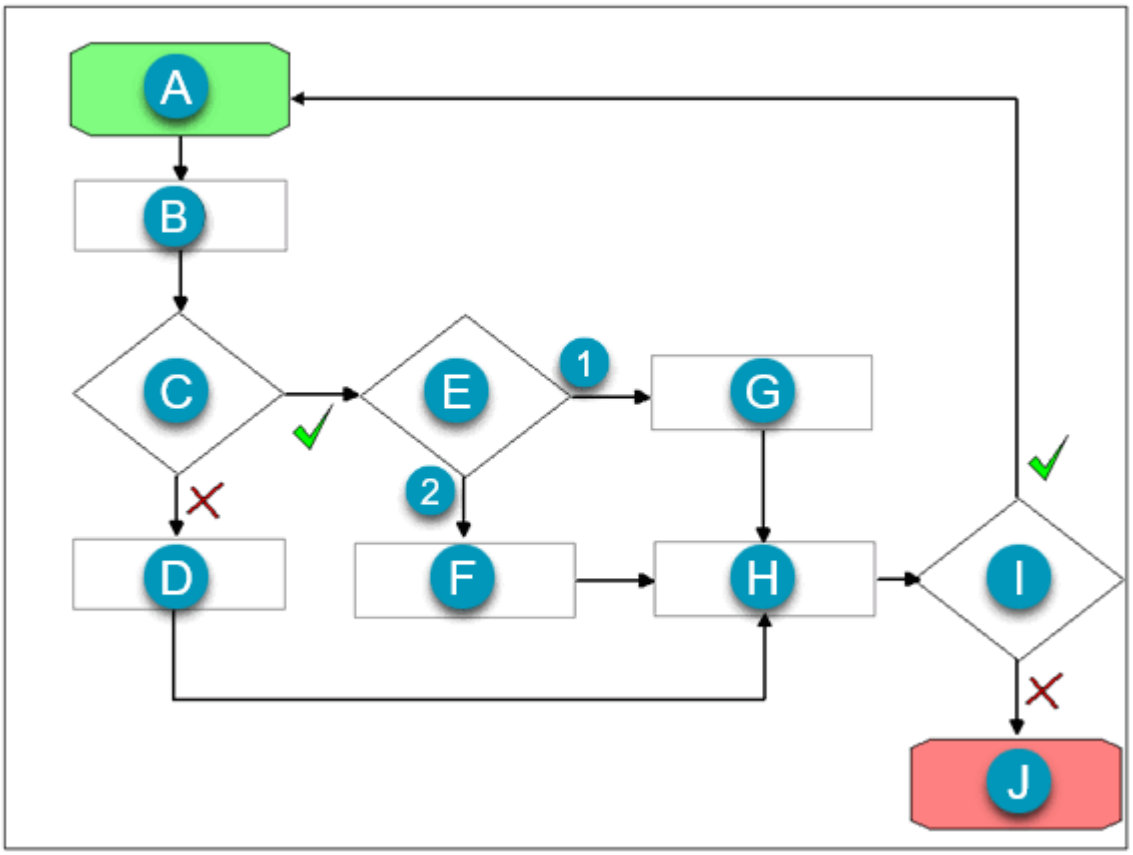
1. In your Internet browser, access this site: https://downloads.ms.hexagonmi.com/docs/FilesInHelps
2. Download the file "creating_hyperview_reports.pdf".

Report Generation Sequence

This topic describes the process by which the report objects in report templates are bound to measurement data and drawn in the Report window during the report generation process.

- PC-DMIS executes each command from the measurement routine.
- Information from each command goes to the report template for possible processing.

- Report objects on the report template are queried, and if the command from which the information came is defined in the **Rule Tree Editor** (for information, see "Defining a Rule in the Rule Tree Editor") to call a label template, then that label template is called. If not, the information will not be displayed in the final report.
- Data is sent to any called label templates to be formatted and displayed according to how the GridControlObject and other reporting objects in the label template are defined (for information see "The Object Bar").
- The report template finally displays the called label templates with their formatted data and displays its own information and any static elements in the Report window.



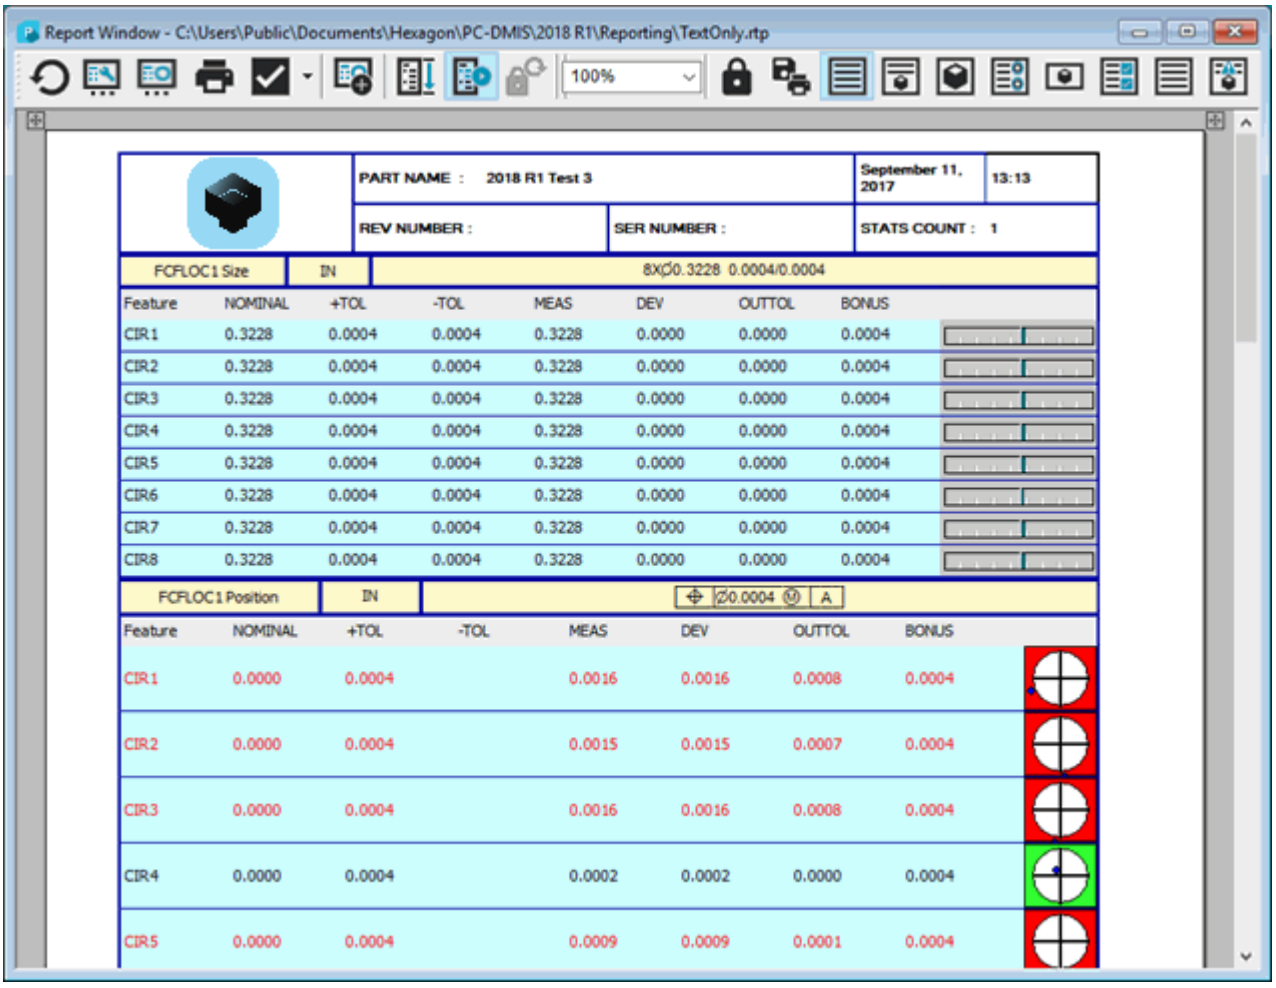
*A - **Measurement Routine Executes a Command***
B - Data from Command Goes to Report Template
C - Command Defined in Rule Tree Editor (RTE)?
D - Nothing Happens
E - RTE Calls Label Template or Text Display
E1 - Label
E2 - Text
F - Textual Message Displayed Instead of a Label Template Call
G - Label Template Formats and Displays Passed Data
H - Report Window Displays Information for Command
I - More Commands to Execute?
J - End

About the Report Window

To display the Report window, select **View | Report Window**. This window displays your measurement results. The Report window acts as any other window in the PC-DMIS application and is subject to the operations on the **Window** menu as well. The Report window's title bar displays the pathway and filename of the current loaded report template. The Report window also has its own **Reporting** toolbar.

With Report Templates

If you use report templates, this window, after measurement routine execution, displays your measurement results and automatically configures the output according to a default report template. You can set any report template as the default report template, but initially PC-DMIS uses the "TEXTONLY.RTP" template.



Report Window showing a standard, text-based report from TEXTONLY.RPT

The Report window contains static content based on the selected report template and the current measurement routine. See "Creating Templates".

With Custom Reports

For a Custom Report, this window does not use a report template to configure or display its data. Instead, it loads the information that you've already defined in the stored custom report. See "Creating Custom Reports".

Reporting Toolbar

Reporting Toolbar

The Report window's **Reporting** toolbar performs these functions:

1. **Redraw the Report** - Redraws and updates the report with newly added changes. If you modify the current report template, label template, or custom report, or your measurement routine changes, click this icon to redraw and update your report to use the newly-modified template or new data from your measurement routine.

2. **Preview Pane** - Opens and closes a pane of thumbnail images so that you can preview the report. Each image on the pane corresponds to a page on the report. For more information, see "Working with the Preview Pane" in this chapter.

3. **Template Selection** - Displays a dialog box that allows you to manage your templates and select a template from which to generate your report output. For more information, see "Applying or Removing a Report Template".

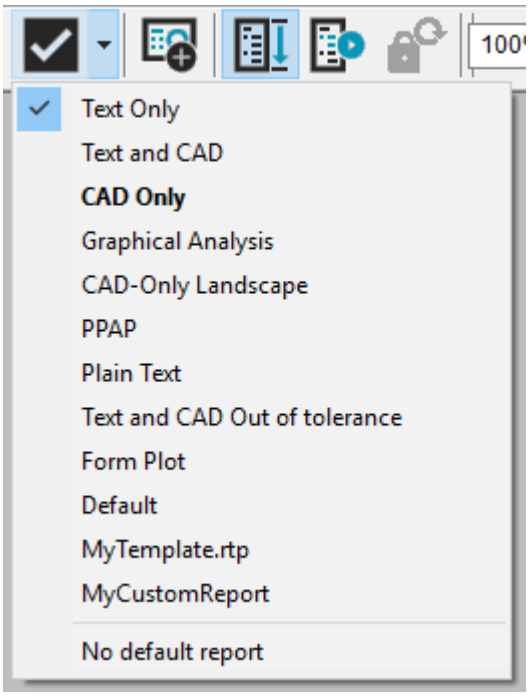
4. **Custom Report Selection** - Displays a dialog box that allows you to create a new blank custom report or open an existing custom report. For more information, see "Creating Custom Reports".

5. **Print Report** - Prints the report based on the output settings defined for the Report window. For information on defining your output, see "Setting Output and Printer Options for the Report Window" in the "Using Basic File Options" chapter.

6. **Set this report as the default report** - Sets the current template on the screen as the new default template for your current measurement routine. PC-DMIS automatically uses the defined default report template whenever you open your measurement routine at a later date. Initially, this default report is set to TEXTONLY.RTP.

The drop-down menu next to this icon lets you set a default report without having to load it first. It displays all the saved report layouts.

To set the default report, select the item from this list. PC-DMIS places the check mark next to it to indicate it as the new default report. The currently loaded report is indicated by a **bold** font.



For example, in the above image, the check mark indicates TextOnly.rtp as the default report and CADOnly.rtp as the current loaded report.

If you select **No default report** then nothing appears in your Report window the next time you load the measurement routine and access the Report window.

Setting a Default Report for All Measurement Routines

If you want to set a default report for all measurement routines, use the PC-DMIS Settings Editor, access the **FileMan** section, and set the `DefaultReportTemplate` entry to the name of the report template you want to use. For information on entries, see the "Modifying Setting Entries" appendix.

7. **Add Template to Toolbar** - Saves the current report template or custom report as a stored report, and a new stored report icon appears on the toolbar with the same name as your template or custom report to the right of the standard report icons. When you click the added icon, the Report window automatically uses the saved template or custom report to display your report.

8. **View Report Mode** - Generates the report from the first command to the last command in the measurement routine, regardless of how PC-DMIS last executed the measurement routine.

9. **Last Execution Report Mode** - Shows only those items executed in the most recent measurement routine execution. It also shows the commands in the same order in which they were executed. If commands are executed multiple times due to a loop, it shows those multiple executions as well.

   The `SaveExecuteList` entry in the **Reporting** section of the PC-DMIS Settings Editor determines whether or not this information is retained when you later re-open your measurement routine. By default, this functionality is enabled.

   - If set to 1, PC-DMIS stores the items reported during your last execution within your measurement routine, so you can easily view them later by selecting the **Last Execution Report Mode** icon.
   - If set to 0, PC-DMIS only stores the information temporarily. If you close your measurement routine, PC-DMIS clears out this information.

   Partial Executions and Last Execution Report Mode

   If you perform partial executions, PC-DMIS appends the reported items to the execute list, potentially causing items to be reported that you don't need reported. You can clear out any partially-executed items from the stored execute list by performing a full execution.

10. **View Last Saved Report** - Restores the saved report data to what it was at the time it was last locked. This includes the execute list, temporary modifications made, and the mode that was last used (either Report Mode or Last Execution Report Mode).

11. 
Selecting an item from this list sets the report's magnification in the Report window. The zoom level doesn't affect how the report prints out, but you may find these options helpful when previewing the report or determining what template to use.

- For small percentages, the pages are laid out side by side horizontally first and then vertically. You can also type in a specific magnification. Using a small percentage makes it easier to rearrange pages. For more information, see "Rearranging Report Pages".
- For large percentages, where you are zoomed in on one portion of the report, you can pan the report by either using the scroll bars or by holding Ctrl and dragging on the main page of the report (dragging on a label moves that label). PC-DMIS drags the image in the direction that you pull the mouse.

12. **Lock the Report** - Locks the Report window so that modifications can't be made to any reports in the window. In addition, whenever you click this icon, PC-DMIS saves the following:

    - Temporary modifications you made
    - The execute list
    - The type of report mode used (**Report Mode** or **Last Execution Report Mode**)

    You can restore this saved information by clicking the **View Last Saved Report** icon.

    PC-DMIS shows the icon as "pressed" to indicate it is locked:

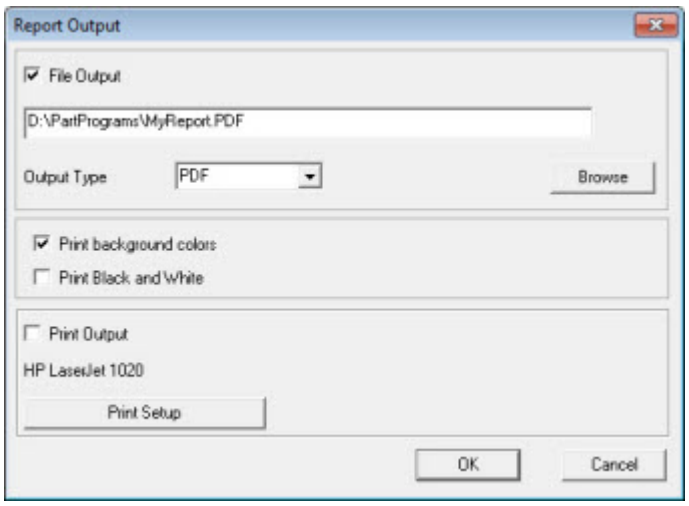
    Also, with the Report window locked, the mouse pointer changes to this symbol whenever you move the mouse over the window to indicate that the report is in a locked state and cannot be modified:

    You can still scroll, print, and view items in the Report window, but you cannot make any modifications to any report until you unlock the window by clicking the icon again.

13. **Save** - Saves the edited custom report with the same name. PC-DMIS enables this button if you enter edit mode with **Edit report** below.

14. **Save As** - Saves the custom report with a new name. PC-DMIS enables this button if you enter edit mode with **Edit report** below.

15. **Save/Print the Report** - Displays a **Report Output** dialog box where you can save the report as a .pdf, .rtf, or .txt file or send it to the default printer.



File Output - Determines whether or not the software sends the report to a file when you click **OK**. The box beneath this check box defines the pathway and file name for saving it as a file. Make sure the filename in this box lists a valid extension.

Output Type - Defines the output type to generate when saving the report as a file. If you type a different extension, the report is not saved to the file.

PDF - Generates a .pdf file using the current report template for the output.

RTF - Generates an .rtf file using the current report template for the output.

TXT - Generates a simple plain-text report using the default.rtp template. It doesn't have any formatting.

3D PDF - Generates a .pdf file as 3D PDF. In this type of .pdf file, you can manipulate the CAD model directly in the .pdf. For more information, see "Working with PDF 3D Files".

Print background colors and **Print Black and White** - Determines whether or not to generate the report with background colors or as a black and white report. For information, see where these are already documented in the "Setting Output and Printer Options for the Report Window" topic in the "Using Basic File Options" chapter.

Print Output - Sends the report displayed in the Report window to the selected printer when you click **OK**. Initially, this is set to your default printer.

Print Setup - Displays the standard Windows **Print Setup** dialog box so you can choose a different printer or change printer options.

16. **Edit report** - If your report is a custom report, this opens your report in edit mode. If your report is one of these supported template reports (Text Only, Text and CAD, CAD Only, or CAD-Only Landscape), the software converts it into a custom report first, and then the software enters edit mode.

> Template conversion does not support data from loops.

For information on editing custom reports, see "Editing or Deleting Custom Reports". For information on custom reports and how to create them, see "Creating Custom Reports".

17. **Text Only**
18. **Text and CAD**
19. **CAD Only**
20. **Graphical Analysis**
21. **CAD-Only Landscape**
22. **PPAP**
23. **Plain Text**
24. **Text and CAD Out of Tolerance**
25. **Form Plot**
26. **Default**

For descriptions and examples of the standard reports (items 17-26 in this list), see "Using Standard Reports" below.

27. This style of icon, if found to the right of the **Default** icon, depicts a modified report template that has been saved to the toolbar. You can use the Report Template Editor to modify existing templates or create new ones. For more information, see "Understanding the Report Template Editor".

28. This style of icon, if found to the right of the **Default** icon, depicts a custom report that has been saved to the toolbar. For information on custom reports, see "Creating Custom Reports".

Customizing and Restoring the Toolbar

You can add your own templates or custom reports to the toolbar by using the **Add Template to Toolbar** icon discussed above. When you add a report to the toolbar, a new icon for that report or template appears on the right side of the toolbar. Each new icon you add represents a stored custom report or custom report template.

- To remove any report icons from the toolbar, hold down Shift and then drag the icon off of the toolbar. This only removes the template or report from the toolbar; it does not delete the item from the system.
- To restore the toolbar to its original toolbar icons, you can do the following:

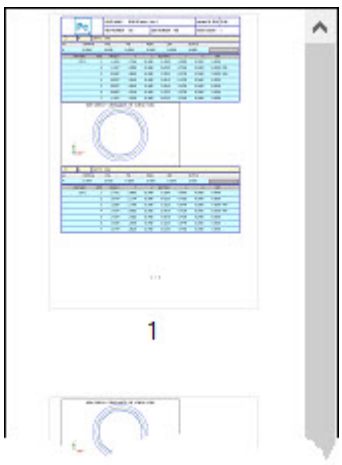
  1. Close PC-DMIS.
  2. Navigate to the C:\Users\<username>\AppData\Local\Hexagon\PC-DMIS\<version>, where <username> is your Windows user name and <version> is the version of PC-DMIS you are using.
  3. Delete reportingtoolbar.dat.
  4. Restart PC-DMIS.

> **!** The **Reporting** toolbar only resides within the Report window. You need to access the Report window to see it. You cannot select it from the toolbar area of the main PC-DMIS interface.

Working with the Preview Pane

The **Preview Pane** button ( ) on the Report window's **Reporting** toolbar opens and closes a pane of thumbnail images so that you can preview the report.

Each thumbnail image on the pane corresponds to a page on the report.



Preview Pane

When the pane is open, you can click on a thumbnail image to go to that report page.

Entering Edit Mode for Custom Reports

To perform certain operations with the preview pane, you need to place your custom report into edit mode. This accesses a slimmed down version of the Custom Report Editor. This lets you edit a report without leaving the usual PC-DMIS menu structure. You can do this through either of these options:

- Click **Custom Report selection dialog** ( ) and then click **Blank Report** and then **Open**.
- Click **Edit report** ( ).

For more complex edits, you can still use the Custom Report Editor.

Adding and Deleting Pages in Custom Reports

In edit mode, you can add or delete pages on your custom report.

To add a page, click the large plus button ( ) after the last thumbnail image; or right-click on any thumbnail image and select **Add Page**.

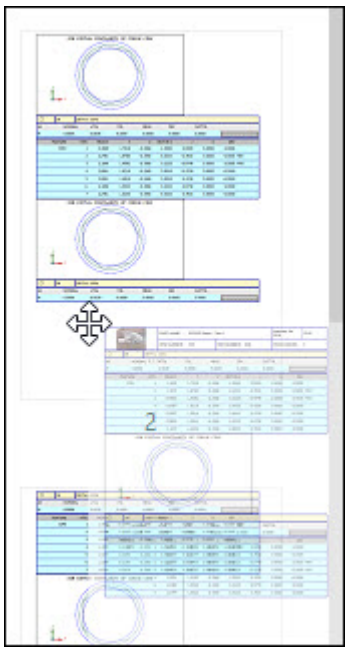
To delete a page, either select a thumbnail image and press Delete on your keyboard; or right-click on the thumbnail image and select **Delete Page**. You must always have at least one page in your report.

For more information on custom reports, see "Creating Custom Reports" in this chapter.

Ordering Pages in Reports

To define the order of pages in any report:

1. Locate the thumbnail image of the page you want to move.
2. Drag that page to the desired location up or down in the preview pane.
3. Release the mouse button when you see the crosshair cursor ( ) to insert the page at that location.



Moving Objects to Other Pages in Custom Reports

In edit mode, you can move one or more objects from one page to another page through the thumbnail images.

1. Select the objects that you want to move until you see the green handles around them. (You can press Ctrl to select multiple objects.)
2. Drag the objects onto the thumbnail image of the page where you want to place the objects.
3. Release the mouse button.
4. Click on that thumbnail image to go to the page, and position the object.

Another way to move objects to another page is to cut the objects (Ctrl + X), click on the thumbnail image of the page, and then paste the objects (Ctrl + V).

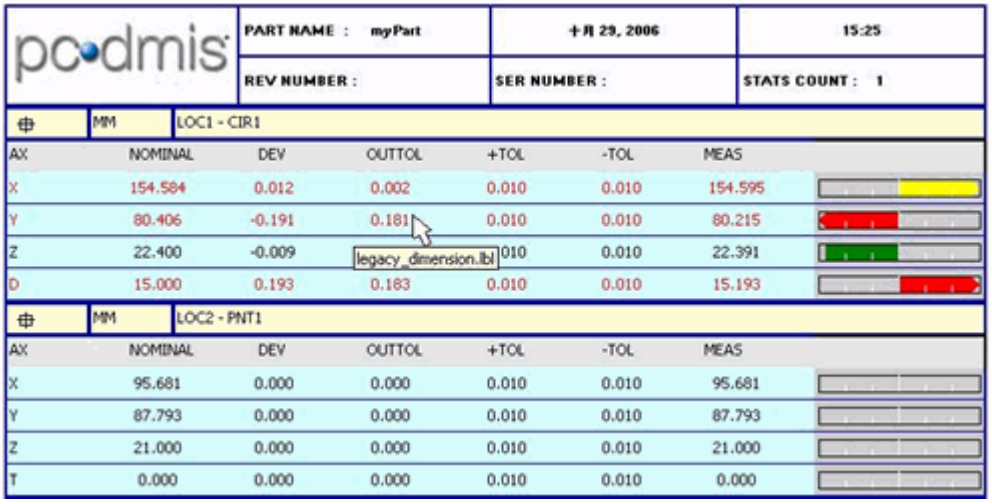
If you select a CADReportObject, and move that to a new page, any labels associated with it also move with it. You cannot move labels to that object by themselves.

Sizing the Preview Pane

You can size the pane with your mouse pointer. To do that, drag the vertical bar that separates the pane from the report. You can size the pane to a maximum of 30% of the report's width and a minimum of 10% of the report's width.

PC-DMIS saves the visibility state of the pane and the pane's width to the current measurement routine. PC-DMIS uses the last used visibility state and width for new measurement routines.

Using Tooltips in the Report Window



Example report showing a tooltip with the name of the label being used

By simply moving your mouse over different parts of the Report window, you can get information in the form of a tooltip about what label is being used, or if there is no label, the tooltip will display either the name of the object or the current page number.

- If the object is a label, the tooltip displays the label template file name.
- If the object is not a label, for example, if it's a **TextReportObject** or a **CadReportObject**, the tooltip displays the object name that is defined in the report template.
- If you hold the mouse over an empty space on the page, (technically the **Page** object), the tooltip displays the page number.

These tooltips provide you with a simple way to find out what objects are being used in the report.

For information on objects, see "The Object Bar".

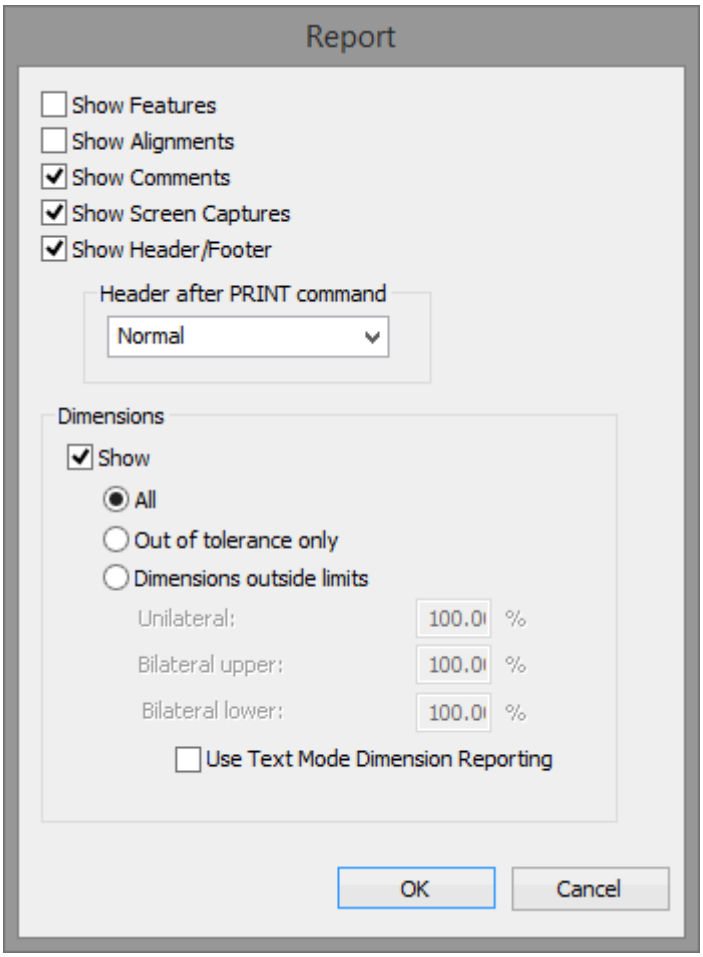
Changing the Report Window's Contents

See the "Shortcut Menus in the Report Window" topic for a list of functions you access to perform some of the modifications discussed in this topic and its subtopics.

While you can permanently change how and what information appears in your Report window by modifying the underlying templates and the rules used, you can also perform modifications to the objects on a Report window directly within the Report window by using the information provided in the topics below.

Please note that custom reports, templates, label templates, and other reporting modifications are NOT backwards compatible.

Edit Text Reporting

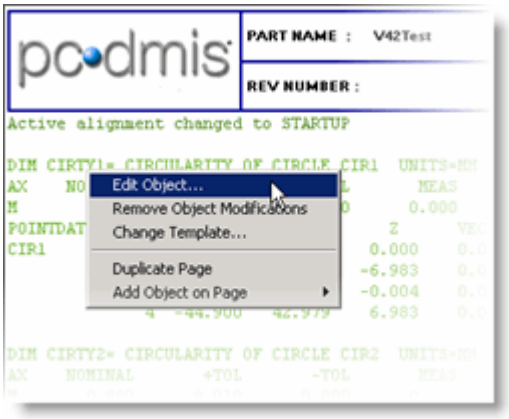


Report Dialog Box

The **Report** dialog box (available with template reporting) lets you determine the overall information that PC-DMIS includes in the Report window and how it displays that information.

You can access this dialog box in these ways:

- Right-click on any text-only reporting text or white space at the end of the Report window and then select the **Edit Object** menu item when the shortcut menu appears.



For additional information on this shortcut menu, see the "Shortcut Menus in the Report Window" topic from the "Using Shortcut Keys and Shortcut Menus: Introduction" appendix.

- Press Shift and then right-click on any label object in the Report window, and then select the **Edit Object** menu item.

The following check boxes let you show or hide various items:

Show Features

This option displays all feature measurements in your measurement routine.

If you are using the default report template, textonly.rtp, and your measurement routine measures a feature with more than the minimum number of points, it also displays a form plot of the feature.

Show Alignments

This option shows alignment changes as they occur during the measurement routine. It will display all alignment changes that occur in the dimension or feature lists.

Show Comments

This option shows any comments that have been added to the measurement routine. (For information on comments, see "Inserting Programmer Comments" in the "Inserting Report Commands" chapter.)

Show Header / Footer

This option displays a header and footer in your report by applying the label template defined in the **File Header** rule of the **Rule Tree Editor**. By default, this is the FILE_HEADER.LBL label template that ships with PC-DMIS.

Show Screen Captures

This option displays any screen capture graphics related to DISPLAY/METAFILE and ANALYSISVIEW commands in the report. (For information on screen captures, see "Using Screen Captures of the Graphic Display Window" in the "Editing the CAD Display" chapter.)

The **Header after Print command** area is enabled if you mark the **Show Header / Footer** check box. This area determines how PC-DMIS handles a report header *after* a PRINT/REPORT command. The list in that area contains these options:

Normal

PC-DMIS generates only one report header. It does not generate a new report header even if you execute a measurement routine with a PRINT/REPORT command in any kind of loop. (For information on the different kinds of loops, see the "Branching by Using Flow Control" chapter.)

Always

PC-DMIS always generates a new report header for any next report output that follows the PRINT/REPORT command.

If File Header executed

PC-DMIS generates a new report header only if you executed the File Header command block before the PRINT/REPORT command. The File Header is the command block in the Edit window that has the part name, revision number, serial number, and so on. (This shows as "File Header" in Summary Mode.) By default, the File Header uses the FILE_HEADER.LBL template during report generation. While you cannot delete the File Header command block, you can skip over it with certain partial execution options, such as **Execute from cursor**. (For more information on partial execution, see "Executing Measurement Routines" in the "Using Advanced File Options" chapter.)

For more information on the PRINT/REPORT command, see "Inserting a Print Command" in the "Inserting Report Commands: Introduction" chapter.

The **Dimensions** area allows you to control the display of dimensions in your reports. To display dimensions, select the **Show** check box. Once selected, the other items in this area become available for selection. These include:

All

Selecting this option acts just as if you had selected both the **Out of Tolerance Only** and **Dimensions Outside Limits** options.

Out of Tolerance Only

If this option is marked, PC-DMIS will only show the out of tolerance dimensions. ("Show Dimensions" must be ON.)

This option is only available when you select **Show Dimensions** and *deselect* **Show Dimensions Outside Limits**.

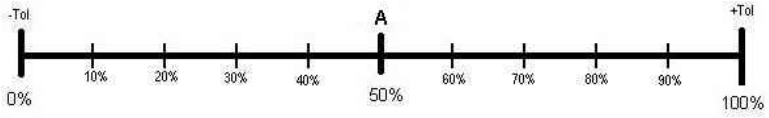
Dimensions Outside Limits

If you select this option, PC-DMIS will only show the dimensions that lie outside the percentage of the tolerance zone.

When you select the **Show Dimensions Outside Limits** check box, the tolerance percentages will become editable, allowing one percentage for unilateral tolerances and an upper and lower percentage for bilateral tolerances.

The tolerance zone can be considered as a range between 0 and 100 percent (similar to how dimension colors are applied to tolerance zone regions or how the colored bar graphs are drawn at the end of dimensions). The lower limit (nominal - minus tol) corresponds to 0% and the upper limit (nominal + plus tol) corresponds to 100%. Consider the following chart where A, on the center of the chart, represents the nominal value:

Chart



Dimensions that have deviations outside the tolerance zone will either be less than zero or greater than one hundred percent.

For a *unilateral* dimension (like roundness, which only has a plus tolerance), the zero deviations are at zero percent, and out of tolerance is anything larger than one hundred percent.

Unilateral Example

Nominal: 0.0000

Measured: 0.0028

Deviation: 0.0028

Plus Tol: 0.0050

Minus Tol: 0.0000

Because this deviation is 56% of the tolerance range, it will be displayed if Unilateral Percentage is less than 56%.

For a *bilateral* dimension (like distance, which has both a plus and minus tolerance), the zero deviations are somewhere in the middle. If the tolerances are equal, the zero deviations will be at the fifty percent position.

Bilateral Upper Example

Nominal: 3.0000

Measured: 3.0075

Deviation: 0.0075

Plus Tol: 0.0100

Minus Tol: 0.0100

The percentage is calculated using the Lever Rule:

(measured value – lower limit) / (upper limit – lower limit) * 100.

With this data, it would be:

*(3.0075-2.9900) / (3.0100-2.9900) * 100. = 87.5%*

This dimension will be displayed in the inspection report if the Bilateral Upper Percentage is *greater* than 87.5%.

Bilateral Lower Example

Nominal: 3.0000

Measured: 2.9925

Deviation: 0.0075

Plus Tol: 0.0100

Minus Tol: 0.0100

The percentage is calculated using the Lever Rule:

(measured value – lower limit) / (upper limit – lower limit) * 100.

With this data, it would be:

*(2.9925-2.9900) / (3.0100-2.9900) * 100. = 12.5.%*

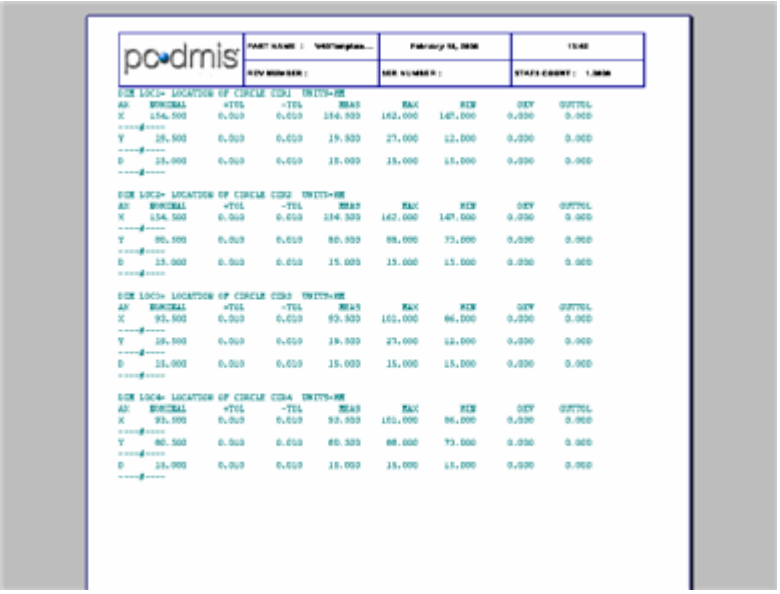
This dimension will be displayed in the inspection report if the Bilateral Lower Percentage is *less* than 12.5%.

Use Text Mode Dimension Reporting

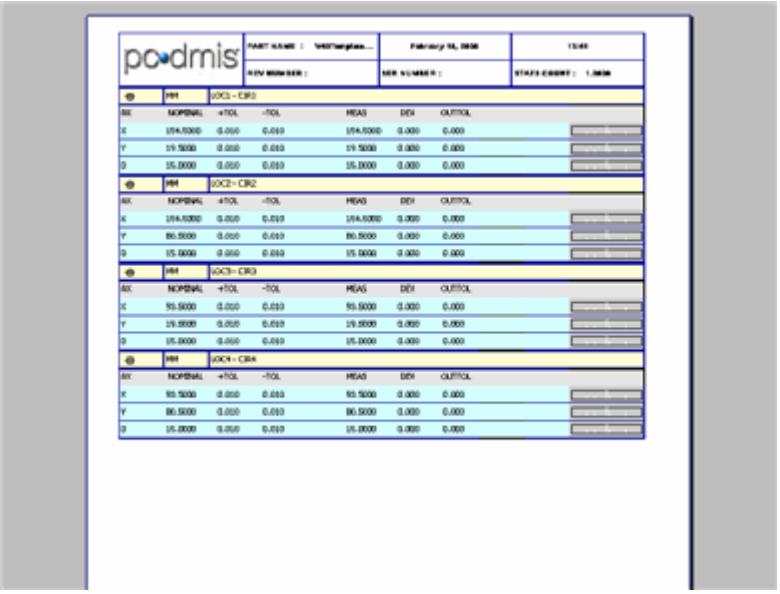
This check box determines whether PC-DMIS uses formatted text (selected) or uses a graphics table (not selected) for displaying the dimensions.

For this report type, you must use only Legacy dimensions in your measurement routine.

Sample Report with "Use Text Mode Dimension Reporting" Selected:



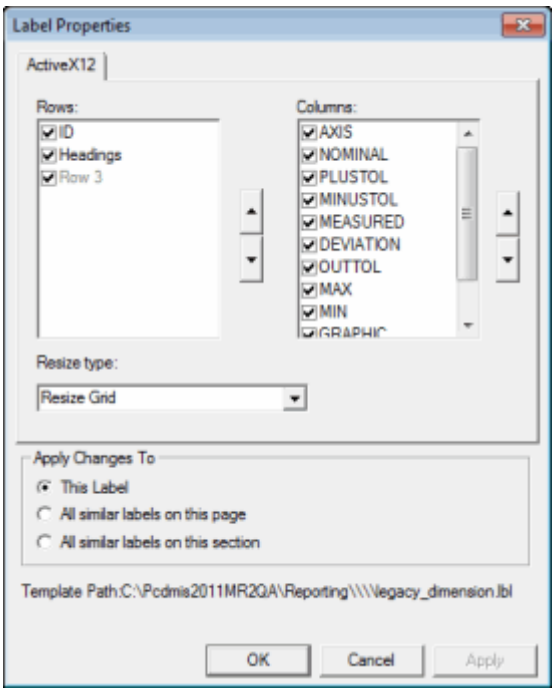
Sample Report with "Use Text Mode Dimension Reporting" Not Selected:



If PC-DMIS cannot find a specified report template, it will use a template named "default.rtp". This generic template provides you with a basic text-based report. Since default.rtp only supports text-based reporting, clearing this check box will do nothing.

Edit Label Reporting

If you right-click on a label and click **Edit Object**, the **Label Properties** dialog box appears.



Label Properties Dialog Box

With this dialog box you can change the order of columns and rows, or you can control the visibility state of individual columns and rows.

> **To change the order** - Select a row or column, then click the black up or down arrow.
>
> **To hide or show an item** - Clear the check box next to the item to hide it. Select the check box to display it.

Once you have made the desired modifications to the label, select one of the option buttons at the bottom to apply the changes to the current label, all similar labels on the current page, or all similar labels in the entire section.

Determine what the label will do whenever you hide or show columns, by selecting an item from the **Resize Type** list. For a label associated with a CadReportObject, **Resize Grid** is the only option. For other label contexts, these three items are available:

> **Resize Grid** - This retains existing column sizes and resizes the label to fit the new width.
>
> **Resize Columns to Fit** - This retains the label's existing width and resizes each column equally to fit the existing width.
>
> **Hide Text** - This doesn't resize the label or the columns. It simply hides the text.

Click **OK** and PC-DMIS will change the display.

Edit Label Positioning and Size

If your label has leader lines or it is a free label (it isn't part of a TextReportObject), if you press CTRL and then click on a label (or if you drag the mouse to box-select a label), you will see that it becomes selected. Once selected, you can drag it to a new location or re-size it by clicking and then dragging the black square handles that surround the selected label.

Edit CAD Model Reporting

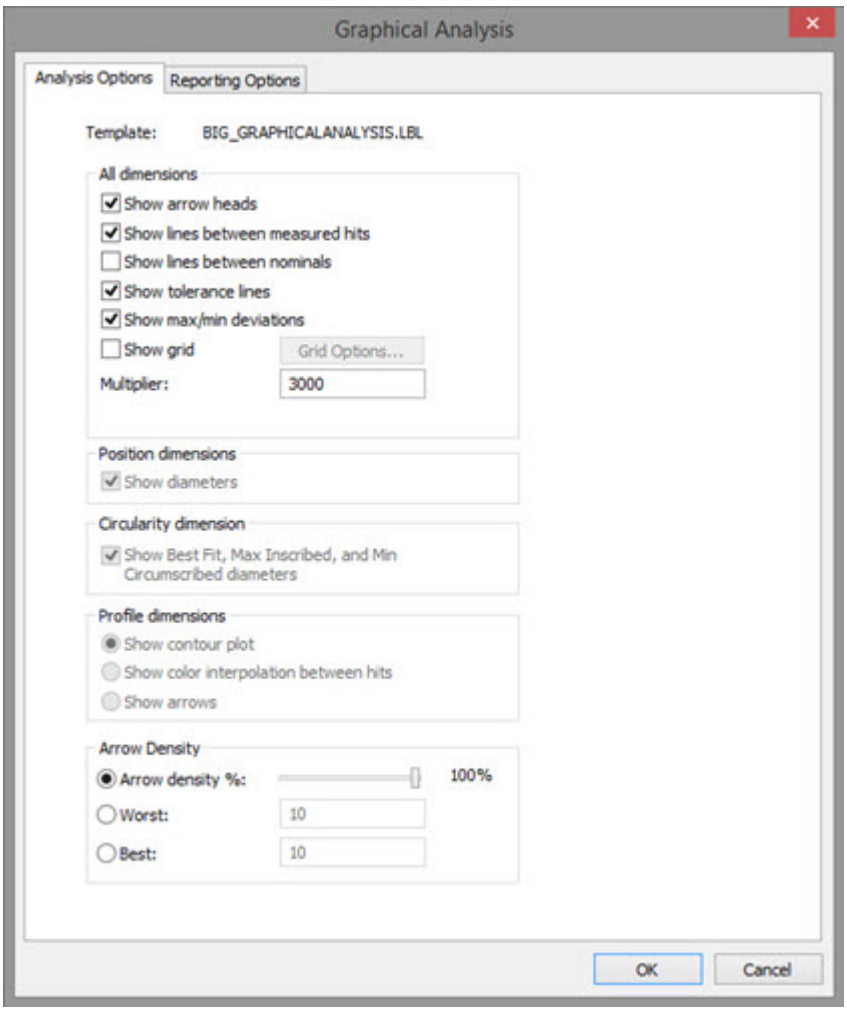
If you double-click on any CadReportObject, it becomes "active". This means you can rotate or zoom the CAD model to how you like it, just as you can inside the Graphic Display window. Click outside of the CadReportObject to use the new orientation and zoom level. See "CadReportObject" for information on this.

If you right-click on a CadReportObject in the Report window, and select **Edit Object**, PC-DMIS displays the **Label Layout Wizard**, allowing you to quickly modify label positions and the CAD model's location directly within the Report window. See "The Label Layout Wizard" topic under the "CadReportObject" for information on how to use this wizard.

You can size and move the CadReportObject as described in "Edit Label Positioning and Size".

Edit Graphical Analysis

If you right-click on an **AnalysisWindow** object in a Report window and choose **Edit Object**, a **Graphical Analysis** dialog box appears:



For information on the options on these tabs, see the "Changing Properties" sub-topic in the "AnalysisWindow Object" topic of the current chapter.

The items that appear shaded are items that are not available for modification on the fly. However, you can modify them at the label template level. For information on editing label templates, see "About Labels and Label Templates" in this chapter.

Changing Label Templates on the Fly

PC-DMIS provides you with a way of changing on the fly a label template used in a report.

Changing a Single Label Template

From the Report window (**View | Report Window**), select the label template and then right-click on it and select the **Change Template...** menu item. You can then select the new template to use from the **Open** dialog box.

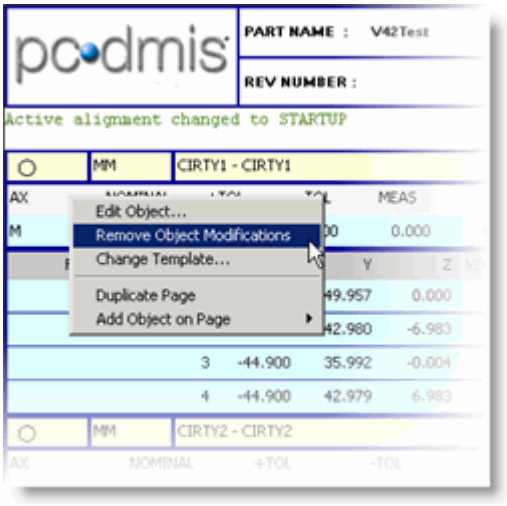
Changing Multiple Labels on the Same Page

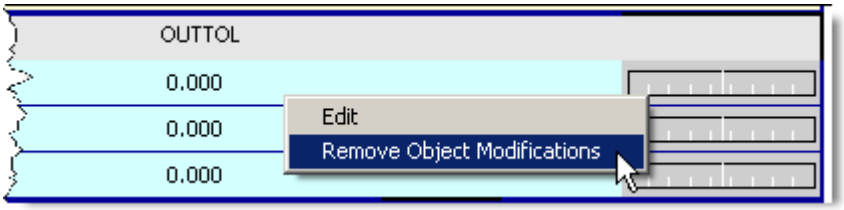
To select and replace multiple labels on the same page, hold down CTRL, select multiple templates, and then select the **Change Template...** menu item. Alternately, you can choose **Select Matching Labels** to choose all the labels in a CADReportObject that use that same label and are on the same page.

Removing Report Window Modifications

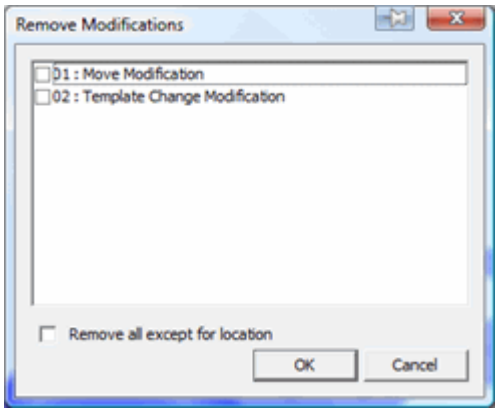
Removing Modifications to One Object

To quickly remove modifications that you have made to a report object (a TextReportObject, CADReportObject, or Label object), right-click on the desired object, and select the **Remove Object Modifications** menu item.





- If only one modification was made to an object, PC-DMIS will return the report object back to its default state.
- If more than one modification was made, PC-DMIS displays the **Remove Modifications** dialog box. This dialog box contains check boxes next to each type of modification made, allowing you to remove targeted modifications to the report object by selecting the modification to remove and clicking **OK**. The **Remove all except for location** check box removes all modifications made to that object except for repositioning changes.



A Sample Remove Modifications dialog box showing two different modifications on an object.

Removing All Modifications

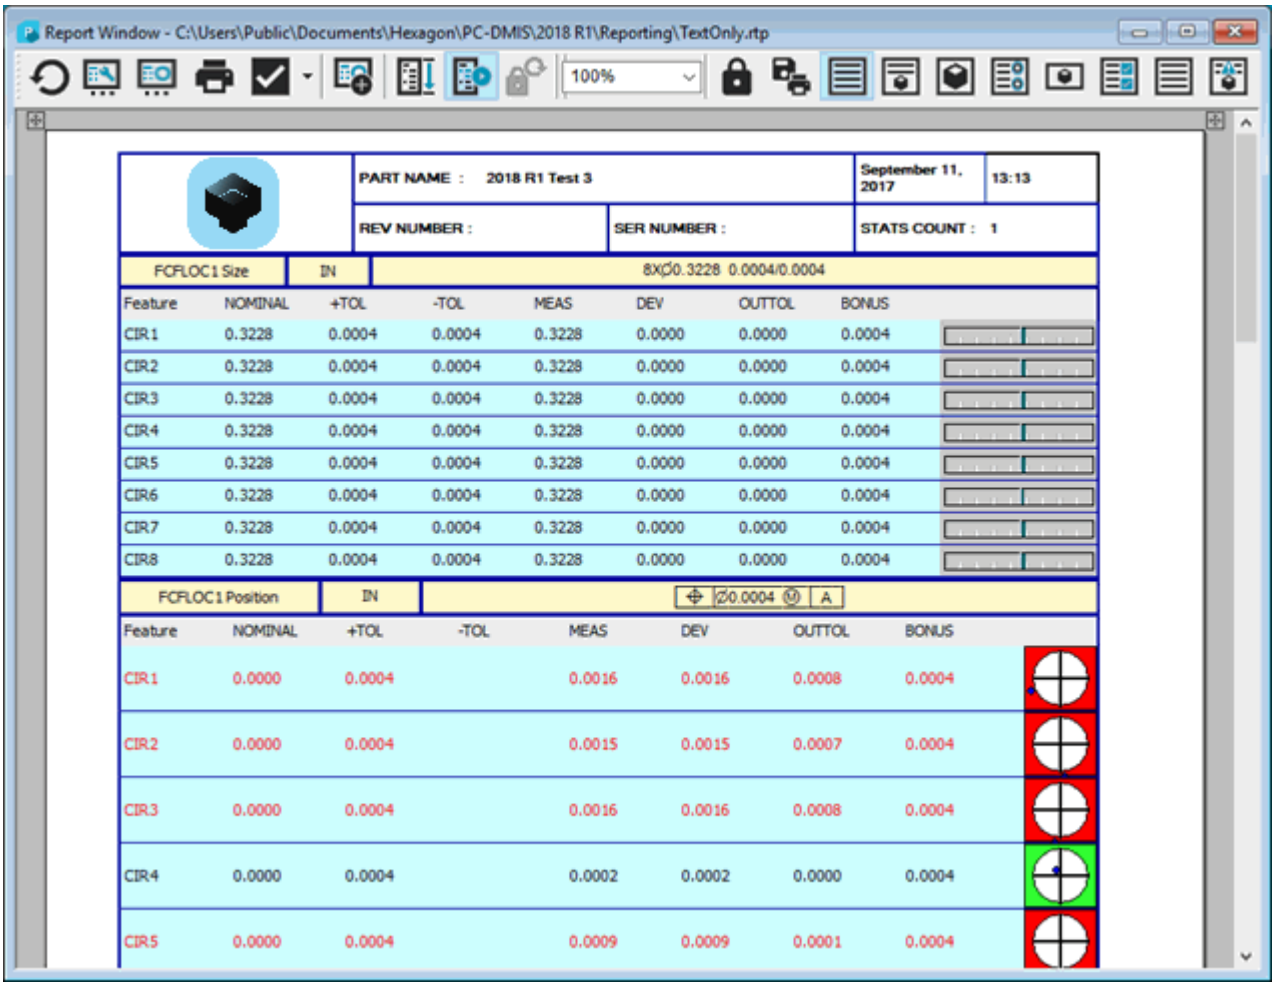
To quickly remove all object modifications on a report template, select the **File | Reporting | Clear Template Associated Data** menu item.

Removing Pan, Zoom, Rotate Modifications for a CAD Object

You can also remove just pan, zoom, and rotate modifications for the CADReportObject. To do this, right-click on the object in the Report window, and choose **Remove CAD Reporting Object Pan/Zoom/Rotate MOD**. Other mods (such as section cuts, various label definitions, solid or wire displays and so forth) are not affected.

Using Standard Reports

The default standard report template, TEXTONLY.RTP, is a simple template that plugs measurement data into a TextReportObject to show text-based information in a more graphical way.

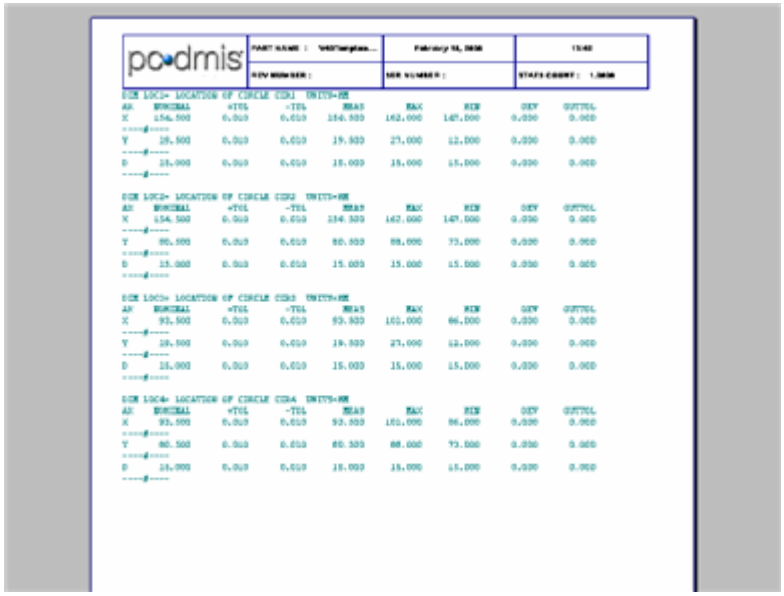


Report Window showing a standard, text-based report

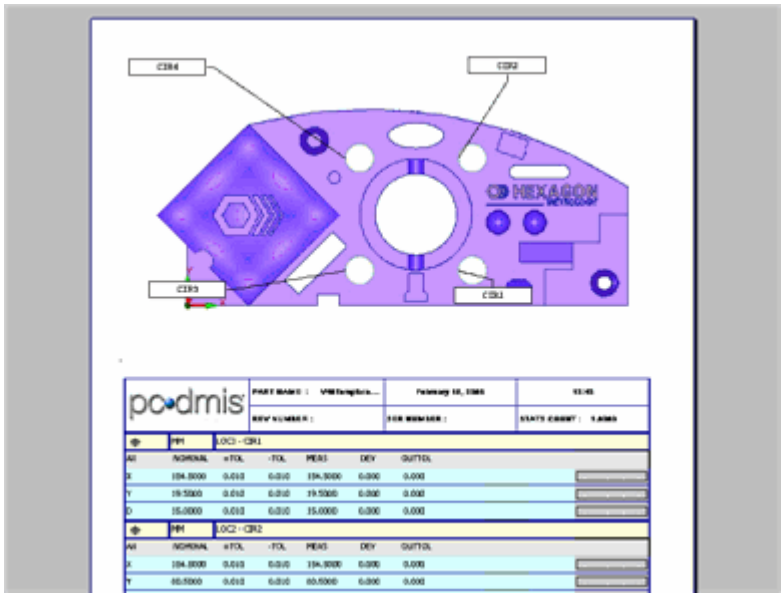
If the TEXTONLY.RTP standard report template doesn't show what you need, PC-DMIS also ships with additional standard report templates that you may find useful. You can

easily change the layout used for the current report by clicking the desired icon from the **Reporting** toolbar. These are the standard report templates:

- **Text Only** (TEXTONLY.RTP) - This template uses the TextReportObject with some standard labels included.



- **Text and CAD** (TEXTANDCAD.RTP) - This template uses the TextReportObject and the CadReportObject with some standard labels included.



- **CAD Only** (CADONLY.RTP) - This template uses the CadReportObject with some standard labels included in portrait layout. Since this template supports fewer labels than CADONLY_LANDSCAPE.RTP (up to 10), the labels are larger and more detailed.

- **Graphical Analysis** (GRAPHICALANALYSIS.RTP) - This template uses the Analysis Object to provide you with a graphical analysis of each form dimension (such as Flatness, Roundness, and so forth) sent to the report. It will not show an analysis for non-form dimensions. PC-DMIS graphically displays the deviation of each individual hit for the dimensions used. The report displays the error in the form of individual arrows for each hit. These arrows, with their colors and directions, indicate the relative size of the error, as well as its direction.

- **CAD-Only Landscape** (CADONLY_LANDSCAPE.RTP) - This is similar to **CAD Only**, but it displays in landscape layout. Since this template supports more labels than CADONLY.RTP (up to 30), the labels are smaller and less detailed.

- **PPAP** (PPAP.RTP) - This template produces a report that can be used in Production Part Approval Process (PPAP).

- **Plain Text** (PLAINTEXT.RTP) - This template produces a simple report without any formatting. The report retains its table-like organization.

- **Form Plot** (FORM PLOT.RTP) - This template produces a very similar report to the graphical analysis report, except it produces a larger output, displaying one form analysis per page. You must use a form dimension (circularity, cylindricity, flatness, straightness, line profile, or surface profile) to see data in this report.

- **Text and CAD Out of Tolerance** (TEXTANDCAD_OOT.RTP) - This template produces a text and CAD report showing the out-of-tolerance dimensions.

- **Default** (default.rtp) - This template produces a raw text (legacy) report. This is similar to reports used in older versions of PC-DMIS when the software didn't have a dedicated Report window. PC-DMIS defaults to this report if it cannot locate or display other report templates.

These templates are accessible from the **Report Templates** dialog box by default. For information on accessing and using this dialog box, see "Applying or Removing a Report Template". The actual template files are located in a public Reporting sub-directory.

You can find the Reporting folder at this location. This folder contains all the templates that the Report window uses:

C:\Users\Public\Documents\Hexagon\PC-DMIS\<version>\Reporting

<version> represents the PC-DMIS version. If you want to customize existing templates or create new ones, do so in that directory.

If you need to restore any modified template to its factory settings, you can copy it from the DefaultReportingTemplateBackup directory located within the PC-DMIS installation directory and paste it the above Reporting directory.

Do not modify the templates in the DefaultReportingTemplateBackup directory.

If you load a measurement routine that uses a report template that does not exist in the specified reporting directory nor in the directory where you installed PC-DMIS, then PC-DMIS generates a text-only report template on the fly called "default.rtp". This allows you to always see a report in the Report window even if you don't have the specified report template. Remember, default.rtp only displays information in a text-only format. This means you cannot deselect the **Use Text Mode Dimension Report** check box in the **Report** dialog box. For information on accessing and using the **Report** dialog box, see "Changing the Report Window's Contents".

Report Window showing a legacy text report

This topic discusses how you can get a legacy (old style) text-only report to show up in your Report window. PC-DMIS version 3.7 and earlier used this report type.

For this report type, you must only use legacy dimensions in your measurement routine.

You can toggle between using legacy dimensions and the newer Geometric Tolerance commands from the **Insert | Dimension | Use Legacy Dimensions** menu.

For information on using the .DAT files with this template, see "Using .DAT Files in Generated Reports".

1. Select **View | Report Window** to open the Report window.

2. From the **Reporting** toolbar, click the **Default** icon .

3. *This step is optional.* If you intend to modify the finished report inside an RTF editor, you may want to change how RTF files are converted. In the PC-DMIS Settings Editor, expand the **Printing** section, and set `DoNotUseAmyUniRTF` to **2**. Click **Save Setting** and then click **OK**. This makes the text for the report print to RTF files like it used to in 3.7 and earlier. If this is set to 0 (the default), characters show up inside of text boxes.

Reported Tolerance Zones for Form Dimensions

PC-DMIS displays the tolerance zone for form dimensions as a linear graphic. For text mode reporting, this zone is comprised of characters with the number sign (#) indicating the amount of deviation. For non-text mode reports, this is shown as a bar graph with the bar growing larger from left to right as the deviation increases. For the non-text mode dimensions the color of the bar graph changes as deviations move towards out of tolerance.

For form dimensions (Straightness, Flatness, Circularity, and Cylindricity) there is no negative tolerance, so the linear graphic represents the deviation from perfect form (0 tolerance) where the extreme left of the graphic is 0 tolerance and the extreme right of the graphic is the maximum allowed tolerance.

Example showing text mode and non-text mode tolerance zones.

In the graphical example given above, the tolerance zone is indicated in both text-mode and non-text-mode with a deviation of 0.186 and a maximum tolerance of 0.3.

Here are some additional examples showing how a Circularity dimension's tolerance zone appears inside of PC-DMIS as a text-mode and non-text mode report respectively:

```
FCFCIRTY1 = CIRCULARITY OF CIR1   UNITS=MM
AX     NOMINAL       +TOL       -TOL       MEAS        DEV      OUTTOL
M        0.000       0.030      0.000      0.027       0.027      0.000 -------#
```

A sample text mode tolerance zone.

FCFCIRTY1	MM	◯ 0.03				
Feature	NOMINAL	+TOL	-TOL	MEAS	DEV	OUTTOL
CIR1	0.000	0.030		0.027	0.027	0.000

A sample non-text mode tolerance zone.

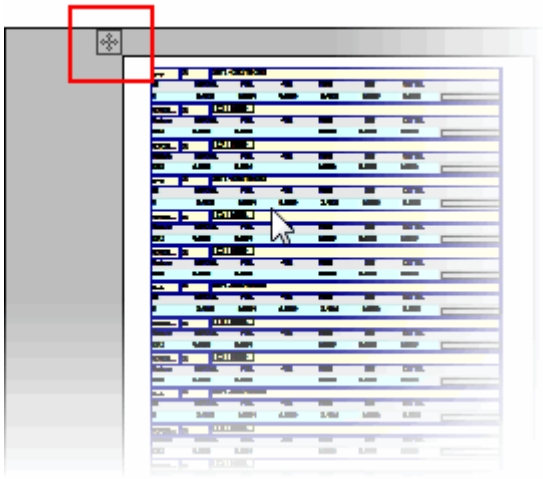
Rearranging Report Pages

PC-DMIS provides you with a drag-and-drop approach to rearranging pages in the Report window (**View | Report Window**).

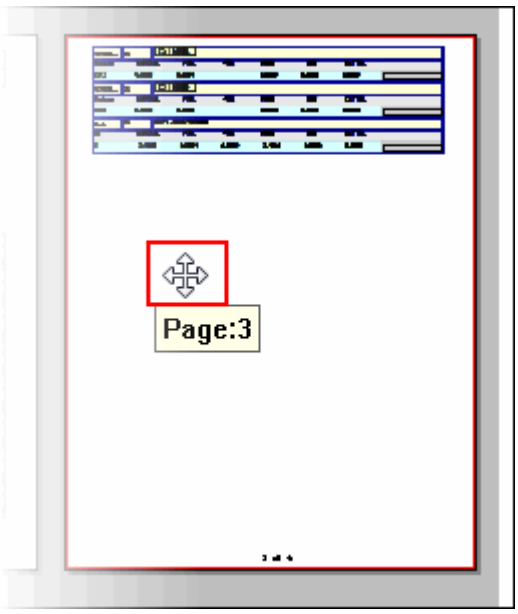
You can also rearrange pages with the Preview Pane. For more information, see "Working with the Preview Pane".

To rearrange pages, use this procedure:

1. Size the report magnification to where you can view the pages you want to rearrange, probably somewhere around 25%.
2. Hover your pointer over any report page. Notice that at the top left of the page, a small cross-hair icon appears. Click that icon.



3. Drag your pointer to drag the current page.
4. Drag the page on top of an existing page. The target page receives a red highlight and the pointer cursor changes.



5. Release the mouse button. PC-DMIS arranges the ordering of the report pages according to the direction in which you dragged the report page.

    - If you drag and drop the page to a page earlier in the existing page sequence, the software inserts the page *before* the page on which you dropped it.
    - If you drag and drop the page to a page later in the existing page sequence, the software inserts the page *after* the page on which you dropped it.

    Suppose you have a sequence of seven pages in your report: p1, p2, p3, p4, p5, p6, p7. If you drag p4 and drop it at p2 (earlier in the sequence), the order will be p1, p4, p2, p3, p5, p6, p7. If you then drag p4 and drop it at p5 (later in the sequence), the order will be: p1, p2, p3, p5, p4, p6, p7

6. Continue rearranging pages as needed.

Modifying Standard Templates

You may want to modify the standard reporting and label templates that ship with PC-DMIS.

- To change your report's header, see "Modifying the Report's Header".
- To change properties in a standard template report, open the template in the template editor, right-click on the object, and modify its properties in the **Properties** dialog box. For information, see "About Object Properties".

If you want to create entirely new templates, see "Creating Templates".

About the Reporting Directory

You can find the Reporting folder at this location. This folder contains all the templates that the Report window uses:

C:\Users\Public\Documents\Hexagon\PC-DMIS\<version>\Reporting

<version> represents the PC-DMIS version. If you want to customize existing templates or create new ones, do so in that directory.

If you need to restore any modified template to its factory settings, you can copy it from the DefaultReportingTemplateBackup directory located within the PC-DMIS installation directory and paste it the above Reporting directory.

Do not modify the templates in the DefaultReportingTemplateBackup directory.

Using .DAT Files in Generated Reports

PC-DMIS uses the LOGO.DAT, HEADER.DAT, and ELOGO.DAT data files to a limited extent in a generated report. For information on these data files, see "Modifying the Edit Window's Headers and Footers" in the "Using the Edit Window" chapter.

- LOGO.DAT populates the beginning of the report.
- HEADER.DAT populates the header of each subsequent page.
- ELOGO.DAT populates the ending text on the last page of the report.

Conditions for this to Work

- You must use a report template that does not contain rules, such as default.rtp.
- The `UseLogoElogoHeaderDat` entry in the **Reporting** section of the Settings Editor must be set to 1, the default value.

Limitations of Using .DAT Files

- Bitmaps are placed at the top of the report, regardless of where in the .DAT files they're defined.
- The last page will not contain the HEADER.DAT information if the only item on the last page is ELOGO.DAT.

Modifying the Report's Header

Many users want to change the header in some way. Usually, they want to modify the default image that appears in the default report's header to something more company-specific. You can change the header image by following one of these procedures below.

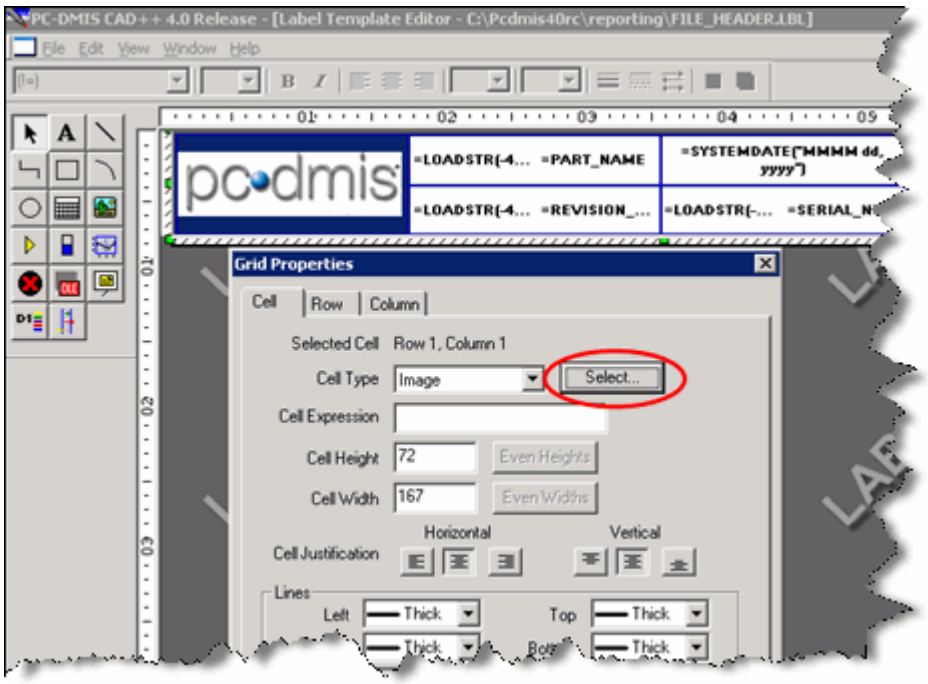
To Change Only a Header's Image:

If you only need to change the image but not other elements in the header, we recommend this:

1. Access the report in the Report window or load a custom report inside a Custom Report Editor.
2. Right-click on the header (such as FILE_HEADER.LBL).
3. Choose **Change image** to show the **Open** dialog box.
4. From the **Open** dialog box, locate the desired image, and then click **Open** to update the report with the image. This action also updates the underlying label template (.lbl) with the new image.

To Modify an Entire Header in the Label Template Editor:

1. Open the label template in the Label Template editor.
    - Select **File | Reporting | Edit | Label Template**. An **Open** dialog box appears.
    - Select the FILE_HEADER.LBL template and click **Open**.
    - In the Label Template Editor you should now see the edit area filled with a GridControlObject. This object controls all the header data that you see in the report.
2. Change the header's image.
    - Double-click on the GridControlObject. You will see a hash border around the object. This tells you that you can edit the code or items inside of the header.
    - Right-click on the PC-DMIS graphic, and a **Grid Properties** dialog box appears.
    - In the **Cell** tab, click **Select**. An **Open** dialog box appears.



Example showing the button to use to change the report header's graphic

- Navigate to the new graphic image you want in the header, select it, and click **Open**. The dialog box closes.
- Click **Apply**. The new graphic appears in the cell.

3. Make other modifications to the header as desired.
4. Save and test the modified label template.
   - Once you have configured things as desired, click **OK**, and then select **File | Save** to save your changed Label Template.
   - Select **File | Close** to close the Label template editor, returning to your measurement routine.
   - Select **View | Report window**. If your change doesn't immediately appear, select the **Redraw the report** icon from the **Reporting** toolbar.

Here are some other options to consider:

Using LOGO.DAT, HEADER.DAT, and ELOGO.DAT in Generated Reports

To a limited extent, you can use the # keywords contained in these .DAT files to define the information that appears in your generated report. See "Using .DAT Files in Generated Reports" for more information.

See "Modifying the Edit Window's Headers and Footers" in the "Using the Edit Window: Introduction" chapter for information on the # keywords.

Converting LOGO.DAT, HEADER.DAT, and ELOGO.DAT Keywords

You can also use PC-DMIS's own Report Expressions to accomplish the same thing as the # keywords contained in the .DAT files.

The following table details the equivalent Report Expression or report object to use and where to use it.

.DAT # Keyword	Functionality	Equivalent Command in Report Template
#DATE	Inserts the current date.	=SYSTEMDATE("MMMM dd, yyyy")
#TIME	Inserts the current time.	=SYSTEMTIME("HH:mm")
#PAGE	Inserts the current page number.	=Page()
#TRn	Inserts the value of tracefield n, where n is the tracefield number.	=TRACEFIELD(n)
#PARTN	Inserts the measurement routine name.	=PARTNAME( )
#DRWN	Inserts the revision number.	=REVNUM()
#SERIALN	Inserts the serial number.	=SERNUM( )
#SEQUENCE	Inserts the sequence number.	(Not applicable)
#SHRINK	Inserts the scale factor.	=MEASSCALE()
#NMEAS	Inserts the total number of dimensions.	=NUMMEAS()
#NOUT	Inserts the total number of dimensions that are out of tolerance.	=NUMOUTTOL()

#ELAPSTIM	Inserts the time elapsed between start and end of execution.	=ELAPSEDTIME()
#BMP=bitmappath	Inserts a bitmap of the specified full path and name.	Use Bitmap object

For information on using other expressions in your report templates, see "About Report Expressions".

For information on limitations on using variables inside report headers, see "Displaying a Variable's Value".

Changing the Report's Text Colors

At times you may want to modify the default text colors used in your report. To change these text colors, access and modify the **Color Editor** dialog box for your report template's TextOnlyObject:

1. Select **File | Reporting | Edit | Report Template**.
2. Select the report template for which you want to change the colors.
3. In the Report Template editor, select the **TextReportObject**, and right-click on it to access the **Properties** dialog box for that object.
4. Select the **Colors property** from the **Properties** dialog box.
5. The **Color Editor** appears. This is the same editor as used for the Edit window, but in this case it modifies the TextOnlyObject used in your report template. For information on how to use the Color Editor, see "Defining Edit Window Colors" in the "Setting Your Preferences" chapter.
6. Make your changes, and then save the template.
7. Load the template into the Report window.

Adding Notes to a Report

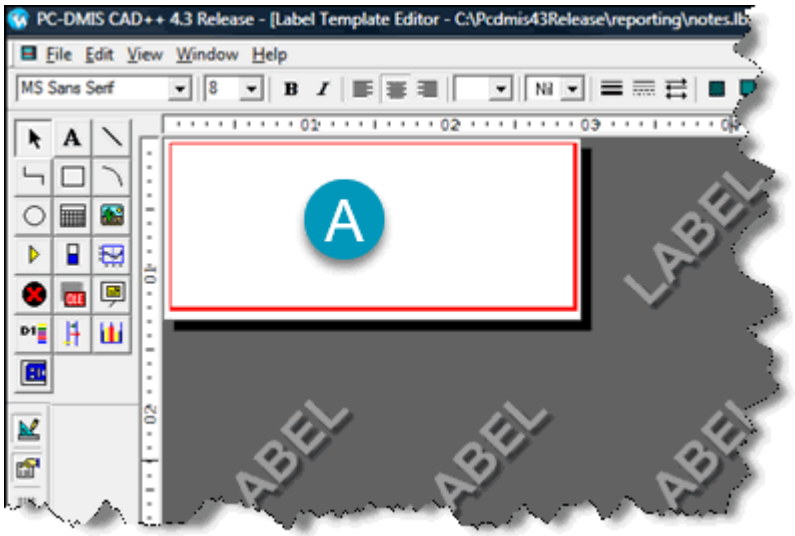
It's often useful to add your own notes to a report after it has executed. One way to add notes is to use PC-DMIS's standard Comments functionality and allow PC-DMIS to display the comments in the Report window. But this approach has some limitations. Displaying comments only works on report templates that use the TextReportObject. Besides, by default, standard comments aren't very visible, and they only appear within the

TextReportObject at the location they were executed. Also, you aren't able to easily edit them after they're on the report. For information on comments, see "Comments" in the "Using the Edit Window" chapter.

However, if you want more flexibility, consider the option of adding a note box into which you could type your notes directly onto the final Report. The following steps provide you with a procedure on how to do this:

Step 1: Create the Note Box

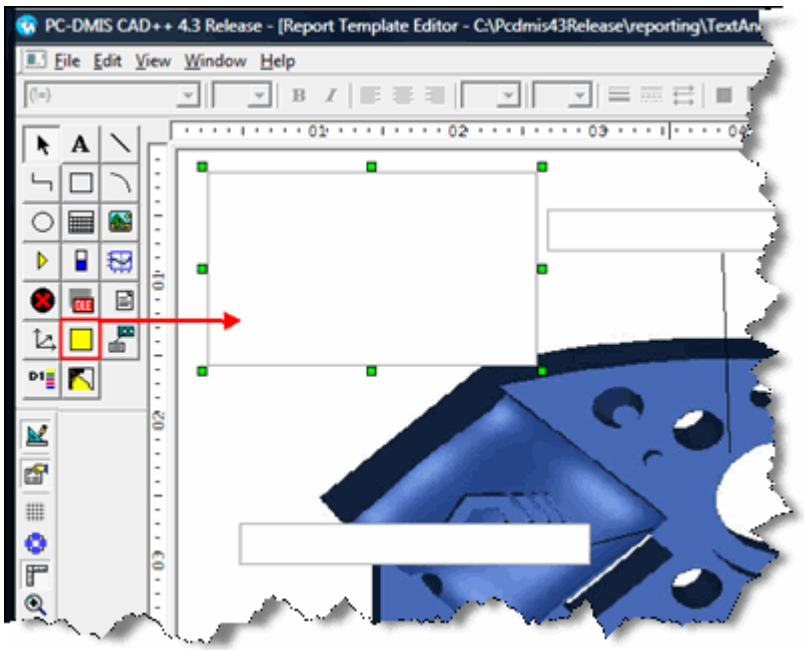
To create a note box, create a new label template inside the Label Template Editor, and drag a **Text** object onto the editing area. Format the object with font size, font color, background color, and borders as desired. If you want your note box to be transparent, select the **NIL** background color. Set the object's **Text** property to hold this value: "Right-click here and select Edit Object to modify this note text." Save your label template.



A new label template named notes.lbl
(A) - Right-click here and select Edit Object to modify this note text.

Step 2: Tie the Note Box onto the Report Template

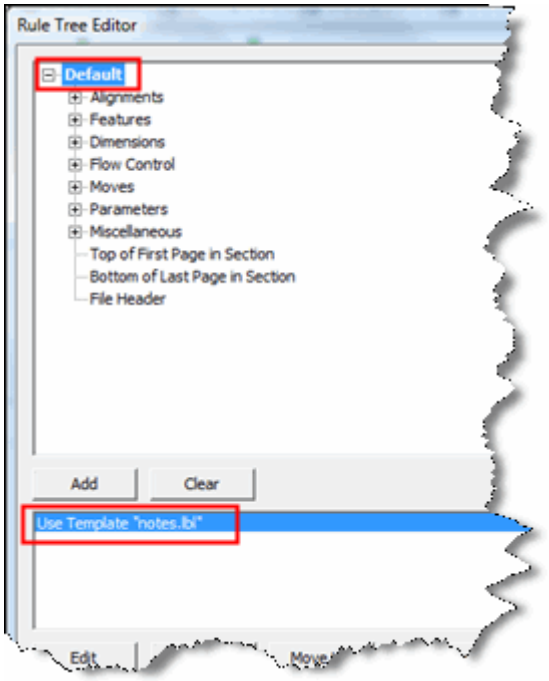
Open up a report template inside the Report Template Editor that you can edit. Drag a **Label** object onto the editing area, and position it more or less where you want the note box to appear. You can change its final position in the Report window.



A label object added onto a TextAndCad Report

Step 3: Tell PC-DMIS When to Display the Note Box

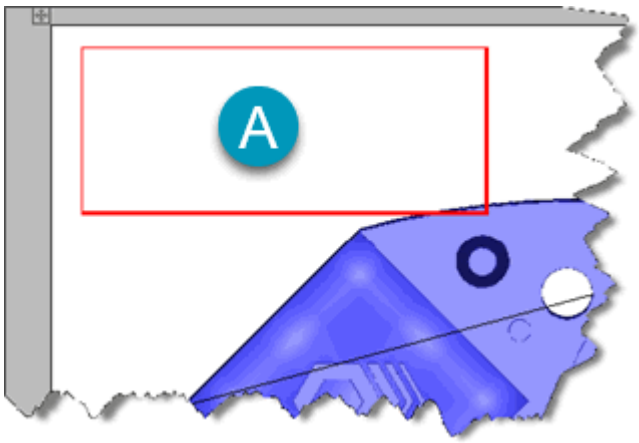
Right-click on the label object to access the **Properties** dialog box, and then click **Rules** to bring up the **Rules Tree Editor**. The new label object does not yet have any rules. Add a rule for the **Default** item at the top of the tree, and have the rule pull in the label template you saved in Step 1. This action causes the label template containing your note box to show up on every page of the report. Save your changes.



A rule specifying to load notes.lbl assigned to the Default item

Step 4: Test the Report

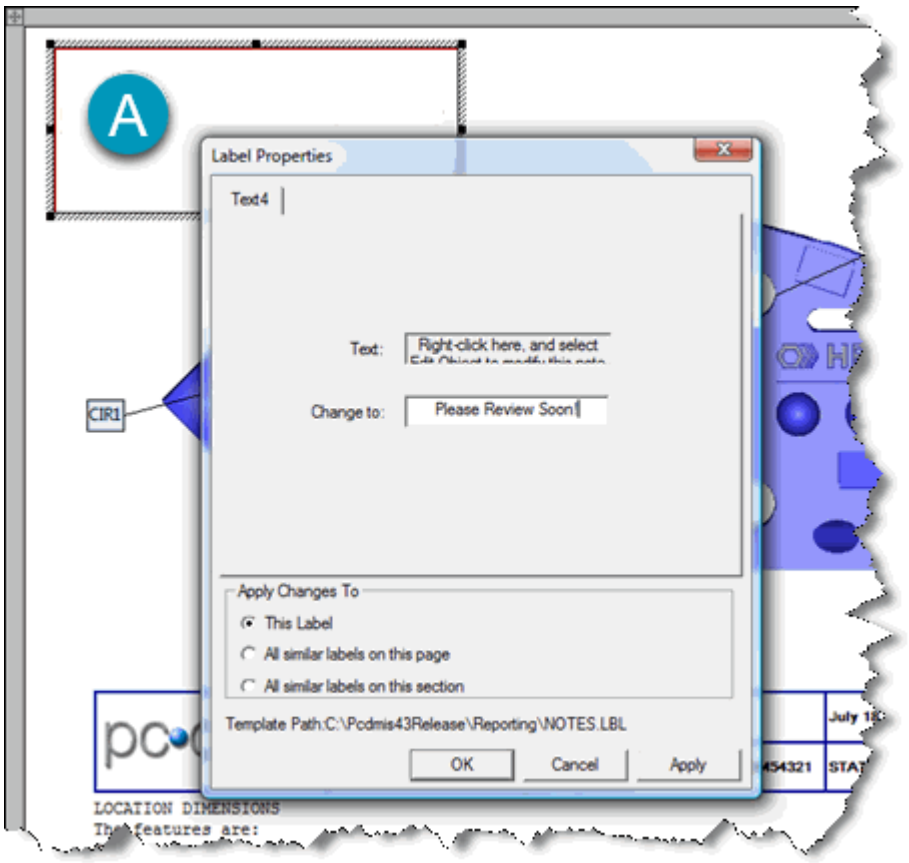
Access the Report window and load in your modified report template. Notice that your note box appears with the instructions on how to change its default text. Double-click to activate the object and drag it to a new location if desired.



A note box with default text
(A) - Right-click here and select Edit Object to modify this note text.

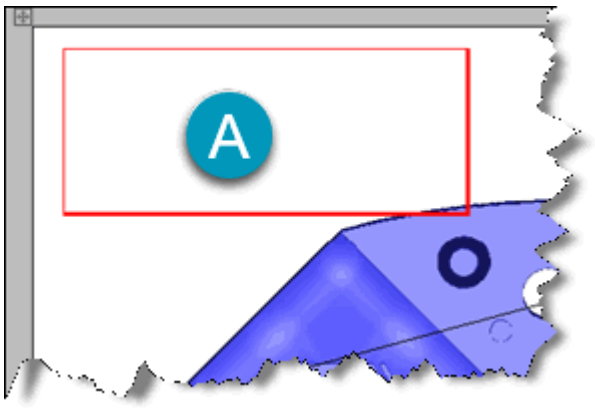
Step 5: Modify the Note Box Text

To change the text in the note box, right-click the object and select **Edit Object**. A **Label Properties** dialog box appears.



The Label Properties dialog box
(A) - Right-click here and select Edit Object to modify this note text.

Type your new note text in the **Change to:** box and click **OK**. PC-DMIS updates your text.



A note box with updated text
(A) - Please Review Soon

And that's all there is to it. Of course, you can modify the note box to better suit your needs. For example, if you wanted a table-like structure in your note box, on Step 1, instead of a single text object in the label template, you could add in a **GridControlObject** into the label template and then overlay the cells with **Text** objects.

If you wanted to show only the note box based on certain conditions, you could change the rules used in the **Rules Tree Editor** in Step 3. For example, if you only wanted the note box on the first page of your report, you would use the **File Header** item instead.

Adding Watermarks to Certified Measurement Routine Reports

You can add a watermark to generated reports for certified measurement routines. The UseWaterMarkText Settings Editor entry controls whether the watermark appears, and WaterMarkText Settings Editor entry specifies the watermark text.

About the Reporting and Form Editors

The Report Template Editor, Label Template Editor, Custom Report Editor, and Form Editor modify existing or create new, templates, custom reports, and forms. These editors share many of the same common user interface elements: the menu bar, the toolbars, the object bar, and so on. While the individual icons or items on these menus may change between editors, the look and feel are essentially the same.

The user interface is discussed in the following topics.

Menu Bar for the Form and Reporting Editors

File menu

File | New - Creates a blank template or form.

File | Open - Opens a previously stored report template file or form.

File | Close - Closes the template editor or form.

File | Save As - Saves the current template or form with a new file name. See "Saving a Template or Form to an Earlier Version".

File | Edit / File | Run - Lets you toggle between the editor's two modes: *Edit Mode* and *Run Mode*. Run mode lets you "run" or test a form. Edit mode lets you modify a template or form. (Run mode only works with the Form Editor; it does exist in the Report or Label template editors.)

File | Exit - Exits PC-DMIS. If you have unsaved changes, PC-DMIS will display a message box asking if you would like to save them.

Edit menu

Edit | Layout | Align Objects, Space Evenly, Center in View, Make Same Size - These submenus lets you layout, align, and space objects in the editor. See the "Layout Bar" for additional information.

Edit | Layout | Properties - Displays the property sheet for the currently selected object. If no object is selected, this displays the property sheet for the editing area (called a "Section" or "The Frame/View"). See "Property Sheet" and "About Sections".

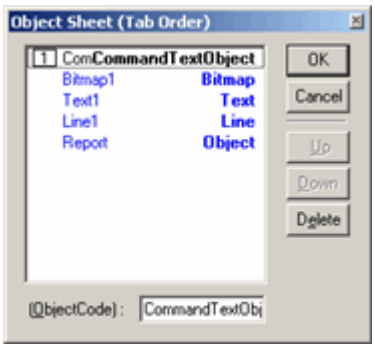
Edit | Layout | Check Mnemonics - This menu item ensures that any shortcut keys using the ALT key plus a letter are unique on form or template items that have a text display (such as buttons).

To define a shortcut key for a form or dialog box control, type an ampersand symbol (&) before the character. For Example:

A button with the text label of "&Continue", looks like "Continue" on the form and is accessible with ALT + C.

Edit | Layout | Grid Settings - Displays the **Grid Settings** dialog box. This dialog box lets you display or hide a grid of points on your layout's background. See "Working with the Grid".

Edit | Layout | Objects - Displays the **Object Sheet** dialog box. Use this dialog box to view or select the objects in the Form and to set their tab order. See "Object Sheet". (Only available in the Form Editor.)



Object Sheet Dialog Box

Edit | Order - This submenu lets you move objects behind or in front of other objects that overlap each other.

Edit | Undo - Lets you undo the last action taken in the editor.

Edit | Redo - Lets you redo the last undone action.

Edit | Cut - Cuts the object and stores it for pasting.

Edit | Copy - Copies the object and stores it for pasting.

Edit | Delete - Deletes the selected objects.

Edit | Paste - Pastes the cut or copied object. If from a copied object this often this pastes the object right on top of the copied object, so you will need to drag it to a new location or else it will overlap the object from which it was copied.

Edit | Paste Special - This differs from the standard **Paste** menu item since it allows you to maintain a link between the pasted item and the source from which it was copied so that if the source changes, the pasted item will also get updated. For Example:

Suppose you want to place a Microsoft Excel chart object in your Hyper Report, and you want to keep the chart's data in synch with the data from the Excel file. To do this:

1. In the Microsoft Excel file, copy the chart object.
2. Access your template or form.
3. Select **Edit | Paste Special**. The **Paste Special** dialog box appears.
4. Select the **Past Link** option.
5. Click **OK**. The chart object appears in your template or form.

Now, if you make changes to the data for your chart object in your Excel file, PC-DMIS will update the chart object in the report or form.

Edit | Set Tab Order - This lets you determine the objects that get selected when a user presses TAB to cycle through objects in Run Mode. (This only works in the Forms Editor.)

Edit | User Assigned Properties - Accesses the **User Assigned Properties** dialog box, allowing you to manage all your user assigned properties at once. See "Working with User Definable Properties". (Only available in the Report Template Editor.)

View menu

View | Graphic Display Window, Edit Window, Preview Window, Form Editor, Marked Sets Window, Basic Script Editor, Inspection Report, Probe Readouts, Probe Toolbox - Shows or hides these PC-DMIS windows or editors. Most of the time these do not serve any purpose when working in the editor, and you can hide them.

View | Object Bar - Displays the editor's Object Bar. See "Object Bar".

View | Layout Bar - Displays the editor's **Layout Bar**. See "Layout Bar".

View | Font Bar - Displays the editor's **Font Bar**. See "Font Bar".

View | Ruler Bars - Displays the rulers on the top and left sides of the editor. See "Toggle Ruler".

View | Snap Points - Displays the "snap points" for any of the objects in the editor. See "View Snap Points".

View | Route - This only functions with snap points. On complex pages with a lot of objects, you may find it useful to use the this menu option to see the chain of objects connected to the currently selected object via snap points. This menu option selects all objects connected in some way by snap points to the currently selected object. (Only available in the Form Editor.)

Windows menu

This menu lets you perform standard window manipulations with any of the windows in PC-DMIS. See the "Navigating and Displaying Multiple Windows" chapter.

Help menu

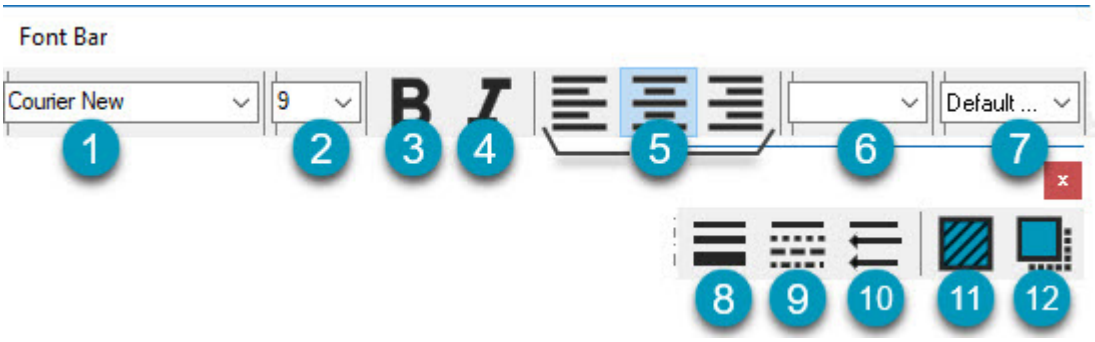
Help | Index - Accesses the PC-DMIS Help file.

Help | Using Help - Displays a topic about using the Help file.

Help | About PC-DMIS - Displays the **About PC-DMIS** dialog box, showing information about your version of PC-DMIS.

The Font Bar

The editor's **Font Bar** lets you modify frequently modified font, color, background, line, and other properties for various objects.



The following options are found on the **Font Bar**:

1. This list defines the object's font if it supports text. You can also set this in the **Font** property.
2. This value defines the object's font size if it supports text. You can also set this in the **Font** property.

3. **Bold** - This button displays your object's text in boldface. You can also set this in the **Font** property.
4. **Italic** - This button displays your object's text in italics. You can also set this in the **Font** property.
5. **Left**, **Center**, and **Right** - These buttons align your text to the left side, center, or right side, of the object. You can set also this in the **Alignment** property.
6. This list defines the background color of your object. You can also set this in the **BackColor** property.
7. This list defines the foreground color of your object. Foreground sets any text and border colors. You can also set this in the **ForeColor** property.
8. **PenWidth** - This button sets the border or line's width. Clicking this multiple times switches between various options. You can also set this in the **LineWidth** property.
9. **PenStyle** - This button sets the style of a line (does not apply to borders). Clicking this multiple times switches the line style between a solid line and various dotted lines. You can also set this in the **LineStyle** property.
10. **Arrowhead** - This button places arrowheads at the end or ends of a **Line** object. Clicking this multiple times switches the arrow to different locations on either or both ends of the line. You can also set this in the **Arrowhead** property.
11. **Hatch Style** - This button sets a background pattern, called a "hatch style", on an object that supports hatch styles. Clicking this multiple times switches between the available hatch styles. You can also set this in the **HatchStyle** property.
12. **Shadow Style** - This button sets a shadow under the object if the object supports shadows. Clicking this multiple times switches between the available shadow styles. You can also set this in the **ShadowStyle** property.

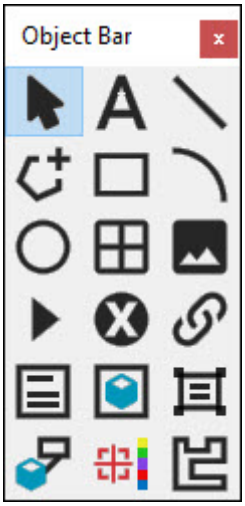
The Object Bar

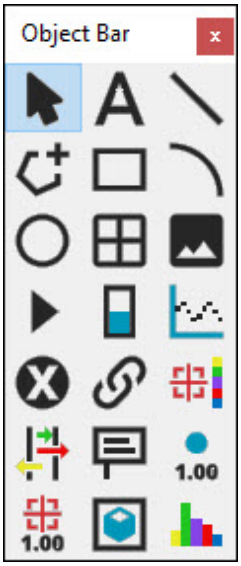
The **Object Bar** is a toolbar that lets you insert various objects into a template or objects and controls into a form. You can insert text, pictures, multi-media, dialog box controls, special PC-DMIS specific objects, and other items to help you create custom labels, reports, and forms.

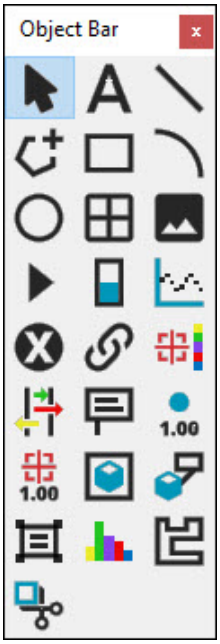
This bar appears whenever you enter an editing environment such as the Report Template Editor, the Label Template Editor, the Custom Report Editor, or the Form Editor.

The **Object Bar** comes in one of these types, one for each editing environment:

Report Template Editor	Label Template Editor	Custom Report Editor	Form Editor
			







Adding Objects:

To add an object to a template, custom report, or form:

1. Inside the appropriate editor, access the **Object Bar**.
2. Click on the object you want to insert into your report.
3. Next, hold down the left mouse button and drag a rectangle on your current section.
4. Finally, release the mouse button.
5. Upon creation, the object is selected, as shown by small green squares, called handles, at each corner of the object.

A sample Text object showing handles

Selecting and Manipulating Objects:

To manipulate an object you have to first select it. To select an object, click on the object so that the green handles are showing.

To drag an object to a new location - Select the object. Click and hold the mouse on top of the object, then drag it to the new location. Release the mouse.

To resize an object - Select the object, move your mouse over one of the green handles until it changes to a resize cursor, a line with two arrows. Then click on the handle and drag the mouse to a new location. Release the mouse. The object expands or shrinks.

To change an object's properties - Select the object, right-click on the object so that the **Properties** dialog box appears. Select properties and change them as desired.

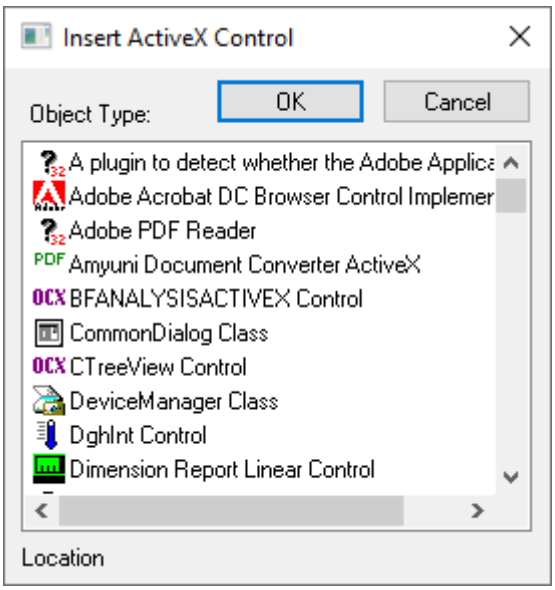
To align, group, ungroup, and perform other operations - Use the **Layout Bar** or the **Edit | Layout** and **Edit | Order** submenus.

Coding Objects to Change Dynamically

For some objects, you can use BASIC scripting to dynamically change certain properties of those objects. For example, you could use code to automatically populate plotted points on a Graph object, or you might want to use the Gauge object like a bar graph of some sort. For an example of how to do this, see the topic, "Example of Using BASIC Scripting to Dynamically Change the Gauge's Value".

ActiveX Object

The **ActiveX** Object inserts an ActiveX control into your template or form. Once it inserts the control, PC-DMIS displays the **Insert ActiveX Control** dialog box.



Insert ActiveX Control Dialog Box

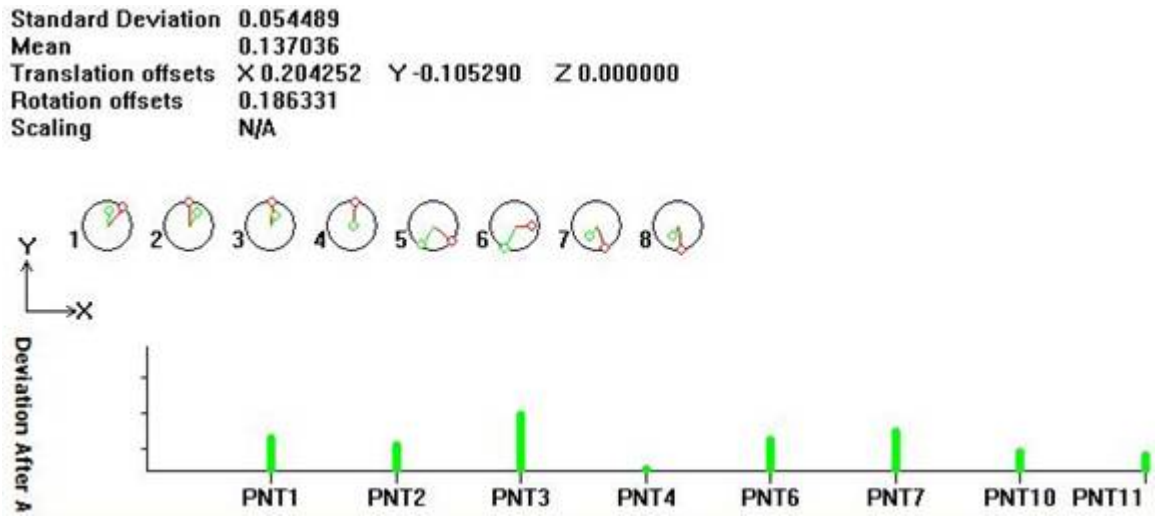
This dialog box allows you to select the type of control you want to insert from a list of known controls on your computer. The controls in the **Object Type** list are unique to each computer, based on the programs installed on your computer. ActiveX controls expand the possibilities of what you can do in a form or template. For example, you could insert a chart control and then with Visual BASIC code, pass measurement routine data to dynamically create the chart.

PC-DMIS ActiveX Controls

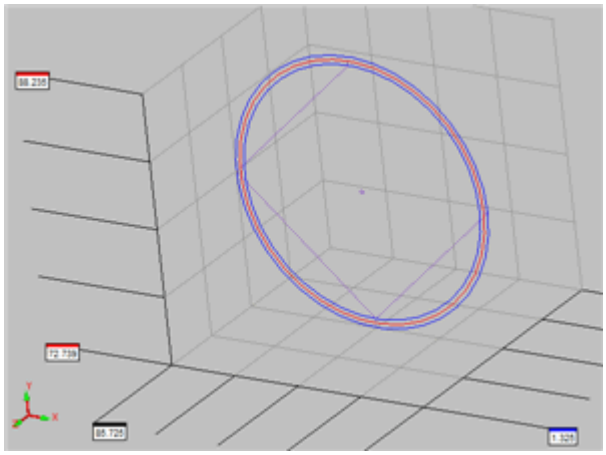
PC-DMIS ships with ActiveX controls, most of which are related to feature analysis. The feature analysis controls appear in certain cells of the **GridControlObject** on some of the standard labels that come with PC-DMIS. In general, the software uses these controls to display graphical analysis information. You can insert these into your own templates or forms from the **Insert ActiveX Control** dialog box.

The PC-DMIS ActiveX controls related to feature analysis are shown here with graphical examples:

BFANALYSISACTIVEX:



DIMANALYSISACTIVEX:

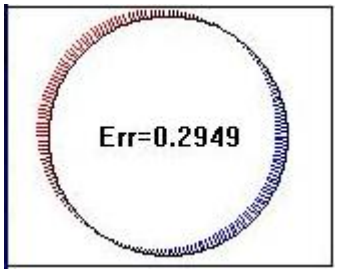


Dimension Report Linear:

Dimension Report Linear2 (Surfer NT Style Control):

Dimension Report Radial:

FeatureAnalysisActiveX:



The PC-DMIS ActiveX control that is not related to feature analysis is:

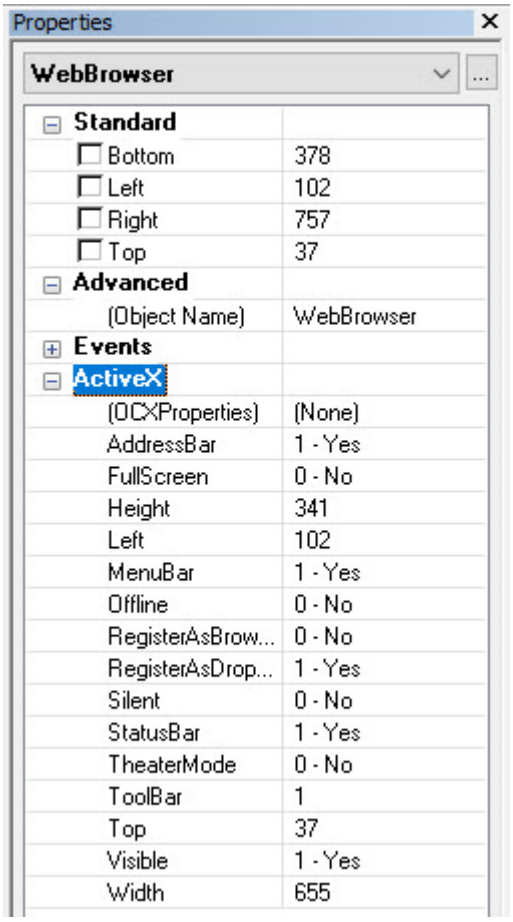
DataFileFormatControl
This control allows the interpretation of .dat files (logo.dat, elogo.dat, and header.dat) in your template-based reports. See "Some PC-DMIS ActiveX Controls" and "Using .DAT Files in Generated Reports".

As with any other object, the PC-DMIS ActiveX object also contains properties, both standard and unique, that you can modify using the **Properties** dialog box. The topic below contains information on accessing those properties.

Accessing an ActiveX Object's Methods and Properties from Basic

If you add a control, you can access its events and properties through the property sheet just like any other object.

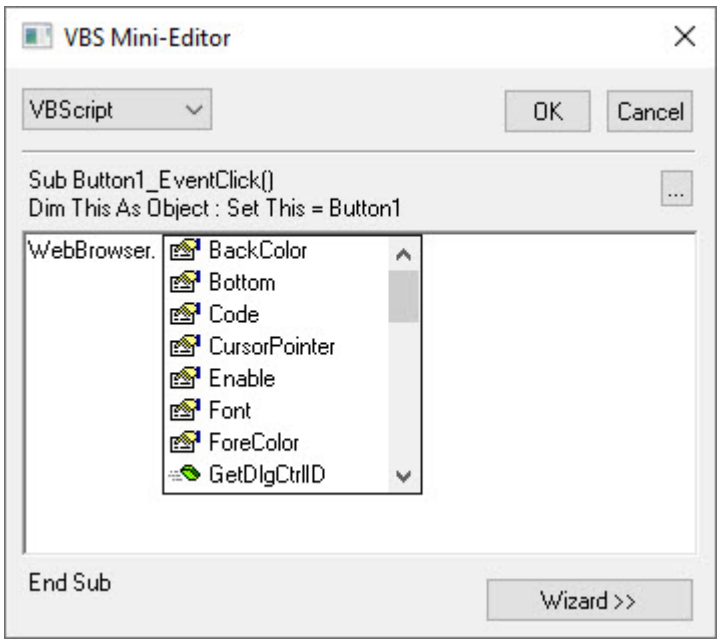
For example, suppose you add a **Microsoft Web Browser** control and set its `(Object Name)` property to `WebBrowser`. Because it is an ActiveX object, a new section of properties is visible, called **ActiveX**. That section contains a user-accessible list of variables and properties with their default values.



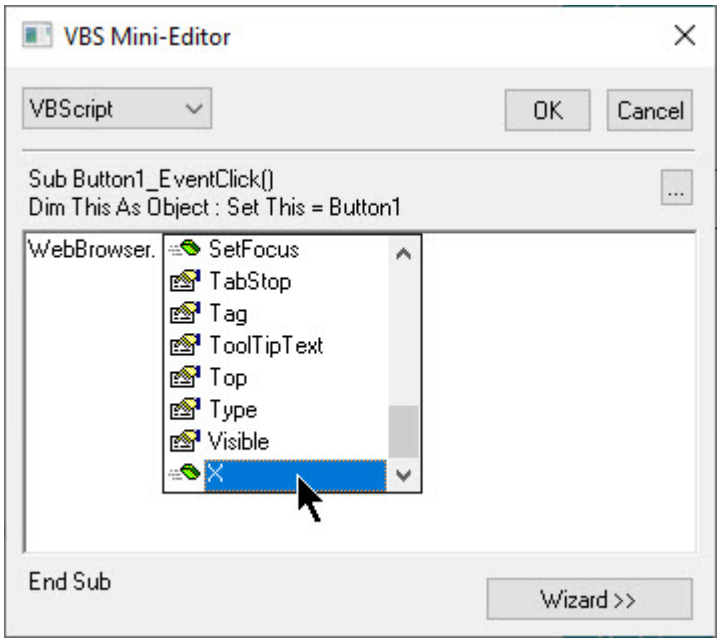
Microsoft Web Browser Control Active X Properties

To set properties for the ActiveX control inside the **VBS Mini-Editor** for an event handler

1. Type the name of the ActiveX control. For example, if you used the example above, you would type **WebBrowser**.
2. Then type a period after it. A window appears so that you can access the variables and methods.



3. Select the **X** from the list. PC-DMIS opens another popup window that lists a set of internal editable variables for the ActiveX control.



In this way you can access an Active X object's methods, properties, and events.

For information on the properties of the different PC-DMIS ActiveX controls, see the "Using PC-DMIS ActiveX Controls" topic in the PC-DMIS Core documentation.

Arc Object

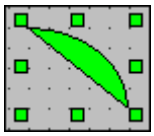
The **Arc** object inserts an elliptical arc into the template or form. A default arc doesn't have a fill color and has a beginning angle of 0 degrees and an ending angle of -90 degrees.

Along with the ability to resize the object, add a fill color, add a border color, and change other attributes, the following editable properties are included for arc objects:

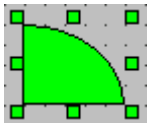
Angle1
This number sets the start angle for the arc. The default is 0 degrees.

Angle2
This number sets the end angle for the arc. The default is -90 degrees.

IsWedge
If set to NO (the default), PC-DMIS draws a filled arc without a wedge, like this:

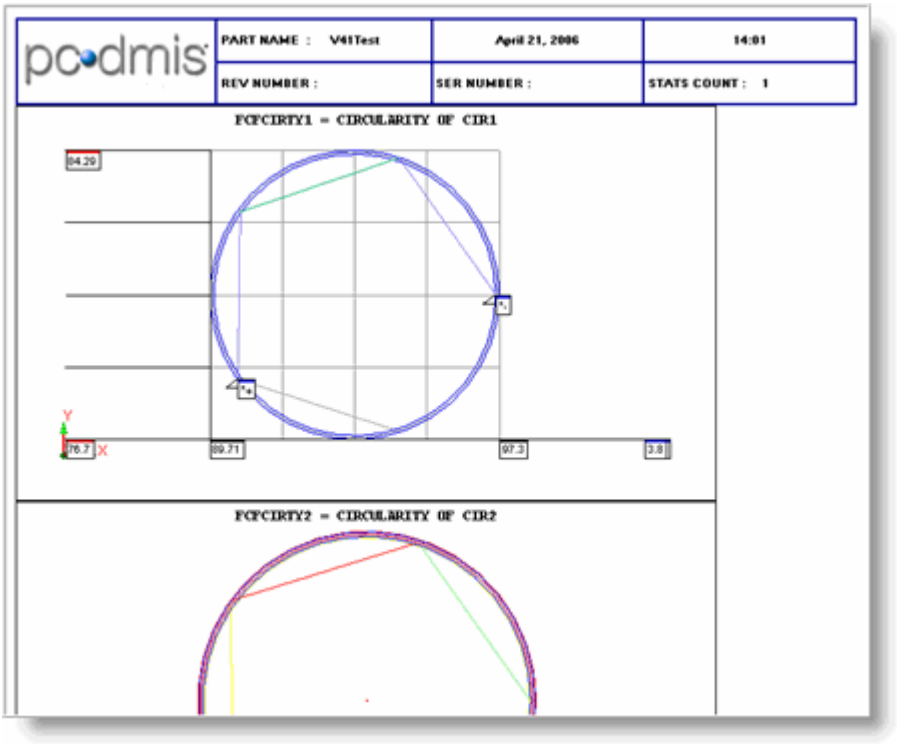


If set to YES, PC-DMIS draws a filled arc with a wedge like this:



AnalysisWindow Object

The **AnalysisWindow** object is used to insert a PC-DMIS Graphical Analysis window into a label template or into a custom report. Then, in the Report window, PC-DMIS displays a graphical analysis of dimensions that use a report template, using the label template with an analysis object in it.



Report Window showing the graphical analysis of the dimension.

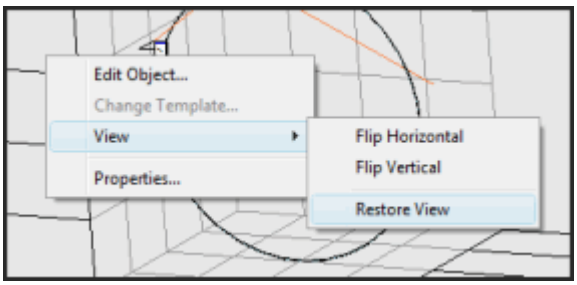
For information on the Analysis window, see "Inserting Commands Related to the Analysis Window" in the "Inserting Report Commands" chapter.

> The AnalysisWindow object functions only with Feature Control Frame dimensions. It does not function with Legacy dimensions.

Manipulating the Object

You can double-click on this object to *activate* it in the Report window. This lets you manipulate its display in the Report window on the fly. Once activated, you can use your mouse wheel to zoom in or out on the object's graphical display and change its rotation. Double-clicking outside of the object *deactivates* it. You can also right-click on the object in the Report window to access the **Graphical Analysis Options** dialog box described below.

If you need to revert a rotated graphical display in the object back to its original orientation, right-click on the object, and select **Restore View** from the **View** menu on the shortcut menu. This restores the orientation of the displayed graphical information in the object to its original vector.



Restore View Menu Item

The other menu items in the **View** menu, **Flip Horizontal** and **Flip Vertical**, flip the horizontal or vertical orientation of the object.

Using with Point Info Boxes in Custom Reports

When adding an **AnalysisWindow** object to a custom report, you can use the following two properties to control what point information is displayed and how it should look by defining the label template to use:

- **PointInfoLabel** - This property displays the **Browse Files** dialog box, showing the label templates in your Reporting subdirectory. You can use this dialog box to select the label template you would like PC-DMIS to use when creating Point Info boxes inside of the **AnalysisWindow** object. Once selected, the property will display the label name and any Point Info boxes that exist within the **AnalysisWindow** object will be immediately updated.

  PC-DMIS remembers the selected template and uses it for subsequent **AnalysisWindow** objects that are added into the Custom Report editor. The defined template is also stored in the `LastUsedPointInfoLabel` entry under the **Reporting** section of the PC-DMIS Settings Editor.

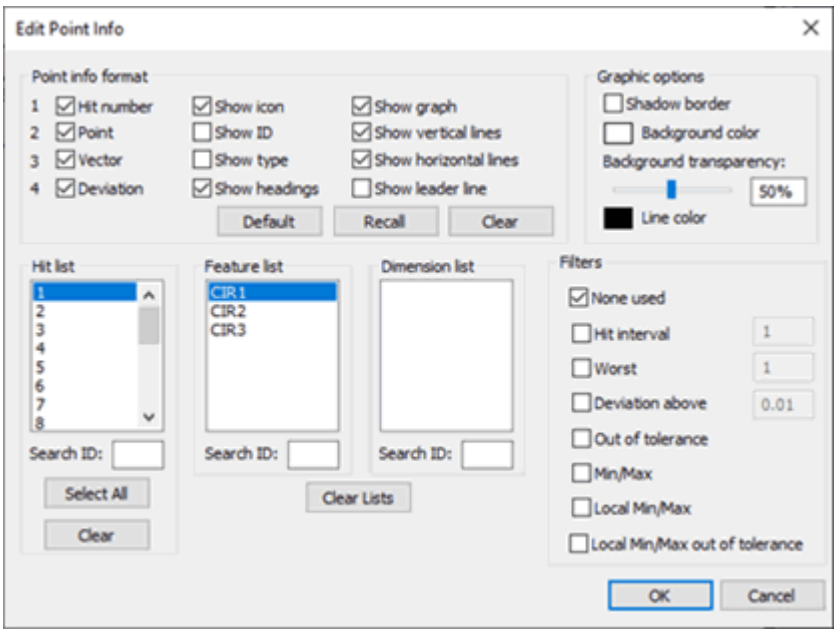
  If you do not define any label template in this property, any Point Info boxes used are generated the same as if you had dragged a **PointInfo** object onto the Custom Report editor. In that case, it does not use a label template, but is created internally.

  Some label templates to consider using are: ga_point_info.lbl, ga_point_info2.lbl, and ga_point_info_devonly.

  To clear this property, open the **Browse Files** dialog box, remove the filename listed in the **File name** box, and click **Cancel**.

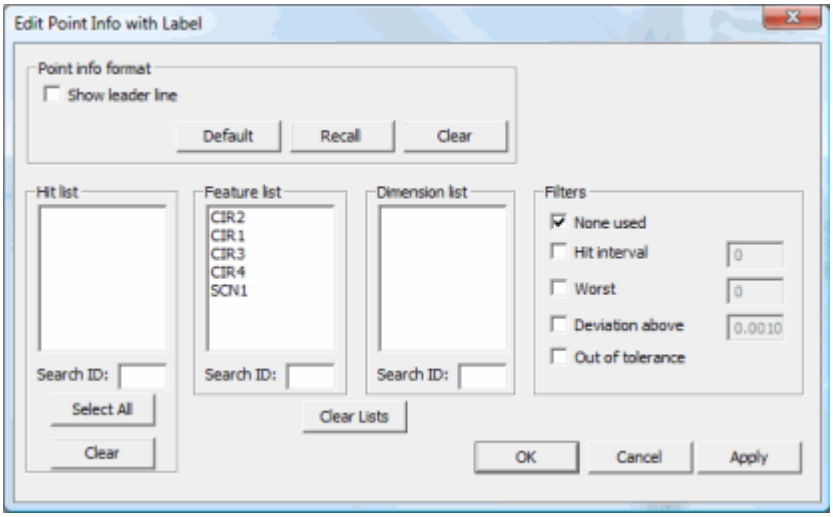
- **SelectPointInfo** - This property displays the **Edit Point Info** dialog box. That dialog box allows you to create Point Info boxes inside the **AnalysisWindow** object's window. This dialog box comes in two different styles depending on whether or not you have a label template defined in the `PointInfoLabel` property.

  If you do not have one defined, then the standard **Edit Point Info** dialog box appears:



Edit Point Info Dialog Box

If you do have one defined, then a slightly different **Edit Point Info with Label** dialog box appears:

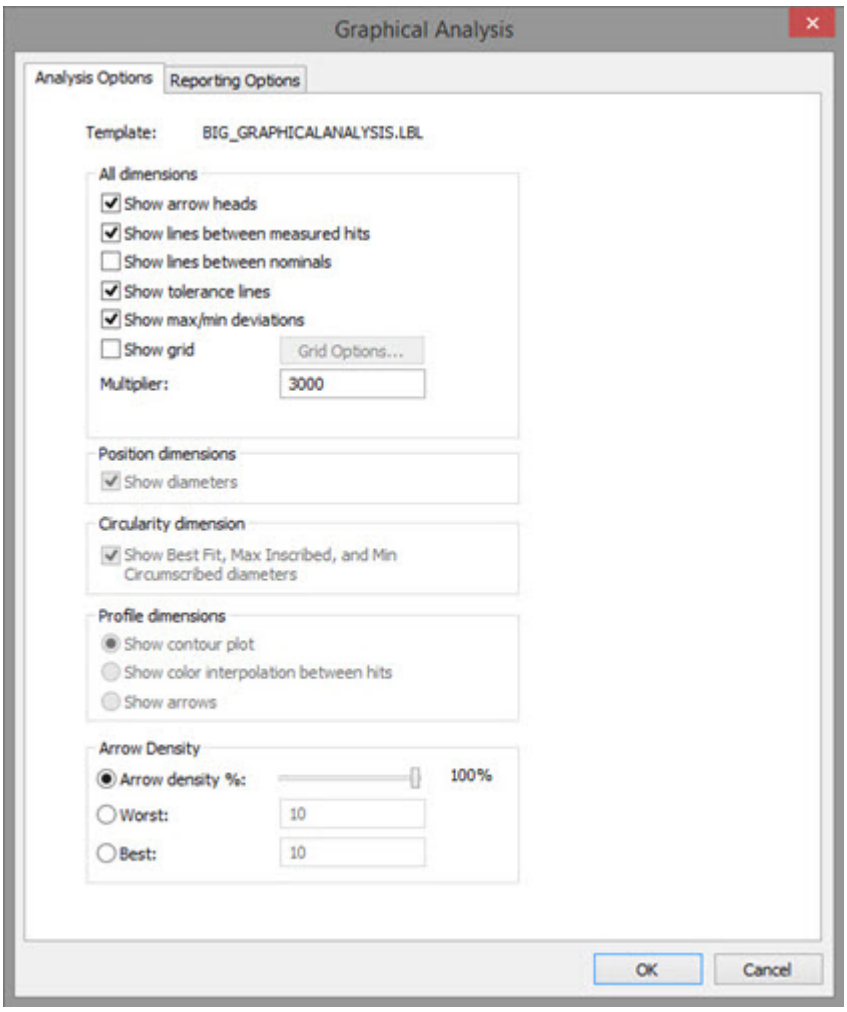


Edit Point Info with Label Dialog Box

These dialog boxes are similar, but if you have defined a label, you can only choose to hide or display leader lines using the **Point info format** area. This is because the other items do not apply if you are using a customized label template. For information on the available items in either of these dialog boxes, see the "Inserting Point Info Boxes" topic in the "Inserting Report Commands" chapter.

Changing Properties

To determine what this object displays, you can modify its many properties. You can also use the `(Settings Dialog)` property to access the **Graphical Analysis** dialog box inside the template editor. This dialog box lets you set many of the **AnalysisWindow** object's properties. There are two tabs:



Graphical Analysis Dialog Box

Note that when you open the **Graphical Analysis** dialog box from an analysis view, it shows the tab names as **Analysis Options** and **Display Options**. When you open the dialog box from within a report, it shows the tab names as **Analysis Options** and **Reporting Options**.

Analysis Options tab

For a description of the options on this tab, see "Dimension Options" in the "Inserting Report Commands" chapter. (The **Template** name near the top of the tab appears only if you edit an **AnalysisWindow** object within the Report window. For information on how to edit directly within the Report window, see "Edit Graphical Analysis".)

Reporting Options tab

For a description of the options on this tab, see the corresponding properties under the "Available Properties" subtopic below.

Here are the properties that are tied to the options on this tab:

Line color (measured) - see "MeasuredLineColor"

Line style (measured) - see "MeasuredLineStyle"

Line color (nominal) - see "NominalLineColor"

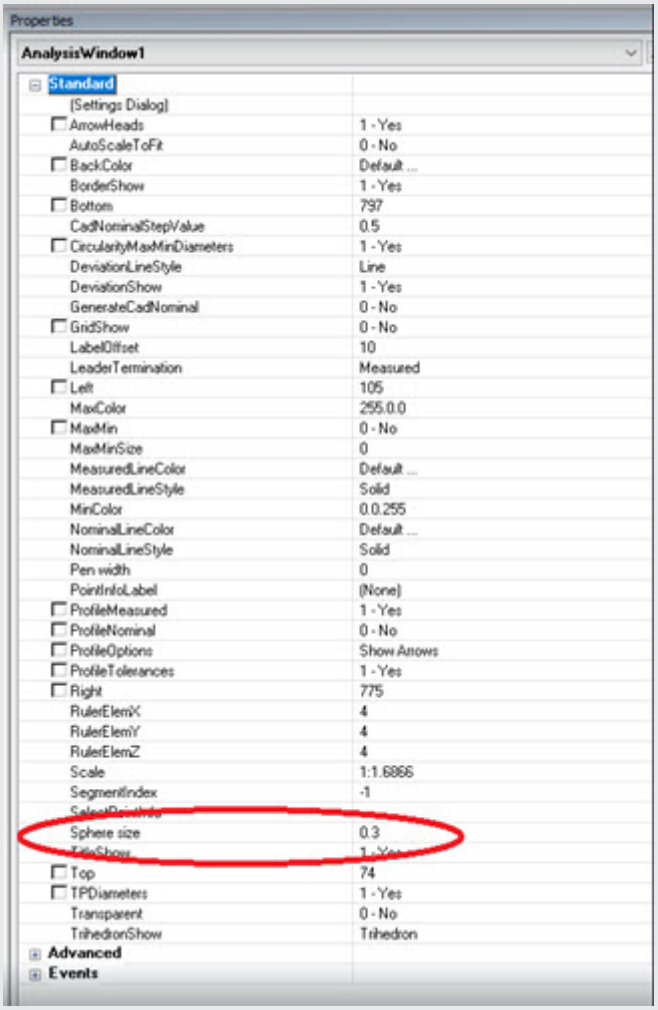
Line style (nominal) - see "NominalLineStyle"

Line style (deviation) - see "DeviationLineStyle"

Sphere size - PC-DMIS only enables this option when you are in **Line** mode. This value defines the diameter of the line's tip in mm. If you run PC-DMIS in inch units, the software converts the value you enter to mm for display purposes only.

You can set this value in the Settings Editor with the `AnalysisViewLollipopSphereSizeInMM` setting. For details on this setting, see "AnalysisViewLollipopSphereSizeInMM" in the PC-DMIS Settings Editor documentation.

You can view this and other properties of the analysis object on the report. For example, select **File | Reporting| New | Custom Report** and then create the analysis object on the report. Then right-click the object and select **Properties**. PC-DMIS lists all the properties related to the analysis object report:



Example of the analysis object report properties

Show trihedron - see "TrihedronShow"

Min/Max ball size - see "MaxMinSize"

Minimum ball color - see "MinColor"

Maximum ball color - see "MaxColor"

Background color - see "BackColor"

Line Size - see "PenWidth"

Leaderline termination - see "LeaderTermination"

Show Deviation - see "DeviationShow"

Show Title - see "TitleShow"

Show Border - see "BorderShow"

Available Properties

The available properties for this object are listed below:

All properties are used in Custom Reports unless otherwise stated. Those properties followed by an asterisk (*) are also used in Report Template Builder.

(Settings Dialog) *
Displays the **Graphical Analysis Options** dialog box for the selected AnalysisWindow object.

Arrow Best Value
Defines the number of best deviations for which to display arrows.

Arrow Density Options
Determines how to handle arrow density.

`0 - by Percent` - This uses the percentage defined in the **Dimension Analysis Options** dialog box's **Arrow density** slider.

`1 - by Worst` - This uses the `Arrow Worst Value` property.

`2 - by Best` - This uses the `Arrow Best Value` property.

Arrow Worst Value
Defines the number of worst deviations for which to display arrows.

ArrowHeads *
Same as the **Show Arrow Heads** check box in the dialog box.

AutoScaleToFit
Scales the information being analyzed so it fits within the boundaries of the object.

BackColor *
Common Properties

BorderShow *
Shows or hides the AnalysisWindow object's border.

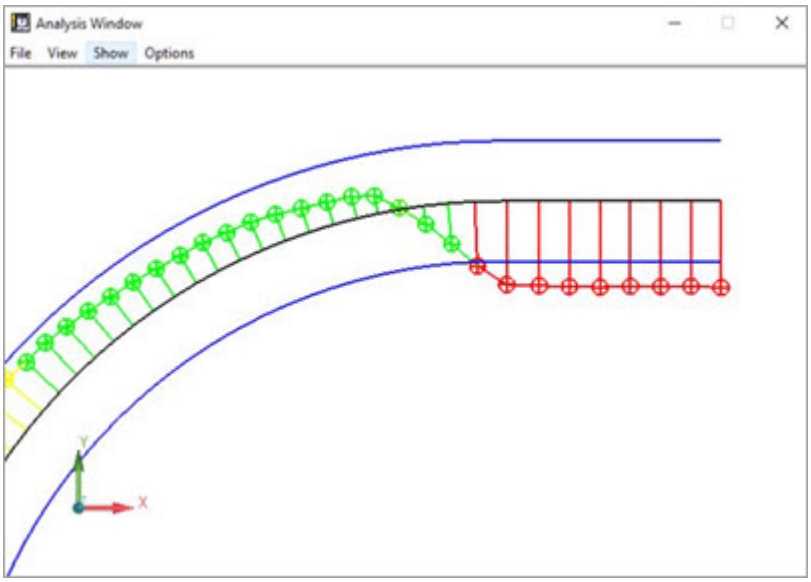
Bottom *
Common Properties

CadNominalStepValue
Defines the density of the points projected along the polyline to the CAD interpolation for the points inserted from the CAD model in the `GenerateCadNominal` property.

CircularityMaxMinDiameters *
Same as the **Show Best Fit, Max Inscribed, and Min Circumscribed Diameters** check box in the dialog box.

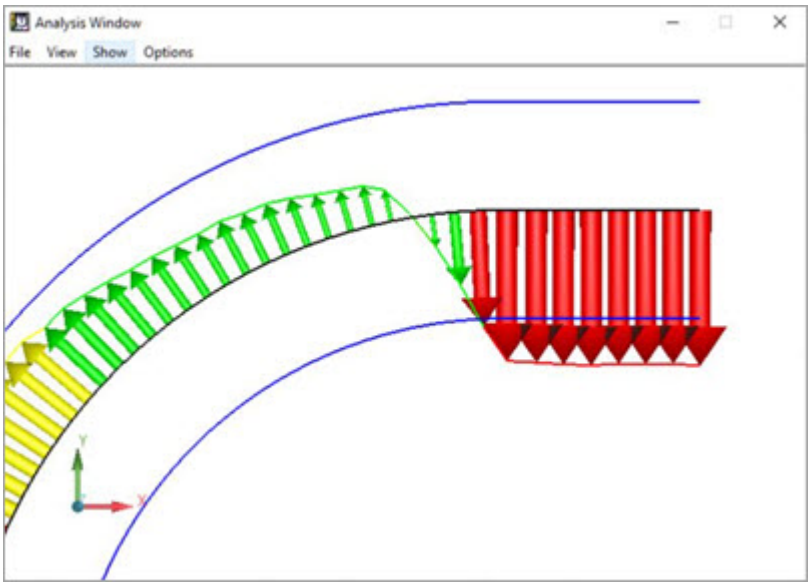
DeviationLineStyle
Defines the deviation line style.

`Line` - Deviation lines are drawn as simple lines that terminate with lollipop style heads.



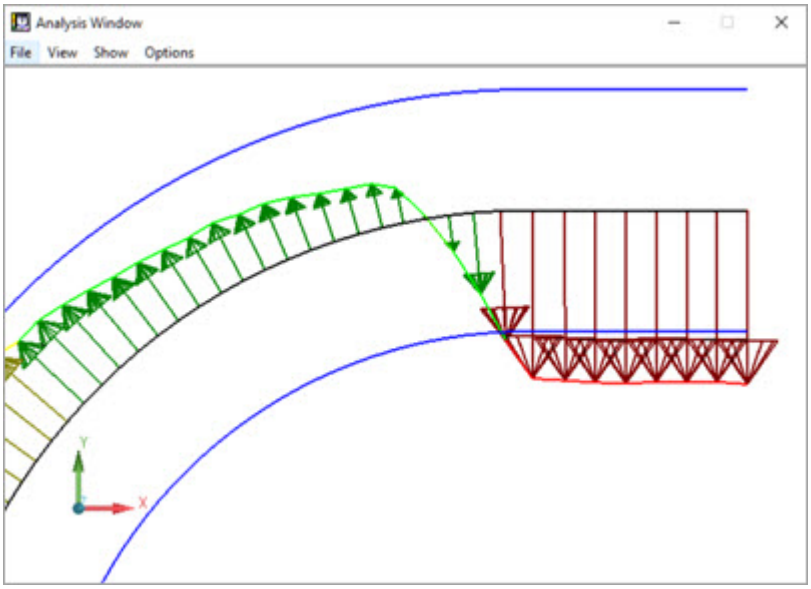
DeviationLineStyle - Line Option

`Cylinder` - Deviation lines are drawn as shaded cylinders that terminate with arrowheads.



DeviationLineStyle - Cylinder Option

`Unshaded Cylinder` - Deviation lines are drawn as wireframe cylinders that terminate with arrowheads. This option is only available from the **Display Options** tab of the **Graphical Analysis** dialog box.



DeviationLineStyle - Unshaded Cylinder Option

DeviationShow
Shows or hides the deviation lines. By default these are drawn as arrows.

Enable *
Common Properties

GenerateCadNominal
Generates a smoother nominal polyline by projecting additional points onto the CAD model as needed in order to see a line that more closely matches the CAD model. The density of these additional points can be increased or decreased using the `CadNominalStepValue` property.

GridShow *
Displays the 3D grid-like backdrop for the Analysis window.

LabelOffset
Positions a user-defined Point Info label at the specified offset distance from the hit location. The label to use is defined in the `PointInfoLabel` property.

LeaderTermination
Sets the termination location for any leader lines between Point Info boxes and their associated point locations:

`End of Arrow` - The leader lines point to the end-of-arrow locations.

`Nominal` - The leader lines point to the nominal point locations.

`Measured` - The leader lines point to the measured point locations.

Left *
Common Properties

MaxColor
Determines the sphere point color for maximum deviations. The default is red `(0.0.225)`.

MaxMin *
Same as the **Show Max/Min Deviations** check box in the dialog box.

MaxMinSize
Determines the diameter of the sphere point that marks the Max/Min points in the **AnalysisWindow** object. The default is `0`.

MeasuredLineColor
When lines are displayed between the measured hits, this determines the line color used.

MeasuredLineStyle
When lines are displayed between the measured hits, this determines the style used. You can choose `Solid` or `Dashed`.

MinColor
Determines the sphere point color for minimum deviations. The default is blue `(255.0.0)`.

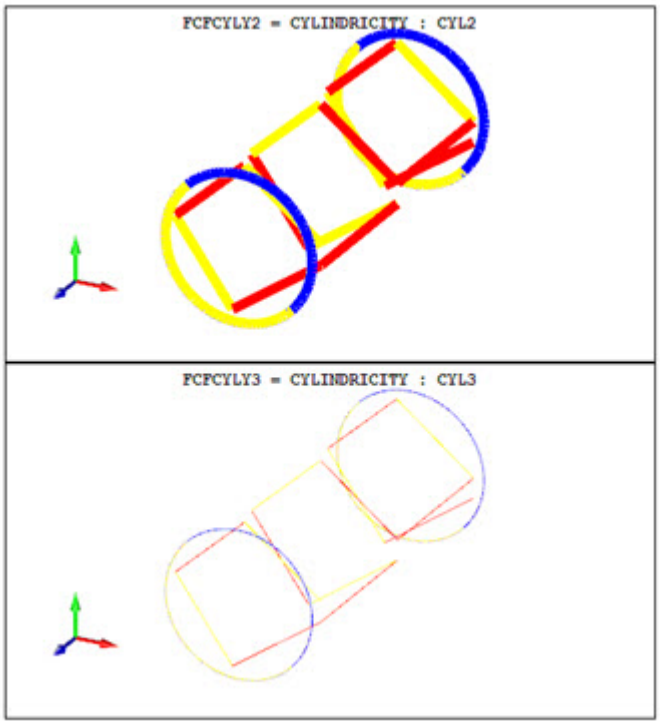
NominalLineColor
Determines the color of the nominal graphical line.

NominalLineStyle
Determines the style of the nominal graphical line. You can choose `Solid` or `Dashed`.

PC-DMIS Command Objects
Common Properties

PC-DMIS Reference
Common Properties

PenWidth
Sets the line size for the lines in the analysis object. The default is 0. The maximum line width is determined by your graphics card and driver.



PenWidth of 8 (top) and 0 (bottom)

PointInfoLabel
Selects the label template to use for Point Info boxes tied to the **AnalysisWindow** object. Use-defined labels in this object cannot be moved except by using the `LabelOffset` property.

ProfileMeasured *
Same as the **Show Lines Between Measured Hits** check box in the dialog box.

ProfileNominal *
Same as the **Show Lines Between Nominals** check box in the dialog box.

ProfileOptions *
Same as selecting one of the option buttons from the **Profile Dimensions** area in the dialog box.

ProfileTolerances *
Same as the **Show Tolerance Lines** check box in the dialog box.

Right *
Common Properties

RulerElemX
Same as **Number of elements** XYZ boxes discussed in the **Analysis Grid Options** dialog box.

RulerElemY
Same as **Number of elements** XYZ boxes discussed in the **Analysis Grid Options** dialog box.

RulerElemZ
Same as **Number of elements** XYZ boxes discussed in the **Analysis Grid Options** dialog box.

Scale
Scales the Analysis window by a specific ratio. The format is n1:n2 where n1 and n2 are two numbers. For example, a value of `1:3` would display the info in the Analysis window at three times its normal size, and a value of `2:1` would display the info at half its normal size. The property also displays the current zoom ratio if you zoom using the mouse buttons.

> The `AutoScaleToFit` property must be set to `No` for the `Scale` property to work.

SelectPointInfo
Displays a dialog box so that you can select the point information to display in Point Info boxes in the **AnalysisWindow** object.

TitleShow *
Shows or hides the text of the items being dimensioned at the top of the **AnalysisWindow** Object.

Top *
Common Properties

TPDiameters *
Same as the **Show Diameters** check box in the dialog box.

Transparent
Disables any color defined in the `BackColor` property and makes the object transparent, showing other objects behind it.

TrihedronShow
Shows or hides the trihedron symbol. Alternately, you can select **Ruler** to show a ruler along each axis.

Visible *
Common Properties

Border Object

The **Border** object inserts a rectangular border into the template or form. Along with the ability to resize the object, add a fill color, add a border color, and change other attributes, the following editable properties are included for border objects:

HighlightColor
This sets the color used for the `BorderStyle` property.

BorderStyle
This sets the 3D highlight style of the object's border. Options include `Normal`, `3D`, `Sunken` and `Raised`.

Image Object

The **Image** object allows you to insert a pre-created bitmap graphic into your template or form. When you click this icon and drag a box in the editor, a dialog box opens.

Bitmap Dialog Box

- The **OK** button inserts the bitmap loaded into the dialog box into the form or template.
- The **Cancel** button closes the dialog box without inserting any bitmap.
- The **Copy** button copies a bitmap to the Clipboard that you have already loaded into this dialog box through the **Load** button.
- The **Paste** button pastes a copied bitmap graphic from the Clipboard into the dialog box. After you paste a graphic you can select the **RLE** check box to compress the graphic when it's saved with the report.
- The **Load** button loads a graphic image (bitmap or JPEG file) into the dialog box. After you load the graphic, you can select the **Link** check box to link the bitmap to the template or form by its directory path. This means if the graphic gets updated, it will appear in its updated form inside the template or form.
- The **Clear** button clears the loaded bitmap out of the dialog box.
- The **Transparent** list specifies one color within the bitmap to make transparent.

Along with the ability to resize the object and change other attributes, the following editable properties are included for bitmap objects:

Bitmap
This contains the file name for the bitmap.

Layout
`Center`, `Left`, or `Right` is the alignment of the bitmap within the rectangle.

`Stretch` expands or shrinks the graphic to fit the size of the box.

`Size to Fit` automatically expands the rectangle size to fit the size of the graphic.

Button Object

The **Button** object inserts a button control into a form. You can choose the action the form will take when the button is clicked by modifying the `ButtonType` property.

Along with the ability to resize the object, change colors, and change other attributes, you can further customize button objects by using these properties:

Default
This determines how buttons will respond when you press the Enter key.

`YES` - The button responds to a pressed Enter key even if another button has the focus.

`NO` - If Enter is pressed only the button that has the focus will respond.

ButtonShape
This determines the look of the button. Options include:

`0 - Normal`: Changes shape to a standard button.

`1 - Property tab Inactive`: Changes shape to an unselected property sheet tab.

`2 - Property tab Active`: Changes shape to a selected property sheet tab.

Text
This determines the text that appears on the button.

Bitmap
This places a bitmap of your choice on top of the button face. It uses the same dialog box and properties as described in the "Bitmap Object".

Layout
This determines the position of the bitmap or text on the button's face. The values include:

`0 - Center`

`1 - Left`

`2 - Right`

`3 - Top`

`4 - Bottom`

ButtonType
This determines the action a button will take when it's clicked.

`0 - Cancel`: Closes the form and does nothing.

`1 - EventClick`: Executes a C++ or VBScript action.

`2 - Goto`: Goes to the Multi Document Interface (MDI) associated file.

`3 - Help`: Invokes the WinHelp() function using the HelpContextID property to open the proper topic.

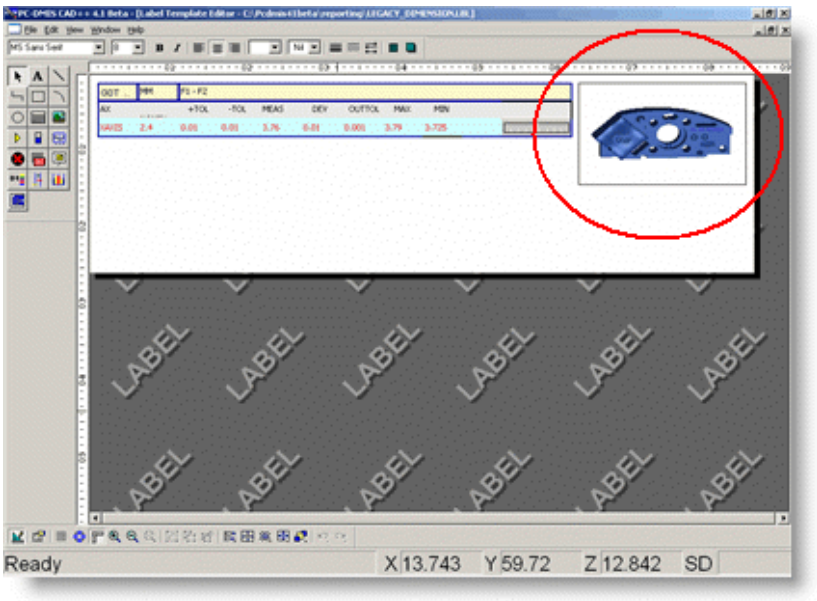
`4 - OK`: Records changes and closes the form.

`5 - Record`: Records changes and keeps the form open.

GotoPath
This determines the MDI associated file the form will go to when the button is clicked. This is mostly used to implement property sheet-like controls.

CadImageObject

The **CadImageObject** lets you display the CAD image inside of a label template or a form. When you select this item and drag a box in the editing environment, PC-DMIS inserts a **CadImageObject** into the editor, and the object displays a dummy CAD model image.



Label Template Editor showing an inserted CadImageObject

How you size the object in the editing environment determines the size of the object when actually displayed in the Report window or executed form.

The **CadImageObject** contains these properties:

Standard

Bottom
Defines the bottom location for the object in pixels from the top of the editor.

Left
Defines the left location for the object in pixels from the left of the editor.

Right
Defines the right location for the object in pixels from the left of the editor.

Show Border
Shows or hides the object's border.

- `ON` - Displays a border around the object.
- `OFF` - Does not draw a border.

Top
Defines the top location for the object in pixels from the top of the editor.

GraphicsOptions
Determines whether to hide or show labels on the CAD image.

- `0 - None` - Doesn't show labels.
- `1 - Labels` - Shows labels.

Hide all measured features
Shows or hides features on the CAD image.

`0 - No` - Shows features.

`1 - Yes` - Hides features.

`2 - Use entry setting` - (Default) Uses the entry default. This can override the `HideAllMeasuredFeaturesOnReport` entry located in the **Reporting** section of the PC-DMIS Settings Editor.

Hide all points
Shows or hides point features on the CAD image.

`0 - No` - Shows point features.

`1 - Yes` - (default) Hides point features.

`2-Use entry setting` - Uses the entry default. This can override the `HideAllPointsOnReport` entry located in the **Reporting** section of the PC-DMIS Settings Editor.

TrihedronShow
Shows or hides the trihedron on the CAD image.

`0 - No` - (default) Hides the trihedron.

`1 - Yes` - Shows the trihedron.

Advanced

(Object Code)
Defines the object's unique name.

Enable
Determines whether or not this object is enabled for modification in the form or template.

`YES` - Enables the object for modification.

`NO` - Does not enable the object for modification.

Visible
Determines whether or not this object is visible in the form or template.

`YES` - Shows the object.

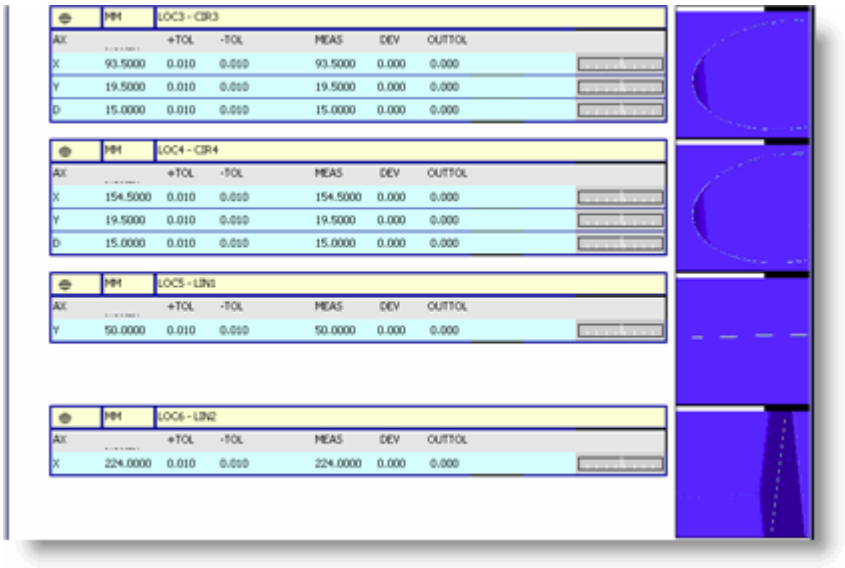
`NO` - Hides the object.

Events

EventReportData - This is the event that pulls report data from PC-DMIS into the template or form.

CadImageObject on Labels

You can use the **Rules Tree Editor** dialog box to display the label template in a report template for a particular dimension or feature. In such a case, the Report window displays the portion of the CAD model that contains that dimension or feature.

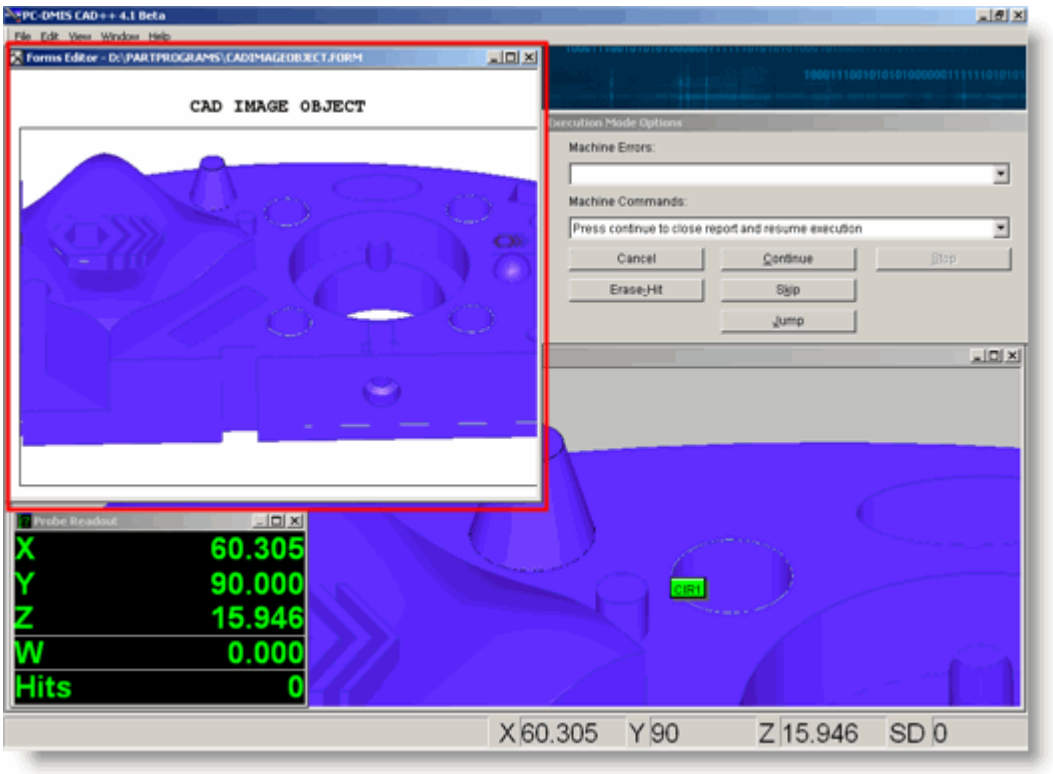


Report window showing a CadImageObject next to each displayed dimension

You can scale, scale to fit, rotate or translate this CAD image from the Report window. To do this, double-click on the CAD image to make it editable, and then manipulate the image just as you would the model in the Graphic Display window. To return to the Report window, storing your changes, double-click outside of the object.

CadImageObject on Forms

When it is used on a form, the CadImageObject is bound to the current viewset when PC-DMIS executes the form command. Once you execute the form (CTRL + E) or the measurement routine that calls the form, you cannot modify the CadImageObject.

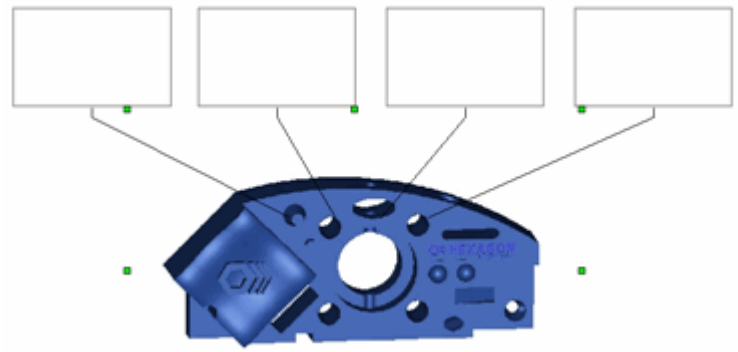


Form window showing a CadImageObject during measurement routine execution

For additional information on forms, see the "Creating Forms" topic in this chapter.

CadReportObject

The **CadReportObject** (CRO) lets you view your CAD drawing inside a finished report. When you initially drop the CRO into a report template, PC-DMIS automatically launches the **Label Layout Wizard**. After using this wizard to position the labels you want PC-DMIS to use, you will see a dummy graphic of the Hexagon test block, and if no rules are defined, dummy labels as well. It will look something like this:



A sample CRO inserted into a report template.

Remember, these dummy items are simply representations of what you want on your report. In the actual Report window, it shows the actual CAD model. The labels display a picture of the label template defined by the first rule in the rule tree of the CRO. If the label is not associated, and no rules apply, it draws the dummy label image.

How it Works in the Report Window:

In the Report window, your CAD display initially appears exactly as shown in your Graphic Display window when it finishes executing your measurement routine or at the time you redraw your report, except that it does not zoom in any closer. If you make modifications to a CRO in the Report window, PC-DMIS retains those changes to the CAD image on the report—even after subsequent measurement routine executions—until you right-click on the CAD view(s) inserted into your report and select **Remove Object Modifications** or until you select **File | Reporting | Clear Template Associated Data**.

While your Report window often shows your entire CAD drawing, it only shows labels and leader lines for those features you have specified in the **Rule Tree Editor**. For example, if your measurement routine has four measured circles and two measured lines, yet in the **Rule Tree Editor** your CRO displays labels only for the measured circles, then the report only shows label information for those circles, even though you may have measured the lines as well in your last execution.

Also, if a CRO is configured to display—using the **Label Count** list on the **Label Layout Wizard**—a fewer number of labels than the number of features it is specified to report on in the **Rule Tree Editor**, then the Report window displays additional instances of your CAD drawing on additional pages in the Report window. These additional images show leader lines and labels to any remaining features. This is especially helpful if your labels have a lot of information that may make your report look cluttered if you have more than one or two labels around a part drawing.

If you're using viewsets, your CAD display appears exactly as shown in your viewsets. PC-DMIS inserts a new CAD display on a new page of the report for each viewset encountered during execution. For information on viewsets, see "Working with Viewsets".

Rotating, Moving, and Zooming the CRO CAD Image

You can change the CRO CAD image orientation and zoom level in the Report window, or move it to a new location.

- To rotate the image, double-click on the object to "activate" it. Once activated, click and hold the wheel button. As you do this, drag the mouse. You can also press Ctrl and right-click while dragging the mouse.
- To zoom in or out of the image, double-click the object to "active" it. Once activated, rotate your mouse's wheel button to zoom in and out.
- To move the CRO, right-click the object to select it. Once selected, click the object and drag the mouse.

To cancel zoom or rotation changes, press the Esc key. The CRO is "deactivated" without applying your changes.

To save zoom or rotation changes, double-click outside of the CRO. The CRO is "deactivated", and the CAD image uses the new orientation and zoom level. If you are using the Feature-based label layout on the CRO, the entire report is reloaded with the new orientation and zoom level applied to the CAD image. If the CRO is from a `SNAPSHOT` command, PC-DMIS applies these same changes to your `SNAPSHOT` command in the Edit window.

To save movement changes, click outside of the selected object.

To remove pan, zoom, and rotate modifications for the CRO, right-click on the object in the Report window, and choose **Remove CAD Report Object Pan/Zoom/Rotate MOD**. Other mods (such as section cuts, various label definitions, solid or wire displays, and so forth) are not affected.

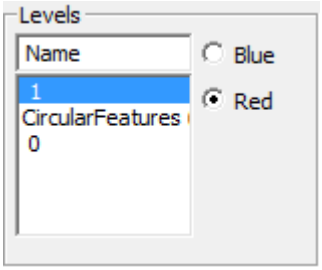
Switching Between Solid and Wireframe Modes

- In the Report window, you can do this by right-clicking the CRO and selecting the **Wireframe** menu item from the shortcut menu.
- In the Report Template Editor, you can do this by right-clicking the CRO, accessing the **Properties** dialog box and setting the **Wireframe** property to either YES or NO.

Additional Functionality in the Custom Report Editor

In the Custom Report Editor, if you activate a CRO, the **View Setup** icon on the **Graphic Modes** toolbar becomes available for selection. The **Edit | CAD Operation | View Setup** menu item also becomes available. Clicking this icon or selecting the menu item displays the **View Setup** dialog box. In this context, you can use this dialog box to only modify the display of the CRO just as you would manipulate the view of the Graphic Display window normally. See "Setting Up the Screen View" for information on using the **View Setup** dialog box to define views.

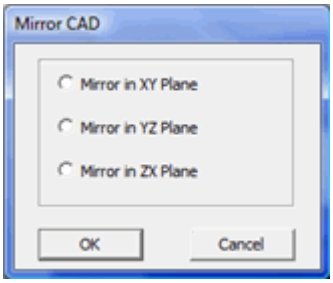
- **Choosing Wireframe or Solid:**
  You can display your CRO in Custom Report Editor as either a solid or wireframe by using the **View Setup** dialog box and marking or clearing the **Solid** check box. Alternately, with the object only selected but not activated, you can right-click on the CRO, select **Properties** from the shortcut menu and then set the **Wireframe** property to either YES or NO. PC-DMIS toggles between a solid or wireframe in your custom report.
- **Viewing Levels:**
  You can use the **View Setup** dialog box to select specific levels of CAD elements to be applied to the object in the Custom Report Editor. The **Levels** area lists any predefined CAD levels.



Levels area showing three levels

Select one or more levels and click **OK**, PC-DMIS displays the selected levels on the selected CRO in your custom report. For information on creating your own levels, see "Working with CAD Levels" in the "Editing the CAD Display" chapter.

- **Mirroring the CAD:**
  PC-DMIS lets you mirror the CAD image contained in that object in the Custom Report Editor. To do this, select the CRO, select **Edit | CAD Operation | Mirror**. The **Mirror CAD** dialog box appears:



Mirror CAD Dialog Box

This dialog box lets you create a mirror image of the part. Select the plane (axis) in which you want to mirror the part, and click **OK**. PC-DMIS displays the mirrored CAD model on the selected CRO. See "Transforming a CAD Model" for additional information on Mirroring CAD in the Graphic Display window.

See "Creating Custom Reports" for information on custom reports.

Using Image Caching

PC-DMIS lets you cache your part's image once and use the image cache later in reporting contexts instead of always using your measurement routine's associated .cad file. You may find this useful in situations where you have a very large .cad file that takes a long time to load into the Graphic Display window. Once you cache your images for a particular report, you won't need your .cad file to view that report.

To cache your image:

1. Close PC-DMIS and open the PC-DMIS Settings Editor.
2. Under the **Reporting** section, set the `UseImageCachingScheme` entry to **1**.
3. Close the PC-DMIS Settings Editor and restart PC-DMIS.
4. Load the measurement routine and the .cad file as usual.

5. Open the Report window and select a report template that uses the CRO.
6. Generate the report.
7. Make any desired modifications to the CRO items used in the report.
8. Print your report.

This process caches the images used in this particular report. Now if you delete (or rename) your .cad file to speed up the measurement routine opening process, this same report uses your cached images. Note that other reports that use the CRO are not cached however, and you need to load the .cad file as usual.

Properties:

Many of the properties in this table are covered in more detail in the "Label Layout Wizard" topic.

AutoZoom
Determines if the object automatically zooms and focuses attention on only that portion of the CAD model where label objects are currently displayed.

Draw wires in shaded mode
This determines whether or not PC-DMIS displays a wireframe of the CAD object on top of the shaded image when viewing the CAD model in a solid surface view.

Label Layout
This opens the **Label Layout Wizard**. This lets you quickly layout multiple labels around your CAD drawing. See "The Label Layout Wizard" for more information.

Leader Line ArrowHeader Height
Defines the height of the arrow on the leader line.

Leader Line ArrowHeader Style
Defines the style of the arrow on the leader line.

Leader Line Color
Defines the color of the leader line.

Leader Line ending at two features for angle
Determines if the leader line splits to point to both features.

Leader Line ending at two features for distance
Determines if the leader line splits to point to both features.

Leader Line Feature Mode
Determines whether the leader line points to the feature's centroid or to the usual drawn location.

Leader Line Style
Defines the style of the leader line.

Leader Line Termination
This draws the leader line from the label to either the **Measured** feature on the CAD or the **Nominal** feature on the CAD. See description in the Label Layout Wizard.

Leader Line Width
This defines the width of the leader line in pixels.

RuleTree
This opens the **Rules Tree Editor** dialog box. This dialog box lets you define conditions and actions for this object. See "About the Rule Tree Editor" for more information.

ShowBorder
This draws or hides a border around the CRO.

Single Click Rule Tree
This lets you browse and select a label template that PC-DMIS displays when you click on a label from the Report window.

TrihedronShow
Shows or hides the trihedron on the CAD image.

`0 - No` - (default) Hides the trihedron.

`1 - Yes` - Shows the trihedron.

Wireframe
This property lets you show the CRO in your report in either a wireframe (if set to `YES`) or solid surface view (if set to `NO`).

Hide all measured features
Shows or hides features on the CAD image.

`0 - No` - Shows features.

`1 - Yes` - Hides features.

`2 - Use entry setting` - (Default) Uses the entry default. This can override the `HideAllMeasuredFeaturesOnReport` entry located in the **Reporting** section of the PC-DMIS Settings Editor.

Hide all points
Shows or hides point features on the CAD image.

`0 - No` - Shows point features.

`1 - Yes` - (default) Hides point features.

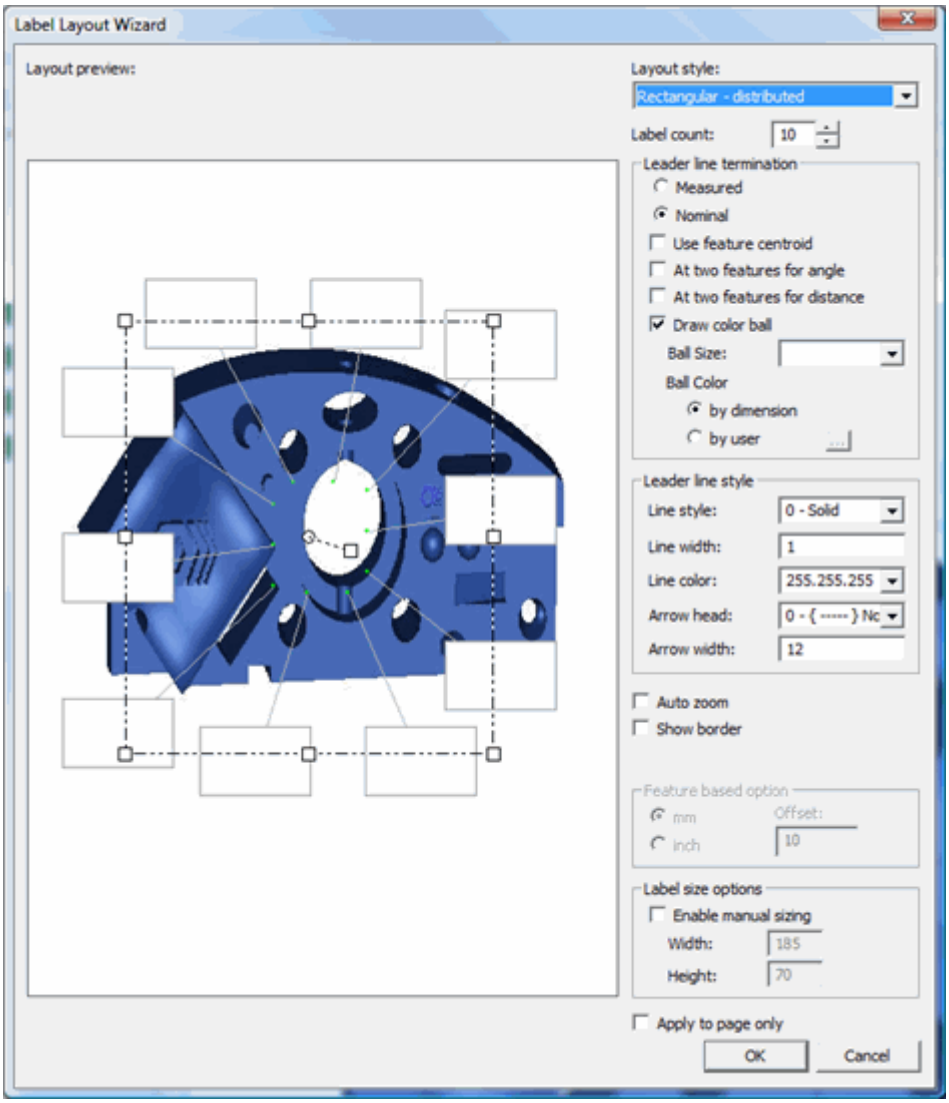
`2-Use entry setting` - Uses the entry default. This can override the `HideAllPointsOnReport` entry located in the **Reporting** section of the PC-DMIS Settings Editor.

Colormap is own page
Shows a colormap alone on its own page or with other objects. This property works with pointclouds (COP) Surface Colormaps; it does not affect Profile dimensions that have an embedded colormap.

`0 - No` - The colormap resides with other objects, and the report does not add a new page with only the colormap.

`1 - Yes` - (default) The report adds an additional page before the usual colormap page with only the colormap and its color key.

The Label Layout Wizard



Label Layout Wizard

The **Label Layout Wizard** is a tool that lets you quickly arrange multiple labels around your CAD drawing in the Report Template Editor and determine how the leader lines are drawn. In the Report Template Editor, this wizard appears automatically whenever you insert a **CadReportObject**. It also appears when you select the **(Settings Dialog)** property for a **CadReportObject**.

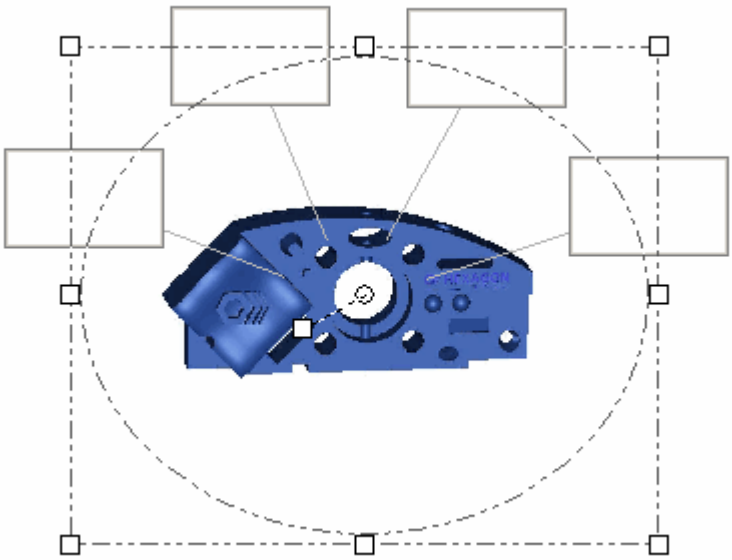
You can also utilize this wizard in the Report window. To access it, right-click on the **CadReportObject** in the Report window and select **Edit Object**. In the Report window, the wizard displays the real part model used with your measurement routine. In the Report Template Editor, however, it displays the Hexagon test block as a filler model.

Any changes you make inside this wizard will automatically change the appearance of the **CadReportObject**.

This wizard contains these two main parts:

- **Layout Preview** area
- **Settings** area

Layout Preview area



The **Layout Preview** area lets you preview how the layouts will appear around the **CadReportObject**.

Depending on how you want your labels to appear, you can rotate labels along either a rectangular or an elliptical path by clicking on the square, white handle, located at the center of the rectangle or ellipse and dragging it to a new location. You can click and drag any of the outer white handles to size this rotation path.

If you want to relocate your part drawing, click on it and drag it to a new location.

The following options are available:

Layout Style list
The drop-down list lets you control the spacing and rotate paths for the labels in the **Layout Preview** area. You can choose between these options:

Rectangular - Distributed - This creates a rectangular path that labels rotate around. The labels are distributed equally around the rectangle.

Rectangular - Packed - This creates a rectangular path that labels rotate around. The labels are close together along one side of the rectangle.

Elliptical - Distributed - This creates an elliptical path that labels rotate around. The labels are distributed equally around the ellipse.

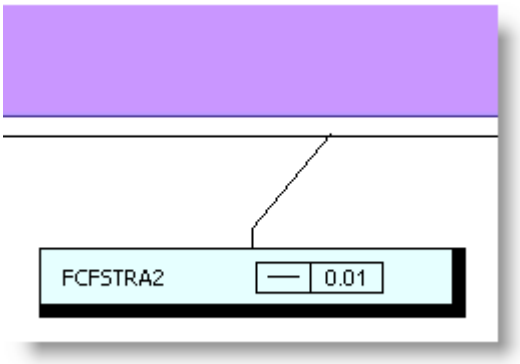
Elliptical - Packed - This creates an elliptical path that labels rotate around. The labels are close together along the ellipse.

Feature Based - This setting automatically places in the Report window all the feature labels around the part model in locations close to each feature's location. This is useful when you have, for example, a large amount of edge points and you want to display all their labels in one CAD drawing. Selecting this option disables the Label Count box and enables the Feature Based Option area where you can define the minimum leader line length.

Feature Based - Restricted - This acts the same as Feature Based except that it enables the Label Count box, allowing you to restrict the number of labels that will appear in the object in the Report window. If the object needs to display more labels than you have defined, the extra labels will appear in additional instances of the CAD drawing on new pages.

Leader Line Termination area
This area lets you choose where the leader lines from the labels will terminate on the CAD drawing.

Measured - This option terminates the leader line at the measured value's position.



Nominal - This option terminates the leader line at the nominal value's position.

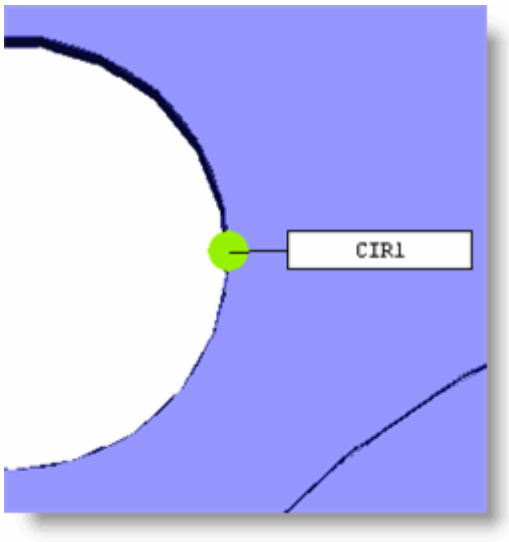
Use Feature Centroid - This check box terminates the leader lines to the centroid of the feature.

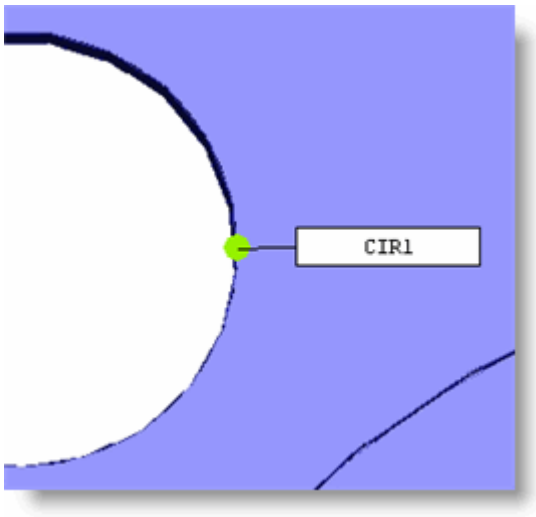
At two features for angle - This check box draws a single leader line from the label that then splits into two lines pointing to the two features making up an Angle dimension.

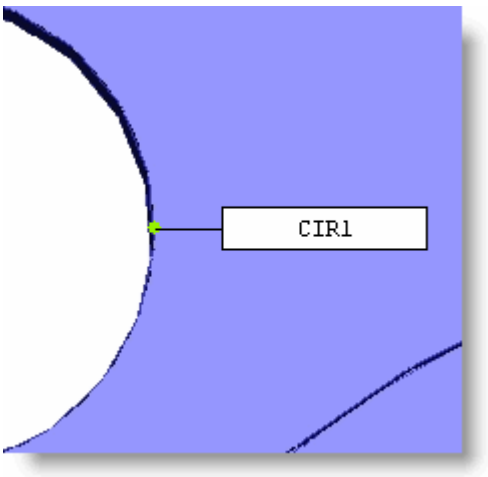
At two features for distance - This check box draws a single line from the label that then splits into two lines pointing to the two features making up a Distance dimension.

Draw Color Ball - This check box draws a colored ball where the leader line terminates. The color of the ball matches the tolerance color band for that feature's value.

Ball Size - This list determines the size of the colored ball drawn where the leader line terminates. It becomes enabled for selection when the **Draw Color Ball** check box is selected. You can choose between small, medium, and large. In addition, to define a more specific size, you can type a number in this box. This reflects the diameter of the color ball in pixels.







Ball Color by Dimension - This option colors leader line termination balls with the dimension's deviation color for the worst reported axis.

Ball Color by User - This option colors leader line termination balls with a single color that you select. To set the color, click on the **...** button and specify the color using the **Color** dialog box.

Leader Line Style area
This area lets you define what leader lines look like in the report.

Line Style - Defines the line style:

- *Solid*
- *Dash*
- *Dot*
- *Dash-Dot*
- *Dash-Dot-Dot*

Line styles only work at the default line width of 1. Wider lines will only use the Solid line style.

Line Width - Sets the line width in pixels.

Line Color - Defines the color of the line by setting RGB (Red, Green, Blue) values, consisting by three numbers separated by periods. You can either type in specific values for the colors, or you can select the **...** item from the list to access a standard **Color** dialog box and select your line color from that.

Arrow Head - Defines whether or not the leader lines have Arrow Heads.

- **None** - Lines do not have arrow heads.

- **Both** - Lines have an arrow head at each end.

Arrow Width - Defines the width of the arrow head in pixels

Show Border check box
This check box draws or removes a border around the entire CADReportObject inside the template editor or Report window.

Auto Zoom check box
This check box will automatically zoom in on the CAD display in the Report window in such a way that it focuses the attention on only that portion of the CAD model for which label objects are currently displayed.

Feature Based Option area
This area becomes enabled when you select **Feature Based** or **Feature Based-Restricted**. It contains two option buttons, **mm** and **inch**, and an **Offset** box. You can use the **Offset** box to define the minimum leader line length used with the labels. Depending on available room in the CadReportObject, the leader line length may grow, but it will never go below this minimum value.

Label Count box
This changes the maximum number of labels a report's page will display. It becomes disabled when you select **Feature Based**.

Label Size Options area
This area lets you switch between automatic or manual sizing of label objects. To make your label objects a specific size, click on **Enable Manual Sizing** and type in values in the **Width** and **Height** boxes.

Changing the labels sizes affects design purposes only. It does not affect label sizes in the actual Report window.

This area only appears when using the wizard in the Report Template Editor.

Apply to page only check box
Applies the changes made in the wizard to just the current page.

Colormaps and the CadReportObject

Laser scanners can scan and store thousands of points. PC-DMIS can then create colormap commands from these points. These colormaps can show deviations in a colored overlay. In the report, it does this with the CADReportObject (CRO).

For information on colormap commands, see the "Surface Colormap" and "Point Colormap" topics in the "PC-DMIS Laser" documentation.

For Standard Reports

The Report window shows a CRO on a new page for each marked colormap command. These CROs show the cad image with the colormap overlay. The colormap command defines what colormap appears.

For Custom Reports

You can add your own CRO and then drag a specific colormap command onto it.

In this way you can still view the colormaps but keep measured features and points hidden if **Hide all measured features** and **Hide all points** properties are set to **Yes**.

- For surface colormaps, if you associate more than one surface colormap to a CRO, it uses the last associated surface colormap.
- For point colormaps, you can combine point colormaps with other colormaps (point or surface) and show them all.
- If you drag and drop the same colormap onto the CRO where it's already been dropped, PC-DMIS removes that colormap from the CRO.
- If you do not associate any colormap with a CRO, PC-DMIS still attempts to show a colormap for that CRO. When it runs the `REPORT/CUSTOM` command it searches up from the insertion point. It uses the first colormap above the `REPORT/CUSTOM` command for the CRO. For information on the `REPORT/CUSTOM` command, see "The REPORT Command" in the "Inserting Report Commands" chapter.

For an example of dragging and dropping onto a CRO in a Custom Report, see "Dragging and Dropping Information into a Custom Report".

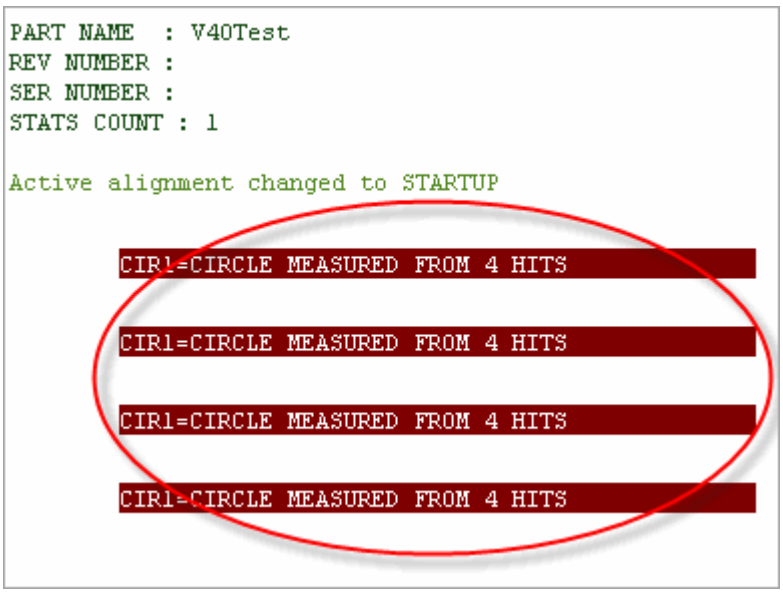
For information on Custom Reports in general, see "Creating Custom Reports".

CommandTextObject

The **CommandTextObject** merely acts as a container for a simple string of text that gives an overview of a feature or dimension.

When you use a template with this object with actual report data, PC-DMIS will display a string of text that shows, for a feature, the feature's text label, the feature's type, and how many hits were used to measure the feature. For a dimension, it shows the dimension's name and type and what units of measurement are used in the dimension.

A label that has only the **CommandTextObject** with actual report data might look something like this when displayed in the Report window:



Report showing the circle features generated from a label that uses a CommandTextObject.

Colors
Lets you change the colors of the text displayed. By default, PC-DMIS causes this object to use the same colors scheme as used in the Edit window's Command Mode, so if you click this property PC-DMIS displays a message box asking if you want to create an independent color set. Clicking **Yes** accesses the **Color Editor** dialog box. You can then use this editor to define a new color scheme for the selected CommandTextObject.

See "Defining Edit Window Colors" in "Setting Your Preferences" for information on how to use the **Color Editor**.

Empty Lines In Text Mode
This determines the number of blank lines to add between dimensions when dimensions are displayed as text.

Checkbutton Object

The **Checkbutton** object inserts a checkbutton object, or check box, into the form. Check boxes, unlike option buttons, are never mutually exclusive. You can select as many check boxes as desired (provided they are enabled for selection).

Along with the ability to resize the object, change colors, and change other attributes, you can further customize check boxes by using these properties:

AlignTextLeft
If set to YES, this moves the text to the left of the check box like this:

Text Here [ ]

If set to `NO`, this moves the text to the right of the check box like this:

[ ] Text Here

Bitmap
This allows you to specify a bitmap to use if `OwnerDrawn` is set to `TRUE` and if the check box is selected.

Additionally, the specified bitmap must be the same shape as a standard check box.

BitmapOffState
This allows you to specify a bitmap to use if `OwnerDrawn` is set to `TRUE` and if the check box is *not* selected.

Additionally, the specified bitmap must be the same shape as a standard check box.

HelpHotButton
Selecting `YES` shows a question mark help button next to the check box.

Clicking this button in run mode launches the PC-DMIS Online Help.

OwnerDrawn
This specifies how the form should draw the check box.

If set to `TRUE`, the check box gets drawn from a bitmap specified in the `Bitmap` and `Bitmap (Off)` properties.

If set to `FALSE`, the check box is drawn normally.

TriState
Enables (if set to `1 - YES`) or disables (if set to `0 - NO`) a check box's third state. Instead of just the checked or cleared states, this can add an additional third state to allow for cases when *a portion* of a selected option is true.

Text
The text specified here gets displayed on the check box control.

ComboBox Object

The **ComboBox** object inserts a combo list into your form. Using this list you can display options to select when you click the list in run mode.

Along with the ability to resize the object, change colors, and change other attributes, you can further customize this object by using these properties:

ComboType
This specifies the type of combo list. You can select either `Droplist` or `Dropdown`.

FlexHorizontal or **FlexVertical**
When the view is resized when viewing the form in run mode, you can elect to shift, expand, or keep objects proportional.

Selecting `Shift` moves the object to the right or down.

Selecting `Expand` enlarges the object right or down.

Selecting `Proportional` centers the object.

HelpHotButton
Selecting `YES` shows a question mark help button next to the check box.

Clicking this help button in run mode launches the PC-DMIS Online Help.

ListItems
This defines the list of items and the associated values (see the description of the **List Choices** dialog box described in the "Radiobutton Object").

NumDropped
The number specified determines how many list items the form displays when you click on the list in run mode.

Sort
Selecting `YES` sorts the list items in alphabetic order.

UseColors
This determines whether or not this control should use colors specified in `BackColor` and `TextColor` properties.

Dimension Color Key Object

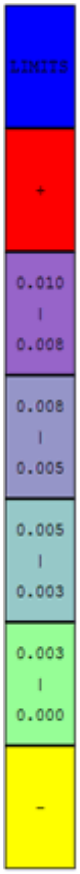
The **Dimension Color Key** object is used to drop a color key directly into the template. This color key depicts the colors that are used to represent the dimensional tolerance zones for analysis and histogram objects.

To see how these tolerance zones are defined or to change the colors representing each tolerance zone, see "Editing Dimension Colors" in the "Editing the CAD Display" chapter. Note that the **Decimal Places** value discussed in that topic does not affect the decimal places in the **Dimension Color Key** object here. That value only applies to the color bar in

the Graphic Display window. The decimal places for the **Dimension Color Key** object is hard coded to three decimal places.

Sample Horizontal Dimension Color Key Object

Sample Vertical Dimension Color Key Object



The following properties can be set:

BorderLines
This shows or hides the border line around the object.

LabelText
This shows or hides the overlay text on the color bar.

LimitsColor
This shows or hides the LIMITS color from the bar. This is the color used to draw the tolerance limits (tolerance lines).

ShadowStyle
This sets the location of the 3D shadow on the resulting object. Available locations are:

`Top/Left`, `Bottom/Right`, or `None`

DimensionInfo Object

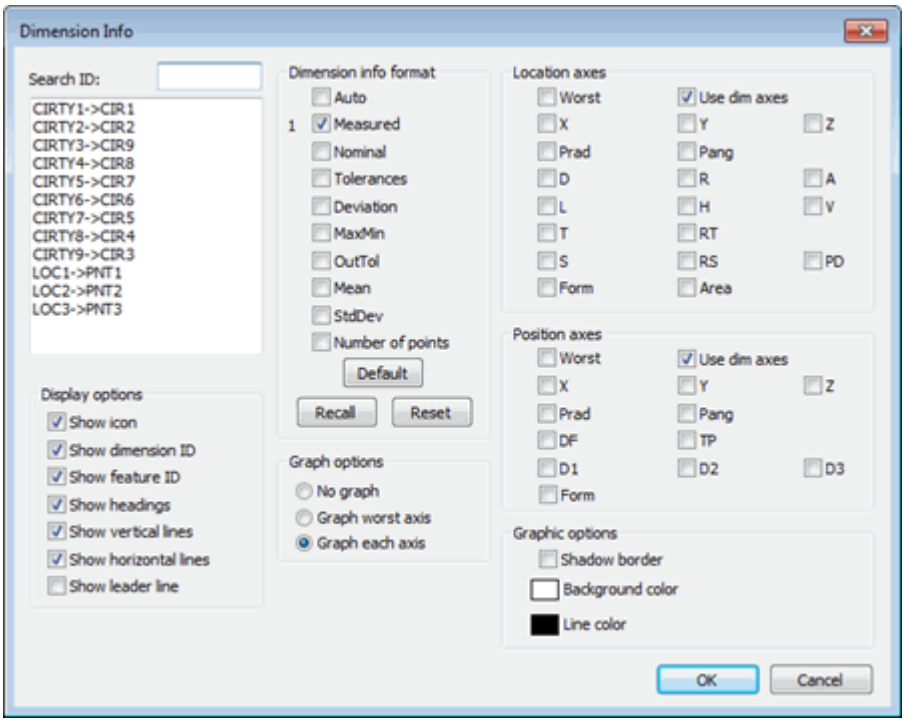
The **DimensionInfo** object acts as a container to hold individual dimension information in your report.

How to Use in a Label Template

From the Label Template editor's **Object Bar**, you can add and size a **DimensionInfo** object. Once you save the label template, you can use the **Rule Tree Editor** dialog box for a new or an existing report template to specify the dimensions for which PC-DMIS calls and displays that label template. For information on how to use the **Rule Tree Editor** dialog box, see the "About the Rule Tree Editor" topic in this chapter.

How to Use in a Custom Report

From the Custom Report editor's **Object Bar**, you can drag and drop a **DimensionInfo** object into the editor's canvas. The **Dimension Info** dialog box opens so that you can choose a dimension to associate with the object.



Dimension Info Dialog Box

From the dialog box, you can choose the dimension from the dimension list. Once you click **OK**, PC-DMIS displays a table on your report that contains the dimension information.

For complete information on how to use this dialog box to display dimension information, see "Inserting Dimension Info Boxes" in the "Inserting Report Commands" chapter.

Below are the properties specific to this object:

For most properties, you can set them from the **Dimension Info** dialog box. You can open this dialog box at any time with the **(Settings Dialog)** property.

DimID
Defines the feature or dimension ID containing the hits that you want to display.

GraphOption
Defines if the graph is displayed and what it shows. The value can be one of the following numbers:

0 - Hides the graph.
1 - Graphs the worst axes.
2 - Graphs each axis.

LocOrderA
A value greater than 0 displays the A location axis and orders it according to the value given.

LocOrderAR
As above, except the AR (Area) axis is displayed and ordered.

LocOrderD
As above, except the D axis is displayed and ordered.

LocOrderForm
As above, except the Form axis is displayed and ordered.

LocOrderH
As above, except the H axis is displayed and ordered.

LocOrderL
As above, except the L axis is displayed and ordered.

LocOrderPAng
As above, except the Polar Angle axis is displayed and ordered.

LocOrderPD
As above, except the PD axis is displayed and ordered.

LocOrderPRad
As above, except the Polar Radius axis is displayed and ordered.

LocOrderR
As above, except the R axis is displayed and ordered.

LocOrderRS
As above, except the RS axis is displayed and ordered.

LocOrderRT
As above, except the RT axis is displayed and ordered.

LocOrderS
As above, except the S axis is displayed and ordered.

LocOrderT
As above, except the T axis is displayed and ordered.

LocOrderUseDimAxes
As above, except only the dimension axes for the location are displayed.

LocOrderV
As above, except the V axis is displayed and ordered.

LocOrderWorst
As above, except the Worst axis of the location is displayed.

LocOrderX
As above except the X axis is displayed and ordered.

LocOrderY
As above, except the Y axis is displayed and ordered.

LocOrderZ
As above, except the Z axis is displayed and ordered.

OrderAuto
A value greater than 0 displays and orders the default information automatically.

OrderDeviation
As above, except the deviation value is displayed and ordered.

OrderMaxMin
As above, except the maximum and minimum values are displayed and ordered.

OrderMean
As above, except the average of all the deviations is displayed and ordered.

OrderMeasured
As above, except the actual measured dimensions are displayed and ordered.

OrderNominal
As above, except the nominal values are displayed and ordered.

OrderNumberPoints
As above, except the number of points used to measure the feature or dimension are displayed and ordered.

OrderOutTol
As above, except the out of tolerance value is displayed and ordered.

OrderStdDev
As above, except the standard deviation is displayed and ordered.

OrderTolerances
As above, except the tolerances are displayed and ordered.

ShowDimensionID
A value of 1 displays the dimension ID. A value of 0 hides it.

ShowFeatureID
A value of 1 displays the feature ID. A value of 0 hides it.

ShowHeadings
A value of 1 displays the row and column headings. A value of 0 hides it.

TPOrderD1
A value greater than 0 displays and orders the diameter/width value of the first datum.

TPOrderD2
As above, except the second datum is displayed and ordered.

TPOrderD3
As above, except the third datum is displayed and ordered.

TPOrderDF
As above, except the diameter of the feature is displayed and ordered.

TPOrderForm
As above, except the integrated form dimension is displayed and ordered.

TPOrderPA
As above, except the Polar Angle of the position is displayed and ordered.

TPOrderPR
As above, except the Polar Radius of the position is displayed and ordered.

TPOrderTP
As above, except the position tolerance and its associated deviation are displayed and ordered.

TPOrderUseDimAxes
As above, except only the position dimension axes are displayed.

TPOrderWorst
As above, except only the worst axis of the position is displayed.

TPOrderX
As above, except the X axis of the position is displayed and ordered.

TPOrderY
As above, except the Y axis of the position is displayed and ordered.

TPOrderZ
As above, except the Z axis of the position is displayed and ordered.

EditBox Object

The **EditBox** object inserts an editable box into the form. You can use this object with Visual BASIC scripting to collect information from those running the form.

Along with the ability to resize the object, change colors, and change other attributes, you can further customize this object by using these properties:

Alignment
This aligns the text within the object. Available alignments are: `Left`, `Center`, and `Right`.

ReadOnly
Setting this to `YES` makes the text read-only and therefore not editable when the form is in run mode.

BorderDrawn
Setting this to `YES` draws a border around the control.

CaseOrPassword
This sets the style of the text in the box. You can select one of the following:

`0 - None:` doesn't change the display of the text.
`1 - Lower Case:` displays the case of the text in the box to all lower case.
`2 - Upper Case:` displays the case of the text in the box to all upper case.
`3 - Password:` masks each character of the text with an asterisk.

UseColors
If set to `YES` then the colors specified in `BackColor` and `TextColor` are displayed.

HelpHotButton
Selecting `YES` shows a question-mark help button next to the check box.

Clicking this help button in run mode launches the PC-DMIS online Help.

EditDblBox Object

The **EditDblBox** object inserts an edit box in the form that accepts variables of double types. This has all the properties of the **EditBox** object (see "EditBox Object") with the addition of the `MinimumEq` and `MaximumEq` properties:

MinimumEq
Minimum equation (this value can be a set constant number, a value evaluated from a simple equation, or a returned value from a VBScript).

```
-$, $, CONST
```

MaximumEq
Maximum equation (this value can be a set constant number, a value evaluated from a simple equation, or a returned value from a VBScript).

```
-$, $, CONST
```

EditLongBox Object

The **EditLongBox** object inserts an edit box in the form that only accepts Long numerical values. This has all the properties of the **EditBox** object (see "EditBox Object") with the addition of the `MinimumEq` and `MaximumEq` properties:

MinimumEq
Minimum equation (this value can be a set constant number, a value evaluated from a simple equation, or a returned value from a VBScript).

```
-$, $, CONST
```

MaximumEq
Maximum equation (this value can be a set constant number, a value evaluated from a simple equation, or a returned value from a VBScript).

```
-$, $, CONST
```

Ellipse Object

The **Ellipse** object inserts an ellipse into the form or template. The default ellipse is a circle with the same distance from the centroid of the circle to all points along the circumference; however, you can easily stretch the circle to form an ellipse.

Along with the ability to resize the object, add a fill color, add a border color, and change other attributes, the following editable property is included for ellipse objects:

HatchStyle
This property sets the type of pattern (or hash) to use to fill the resulting polygon. The available patterns are:

Horizontal

Vertical

Diagonal

Reverse Diagonal

Cross

Diagonal Cross

Frame Object

The **Frame** object inserts a frame into the form. You'll generally use this object to set off groups of similar options when designing your own dialog boxes inside your form.

Along with the ability to resize the object, add a fill color, add a border color, and change other attributes, the following editable properties are included for frame objects:

BorderColor
This sets the color of the border.

HiliteColor
This sets the color used for the `BorderStyle` property when you use `Raised` or `Sunken`.

BorderStyle
This sets the 3D highlight style of the object's border. Options include `Normal`, `3D`, `Sunken`, and `Raised`.

BorderWidth
This sets the width of the object's border in pixels.

Text
Text typed here determines the name used for the frame's title.

Alignment
This aligns the text within the object. Available alignments are `Left`, `Center`, and `Right`.

Gauge Object

The **Gauge** object inserts a gauge object into your form, label template, or custom report. This object is not valid in the Report Template Editor.

Default Gauge Object

- If the object's width is larger than the height, the percentile bar moves horizontally.

- If the object's height is larger than the width, the percentile bar moves vertically.

Along with the ability to resize the object, change colors, and change other attributes, you can cause the object's percentile bar to move by using these properties in conjunction with PC-DMIS commands or Visual BASIC code:

ValueEq
Value equation.

This is the current value of the gauge object. Once it is evaluated against the minimum and maximum ranges set in MinimumEQ and MaximumEQ, it displays a percentage number on the gauge.

It can be a set constant number, a value evaluated from a simple equation, or a value returned from a VBScript.

-$, $, CONST

MinimumEq
Minimum equation.

This defines what the 0% value is. If a value of 5 represents 0 percent on the gauge, you would set this property to 5.

This value can be a set constant number, a value evaluated from a simple equation, or a value returned from a VBScript.

-$, $, CONST

MaximumEq
Maximum equation.

This defines what the 100% value is. If a value of 10 represents 100 percent, you would set this property to 10.

This value can be a set constant number, a value evaluated from a simple equation, or a value returned from a VBScript.

-$, $, CONST

ShowText
This shows or hides the percentage number in the gauge.

Example of Using PARAM to Change the Gauge's Value

You can also use the REPORT/CUSTOM command with PARAM statements to change a gauge's value. Suppose you want to change the gauge percentage based on an input comment in PC-DMIS.

1. Add the object into one of the editors and size it as needed.

2. Right-click on it, choose **Properties**, and make a note the **Object Name** property.

3. Inside PC-DMIS, add code similar to the following:

```
C1=COMMENT/INPUT,NO,FULL SCREEN=NO,
   Type a percentage:
CS1=REPORT/CUSTOM, FILENAME=MyCustomReport, Section=-1
   PARAM/GAUGE1.VALUE=C1.INPUT
   PARAM/=
   ENDCUSTOM/
```

When you execute the above code, PC-DMIS stores a number value from the input comment into the C1.INPUT variable. It then looks for a custom report named "MyCustomReport".

Notice the PARAM statement. It modifies an object named **Gauge1**. It then uses a **VALUE** property to set the gauge's value equal to the value stored in the C1.INPUT variable.

Example of Using BASIC Scripting to Dynamically Change the Gauge's Value

You can also use BASIC code in the **VBS Mini-Editor** to dynamically change the value of the gauge at a given time. Suppose you want to create a form that moves the gauge from 0 to 100 percent based on how close a circle's diameter approaches its minimum and maximum allowed tolerances. You can do this by following this procedure:

Step 1 - Create the Form

1. Create a new form and make sure it's in Edit mode. First, you need to create a variable named MYDIAMETER that takes the diameter value of the circle.

2. Right-click on the grid and make sure **The Frame / The View** is selected from the object list on the **Properties** dialog box.

3. Expand the **Advanced** heading in the **Properties** dialog box. Select the value for the **LocalVariables** property. The **Local Variables** dialog box appears.

4. Click the **Add** button to add a new variable. Select **Double** from the **Type** list. In the **Name** box, type **MYDIAMETER**. Leave the **Value** as 0.

Local Variables dialog box showing the MYDIAMETER variable.

5. Click **OK** to return to the **Properties** dialog box. The MYDIAMETER variable is now added to the form.
6. Next, insert a **Gauge** object into the form.
7. Select the **Gauge** object and place and size it as desired. The vertical distance is the total distance the percentile bar can travel.
8. From the **Properties** dialog box, ensure that the added **Gauge** object is selected.
9. Again, under the **Advanced** heading on the **Properties** dialog box, click the **MaximumEq** property. The **VBS Mini-Editor** appears; much of it is unavailable for selection.
10. Select **CONST** from the list. This value allows you to define the gauge's 100% value.
11. Type the maximum allowed value for the circle's diameter. This example measures a one inch diameter circle with an allowed tolerance of .010. So, the maximum allowed value would be **1.010**.
12. Click **OK** to return to the **Properties** dialog box.
13. Click on the **MinimumEq** property. The **VBS Mini-Editor** re-appears. This value allows you to define the gauge's 0% value.
14. Select **CONST** from the list.
15. Type the minimum allowed value for the circle's diameter. Again, since this example measures a one inch diameter circle with an allowed tolerance of .010, the minimum allowed value would be **0.990**.
16. Click **OK** to return to the **Properties** dialog box. Now you need to give the actual value of the gauge the diameter of the circle.
17. With the gauge object still selected from the **Properties** dialog box, under the **Advanced** heading, select the **ValueEq** property. The **VBS Mini-Editor** appears; much of it is unavailable for selection.

18. In the list on the left, select **+ EQ ($)**.
19. In the list on the right, select the **<MYDIAMETER>**.

Using the VBS Mini-Editor to set the value of the gauge object

20. Click **OK** to close the **VBS Mini-Editor**.
21. Save the form. This example gives the form the name of *gaugetest.form*.

Step 2 - Create a Generic Circle Feature

1. Now, you need to create a generic circle feature inside PC-DMIS. Select PC-DMIS's Edit window and place it in Command Mode.
2. Insert a generic feature by typing **GENERIC** and then press the Tab key. Initially, a generic point feature appears in the Edit window with the feature's ID selected.
3. Press F9 to access the dialog box for this generic feature.
4. In the **Feature Type** area, select **Circle**.
5. In the **Data Type** area, select **Nominal Values**.
6. Type a name for the circle in the **Feature Name** box. This example uses CIR1 for the feature name.
7. Type the XYZ and IJK values for CIR1.
8. Select the **Diameter** option and give CIR1 a nominal diameter value of 1.
9. Change any other options as desired and then click **OK** when finished. The code for the generic circle in your Edit window should look something like this:

```
CIR1    =GENERIC/CIRCLE,DEPENDENT,RECT,OUT,$
         NOM/XYZ,1,1,0.95,$
         MEAS/XYZ,1,1,1,$
         NOM/IJK,0,0,1,$
         MEAS/IJK,0,0,1,$
         DIAMETER/1,0
```

Step 3 - Insert an INPUT Comment and Modify Generic Circle

1. Move your cursor *before* the CIR1 feature and insert an input comment to take a measured diameter value (since this example is done in Offline mode, the "measured" values are inserted manually). For example:

```
C1    =COMMENT/INPUT,Please type CIR1's measured
diameter:
```

2. Now go to the command block for CIR1 and on the last line where it says DIAMETER/1,0 change the second parameter, the measured diameter of 0, to C1.INPUT. This assigns the value from the input comment to CIR1's measured diameter.

```
DIAMETER/1,C1.INPUT
```

3. Now, move the cursor *after* the CIR1 feature and embed the saved form by selecting the **Insert | Report Command | Form** menu option.

Step 4 - Insert a FORM/FILENAME Command and Execute

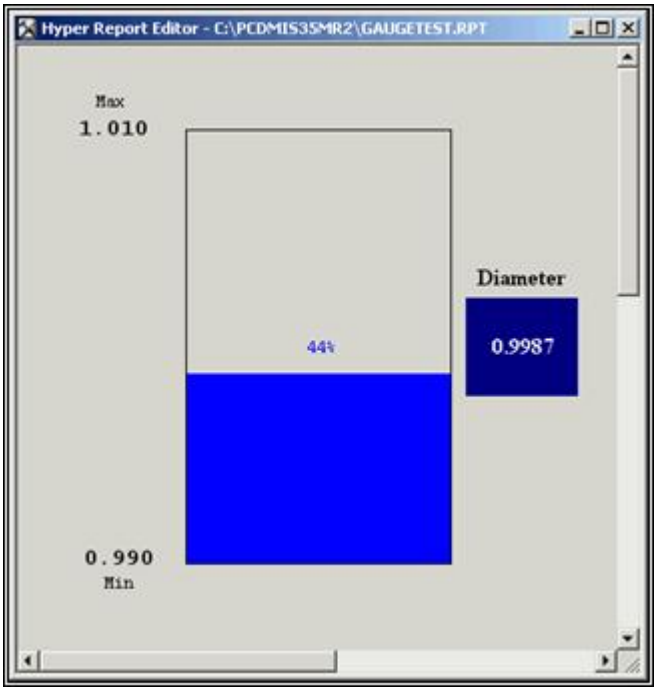
1. Type `FORM` and press the Tab key to insert a `FORM/FILENAME` command block into the Edit window.

2. Now, in the `FORM/FILENAME` command where it says `PARAM/=` , place your cursor immediately before the equals sign and type `MYDIAMETER` . Then move the cursor immediately after the equals sign and type `CIR1.DIAMETER` . The code to embed your form should look something like this:

```
CS1    =FORM/FILENAME=C:\PCDMIS35\GAUGETEST.FORM,
AUTOPRINT=NO
        PARAM/MYDIAMETER=CIR1.DIAMETER
        PARAM/=
        ENDFORM/
```

3. Mark the newly added commands and then execute the measurement routine. The diameter for CIR1 gets passed as a parameter into the form and the gauge object's percentile dynamically changes depending on the circle's measured diameter.

For example, if the measured diameter for CIR1 was .9987 you would get a form that looks something like this:

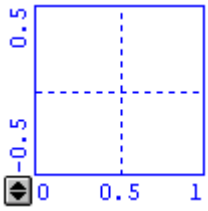


Example of a form showing the gauge object dynamically linked to a feature's measured diameter.

Graph Object

The **Graph** object inserts a graph into your form, custom report, or label template with the ability to dynamically update its data. This object is not available in the Report Template Editor.

The **Graph** object allows you to store and then display an array of data points. You can use X and Y values to specify the points of data on the graph.



Default Graph Object

Along with the ability to resize the object, change colors, and change other attributes, you can cause graph objects to update their data dynamically by using these properties in conjunction with PC-DMIS commands or Visual BASIC code:

ClearAllPoint
If set to `1`, all data points are cleared from the graph the next time your form enters run mode.

If set to `0`, all data points remain in the graph.

Clockwise
Setting this to `NO` reverses the Y axis, making the top negative and the bottom positive.

ConnectPoints
Setting this to `YES` draws lines between the data points on the graph, visually connecting them together.

DataPointColor
This changes the colors used on the X, Y data points and on any lines drawn between points.

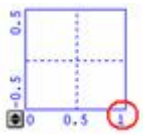
EnablePoint
If set to `1`, your graph accepts the addition of new data points.

If set to `0`, your graph rejects the addition of new data points.

LineWidth
This changes the diameter (in pixels) of the data point.

XDivisions
This divides the X axis of the graph, which essentially adds the specified number of columns.

XMaxEq
This is the X-axis maximum equation. The value used determines the ending value making up the X axis.



You can use a simple equation, or evaluate the data from a VBScript.

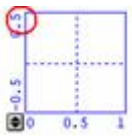
XMinEq
This is the X-axis minimum equation. The value used determines the beginning value making up the X axis.

You can use a simple equation, or evaluate the data from a VBScript.

XPointEq
This is the X value for your data point on the graph. You can use a simple equation, or evaluate the data from a VBScript.

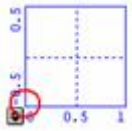
YDivisions
This divides the Y axis of the graph, which essentially adds the specified number of rows.

YMaxEq
This is the Y-axis maximum equation. The value used determines the ending value making up the Y axis.



You can use a simple equation, or evaluate the data from a VBScript.

YMinEq
This is the Y-axis minimum equation. The value used determines the beginning value making up the Y axis.



You can use a simple equation, or evaluate the data from a VBScript.

YPointEq
This is the Y value for your data point on the graph. You can use a simple equation, or evaluate the data from a VBScript.

Click on the up and down arrows near the graph's origin to re-scale the Y axis. These scaling arrows are only visible in the legacy Hyper View report editor and in the Forms editor.

Example of using PARAM to Display Data on the Graph

You can also use the REPORT/CUSTOM command with PARAM statements to specify the graph's data points.

1. Add the **Graph** object into one of the editors, and size it as needed.
2. Right-click on it, choose **Properties**, and make a note of the **Object Name** property value.
3. Set **XDivisions** to 5.
4. Set **YDivisions** to 5.
5. Set **DataPointColor** property to red (255.0.0).
6. Set **LineWidth** to 8.
7. Inside PC-DMIS, add code similar to the following:

```
CS1   =REPORT/CUSTOM, FILENAME=MyCustomReport,
Section=-1
       PARAM/GRAPH1.SETVALUES=0
       PARAM/GRAPH1.XVALUE=0.25
       PARAM/GRAPH1.YVALUE=-0.4
       PARAM/GRAPH1.SETVALUES=1
       PARAM/GRAPH1.XVALUE=0.65
       PARAM/GRAPH1.YVALUE=0.-0.3
       PARAM/GRAPH1.SETVALUES=1
       PARAM/GRAPH1.XVALUE=0.75
       PARAM/GRAPH1.YVALUE=0.45
       PARAM/GRAPH1.SETVALUES=1
       PARAM/=
```

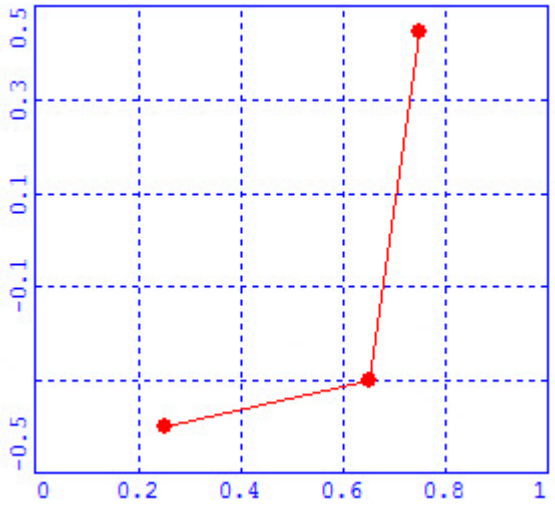
With the above code, PC-DMIS looks for a custom report named "MyCustomReport". Notice the PARAM statements in the REPORT command. They each modify an object named Graph1, and they use these properties to modify the graph:

XVALUE - This defines the X axis location of the data point on the graph.

YVALUE - This defines the Y axis location of the data point on the graph.

SETVALUES - This can be either 0 or 1. A value of 0 resets the list of data points. A value of 1 adds the data point to the list.

The resulting graph looks like this:



Example of Using BASIC Scripting to Dynamically Display Data on the Graph

You can also use BASIC code in the **VBS Mini-Editor** to dynamically display data points on the graph. Suppose you want to have a script that creates the data points automatically when a form is launched. You can do this by following this procedure:

Step 1 - Create the Form

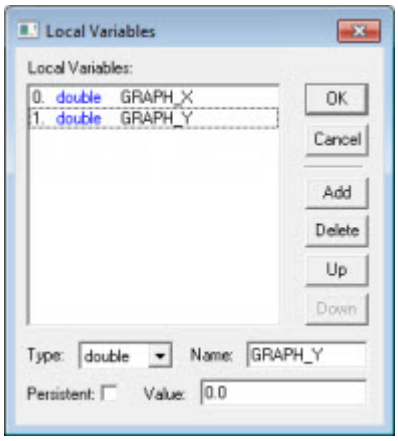
1. Create a new form and make sure it's in edit mode. First, you need to create some variables to take the X and Y values for each data point.
2. Create a **Graph** object, add it to the canvas, and size it as needed. Name it **Graph1**.
3. Right-click on it and choose **Properties**.
4. Set **XDivisions** to **5**.
5. Set **YDivisions** to **5**.
6. Set **DataPointColor** property to red (**255.0.0**).
7. Set **LineWidth** to **8**.
8. Set **YMaxEq** to **CONST** and **1.0**.
9. Set **YMinEQ** to **CONST** and **-1.0**.

Step 2 - Create the Variables

1. Right-click on the grid and make sure **The Frame / The View** is selected from the object list on the **Properties** dialog box.
2. In **LocalVariables** click the value to display the **Local Variables** dialog box.

3. Click **Add** to add a new local variable. Select **Double** from the Type list. In the **Name** box, type **GRAPH_X**. Leave the **Value** as 0.

4. Add another local variable in the same manner and give it a name of **GRAPH_Y**.



Local Variables dialog box showing the two variables

5. Click **OK** to return to the **Properties** dialog box. The two variables are now added to the form.

6. From the **Properties** dialog box, choose **Graph1**.

7. In **XPointEq** click the value. In the **VBS-Mini Editor**, from the left list, choose **+ EQ ($)** and from the right list, choose **<GRAPH_X>**. Then click **OK**.

8. Do the same for **YPointEq** and set it to **<GRAPH_Y>**.

Step 3 - Add the Script

1. In the **EventInitialize** property, click the value to display the **VBS Mini-Editor**.

2. Type this code in the editor:

```
GRAPH_X = 0.1
GRAPH_Y = -0.4
This.Refresh
GRAPH_X = 0.25
GRAPH_Y = 0.5
This.Refresh
GRAPH_X = 0.75
GRAPH_Y = -0.5
This.Refresh
GRAPH_X = 0.85
GRAPH_Y = 0.45
This.Refresh
```

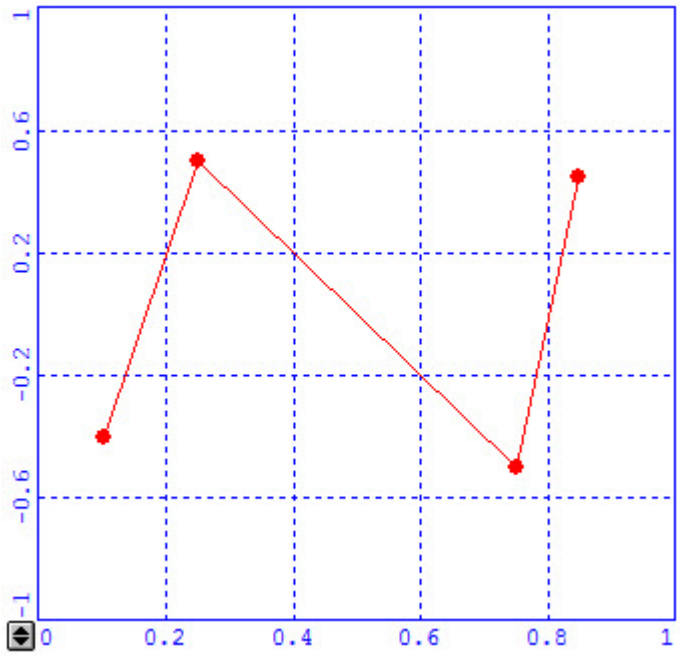
3. Click **OK**.
4. Save the form. This example gives the form the name of *graphtest.form*.

Step 4 - Insert a FORM/FILENAME Command and Execute

In the Edit window's Command Mode, type **FORM** and press Tab to insert a `FORM/FILENAME` command block into the Edit window. In the command block, for `FILENAME`, type a reference to the graphtest.form file that you saved in the above step.

Ensure the commands are all marked and execute the measurement routine.

When the form command is executed, and the form appears, the graph initializes. The script then runs and creates the data points on the graph like this:



Without Using Local Variables

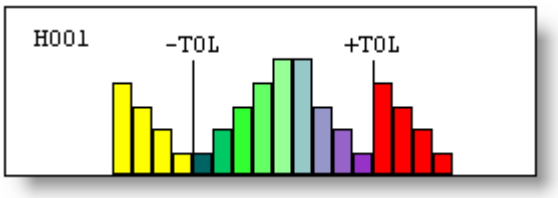
If you like, you can also do the above example without defining local variables at all. In this case, in step 3 above, your code in the **VBA Mini-Editor** would say this instead:

```
this.SetValues = 0
this.XValue = 0.1
this.YValue = -0.4
this.SetValues = 1
this.XValue = 0.25
this.YValue = 0.5
this.SetValues = 1
this.XValue = 0.75
this.YValue = -0.5
this.SetValues = 1
this.XValue = 0.85
this.YValue = 0.45
this.SetValues = 1
```

This code is similar to the code used in the PC-DMIS commands in the "Example of Using PARAM to Display Data on the Graph" topic.

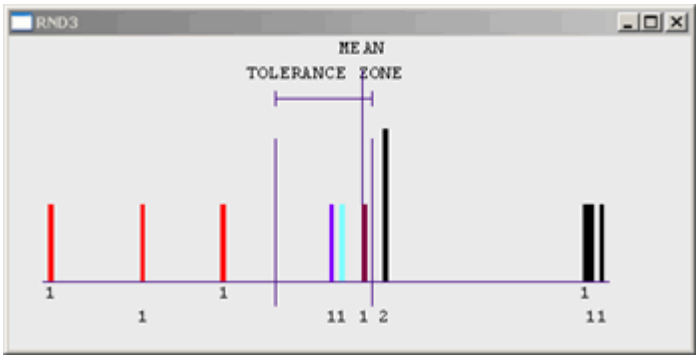
DimensionHistogram Object

The **DimensionHistogram** object displays, in a histogram bar-graph format, the number of deviations within each of the different tolerance zones.



A sample histogram.

When a dimension only has a single tolerance value, such as a form dimension, PC-DMIS displays the tolerance band as a range and not in a fixed location. PC-DMIS will not display -TOL or +TOL in the resulting histogram but will instead show the heading "TOLERANCE ZONE" at the top and include a location for the mean value like this:



A sample histogram with a single tolerance.

Inserting the DimensionHistogram Object

Use the Label Template Editor for a new or existing label template and then add and size the **DimensionHistogram** object so that it appears vertically or horizontally as desired in your label template editor's display area. Next, use the **Rule Tree Editor** dialog box for a new or existing report template to specify under what conditions (for what dimensions) PC-DMIS will call and display that label template. See the "About the Rule Tree Editor" topic in this chapter for information on how to do this.

DimensionHistogram objects are available only for dimensions that are directly calculated using the individual hits of their features, such as Location, Position, and Keyin dimensions.

Changing Histogram Colors

To see how these tolerance zones are defined, or to change the colors that represent each tolerance zone, see "Editing Dimension Colors" in the "Editing the CAD Display" chapter.

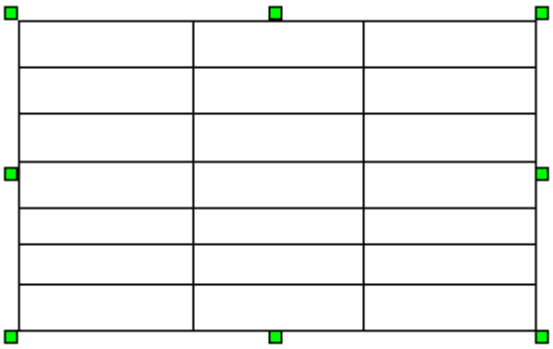
Properties

Properties specific to this object are listed below.

HatchStyle
Same as described in the "Ellipse Object" topic.

GridControlObject

The **GridControlObject** icon inserts a customizable grid of columns and rows into your report or label template.



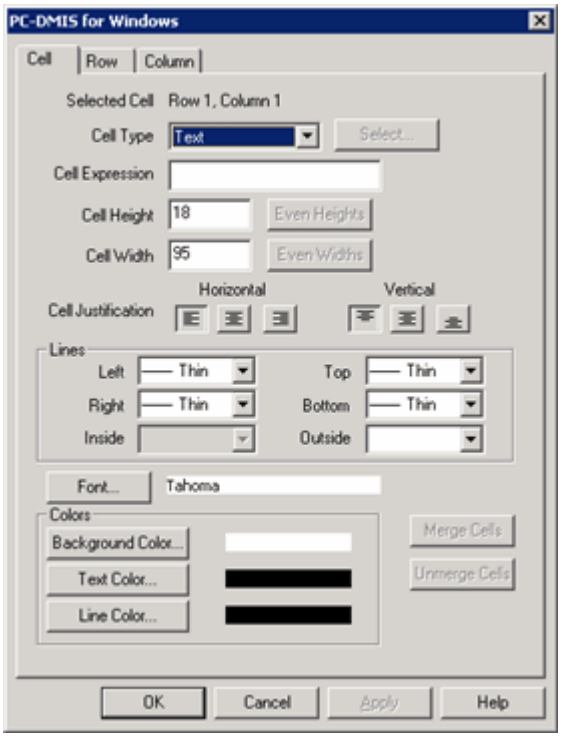
Example of a grid control object.

This unique object is more than just a standard table, though. In fact, you can program the individual cells, rows, or columns using the reporting expression language to cause PC-DMIS to pull and display specific reporting information from your measurement routine.

As with the other objects, you can easily resize and move this object to a new location. When you resize this object, be aware that PC-DMIS dynamically sizes the columns and rows to fit the new object's size.

Accessing the GridControlObject Editor

Once you insert a **GridControlObject**, select it, double-click inside any cell, and then right-click to display a tabbed dialog box. This dialog box gives you powerful formatting and editing abilities that let you program each grid cell to your individual specifications.



Cell tab of the GridControlObject's Editor

See these topics for information on using this editor:

- GridControlObject Editor - The Cell Tab
- GridControlObject Editor - The Row Tab
- GridControlObject Editor - The Column Tab

Properties

`NumColumns`
Determines the number of columns in the grid.

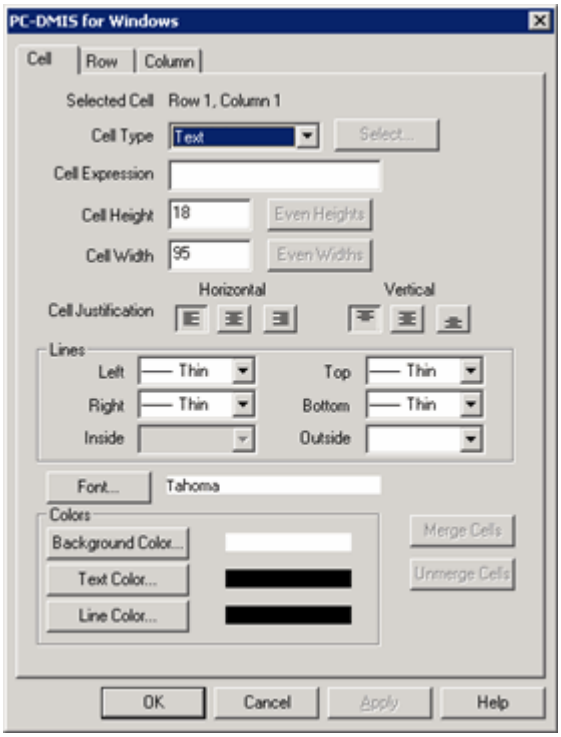
`NumRows`
Determines the number of rows in the grid.

`TableFormat`
Specifies a grid layout name to use. If this property matches the grid layout name in the **Rules Tree Editor**, then you can use the `TABLE/FORMAT` Edit window command to directly control row and column order and visibility for your label template.

`Transparent`
Determines whether or not the grid's background is transparent. If set to `Yes`, the usual white background color becomes transparent; other objects behind this object are then visible through the grid.

Increasing the `NumRows` property adds new rows to the bottom of the available rows. Decreasing them will delete the bottom-most row and work up. Similarly, increasing the `NumColumns` property adds new columns to the right of the available rows. Decreasing the number of columns will delete the right-most column and work left.

GridControlObject Editor - The Cell Tab



Cell tab of the GridControlObject's Editor

Cell Type - Lets you configure what you will insert into the specific cell. Options are:

- **Text** - This option lets you type straight text or an expression command into the **Cell Expression** box. The evaluated expression or the straight text appears in the cell.
- **Image** - This option inserts an image into the cell. You can select it using the **Select** button.
- **ActiveX** - This option inserts an ActiveX object into the cell. Generally PC-DMIS templates use these to display graphical analysis information. You can click the **Select** button to select which ActiveX control to add. For more information on ActiveX objects, see the "ActiveX Object" topic and the "Using PC-DMIS ActiveX Controls" topic.

Cell Expression - This box lets you type a reporting expression into the cell. PC-DMIS evaluates the expression when it uses the template to display the actual report data. For example, to display a feature's ID, type **=ID** into this box. For a robust listing of expressions you can include, see "About Report Expressions".

Cell Height and Width - These boxes let you define the cell's height and width in pixels. Note that if you modify a height, all cells in that row are modified. If you change the width, all cells in that column are modified. If you have varying heights and widths among multiple cells, the **Even Width** and **Even Height** buttons even out the height and width among the selected cells

Cell Justification - These buttons let you set the alignment of the text within the cell, either vertically or horizontally. If horizontal, you can align the text to the left, the center, or the right of the cell. If vertical, you can align the text to the top, the middle, or the bottom.

Horizontal Alignment Buttons

- Left alignment

- Center alignment

- Right alignment

Vertical Alignment Buttons

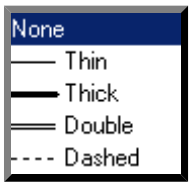
- Top alignment

- Middle alignment

- Bottom alignment

Note that when aligning text within the grid's cell, PC-DMIS uses a default internal value for cell padding. You can use the `GridCellTopMargin`, `GridCellBottomMargin`, `GridCellLeftMargin`, and `GridCellRightMargin` entries in the **Reporting** section of the PC-DMIS Settings Editor to override these default values.

Lines area - This area contains a list for each side of the cell. You can set each side of the cell (plus the outside or inside lines of multiple cells) to a particular line type. Options include: **None**, **Thin**, **Thick**, **Double**, or **Dashed**.



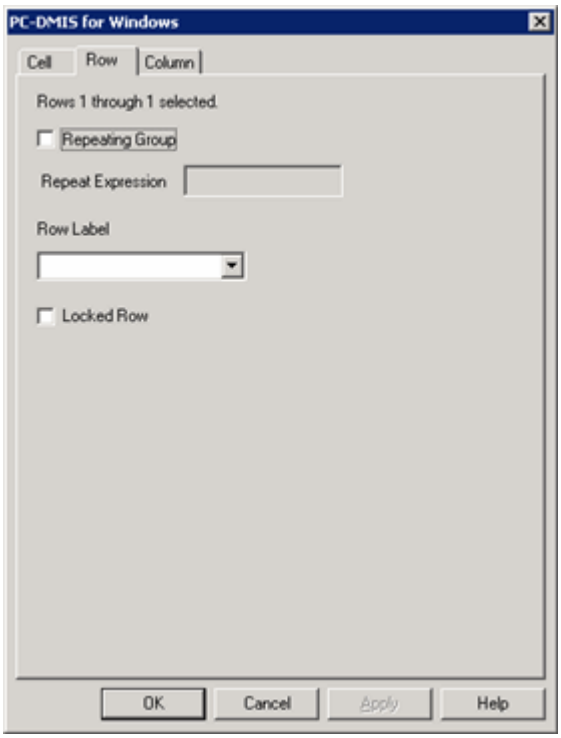
Font - This button displays a standard **Font** dialog box allowing you to set the font, size, style, effects, and color for the selected cell(s).

Colors - This area lets you set the colors for the background, text, or line of the selected cell(s). Clicking one of the buttons displays a standard **Color** dialog box from which you can select a specific standard color or create a custom color.

Merge Cells - This button merges multiple cells together into one cell.

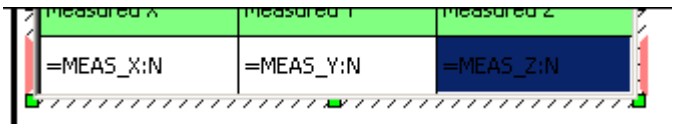
Unmerge Cells - This button unmerges previously merged cells into their original and previous unmerged state.

GridControlObject Editor - The Row Tab



Row tab of the GridControlObject's Editor

Repeating Group - This check box enables the **Repeat Expression** box and tells PC-DMIS that the selected row will continue repeating itself with data from the report until the expression in the **Repeat Expression** box is satisfied. When you select a cell in the GridControlObject, PC-DMIS indicates any repeating rows in the object by drawing small vertical orange bars on their left and right sides.



Example of the orange bars on the left and right sides of the row.

Repeat Expression - This box determines how many times PC-DMIS will repeat the row. You will usually put an expression in this box that will evaluate to a counted number of items. For example, to get the number of axes in a dimension, you would use this expression:

=COUNT(AXIS)

Then in each cell of the row, you would need to append this to existing expressions:

:N

This essentially tells PC-DMIS to repeat the row the counted number of times. So, if the **Cell Expression** box in the **Cell** tab used **=AXIS** to list a dimension's axis, and you changed it to read **=AXIS:N**, PC-DMIS would continue to repeat the row with unique dimension axis data until all axes were reported.

Row Label - The **Row Label** list lets you define a label for your row to use with the Table Format command. When you access the Table Format command's properties, you will see the row labels you've defined here. Using the Table Format command, you can re-define the order of the rows in the grid, among other things.

Locked Row - This check box locks the row so that you cannot modify it using the Table Format command.

GridControlObject Editor - The Column Tab

Column tab of the GridControlObject's Editor

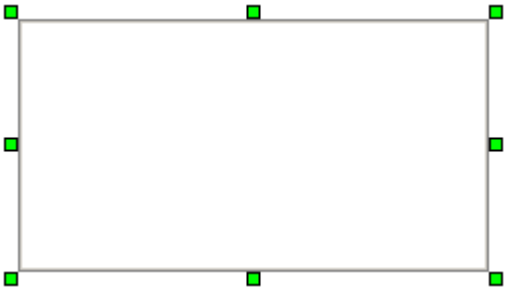
Column Label - The **Column Label** list lets you define a label for your column to use with the Table Format command. When you access the Table Format command's properties, you will see the column labels you've defined here. Using the Table Format command, you can re-define the order of the columns in the grid, among other things.

Label Object

The **Label** object icon inserts a **Label** object into your report template or custom report. Label objects are used to display report data in your report. The **Label** object behaves differently depending on the context in which it is used. If you use the **Label** object in the Report Template Editor, it functions differently than using it in the Custom Report Editor.

Using the Label Object within the Report Template Editor

Click and drag on the Report Template Editor to add this object. When you release the mouse button, the inserted **Label** object looks something like this:



A sample label object.

A **Label** object acts just like a **TextReportObject** or **CadReportObject**; it doesn't contain any real data and merely acts as a placeholder for a label template. The label template actually controls what data gets pulled from a measurement routine execution. If you don't define what the label object will display, then it doesn't appear in the report.

Assign a Label Template

To give a **Label** object something to display, you need to assign a label template for it to use. Follow this procedure:

1. Right-click on the label object. The **Properties** dialog box appears.
2. Click **Rules** from the **Rules Tree** property. The **Rules Tree** dialog box appears.
3. Using the **Rules Tree** dialog box, select an item from one of the expandable lists.
4. Click **Add** to add a rule that uses that item. The **Edit Rule** dialog box appears.
5. Select **Use Label Template for Report** option.
6. Click the browse button ..., and select a label template file (.lbl filename extension).
7. Click **OK** to close the **Edit Rule** dialog box.
8. Click **OK** to close the **Rules Tree** dialog box. The label object you inserted will now display a picture of the label template defined in the first rule in the **Rule Tree** dialog box.
9. Save and test your report template. PC-DMIS will display the selected label when the condition you specified is met.

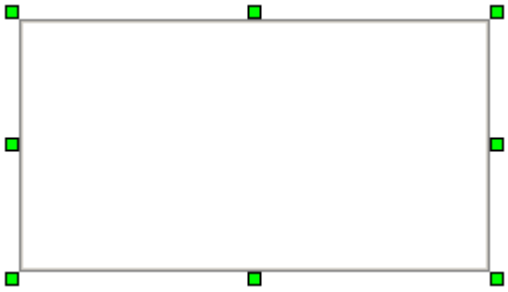
See "About the Rule Tree Editor" for information about creating rules.

Using the Label Object within the Custom Report Editor

One crucial difference between the Report Template Editor and the Custom Report Editor is that in the Custom Report Editor, **Label** objects *do not use their own Rule Tree Editor.* Instead, the **Page** object contains a Rule Tree Editor that defines what label template is used when the different commands and data are inserted into the Custom Report Editor.

Most of the time you will likely simply create your custom report by dragging items from the Edit window's Summary Mode into the Custom Report Editor. In this case, PC-DMIS uses the label templates defined in the **Page** object's Rule Tree Editor for the command you are inserting.

If you do insert a **Label** object into your custom report, PC-DMIS inserts a blank **Label** object, similar to how it would appear in the Report Template Editor:



A sample label object.

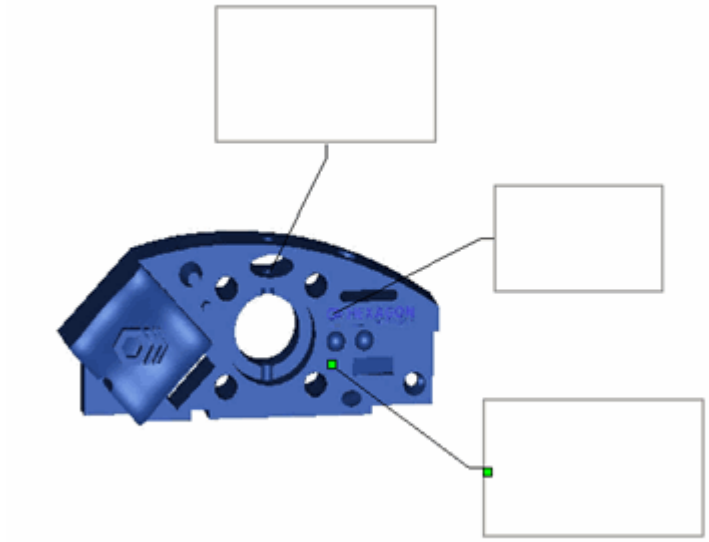
In this state, the object is merely an empty placeholder, and it won't display any data until you drag and drop a command from the Edit window onto the object. PC-DMIS will then display the label template defined in the **Page** object's Rule Tree Editor.

See "Creating Custom Reports" for more information.

Leader Line Object

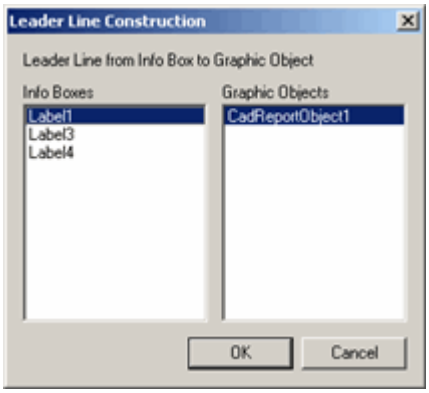
The **LeaderLine** object lets you draw leader line (a connecting line) between a **Label** object and a **CadReportObject**. To do this, simply select the object, then click and drag it from one object to the other.

If done properly, the leader line automatically snaps between the two objects so that if you later change their locations, the leader line changes size and moves accordingly. For example, this figure shows a **CadReportObject** object with three **Label** objects around it all with connecting **LeaderLine** objects.



Three Label objects with LeaderLine objects drawn to a CadReportObject

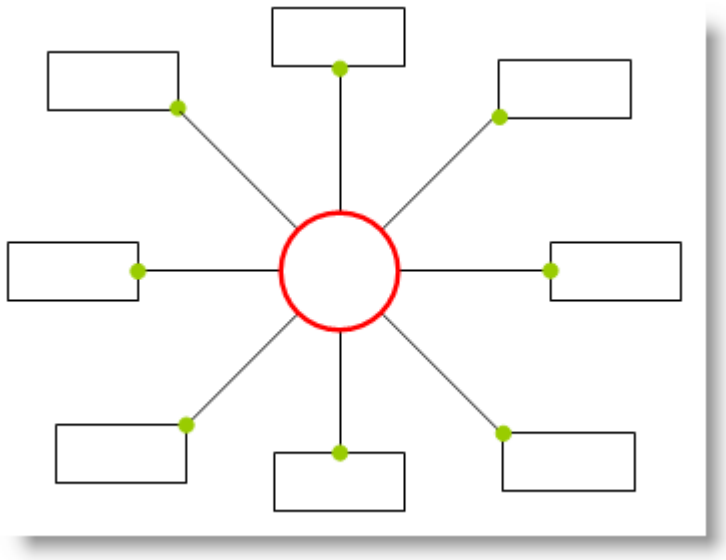
If the leader line can't detect the two objects, a **Leader Line Construction** dialog box appears, allowing you to select the two objects for the leader line.



Leader Line Construction Dialog Box

If you delete the Label or a **CadReportObject** object, PC-DMIS also deletes the leader line object automatically.

In the actual Report window, depending on the location of the label to the feature, the leader line attaches to either one of the edges or corners of the label. Consider this graphical example. It illustrates that where you position the labels (rectangles) in relationship to the feature (red circle) changes where the leader line connects (green dot) on the label.



Example showing the label and leader line connection positions.

The following properties are available:

LeaderLineVisibility
This sets the visibility state of the selected leader line. TRUE shows the leader line. FALSE hides it.

Object1
Defines the first of the two objects between which the leader line will be drawn.

Object2
Defines the second of the two objects between which the leader line will be drawn.

Line Object

The **Line** object allows you to insert a standard line into your form or template. You can then right-click on the inserted line and modify its properties.

Common properties used on a line object are:

PenWidth
This sets the width of the line in pixels.

PenStyle
This changes the line style to `Solid`, `Dash`, `Dot`, `Dash-dot`, and `Dash-dot-dot`.

Arrowhead
This determines if the line should contain an arrowhead and the direction the arrowhead points. You can choose one of these formats:

`----(none)`
`<---`
`--->`
`<--->(both)`

ArrowheadHeight
This determines the height of the arrowhead in pixels.

ListBox Object

The **ListBox** object inserts an open list inside the form.

Along with the ability to resize the object, change colors, and change other attributes, you can further customize this object by using these properties:

BorderDrawn
Setting this to `YES` draws a border around the control.

HorizontalScroll
Selecting `Always` places a horizontal scroll bar on the list box even if the text for a list item isn't long enough to cause it to scroll.

Selecting `None` removes the scroll bar.

ListID
This is the ID of the list. You can set or get this by using the control. It should be in this format:

`item 1\r\nitem 2\r\nitem 3` and so on.

RemoveSelection
Selecting `YES` removes the selection from the list box (`ListID`) when recorded.

Sort
Selecting `YES` sorts the list items alphabetically.

UseColors
This determines whether or not the control should use the colors specified in the `BackColor` and `TextColor` properties.

UseTabstops
This determines whether or not the list box should use tab stops. If set to `YES`, pressing Tab in run mode will eventually make this list box the active control.

VerticalScroll
Selecting `Always` places a vertical scroll bar on the list box even if there aren't enough list items to cause it to scroll.

Selecting `None` removes the scroll bar.

WantKeyInput
This determines whether or not the list box should accept keyboard input.

MultiEditBox Object

The **MultiEditBox** object inserts an edit box that supports more than one line of text. This has all the properties of the **EditBox** object (see "EditBox Object"), plus the following:

HorizontalScroll
Selecting `Always` places a horizontal scroll bar on the control even if the text isn't long enough to cause it to scroll.

Selecting `None` removes the scroll bar.

VerticalScroll
Selecting `Always` places a vertical scroll bar on the control even if the text isn't long enough to cause it to scroll.

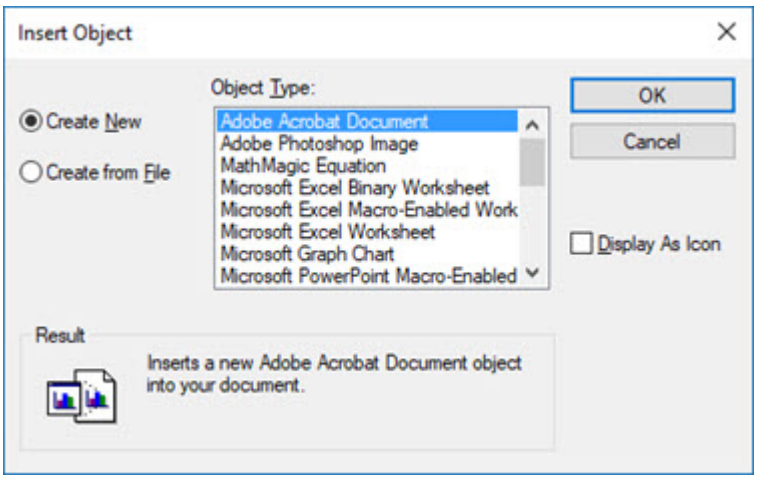
Selecting `Automatic` places a vertical scroll bar only when the amount of text exceeds the vertical height of the box.

Selecting `None` removes the scroll bar.

OLE Object

The **OLE** object embeds or links an object from another application into your template or form. For example, using this object you can insert an editable Microsoft Word file into your template or form to provide special instructions to the operator.

Once you insert an **OLE** object, a dialog box titled **Insert Object** appears.



Insert Object Dialog Box

This dialog box allows you to select the type of OLE object from a list of objects that are currently available on your computer. The OLE objects in the list are unique to your individual computer, depending on what is installed, etc.

If you select **Cancel**, nothing is added to the form or template, and the dialog closes.

DoVerbs
Setting this to `Yes` allows the object to be edited in run mode as well as in edit mode. If set to `No`, the object is read-only in run mode.

OLEProperties
This displays a properties dialog box that lets you choose general properties available to all OLE objects, such as how the object is displayed (icon or not), its size, and so forth.

Accessing an OLE Object's Automation Methods and Properties from Basic

You can access an OLE (Object Linking and Embedding) object's methods and properties from Basic to automate tasks related to the object. For example, you could change a bitmap image, populate an embedded Microsoft Excel spreadsheet object with data, or set the text in an embedded Microsoft Word document.

Suppose you add a Bitmap OLE control, and you name it "BITMAP" by setting its `(Object Name)` property to `BITMAP`, you can add program code to change the bitmap being displayed. To do this, you can access the OLE automation methods and properties for the object named `BITMAP`, with the following code:

```
AttachOLE("BITMAP_X")
```

You can then use the object variable BITMAP_X to set a new property value or perform an automation method call:

```
BITMAP_X.{property} = {value}
```

or

```
BITMAP_X.{automation method call}.
```
